9653. You have proved, so far as it goes, that the colour keeps better, I take it, with zinc than with white lead?—Yes.

9654. (*Lord Henry Bentinck.*) The durability of the paint, as far as I can make out, is no great matter to you or to any shipowner?—There are certain parts of a ship where it gets no chafing and no bad use, on the passenger deck, for instance, and on the boats. Therefore, if you got a durable paint that will last twice as long as ordinary paint, it would be a matter for our consideration, of course.

9655. But it is not so important to you as to a house painter, for instance?—I would not say that. We are out to save pennies as well as the house-painter is.

9656. (*Dr. Collis.*) But you renew more on account of mechanical damage?—Yes, chipping through cargo going up against the paint, and all that sort of thing.

9657. (*Chairman.*) But in coming to the conclusion to abandon the use of lead, you have taken the question of durability into your calculations?—I am

19 July 1911.]

Commander W. H. COYSH, R.N.R.

[Continued.]

dealing with that now. As far as our ships are concerned at Parkston, as soon as the present stock of white lead is used up, I personally shall not order any more.

9658. If this Committee prohibited the use of white lead, it would not affect you?—It would not affect me at all.

The witness withdrew.

Mr. G. SCHÖBERT examined.

9661. (Chairman.) Are you the manufacturer of the composition supplied to the Great Eastern Railway for painting ships' hulls?—Yes.

9662. Is your composition specially intended for preventing the corrosion of iron and steel surfaces?—Yes.

9663. What is the composition of your anti-corrosive paint?—The compositions are chiefly pigments such as zinc and oxide of iron, and in many cases a small percentage of arsenite of lime, which is specially manufactured by us. It is only added in special cases.

9664. How much arsenite of lime would you say there is in your anti-corrosive paint?—In severe cases something between 3 and 5 per cent.

9665. What vehicle is used?—The usual oil—linseed oil and gums and varnish.

9666. Oxidised linseed oil?—Oxidised linseed oil.

9667. And varnish?—It is made into varnish.

9668. Is it used as a varnish specially made to withstand atmospheric influences and heat?—Yes.

9669. Are there any lead compounds in your paint?—None whatever, not even in the varnish.

9670. Are lead driers added?—None whatever.

9671. Is no lead used in any form for driers?—None.

9672. Do you use turpentine for thinning?—No.

9673. What is your thinning material composed of?—Coal-tar naphtha with a flash-point of over 100°.

9674. Do you get a sufficient covering power without the use of either red or white lead?—Yes.

9675. By what means?—By pure chemical oxide of iron, which has greater covering power than either red or white lead, and for white paints, the zinc white—zinc oxide.

9676. Do you consider the covering of red and white lead to be overrated?—I do.

9677. Why?—Because the painters generally know red and white lead as "genuine red and white lead," and they get a pure article, whereas if they ask for a paint such as white zinc or oxide of iron, or red paints, or yellow ochres, they invariably get paints made from pigments which are adulterated with sulphate of barium and other things. Therefore, they cannot have a good covering paint, because they are not manufactured from the pure pigment—that is oxide of iron or zinc oxide. Ochres vary in their composition. They are natural products.

9678. How does the cost of your paint compare with that of lead paints?—The cost per hundredweight is more than the cost per hundredweight of lead paints, but the bulk which we obtain is nearly twice as much as that of lead paints. The specific gravity of lead paint is very great, and the bulk of the lead paint is very small in comparison with our paint, or even the ordinary zinc and pure oxide of iron paints on the market.

9679. Are your paints then very light?—Very light; in some cases as light as 10½ to 11 lbs. to the gallon.

9680. Is that an advantage or a disadvantage?—It is an advantage.

9681. (Mr. Sutherland.) May I ask what paint we are discussing? Is it known by any trade name?—It is "Schoberts Compositions." It is sold under that name.

9682. Is that the only name?—"Schoberts De-oxidising Paints."

9683. (Chairman.) You said just now that the lightness of your paint was an advantage?—Yes.

9659. (Lord Henry Bentinck.) It would not affect any shipowner so much as it would a house-painter?—Precisely.

9660. There would be no great hardship in forbidding white lead as far as shipowners are concerned?—No, I do not think so; I should not say so.

9684. Will you tell me why?—If you have a paint with heavy pigments, as the painter uses it, the heavy ingredients such as lead are apt to separate themselves from the varnish, or they run. For instance, in ships' hulls, where painting has to be done very quickly, the painter brushes up and down once or twice. That is not sufficient. The heavy ingredients of the lead separate themselves from the varnish or begin to run, whereas if the pigment is of light specific gravity this naturally keeps in suspension. That is the case in the drums. Our compositions could be kept for months in the drums and not have a sediment, whereas lead paints or heavy pigments would fall to the bottom and form considerable sediment within a week.

9685. Do I understand that you mean that your light paints adhere better to iron and steel?—On that account—yes.

9686. Do your customers tell you that it is no more costly to use a leadless anti-corrosive paint than to use lead paint?—Yes, those who have used it, decidedly; in fact they have found it cheaper.

9687. Over what period have your paints been in use?—They have been in use from 4 to 5 years.

9688. Can you name a few of the most important customers who have expressed their satisfaction with your leadless paint and have given repeat orders for it?—Yes, the Lancashire and Yorkshire Railway Company, the Great Eastern Railway Company, and Sir Frederick Bolton. We have had repeat orders from those.

9689. For what purpose do the Great Eastern Railway Company use your paints?—For hulls and for boiler plates inside the ship, for the top sides of ships, and for submarine work. Sir Frederick Bolton's Steamship Company have given repeat orders; in fact we had two or three quite recently. Those were for red paints. They found after a little while that they saved considerably. I think they told me at the time that the cost of their lead paints—red and white leads—came to 29s. or 30s. a hundredweight. It was experimented with some years ago, and they found out that our paint, which cost them 39s. a hundredweight, was going considerably farther, and the hundredweight of ours was close on 10 gallons—9½ gallons—whereas 10 gallons of the red and white lead paints weigh nearly 2½ hundredweight. 2½ hundredweights equal 9½ gallons. At 29s. a hundredweight that would bring the paint up close to 60s. for 10 gallons, whereas for our 9½ gallons they pay us 39s.

9690. Have you any other names to tell us?—Yes, the Farrar Groves Steamship Company; Pritchett's and Gold, Ltd., accumulator makers; and the Brentford Gas Company. The District Railway Company have tested it for close on 18 months, and they have promised us repeat orders. The Brentford Gas Company tested it for close on 12 months or more, and the orders came in without anybody calling on them.

9691. What did they use it for in the gas works?—For their gasometers—for the parts which are in and out of the water. Then we have several foreign governments. The Dutch Government have come back, and four or five Dutch gas companies. We had several from Denmark.

9692. Is yours a very large business concern?—It is at the present time not very large, but it looks to be a very promising concern.

9693. Have you made considerable progress in the last few years?—Yes, very considerable progress.

9694. Have you done anything with any other foreign governments?—Yes, we have supplied the Danish Government and the Swedish also.

19 July 1911.]

Mr. G. SCHOBERT.

[Continued.]

9695. Have you had repeat orders from those Governments?—We have had in the case of the Danish Government. We have supplied it to South Africa, and we have supplied it to the Darjeeling-Himalayan Railway. After they made their tests (we sent samples 18 months ago) the orders followed four or five months ago. Then another railway company in Australia sent, through their agents here (Adams and Co.), and the Capetown District Railway have used it at various stations there, and repeat orders have been promised recently.

9696. (*Lord Henry Bentinck*.) Is your paint suitable for use on bare iron chiefly?—Chiefly on iron and steel.

9697. Is it suitable for wood?—Yes, but we do not push it for wood. We make it chiefly for protecting iron and steel—not for decorative purposes.

9698. (*Dr. Collis*.) I understand that it takes the place of red lead on bare iron?—Yes, on bare iron.

9699. A great many steamship companies stipulate that the iron plates shall be covered in the first instance with red lead, and your paint would entirely take the place of it?—Equally well as far as I can see.

9700. Could it be used without any lead basis being previously applied?—Yes; not a quarter of an ounce ever comes into the place.

9701. No lead basis?—No lead basis in the varnish or in the paint.

9702. Take a newly-built ship sent from the builders, treated as it is to-day with red lead, would you be prepared to say that your paint would do as a protection for the bare steel?—I am quite prepared. I have tested it for years and years. The natural effect on a newly-built ship is for the mill scale to come off, whether red lead or my paint is used.

9703. That is a mechanical effect?—Yes, from the vibration of the ship. The mill scale will fall off.

9704. That is not quite a point of comparison between the two paints?—No.

9705. You mentioned the introduction of a percentage of arsenite of lime. For what special paints is it introduced?—Chiefly for outside purposes, to protect against sea air. We use it still stronger for the first coating of vessels which are submerged in water. We use it up to 15 per cent.

9706. Is that rather as an anti-fouling?—Not only as an anti-fouling. It proves an anti-fouling if certain varnishes are added to it, but on a new ship for the first or second coat we would put it on simply for the purpose of anti-corrosion.

9707. Both above and below the water-line?—Yes.

9708. The extent is from 3 to 5 per cent.?—Yes, in submarine work we would go up very likely to 10 or 15 per cent.

9709. Is your paint made at home or abroad?—In England.

9710. In London?—Yes.

9711. Where is the factory?—At Plaistow and Stratford.

9712. Schoberts is the name of the firm?—Yes.

9713. Is the formula which you use an English invention?—Yes.

9714. Your own?—Yes. We have patented it abroad also.

9715. You have said that you use a coal-tar naphtha with a high flash-point—you mentioned 100°. You did not say whether Centigrade or Fahrenheit?—Fahrenheit.

9716. How does that compare with the flash-point of turpentine?—The flash-point of turpentine is, I think, 93 or 95.

9717. So that, roughly speaking, it is very closely the same?—Yes, closely the same, but turpentine is corrosive.

9718. Do you maintain that coal-tar naphtha is not?—It is not corrosive.

9719. You mentioned the point that you did not use any lead driers. What do you substitute for lead driers?—I use air. I treat my oils with air in a particular way. I might add a slight bit of manganese if it is wanted, but in the majority of cases I never do that.

9720. The way in which you prepare your oil produces the effect that is produced by lead driers. You have some form of aeration under heat, I suppose?—Yes.

9721. To produce the same effect as is produced by lead driers?—Yes.

9722. What is your opinion of the way in which lead acts as a drier? Have you studied that point at all?—Yes. Lead acts as a very good drier indeed.

9723. But the chemical way in which it acts?—It forms oleates. It carries oxygen or gives up oxygen.

9724. It transfers the oxygen from the air to the oil?—Yes, and partly its own oxygen.

9725. It acts as a carrier?—Yes.

9726. You produce this effect by aerating your oil?—Yes.

9727. That is the chemical reason?—Yes. In some cases there is a slight percentage of manganese added.

9728. That acts in the same way as a carrier of oxygen?—Yes, more so than lead.

9729. With regard to the gasometers that you mentioned, were they new gasometers, or had they been originally protected by any other coating?—I could not say. They tested at the commencement with scraped plates before they gave us the order. In the case of Pritchetts and Gold, Ltd., it was bare work. It stood for three years. I have a sheet at home showing that the paint after three years was like indiarubber.

9730. It was tensile?—Yes.

9731. What exposure had it had at Pritchetts and Gold, Ltd.?—It was inside and outside of the gasometers. We had it in one of Döwling's purifiers.

9732. The test of paint on gasometers is particularly severe?—Particularly severe. You have ammonia vapours and sulphur vapours and the atmosphere, and it is in and out of the water.

9733. How often does a gasometer in the part which is going in and out of the water require to be painted when covered with your paint?—In this particular instance it stood close on three years before they renewed it.

9734. How often has a gasometer to be painted in the ordinary way when painted as in the past with red lead; do you know from your own experience or from what you have heard?—I should not like to say. In many cases every two or three years or four years they have to be painted.

(*Dr. Collis*.) I have heard it suggested that it is a shorter period even.

9735. (*Mr. Sutherland*.) You do not push your paints for building purposes, for houses and decorative purposes?—No, not for inside work.

9736. Mainly for structural ironwork?—Yes.

9737. (*Mr. Fell*.) Do you use your paint at all for motor car and carriage work?—We have had it on motor car and carriage work underneath.

9738. Where?—Private gentlemen have used it on their motor cars.

9739. How has the paint stood?—Exceedingly well, even on the exhaust box, which gets very hot. It has stood there for six months.

9740. Has the car been painted throughout with your paint?—Not the top parts.

9741. Not the steel work and the body?—Not to my knowledge.

9742. Have you tried it on wheel work at all?—Yes.

9743. Has it been quite satisfactory?—Yes.

The witness withdrew.

19 July 1911.]

Mr. H. B. BAKER.

[Continued.]

## Mr. H. B. BAKER, examined:

9744. (Chairman.) Are you a perambulator manufacturer?—Yes.
9745. What is your firm?—Rothschild and Baker.
9746. Of Birmingham?—Of London and Birmingham.
9747. What length of experience have you had in the perambulator trade?—About 20 years on my own account.
9748. Are you connected with any trade association?—Yes; there is the wholesale perambulator association.
9749. How long has this association been in existence?—For about a year.
9750. Does it now include a fair proportion of the firms engaged in the trade?—Yes, about two-thirds.
9751. Is your own firm one of the leading firms of perambulator manufacturers in the United Kingdom?—Yes, I think that we are about the second largest.
9752. Can you speak to-day in the name of the association?—Not exactly.
9753. Do they know that you are coming here to give evidence?—The secretary did.
9754. Do you think that they would generally approve of what you say?—Yes, I think they would.
9755. How many workers do you employ?—We employ about 180 people at the present time.
9756. How many of these come in contact with paint?—Thirty.
9757. Do you manufacture various patterns and qualities?—Yes.
9758. Have you had any experience of the use of leadless paint for your perambulators?—Yes, for the past three or four years.
9759. Have you used leadless paint exclusively for the last three years?—Yes, we have used nothing else. We dropped the use of crude lead colour three or four years ago.
9760. Do I understand that you use no lead whatever in finishing your perambulators?—As far as we can avoid it. We buy all our paint leadless at present from the paint makers.
9761. What led you to abandon the use of lead paints?—I had a case of lead poisoning or two.
9762. And did that cause you to look round for a substitute?—Yes.
9763. Are you satisfied that the leadless materials that you are now using are equal in every respect to the lead formerly used?—Very nearly. For all practical purposes they are as good.
9764. Do you obtain an equally good finish without the use of lead?—Yes.
9765. Is the cost the same?—Yes.
9766. Can you tell us that you are satisfied that it is no more expensive to use than lead?—Yes; I am sure that it is no more expensive.
9767. Have you had to increase the number of coats of paint used?—No, not even on the cheapest work.
9768. Have you found the durability of the leadless paints equal to that of the lead?—Yes, as far as my experience has gone. I have not seen anything to lead me to suppose that it is not as good as lead.
9769. Your experience covers a period of three or four years?—Yes.
9770. May I take that answer to mean that you have had no complaints from customers as to durability?—Yes.
9771. Do you consider that the three or four years that you have been using the leadless paints is sufficient time to establish their durability?—Ample.
9772. Would you expect to get complaints in very quickly if the paint were unsatisfactory?—I should, within three or four months.
9773. Why is that?—The goods would soon show in the shopkeeper's hands if they were not standing up to the varnish and all that sort of thing. They would chip.
9774. You consider then that three or four years is really a substantial test of the durability of paints on perambulators?—Yes, I do.
9775. Would you say that that test would represent a greater length of time than the life of a motor car?—No. The motor car has rather different usage and is expected to last longer, I suppose—the body work; but I think a perambulator would be a greater test than a motor car. It does not have so many secondary coats or as many coats of varnish on the top to protect the priming coat.
9776. Are you satisfied that the paint you are using is absolutely leadless?—I have a guarantee from the manufacturers that it is so, and I have had no case of lead poisoning since I have been using it.
9777. Are the processes which you follow in painting a perambulator similar to those employed in the carriage painting industry?—Yes; in the better goods it is exactly the same. In the cheaper goods they are modified to some extent.
9778. How many coats would be applied to the cheapest perambulator?—Not more than three.
9779. In the better quality of perambulators would you start with a priming coat of a leadless paint?—Yes.
9780. Would that be sand-papored down?—Yes.
9781. Would filling then be applied?—Yes, the filling would then be applied or two coats of leadless priming would be used.
9782. Do you use an absolutely leadless material for filling?—Yes. I have never had any trouble with that.
9783. Do you use a stopping similar to that used in the carriage painting trade?—Yes.
9784. Is your stopping made up from the same material as the paints?—It is made with a whitening basis.
9785. But it is quite leadless?—It is quite leadless.
9786. I believe there have been one or two cases of lead poisoning in the perambulator trade traced to the use of gimp pins coloured with lead paints?—Yes.
9787. Have you succeeded in eliminating lead even in that branch of your work?—Yes.
9788. Are you using now electro-tinned gimp pins?—Yes.
9789. (Lord Henry Bentinck.) You have noticed a decided improvement in the health of your workmen?—We have not had any lead poisoning since.
9790. (Dr. Collis.) Could you tell me what precautions you were adopting in your factory when you were using lead paints?—Just the ordinary precautions to see that they washed themselves, and did not take food in the workshops and so on.
9791. They had washing accommodation provided?—Yes.
9792. Did they wear overalls?—Aprons.
9793. And did they make use of the washing accommodation?—Yes, when we could get them to do it. We had a deal of bother in that way.
9794. You gave them time in which to do it?—Yes.
9795. So that notwithstanding that they had these aprons, and they were, as far as you could make them, cleanly, with your supervision, cases of illness were occurring?—Yes, we had not very many, but we had a few.
9796. Was it because of the economical side that you had to pay compensation, or was it pure philanthropy that caused you to change over to non-lead paints?—I should think that it was the factory inspector.
9797. What precautions was he suggesting to you to try to get rid of the danger which had occurred and which caused the trouble?—I do not remember that he suggested a leadless paint, but he used to look pretty sharply after the washing arrangements.
9798. Were any suggestions made with regard to trying to remove dust in rubbing down?—No, I cannot say that I remember that.
9799. No question of any exhaust ventilation?—We have that in the shops. It was put in previously.
9800. A localised exhaust ventilation for removing dust?—Yes.
9801. By hoods and ducts?—No. In this case the ventilator is in the centre. It is an arched shop.

19 July 1911.]

Mr. H. B. BAKER.

[Continued.]

9802. A ventilator for the whole room?—Yes.  
9803. Not localised?—No, not like we have in the polishing.

9804. You polish metal?—We have grinding and that sort of thing.

9805. And you have a hood right on to it?—Yes, and on the sand-papering machines.

9806. Sand-papering what?—Sand-papering the woodwork.

9807. Do you build the bodies?—The panels and parts go over the machine.

9808. Sand-papering the paint?—No, sand-papering the wood.

9809. Before it is put together?—Yes.

9810. Could such an appliance be used for removing dust caused in the rubbing down of paint?—No, I do not think so.

9811. Your evidence is important on that point, because you know how these dust appliances are used in removing dust in sand-papering other things?—Yes.

9812. You do not think it practically possible with paint?—A bulky thing like a perambulator body is too big to get under a hood. Even with small body work it would be difficult, and with a full sized carriage it would be practically impossible.

9813. What is the priming you usually put on?—It is a primary colour called "Tinto" from — of

9814. (*Mr. Sutherland.*) They are the white lead people?—Yes. They guarantee it absolutely leadless.

9815. (*Dr. Collis.*) They are white lead corrodors, and if they guarantee it absolutely leadless I think you are pretty safe. Now can whiting be applied as a priming coat on woodwork for your purposes?—Yes. I have no experience of the actual mixing or grinding of colours. We do not grind them. We buy them ground, as most painters of body work do. Whether it contains whiting or barytes, or some of these other bases, I cannot tell you.

9816. I was wondering how far your work would correspond at all with furniture painting on woodwork?—It is different with regard to furniture painting. There is a priming of whiting put on cheap furniture.

9817. And on the better class too. Could it be used on your work?—To some extent it could. We use a filling-in between the lead colours that has a whiting base.

9818. It has been suggested that for priming purposes certain paints, particularly lead paints, have their value for filling the grain of the wood?—That is so.

9819. I was wondering how it was that the furniture people could do some of the high-class work that they do, using a whiting priming coat and nothing else?—I could explain that. Furniture is not used out of doors, and you do not have to have the same stability. It is used as a mere stopping, and not for protecting the wood afterwards. It is simply to fill up the grain so that they can polish on it.

9820. It has been suggested that the lead priming is only to fill up the grain for the after covering, and I was wondering where the difference came in when whiting was used. You do not use it in the perambulator trade?—We do not use it in the perambulator trade. We use a mixture that we make ourselves for stopping. Where we used lead colour previously we are now using this proprietary colour as a substitute, and then we get on to the filling.

9821. With regard to gimp pins, lead poisoning cases occurred from them. It was the custom to put the gimp pins in the mouth?—Yes.

(*Dr. Collis.*) I wanted to make it clear how the poisoning was caused.

9822. (*Mr. Fall.*) I take it that with perambulator work there is an enormous amount of sand-papering?—A good deal.

9823. And practically there is no possibility of adopting a wet rubbing down process?—It is too expensive. It is used on high-class goods. That is

exactly the same process as you have in all coach shops or motor shops.

9824. You said just now that you had had no complaints?—Yes.

9825. You are wholesale people?—Yes, but we should get the complaints very quickly.

9826. With an ordinary perambulator, no one would take the trouble to complain if the paint began to crack?—Do you mean a dealer?

9827. No; a person who buys the perambulator?—I think so. I think people to-day know what they want, and what to expect.

9828. What variety of colours do you use?—We use an immense variety.

9829. Have you any difficulty?—It occurred to me as soon as I started this morning whether a white enamel is absolutely leadless. I do not see why it should not be made so. I have never raised the point.

9830. Do you use any chromes?—Yes.

9831. You get lead there?—You can produce a yellow without having it made in that way, I suppose. We do not use a great deal; most of the colours follow the coach lines, and they are dark.

9832. (*Mr. Robins.*) I take it that much of your dust is caused by sand-papering the filling?—Yes.

9833. I believe in the process of your trade most manufacturers, even those of your own calibre and larger, do the greater amount of the filling up on bassinettes with whiting, vegetable black, and glue?—A good deal of that is done with the cheaper and middle class stuff.

9834. With the best perambulator makers even a very small percentage of lead would be used, taking the highest finished work?—Practically only the first coat and the stopping, when it would be rubbed down wet. Then what would be used for the filling is dry white lead and gold size.

9835. I speak with authority—it is very rare that the perambulator is rubbed down with the wet process?—Not to-day.

9836. The danger comes from the dust from the sand-papering?—I do not use lead at all.

9837. There is no white lead in the stopping at all?—No.

9838. (*Chairman.*) Do you have to contend with foreign competition?—No. The foreign competition we get is with Japan-stoved stuff. American goods.

9839. (*Mr. Robins.*) It surprises me that there is any case of lead poisoning in the perambulator trade?—We have had two or three.

9840. (*Chairman.*) You will find a good many in the statistics. You say that you have for some years given up the use of all lead paints, and shall continue that?—Yes.

9841. Do you think that that ought to be applied to your fellow manufacturers?—I do not see why not.

9842. Do you think that they would object if we prohibited the use of lead in the perambulator trade?—I do not see why they should.

9843. (*Mr. Mason.*) What class of man paints perambulators—a coach painter or brush hand?—We have some very good men who would come out of the same shops as the coach-painter and the motor car painter. They are the same hands. But we have to employ a lot of cheaper labour, and it is among them that we get the trouble.

9844. The better class of man gives less trouble than the cheaper grade?—Yes, he does not do sand-papering, for instance.

9845. (*Chairman.*) He does not come into contact with so much dust?—No; that is the point.

9846. (*Dr. Collis.*) Do you use lead paint for stoving?—No, I do not, not in the Japan. I have never questioned it.

9847. As far as you known, you do not use it in the Japan?—No.

9848. You carry it on in the same way as for japanning furniture?—No.

9849. Such furniture as bedsteads, I mean?—Yes, exactly in the same way as bedsteads.

The witness withdrew.

19 July 1911.]

Mr. H. S. BALL.

[Continued.]

Mr. H. S. BALL examined.

9850. (*Chairman.*) Are you the works manager of Messrs. Chubb and Son's safe-making factory at Wolverhampton?—Yes.

9851. Have you been instructed by your firm to attend here for the purpose of giving evidence regarding the use of lead?—Yes.

9852. Is there any employers' association to which safe manufacturers belong?—I believe not. I have never heard of one.

9853. About how many important firms are engaged in the safe trade?—I should think that six would cover the important names, but there are innumerable small makers.

9854. Is your firm one of the largest of those manufacturing safes in this country?—Yes.

9855. Are you, as representing one of the largest firms, qualified to speak with regard to the safe trade generally?—I think so.

9856. Have any of your colleagues, in other firms, cognisance of your attendance here to-day?—Not that I am aware of.

9857. Would not anything you tell us concerning your own works be applicable, in general, to the other safe manufacturers?—I should say so.

9858. Have you, of recent years, largely abandoned the use of white lead?—Yes, ever since we have been at Wolverhampton Works, and for several years before for the purpose of stopping.

9859. In what form is the zinc white used?—We purchase it in the form of powder and mix it into a paste with gold size and turps.

9860. Would that be precisely the same as with white lead?—Yes, practically so.

9861. Would it be precisely the same in the method of use as in the case of white lead?—Yes, precisely.

9862. Is the stopping rubbed down with sand-paper after it has been applied?—Yes.

9863. Do you consider that this is a dangerous process, when lead is used?—I think it is the most dangerous process of any that we have to do with.

9864. Did you have any experience of lead poisoning cases when you were using white lead?—Yes, we had several cases. I am not personally aware of the nature of them. They were slight ones.

9865. Have you removed this evil by substituting zinc white for stopping purposes?—Entirely so. We have had no single case since.

9866. Apart from the risk of poisoning, do you find the zinc white as efficient as white lead?—Quite so. Our head painter states that, apart from the risk of poisoning, he would prefer to use zinc white.

9867. What are his reasons for this?—He considers it superior in results—finish and durability also.

9868. Do you find the use of zinc in place of lead affects the cost?—Although the zinc white costs about 34s. a hundredweight compared with white lead at 23s. per hundredweight, the lead is so much heavier that there is very little to choose in the cost. I would like to add that I think the balance would be in favour of the zinc.

9869. Do you still use some white lead in your painting operations?—Yes, in the form of liquid paint for brush work.

9870. Safes are used entirely inside buildings and are therefore not exposed to any weather conditions?—That is so.

9871. It appears to be very generally agreed that lead is not necessary for surfaces which are not to be exposed to the weather?—I should say that that is so.

9872. I presume, therefore, that you would have no objection whatever to a restriction being imposed on the use of lead for painting safes, if such a step is taken in regard to other painting?—No objection whatever.

9873. (*Mr. Sutherland.*) Do I understand that you use white lead paint as paint?—Yes; I believe that white lead is the basis of most of our paints.

9874. And you use those?—Yes.

9875. You have no lead poisoning cases?—No, because it is all in liquid form. There is no powder.

9876. The lead poisoning cases came from the stopping?—Yes.

9877. And the rubbing down?—Yes.

9878. (*Mr. Mason.*) You have no objection to using a zinc paint in place of white lead paint?—None at all. We are doing so, all the time.

9879. Perhaps I do not understand. You have given up white lead as a stopping?—Yes.

9880. But I understand that you still use it as a paint?—Yes, as the basis of most paints. It is still in use. I have no personal experience of the effect zinc white would have as the basis for liquid paint.

9881. You are quite content to give up white lead as a paint?—As a stopping.

9882. Only as a stopping?—Yes, purely.

9883. Not as a paint?—No. I have no experience at all from which to speak with regard to that.

9884. (*Chairman.*) I do not think that you quite understand the question. I understood you to say that you would agree to give up the use of lead in all respects?—I would hardly go so far as to say that, because I have no experience at all of zinc white as the basis of liquid paint, but only as dry stopping.

9885. But in answer to my question just now, when I said that it was generally thought that for all internal work lead could be dispensed with, and I asked you whether your firm could dispense with lead, you said "Yes"?—I think I misunderstood. As the basis for liquid paint, I have no experience at all of anything but lead.

9886. Would you have any objection at all to the prohibition of lead entirely?—There again I can hardly answer except with regard to stopping, because I have no experience of anything but lead.

9887. Would it be detrimental to your business if lead was prohibited?—Not if the substitutes were equally good. I know nothing of the substitutes.

9888. You cannot answer the question?—No.

9889. If white lead was prohibited throughout the safe-making trade, would your firm readily acquiesce in such a prohibition?—That I cannot answer.

9890. (*Mr. Fell.*) The stopping would only represent a very small percentage, would it not, of the total amount of paint used?—Yes, I suppose it would.

9891. (*Mr. Sutherland.*) That is the source of lead poisoning, because since you have given it up you have not had a case. Is not that so?—That is so.

9892. I presume that the dry rubbing down would follow the stopping?—Yes; that is the dangerous process.

9893. (*Mr. Kinggate.*) Do you sand-paper the paint—the first priming coats? I understand that the priming coats are all lead?—Yes.

9894. Do you sand-paper them?—No, not till after the stopping.

9895. You stop them completely?—Yes, over the priming coat.

9896. Is there a large quantity of stopping?—Yes, a considerable quantity.

9897. (*Mr. Robins.*) What is the primary reason for using the coat of white lead first, instead of using zinc white first? What is the primary reason for using lead as a base now?—We always have done so, and we continue to do so. We have not found any reason for altering it.

9898. I take it then that the reason is really to make the stopping adhere to the iron?—That is the reason for the priming coat, of whatever material it is made.

9899. Safes are regularly plastered with stopping?—Yes.

9900. If you found zinc white paint adhering, you would be quite willing to use it for the first coat as a base?—Yes.

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

9901. (*Chairman.*) You might ask your firm the question about the prohibition altogether?—Yes.

9902. Perhaps you would kindly let us know their answer?—Yes.

The witness withdrew.

Mr. CHARLES A. LINE examined.

9903. (*Chairman.*) Do you attend here to-day as an expert in the paint trade?—That is so.

9904. Have you studied the subject of the use of lead in paints for many years?—Yes, more particularly in the last 10 years, but really from the time that I was 21 years old: say 35 years.

9905. Were you the founder and for some years head of the firm of John Line and Sons?—Yes, of the original firm of John Line and Sons, Reading.

9906. I understand that you ceased to have any financial interest in the business some time ago?—About 17 years ago, when I heard of the intention of the British wall paper manufacturers to form a combine.

9907. Are you still consulted by them with regard to paint questions?—Yes, constantly.

9908. Do you frequently have painting contracts carried out under your direction?—Very frequently, more or less under my direction, but as a rule it would be to assist a local architect or engineer who had work in hand and came to me as a consultant.

9908. Is your advice sought by others than the firm of John Line and Sons?—Yes, very frequently by practical painters and by the public and professional men also.

9910. Will you name a few architects or others who have consulted you?—Mr. F. B. Andrews, of Colmore Row, Birmingham; Messrs. Osborne, Holland, and Hobbias; also Messrs. Essex and Goodman, Messrs. Cheate, Dunn, Hale, Harris, Harvey, Mansell, Martin, Peacock, Butler, and, in short, most of the leading local architects, &c.; and Mr. Henry Leo, consulting engineer, who, some little time ago, built a factory for Messrs. Mitchell. In that factory there are approximately 14,000 feet of hot-water pipes which had to be painted. Mr. Leo refused to allow the painters to use white lead paint, and he sent for me and I specified a mixture of zinc oxide and zinc sulphide with manganese linoleate drying oil and a little gold size. It was perfectly successful and it did not discolour.

9911. Have you devoted special attention to the possibility of using non-poisonous substitutes for white lead?—Yes, I have.

9912. What led you to study paints from this point of view in the first instance?—When I was about 21 years of age I had an inquiry for what is now a well-known water paint, which was then in its infancy. I carefully went into it and took the advice of chemists, and I was convinced at that time that white lead was more or less unnecessary, and that zinc-sulphide paint ultimately would heat it out. I went in for the thing that I thought was going to succeed.

9913. Did the prevalence of lead poisoning influence you at all in coming to that decision?—Not at that time. I was not concerned about it then; but in the last 10 years I have become astonished and alarmed at it, and that has affected my judgment.

9914. Have you personally known many serious cases of lead poisoning?—Very many.

9915. Can you give us any idea of the numbers?—For months and months, at the suggestion of my brothers, I visited painters personally in and around Birmingham, and it was a common practice to find a fresh case every day. I should say that there are in Birmingham at the present time 150 cases of lead poisoning, very few of which are reported; indeed, only seven cases (according to a lecture by a medical officer of health) amongst house painters and 17 amongst coach painters during 12 months past.

9916. (*Mr. Parsonage.*) We have many cases there?—It is absolutely phenomenal. It is simply appalling. Some master painters will tell you, when you call on them, that they have never heard of a case amongst their men. They say, when you question them, that there might have been one years and years ago in the case of a very dirty painter. If you speak to the operative painter about it, he sometimes considers himself insulted.

He says, "Do you think I am a man of dirty habits?" When you thresh it out with them and get down to the bottom of things, you find out that they are perfectly well aware that the trade in Birmingham is honey-combed with it, and they sigh for relief from the intolerable danger.

9917. (*Chairman.*) You say that you do know that many of these cases are not reported?—I cannot say that they are not reported, but in my opinion they are not, because I have been led to understand that factory inspectors, or, rather, certifying surgeons, are not liable to report them unless the cases occur in a paint manufacturing concern which is under the Factory Acts, for which reason they escape being reported and are never heard of. Moreover, I believe the certifying surgeons habitually omit to report cases which do come to their knowledge; there being no pay for doing so, and it is, in a way, not their business.

9918. They are not bound to report them. Do you consider that lead poisoning cases amongst house painters should be made reportable?—Yes.

9919. Can you produce any statistics to support the statement you have just made?—I cannot say that I have ever compiled statistics, but in the course of preparation for my lectures I have availed myself of information from the Registrar-General; and gentlemen of his staff have computed that in 10 years there could not have been less than 9,418 cases of lead poisoning amongst painters. I have that in writing from the Registrar-General, or, rather, from a gentleman at Somerset House who has charge of the Statistical Department.

9920. Have you something to say about Dr. Jones, of the County Asylum, at Ohell?—I have a letter. It appears that some considerable number of years ago Sir Thomas Oliver reported about Ohell Asylum, and that being so, I wrote to Ohell Asylum in these terms: "April 12th 1911. The Medical Superintendent, Ohelbury Asylum, Essex. Dear Sir, I have been requested to write an outline of the evidence upon plumbism in painters which I have been asked to give before the Departmental Committee upon the prevention or mitigation of this evil result of using lead paints. In the 'British Medical Journal,' 22nd September 1900, Dr. R. Jones' most valuable statistics appear. 133 patients were workers who had used lead, divided thus: painters, 75; decorators, 13; plumbers, 18; gas-fitters, 13; grainers, 3; gas-motor makers, 2; colour grinder, 1; file outter, 1; tea lead roller, 1. Of these persons the mental condition was diagnosed as: mania, 37; melancholia, 33; dementia, 10; dementia and epilepsy, 10; dementia with paralysis, 24; general paralysis, 7; alcoholic mania, 3. And Dr. Jones found lead in brain and cerebellum. I have the honour to appeal to you, Sir, to assist me with later information for which I should be ever grateful to you. I write brief articles and lecture with lantern slides entirely at my own expense, and I have quoted 'Dr. Jones' as proof of the danger to painters of white lead. You may like to know that sulphate of lead is now being made on a commercial basis. Your obedient servant, Charles A. Line." The reply came as follows:—"County of London, Ohelbury Asylum, Woodford Bridge, Essex, April 12th, 1911. Dear Sir, I am just starting off for some time, and I much regret I have not the opportunity to go further into the question of lead and mental diseases. I have read your account with interest and am sorry I cannot help you at present. The condition is less frequent now than when I wrote. Yours faithfully, Robert Jones." I took that to be an admission that he had so written.

9921. (*Mr. Sutherland.*) What is the date of the 133 patients?—I cannot remember, but I think that it is 1899. Sir Thomas Oliver is of opinion that it is less

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

frequent now; that is to say, that there are somewhat fewer painters who become maniacs through using white lead.

9922. (Chairman.) Do you think that that is attributable to the improvement in other trades?—It is impossible for me to say; but I think the painters take more precautions, knowledge on the danger having spread.

9923. Have you collected any statistics of the number of fatal cases?—I have not myself. I have entirely relied on information which I have seen in the Board of Trade Returns, and which was furnished to me by the Registrar-General.

9924. I suppose you know that the Registrar-General's Returns include 284 definite deaths from lead poisoning among painters in the last 10 years?—I understood that those were the reported cases; but I do not think, and I do not for a moment believe, that they are a tithe of the cases that occur—not a tithe of them. They could not be.

9925. (Mr. Sutherland.) You would not multiply that by 10, would you?—I should multiply by more than 10.

9926. (Chairman.) I believe that you are not in any way financially interested in any one brand of paints rather than another?—Not in any way.

9927. Even when you were financially interested in a firm of decorators, was your trade such that it was equally to your interest to supply either lead or zinc paints?—At the time when I was financially interested in John Line and Sons, Reading, the firm supplied decorators. My personal proclivities are very strong indeed in favour of zinc paints and against white lead paints, but I am not financially interested. If a ton of zinc sulphide paint were sold to-day, or a cwt., it would not make a particle of difference to me.

9928. Two important factors in connection with any substitute for white lead are the cost and durability of the paint. Do you agree with that?—Yes, I agree with that.

9929. Has it been your experience that an equally durable paint can be made from zinc at much the same price as a lead paint?—Yes, that has been my experience. I should not hesitate, if I were painting my own property, to discard white lead on economical grounds, and use zinc sulphide, properly thinned, for all undercoating and all interior work.

9930. What do you say about exterior work?—I should also use it, properly thinned, but I should apply varnish over it, or add varnish to the last coat in that case, I think. But to lessen cost of maintenance, I should prefer a paint the base of which would be zinc oxide, containing about half per cent. of lead (occurring naturally in the ore) ground into zinc white paint (not foreign lithopone, however) composed of 36 per cent. of zinc sulphide in the zinc white. Asbestine might be added in a small proportion with advantage. I specify half zinc oxide with half zinc white to make the stiff pasté ground with 20 lbs. of oil to the cwt., supplied ready for being thinned out with turps, oil, and liquid manganese drier.

9931. Are the relative costs and durability of the paints dependent at all upon the pigment?—I think that very much more depends on the thinnings, and if you would allow me, I could explain why.

9932. Yes, please give your reasons?—You might take a semi-transparent, an opaque, or a transparent pigment with suitable thinnings, and you could make it into very durable paint indeed without using a particle of white lead or a particle of zinc oxide. You could also apply improper thinnings to white lead, and it would not be durable at all, especially if you used the kind of driers that most painters, unfortunately, use. On the other hand, you can take zinc oxide and you can apply the right thinnings to it, carefully selecting manganese linoleate drier and get a perfectly durable paint, which, in the opinion of His Majesty's Office of Works, has from two-and-a-half to three-times the durability of white lead, and I believe that it has. Not only so, but if you take zinc oxide and mix it with plumbago—that is to say, with graphite—you can then obtain a protective paint for iron and steel of which I have examples here, which

has phenomenal durability. I have brought some plates of cast iron and steel here which were painted a good many years ago. (The witness produced the plates.) These plates have been hung up inside a factory smoke-stack for approximately 12 months. After being taken down and washed, they have been carried about as samples, and left in the damp and the dry since August 1906. You may cut the paint off the steel with a pocket knife. It is perfectly flexible, as it ought to be. On the other hand, paints which are chippy, which readily break and fracture, are no good. This is graphite. If you cut it off you see that it is perfectly flexible like so much india rubber. This has no zinc oxide in it, but that has.

9933. Which is the better?—For dark colours the graphite is perfectly satisfactory. It has this advantage, that if you apply it on a hot water heating installation, you lose no radiant heat; whereas with aluminium, you lose 25 per cent. of radiant heat. It is not generally known, but it is so. I have proved, in some chemical works close to a gasworks, that if you mix zinc oxide and graphite it resists ammonia fumes, and the presence of sulphuretted hydrogen better than anything they ever had. I call it ferro-sote from *σάζον* (sozein) to protect, and *ferrum*, iron. It protects the iron. It is a simple compound of zinc oxide and graphite which they mix themselves at the works. For light grey tones I use mostly white zinc oxide darkened with graphite or titaniferous magnetic iron oxide.

9934. What are the thinners which you use?—Pale drying oil. These paints should be applied warmed, and either linseed, tung, or sunflower seed oil, prepared or cooked with manganese oil drier may be used with a little turpentine for diluting the stiff paste.

9934a. Are the oils and driers commonly used for lead not suitable for zinc paints?—They are quite unsuitable in my opinion.

9935. Why?—As a rule they are a wet solution of manganese which causes blistering; otherwise they are very often barytes which has very little, if any, drying power. Then they may be lead acetate, which to my mind is very poisonous, or they may be litharge or oxide of lead. All these things are inadmissible in the case of zinc, particularly in the case of zinc sulphide, because if you add oxide of lead to zinc sulphide, the whole thing turns black.

9936. What should be used as driers for zinc paints?—In my opinion, manganese in very small proportions, the linoleate or the borate, or the resinic if properly added to linseed oil which has been previously clarified and heated to 212 degrees, at which temperature you can well stir in the manganese oil and spirit solution drier. It forms an ideal oil for paint, whether white lead or zinc oxide. I believe in the driers being in the prepared oil and not sold separately for using with cold raw oil.

9937. How should the oil be prepared?—I am not able to say positively from my own personal knowledge of having seen it prepared. But I have ascertained from several independent sources how it is prepared, and, putting these different independent observations together, I have every reason to believe that this is what takes place: The oil, linseed or other, should be warmed to about 160 degrees Fahrenheit to coagulate the albumen, just as when you boil an egg the transparent albumen becomes opaque. When it becomes opaque it sinks down, and this can be facilitated by the addition of a little dilute sulphuric acid. This will throw down what we call the footings which consist of impure albumen and resinous oil, which can be used for putty but not for paint. The clarified oil is pumped into another vessel and then heated to 212 degrees Fahrenheit, after which about 2 per cent. of linoleate or borate of manganese is added in a spirituous solution, such as turpentine solution. What I maintain is that it not only mixes—you can easily mix a solid drier with the paint—but you can make this liquid drier amalgamate, which is a very different thing from mixing. It permeates the whole of the oil in such a way that 2 per cent. will do the work of almost 20 per cent. of any other drier, and thereby you save the cracking of the paint.

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued]

9938. Is the oil so treated suitable for zinc paints?—Eminently suitable.

9939. Is it a perfect oil for zinc paints?—It is quite suitable for making enamel or for painting.

9940. Would further driers have to be added to it?—Only in very bad, damp, cold weather when the paint is liable to chill in the drying, then liquid drier is used (not terebine however, that is a lead drier).

9941. Is an oil so prepared not generally known in the trade?—It is well known, but it is exceedingly difficult to sell it until a painter has once bought it. The difficulty is to get him to buy it the first time, because he kicks at 5*d.* per gallon extra. But after he has once bought it he will give 5*s.* 6*d.* a gallon instead of 3*s.* 6*d.* for something else, and he will not make trouble about the 2*s.*

9942. With what particular zinc compounds do you get the best results?—For inside work I have always obtained the best results with sulphide of zinc for undercoating and finishing coats, and with zinc oxide for enamels; but for outside work the sulphide can be used with proper driers and a little varnish or ground into oxide half and half.

9943. What is the value of zinc sulphide?—Zinc sulphide commercially sold has nearly double the bulk of white lead, and it is worth from 22*s.* to 24*s.* per cwt. according to the price of oil. It is about the price of white lead, but with double the bulk. I say to a painter: "Will you have zinc sulphide, because if so we will pack it in two kegs. If you have white lead we can pack it in one keg." The man says: "What is the meaning of that?" and I say: "It covers twice as far," and with equal density, nearly as much as double the weight of white lead.

9944. In what way is it better?—It does not discolour and it is non-poisonous. Its covering power is very great. It is dense. It is considerably better than white lead in covering power. I have a letter in my pocket from a practical man, saying, "It covers better than any white lead I have ever used." Then another advantage is that there are certain staining pigments which are inadmissible with white lead, but which are perfectly admissible with zinc sulphide—anything of a sulphurous nature.

9945. How does it compare with white lead in regard to covering power and density?—Its density is equal to that of white lead, and it has greater covering power. If you spread it out very thinly, it does not obliterate quite as well as white lead. The great point is that you can use it thicker.

9946. Do you consider preliminary priming coats of lead paint necessary before zinc paints are applied?—Not at all necessary.

9947. What would you use for undercoats when painting with zinc paints?—I should use a first class water paint, thinned with a silicate of soda emulsion. We call it petrifying liquid. It has great advantages. You can apply it with a distemper brush instead of a small paint brush, and, however thickly you lay it on, it sets hard right through, and is capable of being rubbed down, and it effects a very great saving in labour.

9948. Does such a water paint give you a hard foundation?—Yes, a perfectly hard foundation. If it form a blob-like a marble on the wall and you break it off the next morning, it is nearly as hard as marble; but if it were white lead running down in a tear it would be simply a little oil sack.

9949. (Mr. Sutherland.) You are speaking with regard to wood?—Yes, not iron.

9950. Wood or plaster?—Wood or plaster.

9951. (Chairman.) Take a paint made of zinc sulphide precipitated with barium sulphate; is this not commonly known as lithopone?—It is; but I would not call it that myself. I have had offers of lithopone as low as 6*l.* a ton. The persons who offered it stated how much zinc sulphide there was in it. I did not believe them, but they said there was very little. Such a paint ought to have at least 25 to 30 per cent. of zinc sulphide in the pigment in my opinion. British zinc white (sulphide) paint contains 36 per cent. of the ZnS. You must not confound it with lithopone.

9952. There is good lithopone and bad lithopone?—Yes; some of it is very inferior.

9953. What would you use for finishing coats?—It would be according to the colour required to be produced. If I wanted a white colour, I should use a good zinc oxide for finishing coats in all cases, although the other could be used with good results.

9954. What do you mean by "a good zinc oxide"?—It is very little understood. Few painters know how the material is produced. It is produced by the direct, or indirect method when the zinc spelter bars are volatilised by intense heat and passed over into the condenser. Then from a portion of the vapour or the gas which is produced from the zinc—that portion which precipitates first—from this vapour the zinc oxide falls through the condenser tubes near the furnace. This is gritty and crystalline and probably very suitable for a rubber company to make tyres with. If you wait until the zinc oxide vapour or gas has travelled through half a mile of pipes, then at the end of the condensing pipe you get an extremely fine product which is practically impalpable and fit for use in the making of enamel or paint. These grades of fineness are called red seal, green seal, and so on.

9955. Is zinc oxide with proper physical properties readily obtainable?—It is readily obtainable, if you have an expert who knows how to buy it.

9956. Is zinc paint equally suitable for finishing with an enamel surface as with a flat surface?—It is quite suitable. The difference is this: if you wish to get an enamel surface you can get it without buying enamel. If you use this drying oil it gives a surface which shows scarcely any brush mark and which looks as good as most enamel work; but if you wish the same zinc oxide ground in oil to dry flat you add turpentine and let it stand overnight, and when the oil floats up you skim it off, and add gold size and it dries flat.

9957. Will you tell us how zinc paints, such as you have described, compare in cost with lead paints in your experience?—As a matter of fact zinc sulphide paints with a given number of coats, as compared with white lead paints with the same number of coats are cheaper. If a painter estimates for 3 coats and he is not bound to use white lead in competition with a painter who is bound to, then the latter will lose the job. The man who uses white lead suffers. He will lose 7*s.* to 8*s.* on every cwt. The man who has estimated for zinc sulphide paints will beat him out entirely, as he had done many and many a time.

9958. Next, on the subject of durability, have you made any tests which enable you to speak with authority?—I did, in my own house, 15 or 16 years ago. I was induced to buy a house and I had the paint burnt off. We began from the wood. With regard to some of it, there may have been a little white lead left on the wood. We did the whole work with zinc sulphide paint, and it wore remarkably well outside for about 10 years, because the finishing coat had varnish in it; but at the same time I must say that I have neglected the painting of the outside and it certainly is not in good condition now. As to the inside of the house which was done at the same time, most of the panels were flatted, and the stiles and rails were finished in a tinted enamel paint, and the whole thing is in good condition still.

9959. (Mr. Sutherland.) After 16 years?—After 16 years.

9960. (Chairman.) What do you say about the outside?—I think I said just now that after 10 years it looked fairly well, but now it does not after 16 years. It certainly ought to have been done again five years ago.

9961. (Dr. Collis.) The outside after 10 years looked perfectly well without repainting?—I will not say that it looked perfectly well, but it was passable.

9962. (Chairman.) Do you know of any cases of outside painting with lead that have lasted for as long in about the same condition?—I have seen many cases of outside painting with lead in Birmingham that were no good at all after three years, but it is a phenomenal atmosphere.

9963. Can you mention other cases where paint work has been done with zinc paints to your knowledge

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

and with satisfactory results?—I might mention Mr. Henry Martin, an architect of Birmingham, who showed me the walls of his staircase painted 27 years ago and washed every year since. I went there with the architect who has charge of the New Zealand schools. The walls of Mr. Martin's staircase are in very good condition now. They were painted with zinc oxide paint. The purity of the colour is remarkable. The same pigment in white lead would have blackened. Ten years ago a painter, since deceased, was called in to repair broken pieces of the plaster on the staircase, and Mr. Martin particularly told him to use oxide of zinc and match the colour; but he used white lead and matched the colour which was tinted with Prussian blue. Where he patched it, it is very much discoloured, but the remainder of the wall is perfectly right after 27 years. That is an inside job.

9964. Can you give any other instance?—One of the best is Messrs. Cadbury Brothers. I have a letter from them.

9965. Would you read it?—Messrs. Cadbury Brothers wrote to me on the 20th October 1910. I ought to say that Sir Thomas Oliver had asked me for any tangible proof of any good business house that had used zinc oxide paints successfully, and I asked Messrs. Cadbury to oblige me with information. This was their reply: "Mr. C. A. Line, 39, Beaufort Road, Edgbaston. Dear Sir, In reply to your inquiries re zinc white paints, we have for years used zinc oxide paints in preference to white lead on every possible opportunity, not only for interior but exterior work. We may add that our experience justifies us in continuing this course." I had been to their works by request to consult with a Mr. Griffin, the gentleman who has charge of their public institutes, &c., and a Mr. Morley, their foreman, with reference to using zinc sulphide paint. While I was there I asked Mr. Morley to take me round the works and show me where they had been using zinc oxide. I kept on saying, "Show me some that was done years ago so that I may see how it has worn." He took me from place to place and I said, "Why do you not show me some of the old zinc oxide painting?" He said nothing until we got out of the works and walked up the road, and then he said to me, "You have been expecting to see zinc oxide painting that was done years ago, have you not?" I said, "Yes, I have," and he said, "It was all done long ago, and it looks exactly the same as if it had been done only last week, does it not?" I thought that it had been done within a month or two, because it was snow-white and in perfect condition on the ceilings and match-boarding.

9966. Have you any other instance to give?—I do not know that I can call to mind any other particular instance. But I know hundreds of instances where zinc sulphide water paint thinned with silicate emulsion has outlasted white lead without discoloration or cracking, and remained washable even in an atmosphere charged with chemical fumes.

9967. Have you any instances with regard to outside painting?—I cannot call to mind any, for the simple reason that painters who buy zinc paints from my brothers' firm very rarely state where they are going to use them. They do not know very often where the paint is used; but I have a case in point now where they know where it will be used. Zinc oxide was specified for 93 tons of ironwork to be erected by Messrs. Keay, of Birmingham, and is to be painted exclusively with zinc oxide paint, and there will be no doubt whatever about that.

9968. Zinc paints are, of course, manufactured largely by paint makers and grinders in this country?—Yes, they are commonly made by almost any paint grinder in England, generally from lithopone.

9969. Are the zinc compounds of which these paints are made, also produced in the United Kingdom?—Zinc sulphide paint is only produced in two works, one at Charlton and the other at Widnes. The Widnes proprietor, I am told, advertises himself as a manufacturer also of zinc oxide.

9970. Do other firms of paint makers import their zinc oxide and zinc sulphide from abroad?—They import the zinc oxide, and they import zinc sulphide under the name of lithopone. It is inferior to English manufacture.

9971. From what countries does it come?—Lithopone comes from Holland, Germany, Switzerland, France, and America.

9972. What do you think would be the effect if the demand for zinc paints were greatly increased in consequence of any recommendations which this Committee might make?—I have not the slightest doubt that capital would immediately be found for the manufacture of zinc oxide in England, and in fact I have been approached more than once. I was asked a few days ago by a solicitor, who represents some exceedingly wealthy clients, whether I really thought there was room in the paint trade for capital, and I said, "Distinctly for two things—one, the manufacture of zinc oxide in England, and the other, the growing of poppy oil on the East Coast." Moreover I hold sunflower seed oil in high esteem as suitable for being cooked or prepared by heat to make it into pale manganese drying oil.

9973. Do you think that the increase in the demand would cause the price of zinc compounds to go up?—I do not think so, because there is always the competition of zinc sulphide.

9974. To sum up then, has the whole of your lifetime's experience in connection with the trade and your study of paints led you to believe that the use of lead in paints could be prohibited without involving any serious difficulties for the users of paints?—I distinctly think so. I do not think it would involve any difficulty for the users of paints, nor do I think that property would suffer in any way whatever, even if it were a question of making a joint for which many engineers use white lead. They might just as well use plumbago. They could make joints without white lead.

9975. Such a prohibition would put an end to the serious loss of life and health entailed by the use of lead paints?—Yes, it would.

9976. (Dr. Collis.) You referred to the fact that you considered that, with respect to deaths occurring from lead poisoning, the information at the disposal of the Registrar-General was not complete?—I certainly do not think it is complete.

9977. Can you, for instance, give us any definite case of death which, in your opinion, was caused by lead poisoning, where the death certificate stated something different?—No, I am not able to do that. I do not know of an individual case, but I should look at the thing just in this light—from the point of view of the enormous number of cases that I meet with of men in a critical state of health. I compare that with the fact that the Registrar-General and his officials have reported something under 300 fatal cases in ten years. I simply take it as a proportion sum, and it is incomprehensible to me how such a small number of fatal cases could have been reported, when there is such a large number of cases of illness. The Registrar-General certainly has good reason for computing that in 10 years 9,400 cases occurred; and yet that only 284 of these people died is quite unthinkable.

9978. But that computation, I think, is calculated on the basis of what we know in factory cases, namely, that each case of death is accompanied by so many cases of illness, and, therefore, he has calculated that the deaths in the house-painting trade would represent so many cases of illness?—Yes, I believe that he has. That is stated in his letters to me. I have the letters here.

9979. So that the 9,400 cases of illness are merely computed on the number of cases of deaths which he knows. If your statement is correct that he has not correct information of the total number of cases of death, the number of cases of illness should be proportionately larger?—Well, that may be so; but my answer to that would be that the people have died, but their deaths have been put down to other causes. I may say that I have the advantage of knowing a medical man, James Jones, now of Lewisham Road, an exceedingly careful

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

and successful homœopathic physician, in whose house my wife lived for seven years. I have always had this homœopathic physician as a personal friend, generally as a consultant. I know the opinions of others, and every one of these gentlemen is agreed that very many fatal cases are attributed to other causes which might have been safely attributed to lead-poisoning.

9980. You mean, for instance, Bright's disease?—Yes, and paralysis, mania, colic, or something or other—all sorts of things really brought on by and inseparable from lead poisoning, but where the cause of death has not been certified as lead poisoning. Possibly the doctor who certified may not have had the means of knowing that it was attributable to lead-poisoning. He may have used his best judgment, and said, "This man died from paralysis." He puts it down as such, and it gets on the certificate as something other than lead poisoning. I make bold to say that the medical profession have not attributed to lead poisoning anywhere near as many cases as they should have done.

9981. While that is a possibility, that is rather a personal opinion; you are not able to justify it by figures?—No, not by figures. I reason it out. I have a note here, "Lead Poisoning, page 563," published by Young, Pentland: "In the five years ending 1890, 1,822 deaths from accidental poisoning in England and Wales. Of these 541 or 29 per cent. due to lead." Now we are told only 94.

9982. Do you know the figures for all industries?—I have another note—that during the five years ending 1895 there were 672 deaths from plumbism.

9983. Those would be taken from the Registrar-General's Death Returns for the United Kingdom?—Yes.

9984. For all industries?—That is taken from the 1891 census. During the five years ending 1895 and the five years ending 1900 there were, respectively, 541 and 672 fatal cases. Taking men in the asylums—132 madmen who had worked in lead—nearly all of them were plumbers, painters, or decorators. I have come to the conclusion that nearly all people who die from lead poisoning are plumbers, painters, or decorators, and there is no question about it. The potteries used to contribute a big share, but they do not contribute a big share now, nor do white lead works.

9985. The whole of the factory industries now contribute less than house-painting alone?—That is so—alI owing to the Factory Department.

9986. Do I understand with regard to first coats of paint which are applied, especially on woodwork, that the surface can be brought up without using lead?—Yes, that is so.

9987. So that you do not hold that lead has any special properties innate to itself in filling up the grain of wood?—Not necessarily. There are other things which are useful for filling up the grain of wood. There are plenty of fillers other than lead.

9988. Lead will do the work, but other things will do it equally well?—Yes.

9989. How far is the filling up of the grain of new wood an important point? I ask the question from this point of view—that in the furniture trade they only seem to use whiting for that purpose?—Plaster very largely.

9990. Whiting is the most usual, is it not?—As a matter of fact the discovery was made years ago by Church, of Grand Rapids, Michigan, that if you heat plaster of Paris (calcium sulphate) to 212 degrees and introduce into it desiccated glue, you can grind the two together and make a perfect wood-filler; but if you attempt to grind them at a higher temperature the glue frizzles, and if you attempt to grind them at a lower temperature it clogs, it is too damp.

9991. So you think that there are several substances, including the one which you have mentioned, which can be used as an absolute substitute for the first priming coat of lead?—Yes, I am of that opinion.

9992. I make rather a point of this, because several of the witnesses before this Committee have laid great stress on the point that it cannot be replaced. But, in your opinion, it can be replaced by several substances?—There are several substances which will fill up wood as well as white lead. In America shellac and zinc

oxide are used, and quite successfully. I have some boards prepared thus here, and the total number of coats from start to enamel finish is four.

9993. In the use of paints not containing lead for outside work, your experience is not so large, is it, as your experience with regard to their use for internal work?—No; on the other hand, my experience is 50 times as large with regard to outside work as inside. The material that I know of that is used for outside work is sulphide of zinc thinned with petrifying liquid.

9994. That contains no lead?—That contains no lead.

9995. What is your experience of that?—It is the most durable thing I know for exterior painting, but I do not always recommend that to be put on if the building has been previously done with a flexible or elastic oil paint, for the reason that it gets very hard and is liable to crack on the elastic oil paint.

9996. That would have contained lead?—Yes.

9997. If you were bringing the work up from the base, what would you use?—I should not use oil paint to bring work up from the base. I would use zinc sulphide-water paint precipitated with barium sulphate and thinned with an emulsion containing a little varnish and silicate of soda or silicate of potash.

9998. Have you had experience of the painting of external surfaces with such paint?—I have had experience of it for 36 years.

9999. With regard to woodwork, how long would you expect it to last if exposed to the air—not bad conditions near gasworks, but ordinary exposure?—I was not thinking of woodwork but of plaster or stucco surfaces, or stonework.

10,000. Let us take that for a moment and then come back to woodwork?—In that case it would last longer than any other paint in existence.

10,001. For how long?—Ten to 15 years on the outside.

10,002. Do you say that it would not want renewing at all for 10 or 15 years?—In certain atmospheres it would not, but in other atmospheres the staining pigments in it would discolour. That would somewhat depend on what was underneath it.

10,003. Let us take an atmosphere in which what you have spoken of would last for 10 or 15 years. If a surface were painted by the ordinary method used to-day with lead paint, how long would it last in such an atmosphere?—Three years in London.

10,004. But in the same atmosphere as the other lasts for 10 years in?—It might last without renewing for five or six years.

10,005. That is four or five years less?—Yes. One is doubly as durable as the other.

10,006. I will not take a bad place like Widnes, but in the atmosphere of Birmingham or of London or Glasgow, how long would you expect the zinc-sulphide-painted house to last?—It would last almost as long in those atmospheres as in any other, but white lead would not.

10,007. How soon would the lead paint want renewing?—It would certainly want renewing in two or three years, or would be unsightly in 18 months.

10,008. Now, turning to the painting of woodwork, the external parts of windows and such like, would you suggest the same method for undercoatings?—Yes, but not for finishing coating. For finishing coating I would certainly advise varnish paint.

10,009. If the woodwork was so dealt with, for how long would it last in an ordinary atmosphere?—It may fairly be expected to last for 10 years.

10,010. For how long would it last under similar exposure if it was painted with lead in the ordinary way?—It would not last half as long.

10,011. Does the presence of the varnish make a material difference, in your opinion?—It does. But there is another consideration which one has to take into account—the oxidising influence of lead on the thinnings. The thinnings being linseed oil, too often contain unsuitable or too much drier.

10,012. We are presuming that the lead painting is done in the best way that it can be done in?—Supposing that that be so, then white lead has the

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

tendency of continuing to oxidise the oil whilst it is in contact with it, and it does oxidise it. This oxidising tendency goes on and cannot be stopped; but there is no such tendency with zinc, or at any rate only what is attributable to atmospheric influences which do not act so prejudicially on zinc as on lead pigments. Of course where sulphuric acid fumes are allowed to permeate the atmosphere, that would destroy zinc paint also.

10,013. Does not that tendency produce a brittleness of film?—It produces a film so brittle that you can easily crack it off. *This is off ironwork inside Snow Hill Station, Birmingham (producing a specimen).* It was under glass, it has not been exposed outside.

10,014. (*Mr. Sutherland.*) Is that white lead?—Yes. I can produce some that came from a drill hall at Stoney Lane, Birmingham, off galvanised iron. After three years exposure of the white lead paint, it was brittle as it possibly could be. It did not adhere properly. I put my knife to it and stripped off a piece 20 inches long. It stood upright.

10,015. Was that on glass?—No, on galvanised iron, which is fluted.

10,016. (*Dr. Collis.*) We are getting from woodwork to metal, but I wanted to clear up the point with regard to the painting of woodwork exposed to external influences. You have had considerable experience of such wood work and you suggest sulphide of zinc paint?—Yes, with petrifying liquid in it—a water paint, not an oil paint.

10,017. You have known it to last for 10 years without requiring renewal?—It was not a zinc sulphide water paint that lasted for 10 years, but a zinc sulphide oil paint.

10,018. There was no lead in it?—No. The varnish was in the last coat.

10,019. Does that materially add to the life of the paint?—Yes, it does, in my opinion.

10,020. That being so, how then would it compare with your zinc or non-lead paint?—If the paint were white lead from the bare wood upwards the oxidation would go on undoubtedly, and it would not last as long as zinc paint; but zinc sulphide paint, on the other hand, needs the addition of varnish and the last coat should be done in that way. If zinc oxide had been added, it would have increased its life.

10,021. If varnish is added to lead paint, that makes the painted surface last longer, but not so long as the surface painted with zinc paint?—I agree; but that ought to be qualified in this way; that very much depends in both cases on whether the thinnings are suitable or unsuitable.

10,022. I am presuming that it is done *secundum artem*—in the best possible way in regard to both?—Yes.

10,023. There are good and bad ways of doing everything. Now with regard to the metal work, there are various preparations, are there not, besides zinc, which can be used on metal work?—Yes. I would strongly recommend the use of graphite paint on the metal work.

10,024. Bringing up from the base?—Yes. As a rule, you will find some red lead on it or red iron oxide paint.

10,025. But without the red lead on it?—Graphite paint, I think, is superior, and in my opinion, ought to be applied on all metallic surfaces before they leave the works where they are constructed.

10,026. Have you known metal treated with non-lead paints from the base, which has stood as well as metal treated with red lead, and has been as protective?—I have not compared it with red lead. Red lead certainly is said to possess some advantages. *This steel plate covered with zinc and graphite has been so treated.* It has been well exposed to extreme heat and frost and damp and everything else, and it has been buried in the ground.

10,027. Your experience has been on house decorating and painting rather than upon engineering work?—Yes. I have not had very great experience in regard to the painting of engineering work.

10,028. We have had other evidence on that point. Your evidence definitely points to the fact that, if

properly treated (by which I understand you to mean not more expensively treated), non-lead containing paints are as effective both as protective paints and with regard to lasting?—Yes, and as decorative paints.

10,029. (*Mr. Sutherland.*) You said that you considered that Birmingham was honeycombed with lead poisoning cases?—Yes.

10,030. Have you figures to support that?—Yes, I have collected them myself. I have been to see the individuals.

10,031. How many cases have you personally seen?—I have personally seen at the very least 150 cases in Birmingham.

10,032. One hundred and fifty cases of painters suffering from lead poisoning?—Yes, supposing that I go to a painter whom I know very well, and he says, "I am sorry to say that I have five men ill." I go to another one, a very good man, whom I have known for 30 years and who was always a deadly opponent of zinc paints, but who has had a waking up. He found that he had to defend a case in the courts and to pay 300*l.* Before the case was settled, he got notice from a surgeon at Oldbury of another case, and so it goes on all round. At Acoc's Green, the best painter there has had to pay 90*l.* to a man who cannot work. I would not have any difficulty in running you round Birmingham with me in a motor-car and spotting 50 cases straight away between breakfast and dinner.

10,033. One hundred and fifty cases amongst Birmingham painters would represent nearly 20 per cent. of the painters?—In my opinion there are a great deal more than 20 per cent.

10,034. It is a very large proportion, and, with all respect, I should question it?—I think that every painter who uses lead is affected. I very much question whether he can possibly escape. A man tells me that he has worked for 30 years with lead paints and there is nothing the matter with him; but when he opens his mouth you can see the blue line on his gums.

10,035. Why do you prefer zinc sulphide to zinc oxide?—It is more easily sold. It is 22*s.* a cwt., and zinc oxide is 4*s.*

10,036. But does that matter if zinc oxide is better than the other?—I do not think it is better for inside work. The other answers perfectly well.

10,037. It is more amenable than zinc sulphide for general purposes?—Yes.

10,038. Why do you mix varnish with it?—As an extra protection in the finishing coat. I should not mix varnish with it for undercoats, but turpentine and gold size and a little oil.

10,039. What the Dutch call stand oil?—No. *This oil is made in London. (The witness produced a bottle of oil.)* It comes from a firm called Adler, at Millbank. I have besought those gentlemen to give me particulars and details of it, but they will not do it.

10,040. That is not the equivalent of Dutch stand oil?—No.

10,041. It is very expensive?—Whatever price the raw linseed oil happens to be, this drying oil is easily saleable at 5*s.* a gallon more all the year round.

10,042. If your zinc paint will stand for 10 years outside and for 27 years inside, what are you going to do with the painters?—As I go round the streets of Birmingham and call on some of my best friends, it is a common thing for them to say, "Come in" and to give me a chair and treat me in a magnificent manner; but when it comes to asking them to recommend zinc for a job they say that they cannot do it. I say, "Why not? you know it is suitable." They say, "We should never be called in again." That is a common answer. If it were a church or a chapel, reason would come to their aid, and they would say, "It will cost 20*l.* for scaffolding and, therefore, the painting must be done with the most durable paint, having regard to its remaining in a good decorative condition." Suppose that they put beautiful tints in white lead, like John Taylor did at Lloyd's Bank, Colmore Row. I said, "You have great experience. Why do you use it for

9 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

Lloyd's Bank? You know that the tints will spoil"; and he said, "But I shall be dead and gone."

10,043. I have used zinc paints for chapel decoration, but after 12 years it has needed doing again?—The condensation in some chapels and the atmosphere where gas is burning would cause that.

10,044. This was in gas. Why do you think that varnish should be added for outside work?—To give it extra protection.

10,045. The Dutch have made a very exhaustive examination of all these paints and with a strong bias in favour of zinc paints, they have come to the conclusion that in all situations, such as railway stations, zinc paints cannot be used because of the acids in the air which soften them?—You will not make me believe that.

10,046. They had a most unbiassed and elaborate Commission to enquire into the subject extending over five years, and they made careful experiments?—I have heard that the Austrians did something of the kind, but the gentlemen who did it perhaps were not well aware of the best methods of thinning. I daresay that they did not know very much about this beautiful drying oil which we have the advantage of.

10,047. In Holland they have the stand oil and other oils to perfection, and there were architects and practical men on the Commission to which I referred just now, as well as chemists?—Do you think they have a drying oil containing 2 per cent. of liquid drier put in when the oil is hot?

10,048. Yes. You will see that in their report?—I should be very much interested to read it.

10,049. (Chairman.) They use a manganese resinate oil?—Yes, or borate. I would add linoleate. It is an advantage. If I were recommending a zinc oxide paint, I would recommend the Dutch oxide made by a process which leaves in it the lead naturally in it. I do not believe in the fad of purity. What is the good of steel without a bit of nickel in it. The 1 per cent. of lead was put there by a power much more wise than we are, and if it pleased God to make zinc oxide with 1 per cent. of lead in it, let us be thankful.

10,050. But zinc oxide is not a native mineral?—The small percentage of lead is in the ore as it occurs naturally, and what is best for the use of man.

10,051. (Mr. Fell.) Have you had experience of the painting of vehicles—carriages or motor cars?—Not so much. It has not been my line of things nor have I supplied coach-builders to any great extent. I think that as a rule coach-builders are very strongly prejudiced in favour of certain good old varnish manufacturing firms, and so on, and it is difficult to induce them to move; and they are right in that respect, because it is serious if the paint and varnish of a coach go wrong.

10,052. But apart from varnish, what do you say about painting coaches with non-lead paints?—Three railway companies I understand are doing painting at the present time without using white lead for the bodies of the carriages.

10,053. (Chairman.) Which are they?—I am not able to say, but the information comes from an office not far from here.

10,054. (Dr. Collis.) What is the office that gave you the information?—If I recollect rightly it was the Home Office, the Factory Department.

10,055. (Mr. Mason.) Is there not a particular name for the oil you have described?—We call it pale boiled drying oil. We are very careful about the word "drying," because the drier has not to be added to it except in bad weather.

10,056. Do I understand that this is a sort of proprietary article that can only be bought from one firm?—No, not at all. If I am correctly informed by experienced decorators upon whom I have called, they say, "We have had it offered to us." The Bournville Village Trust said, "We have had the same article offered to us elsewhere." They had a bottle of it. Messrs. Blundell, Spence and Company, I think, have been buying a large quantity lately of sunflower seed oil with the object of using it to make a drying oil. Chinese wood oil has the remarkable property of drying hard all through instead of drying from the surface

inwards. A small percentage of that is added, so that it aids it.

10,057. This is not linseed oil, is it?—It is practically linseed. That is sold as linseed oil, but we do not require that it shall be stated that it is all linseed. We think that there are better oils than linseed. I should take sunflower seed oil, Chinese wood oil, and the poppy oil to be better.

10,058. (Mr. Sutherland.) The last of those is very expensive, is it not?—There is a big offer now of something like 9,000 or 10,000 tons of it, which we could not have had two or three years ago.

10,059. There is no test attached to it, is there?—Yes. A firm at Hull bought some some years ago and wished they could get more, and when they could get more they immediately placed an order for 25 tons. People will use it if they can get it.

10,060. It is purely in the experimental stage? Yes, amongst most varnish makers; but there are experts who have had long experience of its uses. I have written to Dr. Blackler of the Paint and Varnish Society, and submitted samples to him, and asked him to test them, but I have not heard from him yet. (Since then Dr. Blackler has reported satisfactorily.)

10,061. (Mr. Mason.) You were saying just now that it was possible to make an enamel with zinc oxide without the use of varnish?—No, I did not say that.

10,062. I thought that you did?—What I endeavoured to convey was this—that it is possible to obtain a surface resembling enamel and looking practically as well as enamel without buying enamel. If you use this particular oil with zinc oxide pigment it gives a beautiful surface showing scarcely a brush mark, and it can be mistaken for enamel.

10,063. Have you had any experience of the painting of the inside of factories?—Yes, a very large experience, but not bridges and iron work.

10,064. I do not exactly mean the painting of the insides of factories; but painting as carried on as a factory business. I will put it in that way, as in coach painting or furniture?—I have been called in repeatedly in Birmingham by people who make wooden bedsteads. They used white lead as a base and the bedsteads discoloured and were returned. I recommend zinc oxide and it was perfectly successful, also zinc sulphide for undercoating; but I can save money by using improved zinc white: it combines the advantages of both kinds of zinc pigment.

10,065. (Dr. Collis.) How long ago?—That dates back to at least six years, and the said bedsteads and suites of furniture treated in that way without white lead gave every satisfaction. Messrs. Wales, one firm in Birmingham, have done a lot in that way. You may see in the Midland counties many advertisements on windows of what is called Master polish. The advertisements represent a figure subject—an attractive looking female holding out a box of Master polish, and it reads, "We sell Master polish." The pieces of glass had to be backed up. Previously they were painted with white lead and made to adhere to the outside of the shop window; but they discoloured and looked bad very soon. But since they have used zinc oxide in a proper combination containing varnish they have been quite successful. Mr. J. Ornikshank Smith wrote the formula for that.

With regard to basic lead sulphate, I entirely agree with Sir Thomas Oliver that if a man eats it or if he smears it on his pipe and sucks it it will kill him. With reference to the use of it in a room, I have tried it and I cannot detect the least smell from it other than from the little turpentine in it. There is no nasty leady smell given off. That has been proved. I was invited to go to Liverpool to hear Professor Baly lecture on the toxicity of white lead, and I was favoured with a private view of his apparatus by Mr. Roscoe Hardwick, the Secretary of the Society of Chemical Industry, and he carefully explained to me in the laboratory the whole process by which Professor Baly has been proving the fact, as I understand, that in the vicinity of newly painted surfaces painted with white lead there are certain poisonous fumes given off,—volatile gases. I was interested in this. On my way back from Liverpool, I found my grand-children

S 2

19 July 1911.]

Mr. CHARLES A. LINE.

[Continued.]

both ill. One is three years of age and the other is a year old. I enquired what had happened and I found that the premises next door to where my son and his children lived had been painted, and the children had been subjected to the fumes of hydrated carbonate of lead. The children were in a front room with a bay window. The sun was shining on that bay window and on the next door bay window close to my son's premises. My son has to live in the nearest house that he can get to his work. The fire was burning, the sun was shining and the children were playing in the room. The door was locked and they were left in there with their toys, and they were subjected to the fumes of white lead paint for two hours. Then they were taken out for a walk, and when my son's wife had them out the children began to vomit very badly. She could not detect what was the matter, and they were so bad and exhausted that she went for the doctor. He could not detect what was the matter. It was incomprehensible to him. He did not think that the food was at fault, but that an irritant poison of some kind had caused the illness. I did not tumble to it, at all—you know what I mean. A little later on I wrote to my son and said, "Did not I see painters painting next door at the time?" and he said, "Yes." I certainly had come to the conclusion that the vomiting that those children were subjected to from about mid-day until midnight until they were practically exhausted was caused by the irritating nature of the white lead paint. That is not the only instance that comes to my mind.

10,066. (Mr. Kinggate.) With regard to jointing, you mentioned that engineers were using something for jointing in the place of lead?—Plumbago.

10,067. The only thing that we are interested in in the coach-building industry with regard to jointing is the jointing of wood and ironwork together, where they use lead. Would plumbago be applicable for jointing woodwork and ironwork?—I have not had sufficient experience to say, but if I were doing it myself and if I were going to bolt a piece of ironwork on to the splash-board of a van, for instance, I should not hesitate to bed it in zinc instead of white lead, but I should put gold size or turpentine, at any rate gold size, and a bit of varnish to cause it to adhere, and I would screw it up tightly. There is one point that I would like to mention and that is with reference to the causes of blistering. One of my sons, at 18½ years of age, has been awarded a scholarship at Emmanuel College, Cambridge, for Natural Science, and he is a remarkably good chemist for his age. I asked him to work out for me the chemical equation showing why resinous acid in wood combining with the carbonic oxide in white lead forms (in my opinion) expansive and volatile gas underneath the paint film, causing blistering. He has put it so that the man in the street can understand it. He says:—

"Resinous acid + carbonate of lead = resinato of lead + carbonic acid.

Carbonic acid = carbon dioxide (a gas) + water." So you may safely conclude that the cause of blistering is very largely the use of white lead. Personally I have never seen a single blister anywhere after zinc paint has been used. That ought to be helpful.

10,068. (Mr. Robins.) You were mentioning Cadbury Brothers. Is it within your knowledge that their vans are painted on a non-poisonous system?—No, I have no knowledge of that. I have only knowledge with regard to their works inside and out.

10,069. (Mr. Sutherland.) Is the painting visible now?—Yes, perfectly.

10,070. (Mr. Parsonage.) Do you know that they usually paint at Cadbury's with white lead?—Zinc oxide—very little white lead. They used white lead in the past, but they have given it up.

10,071. Within the last year they have used considerable quantities of white lead paint at Cadbury's, Bournville?—Not within my knowledge.

10,072. In addition to that, they used a paint sprayer for putting on the paint, and we refused to allow our men to work it, and they discontinued the use of it?—Because you found it poisonous?

10,073. Yes?—That was perfectly right.

10,074. I was invited to go down to Cadbury's works to see the process. I know that they still continue to use white lead. It is only very recently if they have given it up. (Mr. Line.) But I now produce their letter stating the fact that I have alleged and signed by a partner in their firm. There are facts known to me which explain the position as you view it. The Cadburys were only experimenting with the paint sprayer. Probably they wanted to prove that white lead paint was poisonous. (Mr. Parsonage.) You suggest, with regard to new wood work, using water paint as a ground for applying zinc paint?—Yes, or for under-coating enamel.

10,075. Would you bring it all up with water paint before you applied the enamel?—Yes.

10,076. That would knock off a great deal of the work of the painter?—Yes, it would lessen the work of the painter.

10,077. Do you think that many customers would agree to their work being done with water paint and a coat of enamel being put on just to bind it down?—I do not know that they would know enough about it, but tons and tons of water paints are sold in Birmingham for that very purpose.

10,078. I have known it used in London, I am sorry to say, to scamp work. It was not in the specification?—I do not think an architect would know enough of the advantages of it to specify it; but I would distinctly disagree with anyone who called it scamping.

10,079. Take Duresco?—We must not mention names, I understand.

10,080. I am using a word that is in common use. It is not a proprietary article?—Yes. Duresco is a registered title. There is an attempt to make it a dictionary word like "linoleum."

10,081. Would you prefer to use it for new wood-work? You suggested water paint?—I would prefer to use zinc sulphide paint—oil paint thinned out with turps and gold size for undercoating. It has the splendid advantage of drying on wood in a damp position.

10,082. You suggested water paint put on with a distemper brush?—Yes, or a ground brush.

10,083. It would require a lot of rubbing down for mouldings?—I would not use it for mouldings, but only for matchboardings.

10,084. There is not much matchboarding. I thought that you referred to general painting work?—I should apply it slightly thinned with a 4" panel brush on window casings, skirtings, and doors. It sets as hard as a rock right through to the wood, and never blisters.

10,085. It will chip off very easily?—I do not think so.

10,086. You get some Duresco, and try it?—I would be very pleased to try it out of compliment to you, Mr. Parsonage, but I have had so many years experience of it, and I have seen so much of it done with perfect results that nobody would induce me to believe that it would chip off.

10,087. You apply the enamel to bind the other?—No. I should finish it with a coat of varnish paint, but not to bind it down. You could not rub the Duresco off without using steel wool. Sand-paper would take a very long time to move it, and in fact would be practically useless.

10,088. How about washing?—It is perfectly washable, and you can scrub it with a wire brush. May I ask you a question? Is there not a bare possibility of somebody having foisted something on you that was not Duresco, because that is a common practice? There are painters in Birmingham, I am told, who buy up old Duresco kegs when they can, and put their own stuff in it, and it goes on to jobs and is palmed off as Duresco. For that reason we put the date under the kegs. I say to architects, "When the painter brings the keg turn it upside down and see the date. Do not say anything to the painter."

10,089. Would not any paint strip off galvanised iron?—I would not recommend water paint for it. I would not recommend Duresco.

10,090. Oxide or sulphide of zinc would strip?—You agree that everything depends on the thinning.

19 July 1911.]

MR. CHARLES A. LINE.

[Continued.]

10,091. Yes?—Supposing that it had been treated with a little dilute sal ammoniac to remove the greasiness off the galvanised iron, then it would be fit to receive the paint.

10,092. It has to be specially prepared before it is painted, you mean?—Yes. Railway companies always prepare it with a coat of turpentine. As to decorative results we cannot get them with white lead because it discolours. (*The witness produced some coloured slides.*) All these beautiful tints in these pictures are produced with zinc oxide.

10,093. (*Dr. Collis.*) If lead was abolished, would there be any tints or colours which could not be obtained as economically as at present for decorative purposes?—Oh no! There would be no increased cost in painting.

10,094. Not in any colours whatever?—No.

10,095. For greens or chromes?—Lead chrome is not permanent; it changes very quickly. You can obtain better chromes without using lead.

10,096. And better greens?—And better greens. —'s Green is made by roasting a combination of potassium chromate and boracic acid.

10,097. So that in your opinion there are no tints or colours which for decorative purposes cannot be obtained without the use of lead?—I do not know of any.

10,098. (*Mr. Kinggate.*) A non-poisonous yellow chrome can be obtained from zinc?—Yes.

10,099. Is it perfectly suitable?—It is perfectly suitable.

10,100. (*Dr. Collis.*) Without entailing a prohibitive expense?—I could not say the relative expense exactly; but my opinion is, from what I have heard, that there is nothing material in the difference.

10,101. (*Mr. Fell.*) Is it a commercial article?—Yes, a commercial article both in yellow and green, made with zinc. I may say, gentlemen, if you have not seen it, that Mr. J. Newton Friend, of the Birmingham University, has written a book which every painter ought to keep by him. It is called "An Introduction to the Chemistry of Paints," and it is very useful indeed. There is a splendid article in the "Building News" which I read when coming up in the train, on "Materials used in paint manufacture," by Heckel. He mentions lead chromate, and says how it is made. My attention was drawn to it by a young Birmingham architect.

10,102. (*Mr. Parsonage.*) I want to clear up what seems to be a misunderstanding. With regard to the number of cases of lead poisoning that you have come in contact with in Birmingham, you did not mean 150 at the present time, did you, but that you had known 150 cases?—By no means. I believe that there are 150 men suffering from it now, and more.

10,103. You believe that there are?—I say that there are. I have no hesitation about that whatever.

(*Mr. Parsonage.*) Dr. Legge put Birmingham second to London and Manchester third. I had London first, Manchester second, and Birmingham third. We have a large number of cases from Birmingham.

The witness withdrew.

## FOURTEENTH DAY.

Thursday, 20th July 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Sir GODFREY BARING, Bart., M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. J. PARSONAGE.  
Mr. A. GARDNER.

Mr. A. L. O. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. EGBERT GRANT HOOPER, F.I.C., F.C.S., examined.

10,104. (*Chairman.*) Will you please give the shorthand writer a note of your qualifications?—I am Superintending Chemist of the Government Laboratory, Chairman of the London Section of the Society of Chemical Industry, and Member of the Council, past Vice-President of the Institute of Chemistry and the Society of Chemical Industry, and past member of the Council of the Chemical Society, and author of two or three books on chemistry, with which I need not trouble you.

10,105. You appear here to-day as the representative of Dr. Dobbie, the principal chemist of the Government Laboratory?—Yes. He wishes me to represent his views on the subject.

10,106. Has he authorised you to give an official reply to certain questions regarding the estimated amount of lead in paints?—He has.

10,107. This Committee when they begin to deliberate on the evidence will probably have to consider the arguments for and against recommending a restriction in the amount of lead to be used in paints?—Yes, I quite understand that.

10,108. If they decided to make such a recommendation, would any special difficulties arise in determining whether or not a sample of paint contains more than

a prescribed percentage of lead?—I do not think that any difficulty would exist.

10,109. The proportion of lead could readily be determined by analysis?—Certainly.

10,110. Even if the permissible proportion were small, say, for example, 5 per cent. of the whole dry substance of the paint?—I think that there would be no difficulty with quite a small quantity.

10,111. As an alternative the Committee may find it necessary to consider the possibility of recommending a restriction in terms of soluble lead?—Yes. There would be no difficulty, I think, in devising a plan for the determination of soluble lead.

10,112. Could a solubility test be applied as in the case of pottery glaze?—Yes, certainly, very much in the same way. One would have to prepare first of all the dry substance of the paint, that is, free it from oil or vehicle, just as one usually has to free the ordinary glaze from the water with which it is mixed.

10,113. Would a solubility limit allow of a freer use of such compounds as white lead?—Not in the case of such readily soluble substances as white lead, but it would allow of a freer use of the less soluble ones, such, for instance, as lead sulphate.

x 7790

S 3

20 July 1911.]

Mr. EGBERT GRANT HOOPER, F.I.C., F.C.S.

[Continued.]

10,114. And, I suppose, sulphide of lead?—And sulphide of lead in the case of black paints. Sulphide of lead, being a black paint, would obviously be limited in its application.

10,115. I suppose you agree that ordinary white lead is all soluble?—Yes.

10,116. With sulphate of lead only about one fourth is soluble?—Yes. One would like at this point to put in a note of caution. It is well in speaking of all lead compounds that one should always speak of them in terms of lead oxide. That is only a part or a constituent of the total compound. Obviously, all the different compounds of lead are made up of lead oxide on one side, and, generally speaking, an acid on the other—in the case of white lead, lead oxide plus carbon dioxide or carbonic acid; in the case of sulphate of lead, lead oxide plus sulphuric acid; in the case of acetate, lead oxide plus acetic acid. So that it is convenient, with the object of comparing one with another, that one should always speak in terms of lead oxide.

10,117. How would you prefer to express the solubility of "ordinary white lead"?—One would say that in ordinary white lead the whole of the lead oxide is soluble. In the case of lead sulphate only about 17 per cent. of it is soluble, but that 17 per cent. of lead oxide is equal to about 23 per cent. of lead sulphate.

10,118. Of sulphide of lead (galena) very little is soluble, less than one-twentieth is it not?—Very little is soluble, but there appear to be some lead sulphides on the market, what one may call commercial sulphides, which show a much greater solubility. The pure lead sulphide is soluble only to a very small extent.

10,119. What other forms of lead sulphide are there?—We have purchased forms of lead sulphide, for example, which gave a solubility in terms of lead oxide equal in one case to 36 per cent. and in one case to 40 per cent. It was not a pure lead sulphide, but it was purchased as lead sulphide, and other people might purchase a similar substance and find that it was not a pure lead sulphide.

10,120. Do you say that some lead sulphide sold contains 36 to 40 per cent. of soluble lead?—Our experience is not very extensive. Out of four which were examined at one time we found that two purchased yielded 35·6 per cent. in one case and 40·7 in the other case, whereas one which we prepared for ourselves, and which we know therefore to be actual lead sulphide with nothing else in it, showed a solubility of only 3·1.

10,121. The chemist must be very cautious then, in accepting sulphide of lead as containing a very small amount of soluble lead?—Yes, when it is a commercial thing, but probably that is not more peculiar to lead sulphide than to the other lead compounds. I daresay that it is within the knowledge of this Committee that white leads, for instance, are sold of almost all grades of purity, and therefore of solubility, but they are not really white leads.

10,122. Speaking of lead sulphate, and taking your evidence with regard to about the fourth of it being soluble oxide of lead, if lead sulphate were used instead of ordinary white lead in making up a paint of definite solubility, one could use four times the amount of sulphate?—Yes.

10,123. That is to say, paint containing 20 per cent. of lead sulphate would have the same solubility as if it contained 5 per cent. of ordinary white lead?—Yes.

10,124. Then under a 5 per cent. solubility rule a master house painter would have the alternative of using not more than 5 per cent. of ordinary white lead, or not more than 20 per cent. of lead sulphate, whichever he considered would make the better paint?—That is so.

10,125. What would be the effect of a limitation of lead in paint in terms of solubility?—It would undoubtedly tend to develop the use of the less soluble lead compounds at the expense of the more soluble lead compounds.

10,126. Would this be a desirable result?—From the point of view of health, certainly. I am scarcely prepared to speak from the point of view of practical application.

10,127. I am speaking with regard to health. You say that it would be a desirable result?—Yes, it would be.

10,128. You have mentioned lead sulphide as available for use in dark pigments. I am speaking now of lead sulphide that contains only 5 per cent., approximately, of lead oxide?—Of real lead sulphide?

10,129. Yes. How much lead sulphide could be used in a paint which has to be of a solubility of under 5 per cent.?—Practically the whole. In the case of a black paint, for example, the black paint might be composed wholly of lead sulphide, and it would still contain not more than 5 per cent. of soluble lead monoxide.

10,130. If the users of a paint find that lead is almost indispensable for certain dark colours, such as dark greens, could not lead sulphide be used?—I do not think any large proportion of lead sulphide could be used in a dark green paint, because it saddens the colour too much. There is no need for it, because the darkness of shade is generally produced by varying the other constituent—the Prussian blue. The Brunswick green paint of all shades would be made up of yellow lead chromate and dark Prussian blue. Now the shade which will be produced will vary according to the proportions of those two. If I want a dark one there will be a relatively small proportion of yellow lead chromate and a relatively large proportion of dark Prussian blue. If, on the other hand, it is very light colour that is required, then the proportion of lead chromate will be large, and the proportion of Prussian blue will be small.

10,131. We have been told that in certain dark colours, particularly dark greens, it is necessary to use more lead oxide than in lighter colours. I want to know whether you consider that lead sulphide could be used as a substitute. What do you suggest could be used as a substitute for the larger proportion of oxide of lead?—I should suggest that in the darker ones the point would be reached by the use of an increased proportion of Prussian blue.

10,132. Would you assume that you could get the same effect, at the same time limiting the amount of danger, by reducing the quantity of lead oxide?—Yes. I think it wants to be made quite clear that a green paint very likely consists wholly of lead compounds. For example, I have the analyses of a group of green paints here which I may use as an illustration of the kind of things that are to be found. All of these paints contain a certain amount of barium sulphate. For instance, the proportion varies in six examples from  $\frac{1}{2}$  per cent. up to 14 per cent. of barium sulphate. All of them contain a small amount, more or less, of chalk, the proportions varying from six-tenths per cent. up to 37 per cent. The Prussian blue varies from 0·6 up to 6·2 per cent. Obviously the one with six-tenths per cent. would be very much lighter than the one with 6·2 per cent. The lead chromate varies from 2·4 up to 13·2 per cent. So that if I take the first example, for instance, with six-tenths per cent. Prussian blue and only 2·4 per cent. of lead chromate, that will represent a very light green. If I go to the other extreme, and take one with 6·2 per cent. of Prussian blue and 5·8 per cent. of lead chromate, that will represent a dark green. The total proportion of lead compounds in these six paints varies from 6 per cent. up to 18 per cent. All the rest of the paint consists of non-lead compounds.

10,133. Eighteen per cent. of raw lead is very dangerous for the workpeople, is it not? I take it that the 18 per cent. is all soluble?—It would be mostly soluble.

10,134. So that we could not get over our difficulty by the suggestion which you put forward?—No, but I am pointing out to you that, first of all, the green paint does not as a general rule contain a very large proportion of lead. It will only contain a total, at the outside, of something like 16 per cent. in the normal condition. If you were to reduce the total lead in a paint to 5 per cent., it would really mean that you would take away two-thirds of the lead compound in such paint as this.

20 July 1911.]

MR. EGBERT GRANT HOOPER, F.I.C., F.C.S.

[Continued.]

10,135. Would that destroy the colour?—No, not of necessity. The yellow lead chromate, for instance, might be represented by the yellow zinc chromate, which is a much less poisonous substance.

10,136. The Home Office have, in another industry, assumed that any excess over 5 per cent. of soluble lead is dangerous to the workpeople using it?—Yes.

10,137. So that no suggestion put forward dealing with anything like 16 to 18 per cent. would be of any effect?—No, but practically the whole of the lead might be replaced by zinc chromate without altering the colour. In other words the yellow portion of the green might be entirely zinc; so that if such a regulation were brought into use the lead would be wholly displaced and zinc chromate would take its place.

10,138. Without much alteration in the price?—There would be some little alteration in the price, but not a very serious one.

10,139. You would not care to speak as to the practical effect of such a change in regard to the durability of the paint afterwards?—No. It has been laid down quite generally that white lead is the most durable paint, and, following that, I take it, all lead compounds, but next to them zinc compounds.

10,140. You would not speak positively from the practical point of view?—I have no knowledge from the practical point of view.

10,141. Could the method of testing for the solubility of a pottery glaze be applied to the estimation of soluble lead in paints?—Certainly. I see no real difficulty.

10,142. Are you prepared to suggest a form of words which could be used?—Yes, I should like to suggest a form of wording, it being understood that with increased experience some slight modification might be necessary. That being understood I think that this form of words would probably suffice: "After the day of no paint or wash shall be sold, or used for colouring, coating, or protecting any wood, stone, metal, or any building or construction, or part of any building or construction, unless such paint or wash is free from lead and lead compounds, or unless when tested in the manner described below it shall yield not more than a definite proportion (say, 5 per cent.) of soluble lead or lead compounds calculated as a percentage of lead monoxide on the dry substance of the paint or wash. By 'dry substance' is meant the paint or wash substance dry and free from turpentine, oil, varnish, and varnish material, gelatine, size, and other fluid or adhesive or water-proofing material."

10,143. Could you also give us a form of words in which the method of testing should be prescribed?—Again I should like to premise that it might be necessary with further experience to vary slightly. But that being understood, I think that this method of testing would probably be applicable:—"Method of Testing.—If the paint or wash be mixed with water, turpentine, oil, varnish, size, or other adhesive or water-proofing substance, it shall first of all be freed as far as possible from such vehicle or adhesive or water-proofing substance by drying or by treatment with ether, petroleum spirit, alcohol, water, or other neutral solvent or solvents. If the residual substance so obtained shall contain insoluble varnish matter, size, or other adhesive material which cannot be removed except by the action of re-agents which affect the other constituents of the paint or wash, then the proportion of such varnish matter, size, or other adhesive material shall be ascertained by suitable means, and a deduction be made for the same from the weight of residual matter taken for the determination of the soluble lead, so that the proportion of soluble lead found to be present shall be calculated as a percentage on the dry matter free from varnish matter, size, &c. For the determination of the soluble lead, a weighed quantity of the dried or dry material, freed as far as possible from oil or other vehicle or adhesive substance as above described, is to be continuously shaken for one hour, at the common temperature, with 1,000 times its weight of an aqueous solution of hydrochloric acid containing 0.25 per cent. of actual or real hydro-

chloric acid. This solution is thereafter to be allowed to stand for one hour, and to be passed through a filter. The lead salt contained in an aliquot portion of the clear filtrate is then to be precipitated as lead sulphide, and weighed as lead sulphate." Those are the actual terms used in the description of the test as applied to pottery glazes.

10,144. With the exception of the removal of turpentine and varnish, and other such constituents, which are necessary additions in the case of paints?—Yes. The point that I had in my mind in reference to some slight modification that might be necessary is connected with this point. On the removal of the oil from the paint it is sometimes found that traces of oil remain with considerable persistency attached to the dry substance of the paint, and if you apply water to such dry substance you will find that it does not, as we say, "take" the water—that it does not mix with the water. It is like oil and water; it tends to form a globular condition. We have had only a very limited experience of actually submitting lead paint substance to the action of this dilute hydrochloric acid solution which I have just described, but in that limited experience we have seen that, in one case at least, there was such a tendency to hold the oil by the dry substance that a slight modification might be necessary in the treatment of that dry substance before it was subjected to the action of the hydrochloric acid to dissolve the lead.

10,145. I take it that this system of testing which you have put forward is similar to the one that Dr. Thorpe invented?—It is similar to that which was worked out in the Government Laboratory for use in connection with pottery glazes.

10,146. (Dr. Collis.) In freeing the lead paint from its oil and other constituents, is it possible that an appreciable amount of lead might be removed as an organic lead compound?—We have not experienced that. Lead oleate, for example, is soluble in ether, and therefore, under certain conditions, supposing the oil was in a very rancid state, showing a large amount of free fatty acid, it is quite possible that a certain amount of lead might go in solution in the oil. It would have to be watched.

10,147. I think you know that Dr. Baly has been showing that lead tends to form an organic lead compound when paint is mixed, and I wondered whether in separating out the oil and other vehicles from the paint it was possible that any appreciable amount of lead would be removed, sufficient to make any difference to the 5 per cent.?—As the result of very wide experience we have no reason to think that that would happen.

10,148. Do you think that the amounts would probably be so small that they would be negligible?—Yes; they would be negligible, but I think that that would have to be watched.

10,149. (Mr. Fell.) Is there any substitute for lead chromate?—Yes, zinc chromate.

10,150. In your opinion is it as lasting as lead chromate?—I am not in a position to say that. I should have thought that it was almost equally good, that is, as good as a zinc paint is as compared with a lead paint.

10,151. One of the difficulties that we have to face is that we have not so far been able to find a substitute for lead chromate?—I think that zinc chromate would be a substitute with which to replace the lead if it is the lead that you want to get rid of, although chromic acid itself is poisonous. The mere replacement of lead would be made by substituting a zinc chromate.

10,152. The chief difficulty comes in with light colours, for instance, when you get primrose colour produced from lead chromate?—Yes.

10,153. The ordinary zinc substitute will not stand the weather in the same way that the lead chromate does?—Possibly not, but I have no experience of that.

10,154. I want to know whether you have any special formula for a material that could be used in place of lead chromate, of equal durability?—I may say as one illustration of where a very delicate colour is required that we have substituted in one official matter a permanent yellow dye substance for lead chromate which was previously used, and so far as that has gone (it is

20 July 1911.]

Mr. EGBERT GRANT HOOPER, F.I.C., F.C.S.

[Continued.]

only a matter of five or six years as yet) it has answered perfectly well in that case.

10,155. Is it exposed without varnish?—Yes, that is exposed without varnish. It is not a paint substance, but a mere colouring substance. I put that forward as an illustration of the substitution from the mere colouring point of view and not from the paint point of view. There are good lasting yellow dye substances which could very easily be used where a very delicate shade was required.

10,156. (Mr. Mason.) By whom do you suggest that this test that you speak of should be made?—I see no difficulty in various officials throughout the country being made responsible for this test; though, if the number were not very great I imagine that all the samples could come to the Government Laboratory. If, however, it was intended that the local authorities should carry out these provisions, then I think that these authorities would probably go to their own local officers, and arrangements such as those connected with the Fertilisers and Feeding Stuffs Act would be applicable in this case.

(Chairman.) At the present moment samples of all glazes that are required to conform to the 5 per cent. solubility standard are taken by factory inspectors and sent to the Government Laboratory, examined, and reported on. If they exceed the limit then proceedings can be taken. In the case of paints, supposing that we had a 5 per cent. solubility standard and said that not more than 5 per cent. of soluble lead was to be used in any paint, the factory inspectors would go round and take samples of different paints and they would send them up to the Government Laboratory to be tested, unless another method is suggested. If they were found to be all right, very well, but if not, prosecution would follow against the employer who provides the paint for the men to use.

10,157. (Mr. Sutherland.) With regard to the point of lead as the base for greens, chromes, and reds, did you deal with that? I am sorry that I was late, because I wanted to hear all your evidence. This is a very important question to paint manufacturers. It is equally as important to paint manufacturers as the lead question is to lead corroders. I have the assurance of a large paint manufacturer that there is no substitute for lead as a base commercially for greens and reds. I do not know whether you dealt with that point or not?—The red has not been dealt with. I might say a word or two upon that. There is a lead chromate, for instance, which is a very valuable colouring substance, but I do not think there would be at all the same difficulty in replacing the red as there would possibly be with the yellow. The red chromate is of such a colour that I think that it could be well replaced by certain shades of oxide of iron on the one hand, and on the other hand by certain shades of vermilion though vermilion is very costly.

10,158. That is the point that I was going to put to you?—It is very costly, so that it would only be in the case of the finer varieties that one would use that.

10,159. There are a great many vermilion substitutes termed "vermilionettes," and they enter very largely into the painting and decorating trade, and the abolition of lead, or its restriction to 5 per cent., would kill that business?—I am not sure that it would. There are other lakes. Those that you were referring to, known as "vermilionettes," are, generally speaking, made by the combination of a lead compound with an artificial red dye substance. It will be known to many of the members of the Committee that quite as good lakes are prepared without the use of lead at all, but by the use of aluminium. In other words, alum produces splendid lakes, and the original lakes were largely alumina lakes. So that as regards vermilionettes I do not think any real difficulty would arise in the replacement of lead by aluminium, as far as the colour goes. I am not dealing with the lasting effect of such paint. That is another matter.

10,160. Lakes are transparent, and are usually used as glazes, not as body colours. The vermilion substitutes give solid body colours which you cannot get with lake. Generally speaking, lake is used thin

over a lighter surface or in small quantities?—That is a practical question which I would not like to answer.

10,161. To deny the trade very valuable colours hits a very large number of people such as manufacturers?—I see them using vermilionettes in painting house doors, and they appear to use them in exactly the same way as ordinary paint is used, so far as regards the upper coat. The under coat has been already applied as a neutral or colourless substance. The upper coat is made of vermilionette.

10,162. I did not hear your evidence as to greens. Did you suggest any alternative for lead?—I suggested that zinc chromate might be a good substitute for lead chromate. We meet with a few of them, but we have no knowledge as to how they wear as compared with lead chromate.

10,163. A large manufacturer told me that a zinc base is commercially impossible for greens, and that they could not get the depth to carry, not the adulteration, but the body which they put in for greens?—You will not forget, sir, in any case that there is a certain amount of conservatism in connection with all trades.

10,164. But I was speaking of a man who has no restriction in his mind in that respect. He is quite open to adopt anything that is good?—I could not speak upon that without actual experimental investigation.

10,165. (Chairman.) Would you say that it would be beyond the wit of man to devise some substitute for lead chromate?—I should not have thought that it would.

10,166. (Mr. Mason.) It has occurred to me that there would be no difficulty in regard to the analysis where paint was bought ready mixed in the same way that one buys a glaze?—No. One would have to free it from oil. There are certain laboratory difficulties, but that is provided for to some extent in what I have drafted. It is conceivable that in certain cases a man without experience might find some difficulty in extracting what is called the vehicle. In the present day that may be composed of many other substances besides merely oil and turpentine. I mean that there is a tendency to use such substances as size and other modified albumenoid substances, even such as casein, which is being used. Those substances are insoluble in such solvents as would take out oil and turpentine completely. But supposing that it were impossible to remove the whole, one would have to make allowance for the fact that, when you operated upon your dry substance, that dry substance might conceivably retain, say, 5 per cent. of an organic material, such as an insoluble gelatine. You would simply calculate on 95 per cent. instead of 100 per cent.

10,167. If a painter bought a ready-made paint he could get a guarantee that it did not contain more than 5 per cent. of soluble lead?—Yes.

10,168. If, however, as one has to do every day, one has to match another paint already on a wall or on a vehicle, the paint is mixed by the painter himself?—Yes.

10,169. He would simply go on adding a little more of this and a little more of the other until he got his shade, and at the end of the time he would not know where he was with regard to the amount of lead?—I quite agree as far as pushing the responsibility back to the original vendor of the paint is concerned. In such a case the painter would take on himself the responsibility. But supposing that the constituents mixed were each, and all of them, of less than 5 per cent. soluble lead, any amount of mixing would make no difference.

10,170. Of course not, but if an entirely lead compound had to be used there would be difficulty there?—White lead for instance?

10,171. Yes?—Then he would pull up the proportion of soluble lead at once.

10,172. There would be greater difficulty in the paint trade than there is with regard to pottery glaze in that respect, you would agree?—Not of necessity. I think that there would be more than there would be in the milk trade, for instance.

20 July 1911.]

Mr. EGBERT GRANT HOOPER, F.I.C., F.C.S.

[Continued.]

10,173. I know nothing whatever about pottery, but I believe that in the pottery trade a man buys his glaze ready mixed. Does he ever mix two or three together?—Yes, he compounds.

10,174. (Chairman.) Very often he does. There are glaze makers who provide glaze ready made, but in a very large number of cases it is mixed in the lead-house of the pottery?—In a large number of cases they use at least three glazes for different pottery and those are of different combinations.

(Chairman.) I have known cases in the pottery trade where a small manufacturer has purchased on the open market remnants of glazes and mixed them altogether and used them.

10,175. (Mr. Sutherland.) Assuming that these restrictions were placed on the trade, would it be possible for a Government department to standardise all these paints?—I would suggest that if a man purchased always under an analysis, he would have the guarantee of standardisation that you refer to. If he went to a wholesale man he might say, "Tell me the composition of this," or he might be content to know that it contained less than 5 per cent. of soluble lead, which would be good enough in a general way without going so far as to say, "What are the constituents?"

The witness withdrew.

Mr. A. GUNNEW examined.

10,181. (Chairman.) You are attending here to-day as the representative of Messrs. Szerelmey and Company, Rotherhithe?—Yes.

10,182. Do you manufacture leadless paint supplied to Government departments and others?—Yes.

10,183. Is your paint intended to be used as a substitute for white lead in paints?—Yes, we think that it should not be necessary to use white lead. I will not say altogether, but very largely, white lead might be superseded by non-poisonous substitutes.

10,184. What is the composition of your non-poisonous paint?—There are two compositions, roughly, one a basis of white zinc (zinc oxide) and the other oxide of iron, and then, of course, the vehicle.

10,185. What vehicle is used?—Linseed oil.

10,186. Are there any lead compounds in your paint?—No, speaking generally.

10,187. What do you mean by "generally"?—Once in a dozen times, perhaps, there may be a very small percentage—5, or 6, or 7 per cent.—of lead in a colour which has a basis of lead.

10,188. Used for what particular colours?—Chiefly in connection with the preparation of greens.

10,189. Do you use any lead for reds, for instance?—No.

10,190. For yellows and greens?—Yes, for yellows and greens.

10,191. What is the maximum amount of lead you use in those circumstances?—I am not prepared to say off-hand. It depends on the colour.

10,192. What is the maximum amount you use in any colour?—I am not prepared to say, because we do not manufacture the yellow pigment. I shall have to inquire from manufacturers.

10,193. Do I understand that as far as your paint is concerned you use no lead at all?—We try not to use any lead at all.

10,194. It is not a question of trying, but do you use any at all?—I cannot say that lead never enters into the composition, but very seldom and very little.

10,195. About how much lead sometimes enters into the composition?—We may get an order for a green paint, and perhaps 5 or 6 or 7 per cent. of the pigment may have a lead basis.

10,196. Would you prepare that green paint yourselves?—Yes.

10,197. Would not you know exactly how much lead was there?—We should not prepare the yellow pigment. We should buy that from a paint colour maker.

10,176. We have to deal with a class of men who are in difficulty with regard to making both ends meet, and they would not worry about the side issues?—It would be quite simple for a man only to purchase a thing that conformed to the regulation that it should not yield more than 5 per cent. of soluble lead.

10,177. The American Government in certain States have had pure paint regulations under which all paint sent out in cans has to have the formula on the can, and the proportions of everything, but I do not think that that has worked successfully?—I had in my mind that declarations of composition are required in certain cases in the United States. It is not a very great hardship. The tendency is to demand more and more an express statement of the composition of articles which are purchased.

10,178. In the States?—Everywhere I should say.

10,179. I do not think that it obtains here?—Not with small men.

10,180. A man deals with firms that he has known for many years, and he knows that they are thoroughly trustworthy. He asks for the best of its kind in what he is buying, and he is content without a declaration?—What I mean is this: directly the State or the local authority interferes with any one constituent, the necessity for knowing what the actual constituents are comes into existence.

10,198. May I take it that, with the exception of green, you use no lead in your compositions at all?—No lead at all. We try to avoid the use of lead.

10,199. But that is not the point; it is not a question of trying, but of what you do. Are lead driers added?—No.

10,200. In no case?—I will not say that. Sometimes lead comes into the preparation of terebene.

10,201. What instances are there where lead driers are added?—Sometimes in the winter time we have to add a small proportion of terebene to help the drying.

10,202. What proportion of lead would that contain?—Perhaps 0·05.

10,203. Something infinitesimal?—Something infinitesimal—very small.

10,204. Do you use turpentine for thinning?—Yes, we use very small quantities.

10,205. Would you go so far as to say that under no circumstances should more than 5 per cent. of lead be added to any colour?—No. I should say that it is possible to get a very wide range of colours by the addition of a very very small proportion of lead.

10,206. You would not go so far as to say that 5 per cent. should be the absolute maximum?—No, I should not say that.

10,207. What would be an outside maximum; could you give us an idea?—It depends upon the colour.

10,208. Take any colour you like?—I think for some colours you need not have any lead at all.

10,209. I know that, but I am speaking of what might be required for some particular colours. Could you give us any idea what the maximum would be?—It might be 50 per cent.

10,210. Do you mean that seriously?—Yes, quite; 50 per cent. of the dry pigment.

10,211. But how much lead would that mean?—Fifty per cent. of the pigment.

10,212. Fifty per cent. of the whole of the paint?—I think paints are supplied—I do not say by us, but by makers—which contain such a proportion.

10,213. Do you think that is absolutely essential?—No, I do not, but if a man is determined to have a certain colour it may be necessary to use that proportion of lead.

10,214. That is what I want to get at. Are there certain colours in which it is absolutely essential to use such a percentage as that?—I cannot answer that. I am not a paint colour producer.

10,215. There may be such colours?—There may be such colours.

20 July 1911.]

Mr. A. CUNNEW.

[Continued.]

10,216. Why do you come here and make a statement that there may be such colours if you do not know?—Because you ask me. You see we have our own processes.

10,217. It is better to say that you do not know than to say there may be, because you raise doubt in our minds? I think you should examine a colour expert on these points. I do know this as a fact—that certain colours are produced from a lead basis, others from a zinc basis, others from a baryta basis, and so on.

10,218. What is the point of your coming here to-day?—We have been makers of non-poisonous paints for the last fifty odd years. We do not use lead at all. When I say that we do not use lead at all, I mean that we are not makers of lead paints. It may occasionally be necessary in the producing of a colour to employ a pigment which contains a proportion of lead in its base. We do not make these pigments ourselves, but buy them from a colour maker.

10,219. Do you get a sufficient covering power without the use of either red or white lead?—Yes. I have here a few specimens that I painted myself yesterday afternoon with zinc (*producing the same*).

10,220. Are you quite sure that you get sufficient covering power with all colours without the use of either red or white lead?—I think if the paint is properly prepared and the work properly done there is no choice between the use of lead or zinc.

10,221. For any colours?—For any colours.

10,222. Then to what do you attribute the request of some people for colours in which it is considered to be quite necessary to use lead?—Lead has more density than zinc and, perhaps, the painter is more accustomed to its use—its application. If he gets hold of a zinc paint it may be improperly mixed. He thins it down, perhaps, too much with turpentine.

10,223. Is it a question of bad mixing?—Very often it is a question of bad mixing.

10,224. Not a question of the virtue of the paint itself?—It is this. If you take a pound of lead paint and a pound of zinc paint, I believe you would get the same amount of covering out of the pound of zinc paint as you would out of the pound of lead paint, weight for weight. Your zinc paint will spread over a larger area, but if you confine it to a certain area (this table for instance) you get the same covering from a pound of zinc as from a pound of lead.

10,225. How does the cost of your paint compare with that of lead paint?—The cost of our paint is rather more in the package.

10,226. Do your customers tell you that it is more costly to paint with the leadless paint than to use lead paints?—I ought to explain our position a little here. We are makers of particular kinds of paints sold under the trade name "Szerelmey Iron Paints." They are made from a basis of oxide of iron or a basis of oxide of zinc of the very best quality. We also specially prepare our oil. I believe the durability of paint is determined more by the oil than by the colouring pigment. We start with the very best oil we can buy and we improve its quality, and consequently our paints are a little dearer in the package, but we think they are cheaper on the work.

10,227. Over what period have your paints been in use?—About 55 years.

10,228. Has your paint always been found to be durable?—Very.

10,229. Do I understand that you have had no complaints on that score?—We have had no complaints on that score.

10,230. Can you name a few of your most important customers who have expressed satisfaction with your leadless paint and have given repeat orders for it?—Here is a list which I had made out yesterday of a few people who have been ordering paint from us for some years past. Some of them go back a good deal longer than others. The ledgers were searched from the present year to 1899. Orders have been received from the Kidderminster Corporation in 1911, 1910, 1909, 1908, 1907, 1906, 1904, 1902, 1901, and 1899. Then the Exeter Corporation 1911, 1910, 1909, and 1908. Then the Grays Thurrock Urban District Council—a

long list—and the East Sussex Asylum. They are public bodies. I said: "Get a few public bodies and get a few private people and other users." We have taken two brewers. There is one at Petersfield, whose orders go back to 1906. That is as far as we searched. Then we have taken brewers at Ely, then two private gentlemen, one at Maplewell, near Loughborough, and one at Debden Hall, Loughton.

10,231. Have you ever received repeat orders?—Yes. Here is a list of some with the years and the months.

10,232. Going back in all cases, how far?—Some 10 years, others less and others further.

10,233. Going back from five to 12 years?—Yes. Here is a letter from the Furness Railway Company, who write to say they have pleasure in stating they have been using "Szerelmey" paint in the Harbour Department for more than 15 years, and it has always given satisfaction. They continue: "It is used for painting the inside of all our floating plant and for the channel buoys, and is excellent for any iron or steel in contact with sea water." The letter further says: "I wish it to be understood that you use this testimony for no other purpose than the one prescribed—for the Home Office Inquiry—and not for advertisement." A letter from Chard says: "I have pleasure in testifying that the quality of Szerelmey & Co.'s leadless paints is excellent. I have used them for a considerable period and find them wear well. On the outside of two properties in this neighbourhood they have stood for more than four years and are still in very good condition." That is from an architect in the employment of the firm of Mitchell, Toms and Company, Limited, wine merchants and rectifiers, brewers and malsters, of Chard, in Somersetshire. Mr. Langton Cole, the official architect of the London Stock Exchange, where our paint has been used from the beginning, says "In reply to your letter of the 7th instant, I have used large quantities of Szerelmey paint for the exterior of the Stock Exchange and other buildings in Throgmorton Street, also for my own and other houses at Sutton, in Surrey. I am pleased to say that the result has in all cases been satisfactory." Mr. Cole's father, who has been dead now many years, showed me Szerelmey zinc paint at his house in Sutton which had then been on over 20 years. I met his son on the station platform four or five years ago, and in answer to a question he said that that paint was still on the doors.

10,234. (*Lord Henry Bentinck.*) On wood-work?—On wood-work inside. That is about 36 years ago.

10,235. (*Chairman.*) Is your paint used as much for wood-work as for iron-work?—Quite.

10,236. And for exterior work?—Yes, generally.

10,237. For outside as well as inside?—For outside as well as inside.

10,238. Do you find the durability outside perfectly satisfactory?—Yes. Do you wish me to speak of paints generally?

10,239. I am speaking of your own paint. Do you say that it is quite as satisfactory outside as inside?—Yes, quite. My brother-in-law has a rectory at a place near the sea, in Kent, on the Romney Marsh, about a mile from the sea as the crow flies. He had the outside of his rectory painted with our paint. At the end of five years, when the house was re-painted with the same kind of paint, the old paint was found to be in very good condition considering the length of time and the exposure of the house—I do not know why the work was re-painted; possibly for appearance sake or to comply with requirements of diocesan authorities.

10,240. (*Lord Henry Bentinck.*) What colour?—Very pale green.

10,241. Was there any lead in it?—I do not suppose there was. It was very pale, perhaps an ounce of colour in 5 pounds of zinc.

10,242. (*Chairman.*) Have you supplied any of your paint abroad?—Yes. The Crown agent for the Colony of Bermuda frequently orders.

10,243. Have you testimonials?—They do not give testimonials, but there are a series of orders extending from 1907 to 1911.

20 July 1911.]

Mr. A. CUNNEW.

[Continued.]

10,244. Do you supply to Bermuda only?—We send to other places. I have not a note of the others. The Crown agents take the Malay States and other places. I do not quite know what ground they cover.

10,245. Do the Crown agents order constantly?—Yes.

10,246. Do you supply your paints to India?—The Great Indian Peninsular Railway, which I believe now is under Government authority, many many years ago used to order our paint, year after year, for their bridge work. This was oxide of iron paint, not zinc. They discontinued the use of our paint, I suppose, on account of its price, and put the specification out to public tender. We lost, and after about three years of tendering successively, and reducing our price to the very lowest possible, we discontinued tendering. We were able by rearrangement of the machinery at our new works to produce the paint at rather less cost, and we approached them again. Tenders came out for 15 tons, and we were asked if we would supply five tons *pro rata*, and we said that we would do so. That paint was sent out to India by three different manufacturers, with special instructions to the engineers that it should be watched. At the end of 10 years from that time we secured their orders again.

10,247. (Lord Henry Bentinck.) What colours?—Red. In discussing the merits of Szerelmey paint as compared with others, the then engineer to the Railway Company said: "We take care we get what we ask for." I said: "We give you more than you ask for." As a fact, we supplied the Company with the specification showing the quantities of oil and pigment in the paint. We did not supply the formula for the preparation of the oil. In the preparation of the oil we give certain advantages which I do not believe any other manufacturer gives. It was prepared originally by Colonel Szerelmey, the originator of our firm.

10,248. (Lord Henry Bentinck.) These testimonials which you have handed in are testimonials for what colours?—All colours.

10,249. Therefore it does not follow, I suppose, that they are all leadless paints by any means?—Yes, all leadless paints. When I say "all leadless paints" there may be some colours in which lead does enter to a very very small extent.

10,250. You said that you had not found any substitute for lead in greens and yellows?—Many of our greens have no lead in them.

10,251. I understood you to say you had not?—No; I meant that there are some tints of green which, as far as I know (I am not quite certain), it would be impossible to reproduce except with a lead basis. Some are of an arsenical basis. We will not use that under any consideration.

10,252. The last witness, the superintendent of the Government Laboratories, suggested that zinc chromate was a substitute for lead in greens. Have you tried that?—I do not know. We probably have zinc chromate on the works. You see these yellow colours have their own distinctive tones, and a man may say, "I want this paint matched." He has to paint a room to a paper, and he says "I want this particular colour matched." Then we have to look about to get the shade of yellow that will produce that colour. We may use a zinc chromate, or we may use something which has a basis of barytes; we may have to use barium, or we may have to use something which has a basis of lead; but the use of lead in our works is a negligible quantity. We set ourselves against its use.

10,253. I understand that, but at the same time I understood you to say that there were certain tints where it would be impossible to find a substitute?—I should not be prepared to say that if I were put on oath, but that is my impression.

10,254. (Sir Godfrey Baring.) Do you find that zinc paint will stand the action of London air well externally?—Better.

10,255. Better than lead paints?—Yes, because the sulphur in the air does not affect the zinc paint as it does lead.

10,256. You would say that zinc paints were specially suitable for exterior work in manufacturing towns?—Yes, in manufacturing towns.

10,257. (Dr. Collis.) Have your paints, which have been used extensively for many years, been used from the first coating for putting on the bare wood and on the bare plaster?—It is quite possible, but as manufacturers we do not know, as a rule, how the painter will use them. As a fact, it is very difficult for us to find out where our paint is used. We simply supply to order. When it leaves our works we have no further control over it.

10,258. It is supplied as any other paint is without any stipulation at all that it should only be used for second or third coats?—Just so. Here is one coat over green (producing the same). That is zinc white, the same as this is (producing another specimen). I put a little pinch of red into it—a very small quantity. That would serve as a primer. Here is one coat on a soft piece of bare wood.

10,259. (Lord Henry Bentinck.) Does that contain no lead?—This undercoat may contain a very very small percentage of lead. I cannot quite say what that is, it has been on about ten years. All these undercoats have been on about ten years.

10,260. (Dr. Collis.) Do you think that if such a percentage as five of lead was permitted by law, there would be any difficulty in obtaining any of the colours to which you referred, when saying that lead it still used for them?—There might be.

10,261. There might still be trouble in producing some of the colours?—Yes; it might result in certain colours being left out and people having to do without them. I do not think that it would constitute a real hardship.

10,262. Take one of these greens: what would be the percentage of lead in such a paint when it is made? Take one of the greens you speak of, which you consider there would be difficulty in obtaining; I suppose there are other substances which would produce it?—I do not know. We do not manufacture such. We have our standard shades, which are prepared expressly to avoid the use of anything that is poisonous.

10,263. And your paint is perfectly satisfactory?—Yes. I have seen colour cards upon which certain greens have been shown which I know must contain arsenic. We should not make such, but I do not say that we should not make a paint which contained a certain percentage of lead. We do not consider it so dangerous, used in a very small way, as arsenic would be.

10,264. (Mr. Sutherland.) Your paint is used mainly for breweries and estates and engineering work, and work of that kind?—Yes.

10,265. It does not enter largely into the building trade through the ordinary channels?—No, it does not. The painter and the builder as a rule are against us.

10,266. I would not put it in that way?—They are.

10,267. They are familiar with the other, and they find it good. Yours is a special proprietary article, is it not?—Yes.

10,268. So that does not imply hostility to your paints so much as familiarity with good stuff which they already possess?—I do not want to say anything against the building trade, but my general experience is that, as a rule, the painter is opposed to the use of our paint.

10,269. But there are a number of paint manufacturers like yourselves and others one could name who really cater for a public quite outside the painting and the building trades?—Yes.

10,270. And you belong to that category?—Yes.

10,271. (Chairman.) Do I understand by that that you do not encourage business from other sources?—We should, but we cannot.

10,272. Why?—First of all the price is against us, and, secondly, our paint lasts too long.

10,273. (Mr. Sutherland.) No, we cannot accept that?—That is a fact.

10,274. (Mr. Parsonage.) You say that the painters and building trades would be against you?—Yes.

10,275. Would your paint require any special thinners for use, or could it be used with turpentine thinners?—We send our paint out as a rule ready for use.

20 July 1911.]

Mr. A. CUNNEW.

[Continued.]

10,276. Absolutely ready for use?—Absolutely ready for use.

10,277. How long would it remain without wanting any thinning? Is there a sediment if it is kept open for a few days?—If it was left open for a few days, a skin would form on the top.

10,278. And would there be a sediment?—In the majority of tints there should be very little sediment. If the paint is well made there will be an absence of sediment. With zinc paint there should be absolutely no sediment.

10,279. Supposing I wanted to do a room egg-shell gloss, if I wanted to do a room dead flat or finished with varnish gloss, could you supply those different paints with those shades direct from your works?—Yes.

10,280. (Mr. Robins.) If lead was abolished altogether, would your firm suffer any great hardship?—We might, because we are a small firm, and although we have been advocating the use of zinc for 50 odd years, other big concerns might squeeze us out.

10,281. You do not think that with the introduction of zinc you would suffer a hardship, do you?—I think if zinc were generally introduced we might suffer because big concerns would be able to manufacture at a less price than we could, and people would not, perhaps, look at the extra advantage we give them. They would think: "Szerelmey is a zinc paint; so-and-so is a zinc paint." They would not differentiate between other zinc paint and our zinc paint, and the zinc paint supplied by another firm might be cheaper, and in consequence we might suffer.

The witness withdrew.

Sir HENRY CUNYNGHAME, K.C.B., examined.

10,282. (Chairman.) You are legal assistant Under-Secretary of State for the Home Department?—Yes.

10,283. I believe that you have devoted considerable attention to the question of lead poisoning arising from the use of lead paints?—Yes, for some years.

10,284. Do you consider the evil to be a very real and serious one?—Yes, and a remediable one.

10,285. In your opinion, is it imperative that some action should be taken in this country to mitigate the evil?—Certainly.

10,286. Either by a measure of prohibition or restriction of the use of lead, or by a code of regulations?—Yes.

10,287. Have you given attention to the action taken in this matter by certain foreign Governments?—Yes.

10,288. What action has been taken in France?—A very drastic one. The law\* dates from the 20th July 1909, and it comes into force at the expiration of the fifth year from that date. "No white lead or linseed oil containing lead or special product containing white lead shall be used in any painting operation of any kind carried out by working painters either on the exterior or interior of buildings." That practically is the law. It is very drastic. The rest of it is only administrative.

10,289. Has any other country adopted a definite measure of prohibition?—Yes, Austria. The Austrian regulation† only goes so far as the prohibition of lead for interior painting generally.

10,290. At what date did that decree come into force?—April 1st, 1909.

10,291. Where the use of lead is still permitted in Austria, the work has to be done under a very strict code of regulations, has it not?—Yes; and the regulations may be summarised very briefly in this way: Regulations as to ventilation, washing and dressing rooms, the marking of vessels containing lead paint, and women and young persons not allowed to handle. Overalls must be worn, and in certain cases there must be examination by a surgeon. That very briefly summarises the sort of regulations. It gives an idea of them. They are rather too complicated and long for me to go into details.

10,292. That is quite sufficient. Have similar codes for regulating the use of lead paints been adopted by other countries where the use of lead has not been prohibited?—In Germany, it is a Gewerbeordnung for the whole German Empire.‡ Unlike some trade regulations of Germany, which are made by individual States, this applies to the whole German Empire. These again are rather long.

10,293. Will you please give a summary of them?—You may say that the workers are not directly to handle pigments containing lead. Then the grinding of white lead with oil or varnish shall not be done by hand. You see that this goes a little beyond the mere

dealing with paint alone; it deals to a certain extent with the manufacture. Then the processes of rubbing down and pumice-stoning of oil colour or stopping not clearly free from lead shall not be done except after damping. That is an important provision. Then there is a rule as to overalls.

10,294. Are the overalls provided by the employers?—It says that the employer shall see that every worker is provided with overalls. I do not know whether there would be any restriction as to charging the painter with that. I do not suppose that they would consider that part of the code. But anyhow the employer has to see that the painter has them. Then, there shall be provided also washing utensils, nail brushes, soap and towels. There one may remark that if you were to make the prohibition of lead universal, and it applied to small cottages and buildings and so on (as to which I will say something presently), I am in favour of it. You could hardly have washing utensils necessarily provided. It goes a little far. I do not quite understand the application of this code. It seems to me to be very general in its character. I do not exactly see how it fits in to the various trades, which is a matter of difficulty.

10,295. (Mr. Sutherland.) Are you speaking of the German regulations?—Yes. Then the employer has to inform workers who handle lead colours of the danger to health, and give them a copy of a warning pamphlet. Then there are other regulations for painting, distempering, whitewashing, plastering or varnishing when carried on in connection with another industry. And then some of the previous regulations are generally applied together with further ones about washing. There is a rule that the employer shall issue regulations which shall be binding on the workers. The employer is to make rules for his workers such as that they shall not consume spirits in any place where work is carried on. I do not know why they have not put beer down, because the acetic acid that arises from the fermentation of beer is quite capable, I should have thought, of changing white lead into the acetate in the stomach, as has been found in certain cases. They have left beer out and only prohibited spirits. They shall not partake of food or drink where the paints are (that is very sensible) or leave their place of employment until they have put off their working clothes and carefully washed their hands. They shall wear working clothes. The smoking of cigars and cigarettes is prohibited during work. A pipe, like the beer, has been carefully preserved—I suppose because they thought that they could not go too far. Then there is this interesting provision—that any worker who, after repeated warning, contravenes the provisions may be dismissed at once without notice, any contract notwithstanding. The employers must entrust the supervision of the workers' health to a duly qualified medical man. Roughly speaking, those are the principal points. I do not go into detail. Then there is a register to be kept of workers, and a register also of their illnesses and dates of recovery. That pretty well gives you an idea of the scope of the regulations.

\* See Appendix VIII. † See Appendix IX.

‡ See Appendix VI.

20 July 1911.]

SIR HENRY CUNYNGHAME, K.C.B.

[Continued.]

10,296. Then with regard to Belgium?—In Belgium the law\* chiefly seems to be directed to this—that white lead shall not be sold in the form of powder or dry when intended for paint work. It must be ground up with oil. Dry rubbing and punicing of surfaces are forbidden altogether if there is lead in the paint. It must be done wet. Then there are provisions for dealing with offences. Those are the chief provisions of the Belgian code.

10,297. Have you formed an opinion as to the probable efficacy of such regulations if a similar code were adopted for this country?—Yes.

10,298. You think such regulations would mitigate the evil, but not remove it entirely?—I have always been of opinion that, if sufficient care is taken, you can use almost any ingredient quite safely, by forbidding it where it is unnecessary, and, if it is to be allowed at all, putting it under sufficiently strict regulations. I do not see why anybody should get lead poisoning at all. I think that it can be remedied and that there ought to be regulations.

10,299. Would it be practicable to enforce such regulations in a trade scattered throughout the United Kingdom?—If that means would it be practicable to absolutely prevent anybody under any circumstances from using white lead when he ought not to do so, I can answer, No. It is not practicable, just as it is not practicable to prevent theft through the United Kingdom. You cannot by law absolutely make sure, in a trade that is carried on largely, that there shall be no breach. But that is not what we aim at. Supposing that you can cure ninety-nine hundredths of an evil (and you can do that), that ought to be sufficient for anybody, and would justify the making of strict regulations.

10,300. But my point is, would it be practicable to enforce such regulations in a scattered trade like house-painting?—I think so. If you said generally "nobody shall use white lead for any purpose at all for paint" I think that in a little while those who did it would be gradually got hold of and hauled up. It would be possible to enforce that generally.

10,301. That is prohibition?—Yes.

10,302. It would be quite easy to enforce prohibition, but would it be possible to enforce rules for the protection of the workpeople in such an industry as house-painting?—You might make a rule that nobody should use any white lead at all if any other kind of paint would do, and that the only times that anybody was allowed to use white lead were in virtue of some special relaxation necessary for his trade, and then I think that those places where the exceptions were granted could be known and could be watched, and there would be no difficulty in administration through the whole country. Notwithstanding that, I do not think you could be perfectly certain that somebody in a corner would not be found breaking the regulations. But I think that you would do an enormous deal of good, and put an end to the great poisoning that is going on now.

10,303. (Mr. Sutherland.) By regulation?—By regulation and by prohibition—the two.

10,304. The Chairman's point was regulation?—Yes.

10,305. (Lord Henry Bentinck.) Similar to the German regulations. Would it be possible to carry those out in England?—I will say something about that in a minute. I should do it in a little different way. I am in favour of the general character of them.

10,306. (Chairman.) You think, I suppose, that the prohibition of the use of lead would be a more practicable solution, with the exemptions that you have suggested?—That is a general question, and I would like to answer it in this way, if you would allow me. In the first place I think that it would be necessary to define what you mean by "lead." For instance, the yellow may be as dangerous as the white lead, and you might have to consider what to do with that—I do not know. It is a smaller thing and perhaps may be left alone. But you would have, I think,

to schedule lead so that no ingenious person could get round the schedule and make something which was not white lead, but which was just as dangerous. You would probably have to give power to the authorities to put in the schedule from time to time anything proved to be an evasion of the regulations which you intended to make. Then there is the marking of packets. The regulation of that would be rather a good regulation—making it illegal to sell white lead unless it was marked as white lead. That would prevent people from buying it and pretending afterwards that they did not know that it was white lead. You could get at somebody for doing that. I do not think that the difficulty that has to be met is at all insuperable, and I only mention it. There are a good many different matters which have to be dealt with. There are the exteriors of buildings and the interiors of buildings, for instance. In the word "building" I comprehend a conservatory, and I would say, "any place where there is a door which a man can enter." I would not call a chicken-house or a dog-kennel a building. I can think of several instances, but I will only mention some. There are difficulties which will have to be met, such as we always meet in the factory department, where we overcome them bit by bit. If you were to be deterred by difficulties of definition you would never do anything at all. You have to meet them, and every lawyer does that successfully after a trial or two. Then there are articles manufactured in a factory, such as wash-hand stands painted white. Then there are objects painted not in a factory—a fowl-house or an agricultural implement painted by a gardener. Then there is an important little group—artistic work. I suppose that you will allow the president of the Royal Academy to continue to paint portraits with a little white lead. It would be a stupid Act that did not allow the use of white lead for that kind of purpose. That is provided for in one of the codes by saying that people may be allowed to grind a very small amount; but I do not like that plan; I would rather make an exemption. Then there is a big group—ships and boats. I believe that for sea purposes zinc white is better than white lead. Many Liverpool firms think so at all events. The question is with regard to foreign ships and boats. You would have to be rather careful how the thing was framed so as not to put English workmen, English shipping, and English shipbuilders at a disadvantage with regard to their foreign rivals. I do not think that there would be more difficulty in that than we have had with the dock regulations. We have met them and overcome them. Then there is work of a scientific character and work on a small scale. With the exception of those matters which I have mentioned, I would like to say that I cannot see why another atom of white lead should ever be used at all. With regard to the interior of buildings, I painted a room of my own nearly ten years ago with zinc white purposely to try what effect it would have. The paint is beautiful to-day. I have had the door in my room at the Home Office painted half with zinc white, and it is excellent. I do not give my own testimony alone—it is absolutely universal. The Netherlands Commission held an extended inquiry, and everybody who has gone into the question says that zinc white will do for interiors. I think it criminal to allow any more white lead to be used for such purposes. You may consider the question of giving time to use up stocks, but that is not a matter with which I am concerned in advising at present. I do not see why zinc white should not be used all over the country where gentlemen's houses exist. I have used it, and all the evidence points to its safety; but you have a little difficulty in one respect. There are a few places where an abnormal quantity of sulphurous acid or sulphuric acid exists in combination with rain or moisture. That moisture combined with those acids (you must have moisture and acid) will change the zinc white into sulphate of zinc. It will soften and deteriorate the paint. I do not think that that applies to motor cars, for instance, because there you have a thick coat of varnish, which prevents rain getting in, and motor cars might be entirely done with zinc white,

\* See Appendix VII.

20 July 1911.]

SIR HENRY CUNYNGHAME, K.C.B.

[Continued.]

but it is possible that in certain places where there is a great deal of sulphuric and sulphurous acid about you would have difficulty. It is a pity that there is any, but there it is, and you have to meet it. It might be necessary to deal with it by way of exemption.

10,307. (*Mr. Sutherland.*) Railway stations are a danger point with zinc, are they not?—Yes. I think that you might exempt the gutters in some places.

10,308. Not the girders?—You might. If once you showed a competent authority like the Secretary of State that it was absolutely necessary for the safety of girders or gutters to use white lead, then I think that under proper precautions he might give for a special industry or for a special place or special time and occasion, leave to use white lead—under such precautions as he might lay down—but I would make the rule, “No white lead for interiors or exteriors,” the exception being white lead which the inspectors could look after, because they would have a list of the exceptions.

10,309. What would you do with a district like Manchester, where the atmosphere is very humid and full of smoke, with regard to external work?—I would consult representatives of the Manchester Corporation and engineers and employers and different people from Manchester, and if they proved that it was absolutely necessary to use white lead for the safety of buildings in Manchester, they should have special leave to do it; but they would have to prove the special circumstances, and special precautions would have to be taken.

10,310. (*Chairman.*) I take it that permission to use white lead would be accompanied by restrictions or special rules to protect workpeople?—It would be accompanied by restrictions as to the mode of using, certainly.

10,311. Even in Manchester, for girders at a railway station, you would not allow the workmen to use white lead in their paints unless concurrently there were restrictions to protect the workpeople?—No; I should discourage its use by every means in my power.

10,312. (*Sir Godfrey Baring.*) The exception to the prohibition would only be allowed by Home Office licence?—Yes.

10,313. (*Mr. Sutherland.*) The French regulations provide: “A regulation of the Public Administration issued after conferring with the Consultative Committee of Arts and Manufactures, and with the Commission on Industrial Hygiene shall, if necessary, specify special operations which may be exempted from the preceding provisions.” That is what you suggest?—That is the same thing. I do not like exemptions, but I recognise the necessity for them as I have said. There are objects not in a factory which you might find it necessary to exempt—for instance, somebody might show you a little trumpery thing like a photographic developing dish which could not be painted with zinc white, because the acids used in photography would dissolve the paint. If you did not exempt those they would all come from Germany.

10,314. The Austrian regulations provide for similar exemptions to the French: “Provided that this regulation shall not apply to the process of laying on a first priming coat over old lead paint when pure white paint is being renewed, or to the process of laying on paint which is frequently exposed to the influence of aqueous or other vapours.” That is a point that you made?—Yes.

10,315. Following that, it says: “The industrial authorities when establishing precautionary measures elsewhere stated may grant an exemption permitting the use of the substances named in paragraph 1.”?—Yes. I mentioned artistic work. That would want exemption. I should draw the Act so that it included artistic work, but I should give special exemption to artists. Then there is work on a very small scale, little tiny things which are necessary; and then there is work of a scientific character, to which reference has been made. It is because I think that there ought to be these exemptions that I am prepared to advocate a very stringent wholesale rule with regard to the use of white lead, allowing it only as the exception.

10,316. (*Chairman.*) A restriction of the amount of lead to not more than 5 per cent. would, no doubt, secure substantial immunity from lead poisoning, as it has done in the Potteries?—I do not like it, but you know now more about it than I do. You have heard the evidence. If you allow them to put 5 per cent. you have always to go fussing about to see that they are not putting six, and you will have immense difficulty over the country. I have read most carefully the whole of the French experiments, and I daresay that you have had them before you. I do not believe that it is necessary for painting to put lead in, but I bow to your decision.

10,317. Would you rather have entire prohibition?—I would have the whole thing prohibited entirely, and if they want an exemption up to 5 per cent. let the trade ask for the exemption. Make it a large exemption if you like, but when you have once a well-marked exemption the inspectors can focus their attention upon it.

10,318. (*Mr. Sutherland.*) You draw a very great distinction, do you not, between the climate of France and the climate of England?—Yes.

10,319. What is available there would not be suitable here perhaps?—I do not think there is much difference except in towns like Manchester.

10,320. Take Lancashire?—I have just come back from there, and they have made it an awfully sulphurous place. I should look round for the places where trees did not grow. If I saw that the trees were not growing well, I should accept that as evidence.

10,321. (*Chairman.*) Supposing that the Manchester Corporation and others came up and said that the trees would not grow and the atmosphere was very bad and very much against the use of zinc paints, you might have to exempt the whole of Manchester. It has been proved beyond question to us that you cannot have regulations to combat the evil?—That is a very good question, and it presses me. I will answer that by saying that it would not be enough for the corporation of Manchester to come and tell me that they were inconvenienced. They would have, by actual experiment, to show that a zinc paint used there was really likely to decay in such a way as to injure the iron gutters and permanent works of their town. If they merely said that with zinc white a little more painting was required, I should say that that was not enough. I should not grant exemption to everybody right and left.

10,322-3. (*Mr. Sutherland.*) No. There would be no value in the restrictions if you did?—No. The only reason why I am for prohibition is, that I want to make it easier to apply a wholesale general rule, and I am afraid that, unless you had some power of easing it, it might be too strong, and perhaps check our trades, which we do not want.

10,324. (*Lord Henry Bentinck.*) Have you studied the substitutes for white lead paints?—No. I only know something of the sulphates of lead and of zinc. I have not made a profound study of it at all.

10,325. We have just been examining a man who supplies paint for outside work to the Stock Exchange in London. That would be a very sulphurous atmosphere, would it not?—Nothing that I have seen in London at all compares with what you have in Manchester. The trees show it. Even plane trees will not grow properly.

10,326. Probably efficient substitutes might be found for bad atmospheres?—Very probably.

10,327. Therefore it would be a dangerous thing to allow Manchester to come to you and ask for exemption when all the time an efficient substitute existed?—If the persons who granted the exemptions did their duty, and if I had the honour of conducting the inquiry, we would find out whether there was a substitute, and if we did not I would only give exemption for a few years, and keep a watch on the substitute question.

10,328. Would it not be safer to lay down a time limit of two or three years before bringing in a general Act?—I think that that solely depends on two things—the amount of white lead in the country, and the expectation of people getting rid of it, and the other uses to which it can be put, which are considerable.

20 July 1911.]

Sir HENRY CUNYNGHAME, K.C.B.

[Continued.]

A certain amount of time should be given for painters to learn the use of zinc paints, because of the different mode of putting it on and handling it.

10,329. My point is: is it not better to lay down a strict time limit, with no exemptions, than to bring in an Act at once and allow exemptions afterwards?—If there were no alternatives to choose from; if it was a question of the present method or total abolition, I would go for total abolition, but it would be rather inconvenient in certain cases. I do not see how artists could paint pictures without white lead. They insist on saying that white lead has better covering power than zinc white.

10,330. You would not allow a whole town to contract out of the Act?—It depends on how the power of exemption was exercised. I do not like it. I agree with you.

10,331. (*Dr. Collis.*) In speaking of entire abolition, the purity of materials is such that there is sure to be some trace of lead even in the preparation of zinc paints, and we should have to consider some small percentage beyond which analysis should not carry you?—I should say, "no person shall knowingly use or prepare any paint containing lead, and in no case shall prepare any substance containing more than .01 of lead"—a trace.

10,332. (*Chairman.*) Does not the best zinc oxide contain about 3 per cent. of lead?—I did not know that. I should not have thought that it contained so much.

10,333. (*Dr. Collis.*) The zinc oxide prepared by the direct method from the ore contains from 3 to 4, or even a higher percentage of lead. We have that point to take into consideration?—If they cannot prepare zinc without lead, it must be taken into consideration. We must not be unreasonable and destroy trade; we can do the thing without that.

10,334. Yes. The point that one has in one's mind rather is that they can get some of the best forms of zinc paint prepared by the indirect method. They can get it nearly pure?—This is a point which I would deal with by the schedule. The Secretary of State should have power to deal with the schedule from time to time, and if he found that the making of zinc that contained lead was a totally unnecessary process, and ought to be struck out of the schedule, it would be struck out.

10,335. You think prohibition, with exemption, better than allowing 5 per cent. solubility?—The difficulty is this: an inspector goes round to a man and says, "Is there any lead in this paint?" and the man says, "Yes, I am allowed to have a certain amount." The inspector says, "How much does this contain?" and the man says, "That is for you to find out. I do not know what there is." The truth might be that he had put in 10 or 20 per cent. that morning. The inspector has to have it analysed, and three weeks elapse before that can be done. The inspector has lots to do, and the end of it is that no action is taken, and everybody mixes paint as he likes. That is why I do not like the 5 per cent. I would much rather have, if possible, a thing that was quite pure. It is bad enough to let them have a certain percentage in the Potteries, but there you have them all in a ring fence where they can be looked after; but how in the world could you look after gardeners and people of that sort, scattered all over the country?

10,336. Do you think that it would be possible to prohibit the sale or exposure for sale of materials which contain over 5 per cent.?—With regard to white lead I would prohibit the making of it for the purpose of paint, the sale of it, and the use of it.

10,337. If you prohibit the making of it, what would you do in cases where, at any rate, a small percentage could not be dispensed with?—If you point out that it is absolutely necessary to allow 5 per cent. to make a thing workable we must allow it, and invent the best means we can of meeting the difficulty that may arise. That is my answer to that. I did not know that there was this necessity for a proportion of lead. I consider allowing a percentage an evil, not in itself so much as by creating very great difficulty of administration.

10,338. Would the prevention of the manufacture or sale meet the difficulty of administration?—It would do

a great deal towards it. If somebody said that he could not make paint flow without a certain amount of lead you would have to allow the oil shop, the paint seller, to sell him lead to an unlimited quantity to mix in his paint, and you would not know how he would use it. A man may not know whether he is using white lead or zinc. It requires rather a knowledgeable man to know which was which, and a gardener would not know which was which.

10,339. Could you not prevent the selling or exposing for sale of an article containing over 5 per cent.?—I agree, but supposing a man mixes up his own paint. If a man is going to mix up paint he will have his materials as a rule by him. It is rather hard to expect him to buy nothing but ready-made paint. Supposing that he is not going to use it up straight away. I would deal with it by way of exemption. I would not draw a hard-and-fast line and say that everybody might use 5 per cent. for ever, but I would give the Secretary of State power to allow the use of 5 per cent. where it was shown to be necessary if that could be shown. Depend upon it, gentlemen, if twenty years hence we are alive we shall wonder why people ever used 5 per cent. at all."

10,340. In Belgium they prohibit the sale of dry white lead.—Yes. I have no objection to your taking away with one hand what you grant with the other if you like, but I do not want the 5 per cent.

10,341. We are trying to see how we can make it administratively possible to deal with this. You would have to catch it at the shop of the manufacturer, and not pursue it to its use?—It would take one a few days and a good deal of thought to see one's way through this labyrinth, but it is worth trying. I am not prepared to do it now.

10,342. (*Mr. Mason.*) Can you tell me whether foreign Governments look after their regulations with the same strict caution as regulations in England would be looked after?—My experience is that a number of foreign countries make extremely strict rules that sound tremendous, and look so on paper, and then do not take much pains to see them observed. The Germans are very particular, but some nations (I will not specify them particularly) are, I think, uncommonly lax. In a country like Turkey you will see the most formidable set of rules, and you say "How do people live under them?" and you are told there is nobody to enforce them. We are all the same. We also in this country have many rules and laws that we do not enforce. If you make rules too strict and impossible to obey, they are of no use. If I thought that the rule that I have suggested was too strict I would not suggest it; but I do not think it is. You will get them all to adopt zinc white before you have done.

10,343. I was inquiring of a large motor manufacturer in a foreign country with regard to white lead regulations, and he said that he had never heard of them. He knew nothing whatever about them. He was using white lead just as happily as ever?—I can perfectly believe it.

10,344. These regulations of foreign countries are shown to us, and we are told what foreign countries are doing, and it is said "Here is Old England far behind"?—You ought to inquire of somebody who has studied the question much more than I have. In Switzerland they have rules, too, I believe.

10,345. (*Mr. Kinggate.*) Is there any French regulation or law with regard to the use of lead in the coach-building industry or motor-car industry? The regulation does not seem to convey to me that they come under Section 1. It says, "Where painting work is done on buildings," but it says nothing about carriages or motor cars? It is only buildings, and I will say at once that I do not think that that is nearly sufficient. I do not at all see why you should forbid it for buildings and interiors and let a whole lot of people in a factory, painting wash-hand stands for instance, be poisoned.

10,346. I was under the impression that it did apply until I saw the appendix?—It certainly does not go far enough if it stops at buildings.

10,347. I did not know whether you would think that it applied to anything done in a factory. To me

20 July 1911.]

Sir HENRY CUNYNGHAME, K.C.B.

[Continued.]

it reads as if it applied only to buildings? I think that you are right.

10,348. (*Mr. Robins.*) I speak as a painter, and there is real difficulty from a painter's point of view with regard to the question of 5 per cent. My experience on first going into the trade was that colour mixing was a general process, and we had to grind the colours with a pestle in a mortar and on a stone, whereas to-day colour makers do that?—Yes.

10,349. In process of time, and with the economics of factories, we find that there are standardised colours which are made at certain works, and that lessens the work of a painter with regard to mixing colours. From one point of view it takes away perhaps to some extent the development of a painter's ability if he is not allowed to mix his own paints, but I hold myself from a health stand-point, that if all paints were mixed by paint makers and were sold ready-made, the difficulty would be removed, and it is being removed. There would have been greater difficulty 25 or 30 years ago than there is to-day, because every coach-painter was mixing his own colours, and he had to grind them before he commenced to paint his coach. It would perhaps be half a day before he could do anything at all, whereas now the colour is standardised, and is ground at the paint makers. In the old time all colours were bought in the dry?—The covering power is greatly improved by the fineness of grinding, which the painter could not get previously.

10,350. He could not get it—that is quite right. My impression is that in years to come there will be less mixing of paint by the painter himself, and it will be far easier to deal with the question?—I thought that it might be worth while to consider whether you will allow 5 per cent. in the manufacture of paints at works properly registered, not allowing it in the case of private people at all.

10,351. My idea is that the painter should not be allowed to mix his paint?—That would meet a great deal of the objection that I have raised.

10,352. (*Mr. Mason.*) Would there be any difficulty in prohibiting imported goods painted with lead colour?—Yes; I think that there would, because you see you would have to cast on the Custom House

Officers the duty of finding out what the paint was. They could be helped in that, and I do not think that the difficulty would be quite insuperable; but there would be that difficulty. People might say "If we are not allowed to paint with white lead why should others enter into competition with us with things painted with white lead?" My answer to that would be that if it could be shown that the painting of imported articles with white lead paint gave a great commercial advantage to the people who were doing it to the detriment of our people, then there might be something to be said for prohibiting the import of such articles. That has been done in the case of lucifer matches. You might make an order of some kind to deal with it. It might be worth considering whether it should be put in an Act, but I do not think the case arises. The advantage over zinc of painting in white lead is so exceedingly small that I do not think that anybody would trouble about it.

10,353. Some old-fashioned people might think that lead was better?—The foreigner would at once proceed to use zinc white, and he would be on a level with the English producer. I do not think that we are concerned with the health of the people in France.

10,354. I do not put it that way, but certain customers might think that motor cars from America painted with lead would last longer?—It might possibly be so, but I should rather doubt it. If you made a rule that nobody should vend such an article it might bother the Americans very much. They could bring the motor cars over, but they could not sell them.

10,355. (*Chairman.*) The Daimler Company have abolished lead altogether?—I quite believe it. The varnish is amply sufficient to protect the cars even in the case of sulphurous fumes.

10,356. (*Mr. Robins.*) A great number of chassis which are painted with lead colours are imported into this country. They have to be sand-papered, and there is extreme danger to the painter from those imported lead-coloured chassis?—He should be obliged to clean them wet. I do not know what rules you would make with regard to that. If you had a rule that they should not be painted with white lead that would meet it.

The witness withdrew.

Captain F. M. TUKE examined:

10,357. (*Chairman.*) Are you the marine superintendent of the Orient Steamship Company?—Yes.

10,358. You are attending to-day to give evidence in regard to the paints which you use on ships?—Yes.

10,359. Do you exercise full control over the painting work on the ships of your line?—Yes.

10,360. How many painters are employed at the Orient Steamship workshops?—They vary from 27 to 40 about.

10,361. In addition, no doubt, some painting is done on board the ships by the sailors?—Yes, a certain amount, a very small amount.

10,362. To what extent do you use lead paints in painting the ships of the Orient line?—We use no lead paint at all with the exception of the funnels and the ventilators. I have found out that there is lead used in those.

10,363. How long have leadless paints been in use for the ordinary internal and external painting of the Orient line?—As long as I can remember.

10,364. Could you give us an estimate of the length of time?—In sailing ships I can go back to 35 years ago and say that we were using white zinc.

10,365. Have you used no lead for ordinary purposes during the whole of that period?—I will not say that we have used no lead, but to a very small extent at any rate.

10,366. May I take it that you have used no lead with the exception of the funnels and the ventilators for the last, say, ten years?—Yes, quite that—that is, for painting.

10,367. Now first with regard to the interiors of cabins. What materials do you use?—Patent enamel

paints. We use rystolite and satinette. Those are the two best enamels on the market.

10,368. Are those built up right from the wood or metal on leadless priming paints?—Yes, on the zinc coating.

10,369. Next, in regard to deck spaces, crews' quarters, and the like, what do you use?—Generally white zinc; otherwise we put a little colour in; sometimes a yellow colour.

10,370. Is it a leadless stone colour paint you use?—Yes. We just simply colour the white zinc to make a little different shade.

10,371. What do you colour that with?—Any yellow stuff they have; yellow ochre or whatever it is.

10,372. What do you use for painting the holds?—White zinc and oxide (red) generally.

10,373. How often is the interior of a ship painted?—The holds about once in four years.

10,374. Are you perfectly satisfied with regard to the durability of the paints which you use for interior work?—Quite.

10,375. Is there any difference between the cost of your interior painting and the cost of similar work done with lead paint?—I should say there is no difference in cost at all. I should say that lead is just as expensive as zinc or zinc as lead.\*

10,376. If painting with lead was cheaper than painting with zinc, would your company go back to lead?—No, certainly not. They would use the best paint for the purpose.

10,377. They would not?—Certainly not.

\* The witness wrote later, "I find lead is cheaper."

20 July 1911.]

Captain F. M. TUKE.

[Continued.]

10,378. Are the results for interiors in every way as satisfactory as where lead is used?—Entirely.

10,379. Now, with regard to external surfaces, what paint do you use for hulls?—Beginning at the top we use ordinary black paint. I could not tell you the constituents of it.

10,380. But there is no lead in it?—There is no lead in it.

10,381. What paint do you use for deck-houses, rails, and other upper works?—An enamel paint for the deck-houses and white zinc for the rails.

10,382. What paint do you use for the funnels and the ventilators?—We call it buff colour. I found out that there is white lead used in it to protect the iron to a certain extent when it is exposed to the weather.

10,383. Can you tell us what percentage of white lead is used in the paint for the funnels and the ventilators?—I know that it is a very small amount, but I could not tell you the exact amount.

10,384. Does the paint used for the funnels and ventilators form a considerable proportion of the paint you use?—No, a very small proportion indeed.

10,385. Would it be impossible to do without lead for painting funnels and ventilators?—I am making the experiment now. I do not believe myself that it will make any difference at all.

10,386. How often are the exterior parts of a ship painted?—Once in London and then again in Sydney, in Australia. They are painted, say, every two months.

10,387. Are you perfectly satisfied with the durability of the paints which you use for exterior work?—Yes, entirely satisfied.

10,388. Supposing that you painted your ships, say, once in every two years, would you still be satisfied with the zinc paint with regard to durability?—Yes; with regard to once in two years, nothing would stand two years' wear with us, I am certain. It would not much matter what you put on.

10,389. You are perfectly satisfied with the durability of the paints that you use for exterior work now?—Yes, quite satisfied.

10,390. Is there any difference between the cost of your exterior painting and the cost of similar work if it were done with lead paint?—I am hardly in a position to say the cost of lead because we have not used lead, but I do not think myself there is any difference at all. I should think that lead was cheaper if anything.

10,391. Lead paint cheaper than zinc?—I should think it was a little cheaper.

10,392. Are the results for exteriors in every way as satisfactory as where lead is used?—As far as I know, they are certainly quite as satisfactory.

10,393. To sum up then, may we understand that it would not affect your company in the least if the use of lead paints were prohibited?—Not in the least.

10,394. (*Dr. Collis.*) Do I understand you to say that you think lead would be cheaper?—Yes; I am under the impression that lead is cheaper than white zinc, but we use so little really that I could not say the price.

10,395. If that is so, why did your company originally decide to use non-lead paints?—It was decided in my early days, when I first went to sea; I think 40 odd years ago.

10,396. (*Lord Henry Bentinck.*) By the company?—No, not by this company. They have never used anything else but zinc paint in this company since I have known them with the exception of the small quantities mentioned before.

10,397. (*Dr. Collis.*) It is really a matter of very old custom?—Very old custom. White lead is never used now because it always turns yellow.

10,398. That gives a reason?—That was one reason I know.

10,399. You renew the paint about once every two months, I understand?—Yes, the external work.

10,400. Is that because it is worn out?—Because it is worn out.

10,401. Is that due to damage or the weather?—Partly the weather, and the hull of the ship is knocked about by lighters and passenger tenders coming alongside.

10,402. That is a traumatic sort of injury. Do you renew mostly because of such injury rather than weather effects, do you think?—I think that the weather certainly has a certain amount to do with it. The damage starts it. Once the surface is rubbed off the weather does the rest.

10,403. Whatever paint you use is rubbed off?—Yes; it does not matter what paint you use. That is why I use the enamel on the external work on the deck-houses. That goes for two voyages, or practically eight months.

10,404. (*Mr. Mason.*) What sort of paint do you use for the hull under the water line?—Wood's composition.

10,405. And on the bare metal, what do you use?—Priming. We put it on about once in 12 months.

10,406. Made of —?—I could not tell you.

10,407. Is no red lead used?—Not that I am aware of.

10,408. Is not lead of any sort used?—I could not tell you. It is a patent thing, and if I asked the people they would not tell me. I know there is copper in it.

10,409. (*Mr. Parsonage.*) With regard to the application of paint by the workmen, do you find any difficulty with the men with regard to applying the leadless paint?—No, none whatever.

10,410. The men that you take on may be employed in using lead paints at different times. You take them on as you require them, do you not? They are not always employed in using the one material?—Our men are practically permanent men.

10,411. You keep a certain number of permanent men, but you take your men on down at the yard at six o'clock in the morning?—At seven o'clock in the morning.

10,412. These men may have been working in house, painting work with lead?—I see what you mean.

10,413. I wish to ascertain whether there is any difficulty with the men using the leadless paint if they come off work where they have been using the other?—Not the least. I should have thought it would have been the other way about.

10,414. I know the hours at which your men are taken on, and I know you have a certain number of permanent staff, but men may be taken on casually. They may come from another yard or a house?—We have no difficulty. No question has ever been raised.

10,415. A man would readily adapt himself to using the leadless paint if he was a painter?—I think so. It would be to his advantage, I should think.

10,416. (*Mr. Sutherland.*) Do you buy the zinc in paste or ready mixed?—In paste, not ready mixed.

10,417. What do you mix it with?—Oil.

10,418. Ordinary linseed oil?—Yes, linseed oil.

10,419. And turpentine?—A certain amount of driers.

10,420. Varnish?—No varnish.

10,421. What sort of driers do you use—patent driers?—Yes, patent driers.

10,422. (*Chairman.*) It is very interesting to hear that on your line of steamers you have never used lead?—Lead to my recollection has hardly ever been used excepting in small quantities as before mentioned. I remember hearing about white lead when I first went to sea, and I know the trouble they used to have in keeping the paint white.

10,423. How many ships have you in your line?—Nine, and it is constant work for those.

The witness withdrew.

## FIFTEENTH DAY.

Wednesday, 26th July 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*.)

Lord HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. GEORGE ELLSON examined.

10,424. (*Chairman*.) You are Resident Engineer to the South Eastern and Chatham Railway at Charing Cross and Cannon Street stations?—Yes.

10,425. Are you in charge of the painting operations on the Charing Cross and Cannon Street river bridges?—I am.

10,426. Have you been instructed to attend here to-day before the Committee for the purpose of giving evidence regarding the materials that are used for painting those bridges?—I have.

10,427. Have you used various non-poisonous painting materials somewhat extensively on the South Eastern and Chatham Railway?—We have used them rather extensively.

10,428. In the first place I believe you are prepared to speak of the use of ordinary coal-tar?—Yes.

10,429. In what way is it prepared for use?—Coal-tar specified as being freed from ammoniacal liquor is obtained. To this is added 5 per cent. by weight of raw linseed oil and 100 grammes per gallon of pure bitumen. The latter ingredient is not coal-tar pitch but natural pitch. The mixture is boiled for three hours in a copper and applied as necessary after cooling. The tar is laid on as thickly as possible, and two coats are given.

10,430. Where has the ordinary coal-tar paint been used?—At Charing Cross and Cannon Street river bridges over the River Thames, and other smaller bridges.

10,431. How has this paint been applied?—In summer we put it on cold. We find if we heat it that the resulting coat is too thin. That is my experience of it. The addition of bitumen corrects this. In winter it is necessary to heat it, or it would be an endless job to put it on. In fact, you could not put it on because it would get too thick. We add bitumen to prevent it getting too thin in the summer, and it gives body to the coating. We also find that the addition of 5 per cent. of rawlinseed oil corrects its tendency to get hard and brittle after it has been exposed for any period.

10,432. Has that paint proved durable?—It has.

10,433. And efficient in every way?—Yes, very efficient indeed.

10,434. Would you please name some of the conditions under which it has been used?—It has been used on the under-side of Cannon Street bridge, on the whole of the main girders, and therefore it has been tested there on an extensive scale.

10,435. How long has it been found to last in that position?—Eighteen years. In 1893 the bridge ironwork was last coated with tar, and it is now in very good condition.

10,436. Was it in a good condition at the end of the time?—It is in excellent condition now. I have two photographs here showing its condition now. It is almost as good at the present time as when it was put on.

10,437. Would you tell us if this particular paint could be used throughout your system for bridges?—Yes, it could be used as far as protection is concerned, but appearance has sometimes to be studied.

10,438. Is its appearance not good?—It is black and you only get a black appearance. But from a

protective point of view it would be as good as anything else.

10,439. How many coats of such paint are applied?—Two usually.

10,440. Have you found it economical for such work?—Yes. The chief item of its cost is that of the labour in applying it.

10,441. That is good for the workmen?—Very good. For underneath work it is economical, as only two coats of tar are necessary as against three coats if lead paint is used.

10,442. Would you say then, speaking from a business point of view, that on the whole it is as economical as lead paint?—Yes.

10,443. Would that paint be durable in other situations?—It is not so durable as other paints when subjected to deleterious atmospheric conditions such as you find in London railway termini, where the conditions are severe owing to the atmosphere being heavily charged with sulphurous fumes given off from the locomotives.

10,444. Are you prepared also to speak of the use of silica graphite paint?—I am.

10,445. Where has that paint been used?—It has been used in Charing Cross station and in Cannon Street station roofs.

10,446. There, I presume, it is exposed to severe atmospheric conditions?—Very severe. The atmosphere is charged, as I said before, with the fumes from the locomotives and with steam, and in the winter months it gets very heavy indeed.

10,447. Unless the paint were a good one, corrosion would take place very rapidly, would it not?—Undoubtedly.

10,448. Have you found this paint efficient under these conditions?—Very efficient.

10,449. How does its efficiency compare with that of lead paint?—It is better than lead paint. I can give you an instance of that. From 1903 to the early part of 1905 we painted Cannon Street station roof with lead paint, as had been the practice on the South Eastern Railway for a number of years. Now in fifteen or sixteen months from the time that paint was put on I found that it was beginning to scale and peel off the underside of the main rafters and the purlin girders. That was seven years ago. We painted Cannon Street roof again with three coats of silica graphite paint two years ago, but there is not at the present time any sign anywhere of any scaling or peeling off. So that I think that that proves conclusively that it is superior to lead paint.

10,450. May the Committee understand that silica graphite paint is absolutely leadless?—Absolutely.

10,451. What colour did you paint the roofs of the stations?—The first coat was a dark chocolate colour; the second coat was a dark grey colour and the third coat was a dark chocolate colour again to get the necessary distinction in the three coats, so that it may be ascertained that three coats have been put on in each place.

10,452. Is a silica graphite paint ever used in a white state?—No, it could not be used in a white state.

26 July 1911.]

Mr. GEORGE ELLSON.

[Continued.]

10,453. You have also had experience of carbonising coating paint, have you not?—Yes.

10,454. Where has that paint been used?—We tested it in Cannon Street station roof when it was painted in 1903, to compare it with lead that was put on at the same time.

10,455. What kind of paint was that?—A black paint. It has a coal-tar base, I believe, but it is a manufactured paint, and it is called "carbonising coating." I do not know how to distinguish it in any other way. This carbonising coating that was put on was applied as a matter of fact in 1904. I examined it about three years after, and then I found that it was just in about the same condition as the lead paint. And then when we came to repaint the roof in 1909 and 1910 I again had an opportunity of examining it very closely, and I found that there was practically nothing to choose between its condition and that of the lead paint. It was equally as good as the lead. The lead paint that was put on was a very good paint. I might say that there were only two coats of carbonising coating put on as against three coats of lead paint. So that is in its favour.

10,456. What opinion have you formed of its durability and efficiency?—That it is equal to the best lead paint.

10,457. I understand that you are prepared to put in a table showing the cost per square yard of painting with the different materials that you have mentioned?—Yes.

10,458. Which of the paints do you find most economical in use?—The silica graphite and the carbonising coating paint, both of which cost a total of 34d. per square yard, made up of 6d. of a penny or material and 1.68 for labour in applying.

10,459. How does the cost of the ordinary lead paint compare with that?—It is a little more costly. The lead material costs a trifle more. The cost of the lead material is 87s. per square yard.

10,460. And the cost of the labour?—The cost of the labour is about the same. The total therefore works out at 2.558d. per square yard.

10,461. What is the cost of painting with coal-tar paint?—The material is very cheap. It costs 135d. per square yard for material, but the cost of labour in applying it is high. It is 3d. per square yard, giving a total, with the material and labour, of 3.135d. per square yard.

10,462. Then it has the advantage in two directions, it is efficient from the point of view of the railway company, and it is satisfactory to the workmen because it gives them more work?—Quite.

10,463. Have you made any trials of leadless white paint?—Yes, in a small way.

10,464. Was it satisfactory?—Yes.

10,465. Entirely satisfactory?—Yes.

10,466. Would you say that it was as good as white lead paint used in similar positions?—I should say that zinc white paint in the atmospheric conditions prevailing in London railway termini is as good as the best lead paint.

10,467. And is it as durable?—Quite as durable and as efficient.

10,468. Then so far as your painting work is concerned would a prohibition of the use of lead cause you any difficulty?—No.

10,469. Now we should very much like to see the photographs you have brought, please. (*The witness produced some photographs.*)—First, I have two photographs which are typical views of the tarred work at Cannon Street railway bridge. There is nothing the matter with that. There is no corrosion there. You see the tar in little ridges. It goes like that after a period of years, but it has perfectly protected the ironwork, from an engineering point of view. I have three photographs of the tarred work at Charing Cross railway bridge (*producing the same*). That is a detailed one. The work is in perfect condition. That shows the end view of the girders in perfect condition.

10,470. (*Lord Henry Bentinck.*) How long has that paint been on?—Five and quarter years. These three are views taken of Cannon Street station roof—silica graphite paint. In those two it has been on for two

years. In this particular case it has been on for three years. That is the wind screen at the end.

10,471. Have you found improvement in these kinds of paints since you began using them at all? Have they changed?—No.

10,472. They have always been satisfactory from that point of view—for how long—five years?—Yes, we have had five years' experience of this. Here are two views taken in Charing Cross station, of the roof work. The influences are very severe, as, in addition to the bad atmospheric conditions, dust settles on the surface of the girder work and holds the moisture, which is very trying to the protective coating on the structure.

10,473. (*Dr. Collis.*) Do you know whether these paints are used at all as on other engineering work elsewhere? Besides the use that your company is putting them to, do you know of any other?—Not from personal experience—only by what I hear from manufacturers of paint, and what I read.

10,474. I thought you might possibly know through them and others the use of the paint. You have had a successful experience, and your experience might possibly have induced others to use them?—I do not know whether that has been so. I believe it has.

10,475. Can you give me the names of any large structures which have been so treated?—No, I am afraid that I cannot offhand, but I do know that people (I cannot bring anyone to mind at the moment) write to Mr. Tempest, the chief engineer of the South Eastern and Chatham Railway, and ask what his experience of this paint is, and on his replying that it is satisfactory, possibly that would be the determining factor in deciding them to use it.

10,476. I wondered whether there were any other large railways that had been using it for their bridges?—Yes, I think so.

10,477. King Edward VII. Bridge at Newcastle and the Forth Bridge, and places like that?—I could not say definitely, but it is in fairly general use on other railways.

10,478. You mentioned that these paints are all dark, and that you cannot therefore get any artistic effect. Is it possible to paint over them with lighter colours successfully?—It is. We have done that at Charing Cross station.

10,479. How many coats would you have to put on if you were going to put on a light coat of zinc oil paint?—You would get a fairly good result by putting one coat on, but you would get a better result by putting on two. You would get no sign of the graphite appearing underneath if you had two coats of lighter colour.

10,480. (*Chairman.*) A leadless lighter colour?—Leadless or lead, whichever you chose.

10,481. (*Dr. Collis.*) You at present put two coats on?—We did that at Charing Cross station. We put two coats of lighter paint on.

10,482. If you were leaving it without decorating probably you would put two or three?—Three of the graphite paint.

10,483. If you were going to decorate with a lighter colour you would only put two coats of the lighter colour?—I would recommend two coats of the graphite and two coats of the lighter colour—four altogether.

10,484. It would require more labour and a little more cost in material?—Yes, if you desire to get a decorative effect.

10,485. It can be obtained at greater expense?—Yes undoubtedly.

10,486. (*Mr. Sutherland.*) What sort of men apply the silica graphite? Are they normal painters?—No. We put ordinary painters to it, but as a rule on engineering work a general labourer is employed.

10,487. It is done by labourers, then, and not by painters?—By labourers.

10,488. Is the woodwork at these stations coated with the same material between the rafters and purlins?—No, we have not coated the woodwork with it, but I do not think that there would be any reason why it should not be used for woodwork.

10,489. But why do not you coat it with it?—Because the woodwork is a light colour. If we coated

26 July 1911.]

Mr. GEORGE ELLSON.

[Continued.]

it with silica graphite paint we should have to put four coats on to get the light colour. We coat only with three coats, which is all that is necessary when using one light colour straight away.

10,490. Three coats of lead paint?—Yes, three coats of lead paint.

10,491. Then those paints are only useful where either black or chocolate or dark red is available?—Yes, those paints alone, but you can use lighter tints over them.

10,492. On the top?—Yes.

10,493. I understood that. What experience have you had with zinc white paint? You say that it is as good as lead paint?—When we painted Charing Cross station some big manufacturers of paint wanted us to test their zinc paint and so they sent along a quantity and it was applied there.

10,494. Ready mixed?—Ready mixed.

10,495. So you do not know what the formula was of that?—No.

10,496. You do not know what it was mixed with?—No.

10,497. It might be varnish and zinc?—It would not be varnish.

10,498. Varnish would be in it?—I do not think I should like to say that.

10,499. Do you know that the Government Commission of Holland investigated this matter for a period extending over five years, and instituted very extensive experiments, and they came to the conclusion that in all situations such as your railway termini zinc paint was not as good as lead?—Well, I cannot agree with that conclusion in view of the experience that we have had:

The witness withdrew.

Mr. JAMES M. ORR examined.

10,507. (Chairman.) Do you attend here to-day as a representative of the Association of Master House Painters in Scotland?—Yes.

10,508. What is the nature of your business, and where is it carried on?—Our business is that of house painters and decorators carried on in Glasgow.

10,509. What is the average yearly number of painters employed by your firm?—The average is about 110, I daresay.

10,510. How long have you been in the painting trade?—Personally I have been connected with the firm for about 25 years. I have been a partner for 18 years. My father has been in business for about 52 years.

10,511. Have you known any cases of lead poisoning or painter's colic?—There were only two cases I ever heard of where painter's colic was suggested as the cause of illness, in the course of 52 years. In at least one of these cases it was very problematical. In the other case the man is a master painter in Glasgow to-day in robust health.

10,512. Have your men had occasional days of sickness possibly due to lead?—Not that I have heard of.

10,513. Do you have periodical medical examination of your men?—No, we do not.

10,514. Then how do you know that they have not had occasional days of sickness?—I am not speaking from any personal knowledge or experience. I never heard of any man ever off sick where his sickness was attributable to anything of the kind.

10,515. But I suppose that you have had a great many cases where men have been off from illness?—Very seldom; not many at all.

10,516. Do you mean to say that your men go from one year's end to the other without being off for a few days through sickness?—I hear of very very few cases.

10,517. Would you hear of those cases if they were away from sickness?—I would hear of most of them—not of all, I must admit.

10,518. You know, I presume, that lead poisoning frequently undermines the health without immediate violent symptoms arising?—I cannot say as to this.

10,500. But what experience have you had?—It was not a very large experience, but it was a severe test. The manufacturers sent two gallons of paint, and it was applied at the same time as we put the other on. I have made two examinations of it since, and I find it standing equally as well.

10,501. You do not know really what the component parts of that paint are?—No, I do not know that. I only know that it was sent to us as being the best zinc paint.

10,502. (Mr. Gardner.) With regard to your structural ironwork and the coal-tar paint, do you only use that on the under-sides of bridges?—No. At Charing Cross railway bridge the three inner rows of main girders, which, as you know, are braced structures, are painted entirely with coal-tar paint, and they are exposed to the weather and the heat of the sun just as any other work outside is. It has been on for 5½ years, and it is in good condition now—excellent condition.

10,503. When you painted in 1903 to 1905 with lead paint, you say it peeled in about two years?—Not entirely. There were signs of peeling and flaking.

10,504. But since you painted with the silica graphite, after two years there was no sign of peeling?—Not anywhere.

10,505. Was the surface of the paint in 1903 as well cleaned as it was the second time?—Yes, it was under my personal supervision in both cases, and I can speak very definitely on that point. It was cleaned very carefully and very well in both instances.

10,506. Then there was no question of scamping?—Absolutely no question of that. Of course, if this were not seen to it would make a lot of difference in the result.

10,519. The incidence of lead poisoning is published month by month by the Board of Trade; do you see the Labour Gazette issued by them?—I have seen it at times.

10,520. Have you noted that 284 deaths of painters have been definitely certified as due to lead poisoning in the last ten years?—I have seen that, but I must say, with all respect, that I question the figures very materially as applying to Scotland, or to house painters alone. I have often been desirous of knowing who really were included under the head of painters. I have seen the figures from these returns, but I could not by any calculation reconcile them with the experience of the painting trade as we know it in Scotland. In a matter of over 50 years we cannot find in our association a trace of a single death that was certified to be due to lead poisoning amongst the whole of the painters of Scotland.

10,521. Would you be surprised to hear that that is precisely the same kind of evidence as we have had from the English employers?—That leads me to say that I have always been curious to know on what basis those figures were made up.

10,522. The basis on which those figures are made up is that the doctor certifies that a particular man has died from lead poisoning, and that his occupation is that of house painter, and the Registrar-General notifies these cases to the Home Office?—But the point is this: In Scotland painters are painters alone. In many parts of England and in Ireland painters are very often plumbers as well, and in England men are employed as painter's labourers. I would like very much to know if painter's labourers are included under the heading, because I can perfectly understand if that is the case the numbers are inflated very materially.

10,523. On page 267 of the July 1911 issue of the Board of Trade returns, it shows a definite increase in the death-rate from lead poisoning among painters; 27 in the first six months of this year and only 19 in the first six months of last year. Do you agree with me that that is an alarming increase?—I would; but at the same time, as I say, that would be subject to the qualification I spoke of.

26 July 1911.]

MR. JAMES M. ORR.

[Continued.]

10,524. But supposing that these figures which I am quoting are most assuredly correct, then would you say that that was an alarming increase?—I would, but at the same time, as I say, I would like very much to know particulars.

10,525. I am afraid that you must take these figures as being absolutely correct?—I do not doubt the figures, but I doubt the class of men to whom they apply.

10,526. These figures that I have given to you are English figures. Scottish statistics have not been collected in past years, but with the same processes and the same materials the risk must be the same?—With the same processes and the same material the risk ought to be the same, but the fact remains that the results are not the same.

10,527. I am not surprised to hear that at all, because in some of the Potteries, in fact a large number of the Potteries in North Staffordshire and in Scotland, they have had no cases at all, and then quite unexpectedly, without any warning, a firm which has been immune has a crop of cases?—All I can say is that, so far as we can discover, there has been absolute immunity practically throughout Scotland from lead poisoning, and there is no variation from year to year.

10,528. But if you were a member of this Committee and you had this appalling number of deaths amongst house painters, and you were told that the conditions prevailing in Scotland were precisely the same as those that prevail in England, would not you make the deduction that the risk was the same whether it was in England or Scotland?—The deduction I would make would be that there ought to be the same proportion of deaths in Scotland, but the fact is that there is not.

10,529. Well, that is what you tell us, but, as I say, most of the employers representing the English house painters have made precisely the same statement. No one knows anything about it. It is something new to them. At any rate, that is the impression that the employers have made on us. No one has heard of any cases; no one has noticed any illness amongst his work-people, although these figures of death are so appalling?—Might I ask if there are any means of arriving at a classification? Is there any means of discriminating between different classes of painters? My own contention is that this appalling death-rate does not apply to house painters proper at all, but that it applies to either painter's labourers or to men working in shops where both plumbers and painters work.

10,530. You understand that it does not apply to painters in workshops?—Is that so?

10,531. It only applies to house painters who are employed in work in houses?—But even within that classification there is this difference: that in both Ireland and England men are employed as painters' labourers. If those men are included in the classification, the basis on which the figures are taken is altogether wrong, because those men are not trained as painters at all, and do not observe the same precautions.

10,532. I do not think it matters to this Committee what the classification of the men may be. What we are sitting here to do is to make some suggestions to avert what is a very serious evil, and whether they are painters or painter's labourers the same thing applies if the men are employed in the use of this dangerous material. Do not you agree to that?—I do to a point, but the point I am on is this: Painters as a class in Scotland are men who take ordinary care in the matter of personal cleanliness. They know that their hands should be kept clean. Men who are not trained painters might very well do things which might lead to lead poisoning, and I hold that they are the men who are bringing this aspersion on the painting trade, because they are not observing ordinary conditions.

10,533. Now from the figures that I have read to you the gravity of the danger is seen, if you compare these figures with those for all lead industries under the Factory Act, in which there have been 20 deaths in the first six months of this year and 19 in the first six months of last year. So that there has been an increase of one only in this instance. Do you follow

that?—Do I understand that those are workers in the painting industries?

10,534. There has only been an increase of one in all the factories, but in the house painter's trade there has been a large increase, and the deaths from lead poisoning in the house painter's trade are more numerous than in all the other industries where lead is used?—Well, I cannot account for that condition.

10,535. These are actual facts. You are not surprised to hear it? The incidence of lead poisoning is greater in the house-painting industry than it is in the whole of the other lead industries put together?—As I say, I do not accept that on the face of it as applying to the house-painting trade.

10,536. But you must admit that it applies to men who are employed in house painting?—Not necessarily; I would like to know how many under that classification are plumbers and painters.

10,537. But it applies to men who are employed in the actual painting. I do not care what their names may be?—But that is where my point comes in. It says in the figures I have seen, "plumbers and painters."

10,538. Dr. Collis will ask you further about that. In addition to this the death-rates from Bright's disease and nervous diseases, due to work in lead, are very high?—Personally I have no knowledge of that. I was not aware of that.

10,539. You may take it from me that they are very high indeed. There are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office?—I take that under qualification. I cannot really speak as to that.

10,540. I am sure you will admit that, if these figures are correct, all this sickness and death is very deplorable?—Yes, if the figures are correct, but that is the point that I question as applying to the house-painting trade.

10,541. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, I am aware of that.

10,542. That the use of white lead has been prohibited to an appreciable extent abroad?—But I would also say that I know in Holland, where they have had five years' careful investigation, they are allowing white lead now after most elaborate and scientific tests for five years.

10,543. And that the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed. Do you know that?—Yes, I know that.

10,544. You may take it from me that, if they do not have prohibition, they will have very strict regulations?—I can quite understand that.

10,545. Do you not think it regrettable that this country should be behind other nations in this respect?—So long as it is behind—yes, but that is a point I do not quite admit. Until I know more definitely about the Dutch, I am not prepared to admit that we are behind.

10,546. I am asking a very simple question. Do you not think it regrettable that this country should be behind other nations in this respect?—As I say, the point depends on what one calls behind.

10,547. Suppose that they protect their workmen from the evils ensuing better than we do?—I quite favour any ordinary protection that is possible.

10,548. Let me put it in this way: If the evil exists as is shown by these figures—if the figures are correct—do not you think that we should do something to remedy it? Would you, as an employer of labour, think so?—I think you should.

10,549. Something must be done, either by regulating the work very closely or by restricting the use of lead?—Well, I certainly do not favour the restriction of the use of lead, but I quite favour such regulations as would minimise the possibility of danger.

10,550. Now no doubt you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—I do not see how it is possible to apply the same

26 July 1911.]

MR. JAMES M. ORR.

[Continued.]

precautions, because the conditions are perfectly different.

10,551. I did not say the same precautions. I said observe precautionary measures of the same kind—I mean with regard to protecting the workmen?—Certainly precautionary measures can be adopted in a factory that cannot possibly be adopted in other places where men are working.

10,552. Will you agree with this, that if the evils are as great as we think they are, precautions should be introduced to protect the workmen from those evils?—I quite admit that.

10,553. And if by any chance we find it impossible, owing to the kind of work in which men are employed, to introduce precautionary measures, then that we ought to abolish the use of lead?—If you find it impossible to have precautionary measures.

10,554. You would then agree that we ought to abolish the use of lead?—Yes, but I do not think that it is impossible.

10,555. I ask you whether you think, if we find it impossible to introduce precautionary measures, we ought to abolish the use of lead?—If that were so, but that is hypothetical.

10,556. I will put the question to you again, because I want a direct answer. If you find, as an employer of labour that it is impossible to introduce precautionary measures to protect the workmen, then I take it you would agree to the prohibition of lead?—Yes, I would.

10,557. Now, perhaps you are not aware of what the details of these precautionary measures would be?—No, I am not aware of that.

10,558. I will tell you. First of all, there is the provision of overalls by the employer, who is responsible for seeing that they are regularly washed. Would you agree to that?—So far as Scotland is concerned it is quite unnecessary. No painter works in Scotland without overalls, which are washed every week.

10,559. So there would be no difficulty in that rule?—I do not personally agree to the giving of overalls to the men where there is a fluctuating number. It would lead to constant friction and trouble.

10,560. Are you aware that in Germany one of the new rules is that the employers are obliged to find the overalls, and see that they are properly cleaned?—I was not aware of that.

10,561. The Home Office lay great stress on the importance of men wearing overalls and on their being properly cleaned?—In Scotland that is the present state of matters, and that largely accounts for the immunity we have, it seems to me.

10,562. You would not agree to the compulsory provision of overalls by the employer and his being responsible for seeing that they are regularly washed?—I think that it would lead to abuse.

10,563. In an industry where I recently deliberated on this question, the employers agreed to provide the overalls, and to see that they are properly washed?—What industry was that?

10,564. The Potteries?—That is where the difference comes in. Men work under one roof, and go in at one door and go out at one door, and a proper check can be kept, but with us it is impossible.

10,565. We, secondly, come to the provision of a meal-room, care being taken that in no case whatever are any of the men allowed to take their meals in a room where lead is used?—That I think applies entirely to a place where men are working under a roof. With two men working in a house ten miles away, could you insist on an employer providing a meal-room for his men.

10,566. I think you will agree with me presently that the precautions would be absolutely unworkable, and then we shall come back to prohibition?—I believe in precautions.

10,567. But they must not be your precautions. They must be what we decide to be proper precautions. They must be precautions that without question protect the workmen. The Home Office have laid it down as a cardinal principle that under no circumstances are any workmen who are employed in handling lead or where lead is used to have their meals in that room?—One

could easily make a rule that the workmen were not to take meals in any room in which they were working. That could easily be arranged.

10,568. I understood you to say just now that it could not?—I beg your pardon. I thought you meant the provision of a special mess-room in a workshop for the taking of meals. One cannot carry a portable mess-room round to every job, but at the same time the rule could be made that men were not to take their meals in what they call the paint shop.

10,569. I suppose you agree that at the present moment a large number of men are obliged to have their meals in the room where they are working?—Not obliged.

10,570. But they do?—Sometimes; not often. Our men very rarely do.

10,571. You are very lucky in the kind of work you employ your men in, but it occurs in many cases?—I quite agree with a rule of that kind.

10,572. Third, the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing, and where they will not collect unnecessary dust when not being worn. Would you agree to making a provision of that sort?—It could be made on jobs of a sufficient size, but in any case a man's outdoor clothing is taken off.

10,573. But is it not very often the case that a workman takes off his coat and hangs it up in the room in which he is working, as I have seen done myself, and so that coat becomes contaminated with the lead dust, which naturally falls about the room?—No. He would hang up his coat in a place where lead dust is not present. May I say that the place where lead dust is is the place where the man is working. He is not working in the paint shop at all, and therefore there is no lead dust there.

10,574. But he mixes the paint in the paint shop?—Yes, but there is no lead dust in mixing white lead. We never use dry white lead. We always get our white lead made up in the form of a pulp.

10,575. I have been to some of these paint shops, and I have seen the paint scattered on the floors, drippings, and so on, and that produces dust. It is trampled under foot, it gets into the air, and men breathe it, and that is highly injurious to them; and it gets on to their clothes too. Now are you prepared to agree to a provision that under no circumstances are the men's clothes to be in such a room?—It is not very workable, but it is possible to work it. It is a question of regulation with the men.

10,576. It is not very workable, you think?—It is not.

10,577. Then, as I mentioned just now, there is the provision of cloak-room facilities, so that clothing put off during working hours shall not under any circumstances remain in a room where lead is used?—I do not see how that is possible in many cases.

10,578. You told us just now how important you consider proper washing accommodation. You mentioned that as a very important point, did you not?—Well, I mentioned that washing is a very important thing.

10,579. One basin or other utensil is insisted on in other lead industries to every five men?—May I ask, if one has 50 jobs and men working in 50 different places, how is it possible to arrange for washing? Still at the same time that does not mean that there are no facilities for washing. On the smallest job a man has an empty pail and water and soap and a cloth with which to dry himself.

10,580. It has been proved beyond question by the Home Office by past inquiries that it is absolutely essential that the men should have every opportunity of getting this dangerous material off their hands before they go to their meals; and the Home Office have laid it down as a strict rule that there should be one basin or other utensil to every five men with hot and cold water, soap, nail-brushes, and a sufficient specified number of clean towels. Do you think that that would be practicable in your industry?—I do not see how it could be done, but at the same time I think that quite ample facilities could be provided apart from that

26 July 1911.]

Mr. JAMES M. ORR.

[Continued.]

10,581. Mr. Sutherland and I went to see some men working in Manchester the other day. Every arrangement was made for them to wash their hands. There was one pail for about six men, and we were told that there was towel accommodation, but the towel had to be found. The men were wiping their hands on their pocket handkerchiefs. That is highly dangerous. Unless the men are certain to be provided with a proper number of towels and they are pretty handy for them, because they have only a certain amount of time in which to get their mid-day meal, and unless the soap and nail-brushes are provided for them, the chances are that they will not bother to use them at all, and so they are at once in a dangerous position. Now can you assure this Committee that it would be possible to provide washing accommodation such as I have suggested, hot and cold water, nail-brushes and towels?—It would not be possible to provide hot and cold water in every case, but every painter who knows his trade at all knows how to get rid of paint from his hands by putting on oil when he is washing his hands with soap, and unless a man is a very untradesmanlike tradesman he will wash his hands several times a day.

10,582. I quite agree, but some men are very careless. You know what men are?—It depends on the men.

10,583. What you have to provide for in this workaday world is for careless men. The State allows you to employ a very dangerous element in your work and says, "If you employ this very dangerous element you must protect the men"; and it is the careless men that you have to provide for. Do you feel absolutely sure that such washing accommodation could be provided for the men as I have suggested?—I do not see that washing accommodation of the kind you mention could be provided in every case, but it could be provided in many cases.

10,584. And in the cases where it could not be provided, the men would be running the risk of the dangers which the Home Office admit are very great?—But I do not admit that.

10,585. I did not say what you thought are very great, but what the Home Office thinks?—Well, I do not think with the Home Office.

10,586. Now let me take you to another point. Provision would have to be made for the avoidance of dust: some means would have to be devised for getting rid of any dust which the men might breathe. Do you think it is possible in every case, by means of an exhaust draught or the like, to remove the dust from the men while they are at work?—No, it is not. You could open the windows.

10,587. That would not do. The wind might be in the wrong direction and might blow the dust in amongst the men. You could not always arrange for a man to stand in a particular part of the room to catch the right kind of wind. Could you possibly devise anything with regard to internal work so that the dust that the men generate in the course of their work could be removed?—It would not be quite possible to do it in every case. Would that mean if they were working in a house of ten rooms an installation in everyone of those rooms?

10,588. Yes?—Working in 50 houses would mean 500.

10,589. I put to you these suggested regulations?—They are quite impossible.

10,590. Now with regard to the fumes in burning off and the spray which may be breathed in certain operations. What would you suggest as a remedy for that?—We can burn off without fumes at all.

10,591. Can you?—Yes, with chemicals.

10,592. I have seen burning off, and other employers have told me that it is impossible to burn off without fumes?—That is not the case.

10,593. I am not speaking of solutioning but of burning off?—The point is this: It is the removal of paint that is wanted. In many cases we do not burn off paint at all. We do it by other means.

10,594. May I ask you to deal with burning off first. Where burning off is in progress, are there any possible means of removing the vapours which arise from burning off, so that the men do not breathe

them?—I do not think so, and I was not aware that there was any particular danger from it.

10,595. It is regarded as a danger. You cannot suggest anything by which that can be remedied?—No, I do not see how it could be done.

10,596. Are you aware that the attention of this Committee has been called to the existence of poisonous emanations from liquid paint?—I was not aware of that.

10,597. That in the actual process of painting a wall, for instance, there are certain emanations in the shape of vapours which arise, and which are highly injurious to the people who are painting?—I have always understood that those emanations applied more to the vehicle with which the lead was mixed than to the paint itself.

10,598. Experiments have been made which show that certain vapours arise from the actual process of painting. How would you meet that danger?—If that is so, I do not see how it could be met at all; but I question it.

10,599. We have had evidence from one witness on the point, and we shall have others before the Inquiry is closed. Now, in addition to these precautions that I have suggested, the Home Office insists—and they would insist in your industry—on a periodical medical examination of the workpeople at the expense of the employer. Would you agree to that?—We would not object to it. I daresay that men would object in the first instance, but if it had to be done it would be done, I suppose.

10,600. In the pottery industry—and I suppose we should not go back on that—medical examination takes place once a month?—It would be a very difficult thing to get a certified examination of every painter once a month, when men are scattered over 100 miles and in inaccessible places.

10,601. The special rule would enact that in no case, unless it was through some illness of the man or the neglect of the certifying surgeon, would men be allowed to work at their occupation unless they had been medically examined. Would that interfere seriously with your trade?—It depends on what that means.

10,602. Well, it means this: that unless a man was ill or unless the medical officer was at fault, you would have to see that every man was examined once a month?—In the painting trade men are taken on and taken off as work may arise. If it means that one would require to send for a doctor every time he took on a new man, and have him medically examined, it would be absolutely impracticable.

10,603. I will not say that you would have to send for a doctor, but you would have to make some arrangements by which a man is certain to be examined?—Supposing a man works in three different places in a month, as many do, is every one of the three employers to get a doctor's certificate?

10,604. One certificate would do. Casual workers in the Potteries get a certificate if they are all right, and keep it in their pockets?—I do not see how it would be possible to have every painter examined once a month.

10,605. May we take it that you see great difficulties in carrying out that practice?—Certainly, very great difficulties.

10,606. You are sympathetically inclined, but you see practical difficulties?—That is what it comes to.

10,607. Then in the pottery industry, in addition to medical examination, the employers have agreed to give compensation to any worker who is withdrawn from work by the doctor's orders on account of doubtful health. Let me give you an illustration of what I mean. Supposing the doctor examines a workman and says, "Look here, you have not lead poisoning but you are very inert. I must suspend you for a month," the employers have agreed to give that man compensation for that month. Would you agree to give similar compensation under similar circumstances?—So long as I was satisfied that the doctor knew what he was doing; but if any man who was laid up with indigestion and cared to call a doctor in was to be off for three or four weeks, I would object to it very strongly.

10,608. Perhaps I did not make myself quite clear. What I mean is this: the doctor in the course of his round examines a man and says: By the look of his eyes, by the look of his gums, or by his wrists, which

26 July 1911.]

Mr. JAMES M. ORR.

[Continued.]

is a very signal sign of lead poisoning, the man is in such a condition that he has not lead poisoning, but the doctor thinks he may get it, and he suspends him for a week or a month, as the case may be, or for three months. The employers in the pottery industry in such cases as that have agreed to give the men half wages up to three months. Would you agree to that?—I would agree to that so long as the signs of lead were really definite.

10,609. That is not the point. The point is, if the certifying surgeon suspended the workman would you agree then to give him compensation?—I believe I might, but I see it is liable to very great abuse.

10,610. The employers in the pottery industry have agreed to that. Would you agree to a similar condition?—Under certain qualifications.

10,611. I cannot take any qualifications?—The qualifications that I speak about are these: a man comes to my shop and is taken on to-day. Next Monday the certifying surgeon says, "You require to be off." Am I to pay that man for three months if he is only three days working with me? That is what it comes to. You are dealing with employers, and the point is who is the employer in a case of that kind. I would be perfectly willing to pay, supposing a man, one of our own men working with us, was thought by the doctor to be in danger. I would pay compensation while that man was off, but I could not do it with a casual man.

10,612. You would have to take it for better or worse, I am afraid. It is the old story. If you employ a man for only a month, and the certifying surgeon suspends him because he thinks he may be liable to an attack of lead poisoning, you would be responsible?—In that case one would not employ a man at all without a medical certificate. That is what it comes to. It would be a very great hardship to the workmen as far as I can see.

10,613. At any rate, may we take it that you would agree to level up to the Potteries?—I would agree to do all that was reasonably possible.

10,614. I did not ask that; "reasonably possible" is a very vague term. I want to pin you, if I can, to the conditions which prevail now in the pottery industry?—But the conditions are not parallel at all.

10,615. Let me put it in a simple form to you: would you agree, if the certifying surgeon suspended any workman because he thought he might be in danger of contracting lead poisoning or plumbism, as it is called, to give that man compensation to the extent of three months at half wages?—So long as he had been three months with us.

10,616. Now, taking all these points into consideration, would you say that you prefer that the industry should be regulated by special rules such as I have foreshadowed, or, as an alternative, that the use of lead should be prohibited or very closely restricted?—I much prefer regulation.

10,617. I must ask you to be kind enough to remember what I have suggested to you would be the regulations. You have told us that in a great many cases it would be absolutely impracticable to carry out those regulations. I ask you again, would you agree to regulations such as I have foreshadowed, being perfectly certain that they must be carried out in every instance; or if they could not, would you agree to prohibition?—If you put it that way, I would rather agree to the regulations as you put them than have the prohibition.

10,618. Then I am afraid I must put it to you in this way: can you tell me how such a code of special rules as I have foreshadowed could be enforced? How, for example, would you remove the dust generated in dry rubbing down with sandpaper?—The point with me is that I do not know that it is altogether necessary to have dust in dry rubbing down with sandpaper. If paintwork is old, then it can be rubbed down with pumice stone and water.

10,619. In every instance? Would you agree that in no instances dry rubbing down should be permitted?—I would not say that, but I would explain. In the case of painting new work, the rubbing down with sandpaper can be done at a time when there is no

powder or dust that will come off; that is to say, while the paint is in such a condition that powder will not come off.

10,620. Would you agree that no work should be done, with regard to painting, that generated dust?—That is, white lead dust?

10,621. Yes?—There is dust of very many kinds in the painting trade, but I think I see your point. One could say that where dry rubbing down was required, it should only be in cases where the rubbing down is done while the paint is not in an absolutely hard gritty condition where rubbing down would generate powder or dust.

10,622. Would you agree that in the future in your painting industry there should be no work performed which generated lead dust?—That is a practical question which would require very careful thought, but I think it is possible from what you have put to me.

10,623. Do you think it is possible? Would you be surprised to hear that the English employers of labour have, all of them, with one or two exceptions only, said that it would be impossible to work free from dust. I have taken them through process after process. They have admitted that dust must be generated, and they cannot get rid of it, and in the end they have said, "We prefer prohibition to these rules; because they are impossible to carry out"?—If one were starting in an old room which had been painted for a number of years, and where the paint was hard, polishing might be done by another process.

10,624. What would you say in regard to new paint after the first coat?—After the first coat I hold that there is no powder or dust to any extent generated.

10,625. In rubbing down after the first coat—in glass-papering between coats—do you say that there is no dust?—No dust to speak of.

10,626. But that small quantity of dust, that you wish to minimise, the Home Office consider a very grave evil. We have had evidence from the greatest medical gentlemen in the country, and they state that almost the whole of the evil, in all the lead industries, is the dust generated in the course of the work, and this Committee must insist, or otherwise the matter will be referred back to us, that in future the men should be protected from beginning to end from any dust that is generated. If you say that it is absolutely impracticable to protect the men in that respect, I want you to tell me so frankly and candidly?—Personally I think our whole Scotch experience goes in the direction of the idea that the thesis that lead poisoning is due to the inhalation of dust is a fallacy.

10,627. But we cannot accept that against the medical evidence of the country?—But doctors differ.

10,628. But they do not differ in this case?—Might I say that we have had 50 years' experience in Scotland where lead dust has been generated, and in all those years there has not been a fatal case that can be pointed out. Is there not something wrong in the line of argument?

10,629. (Mr. Gardiner.) There are lead-poisoning cases in Scotland?—I spoke roughly just now; but what is the number of cases?

10,630. (Chairman.) You do not seriously suggest that there are no fatal cases of plumbism in Scotland, do you?—What I say is that, so far as one can gather from information got carefully in a variety of shops, we have not discovered one fatal case.

10,631. I am afraid that I am not much more forward than I was when I began, because you tell us that you prefer precautionary measures, and when I ask you how you are going to put those precautionary measures into practice, you suggest nothing to us?—No, but I say that in Scotland we have those precautionary measures, which have been effective to a very large extent.

10,632. I am afraid that I shall have to go over the whole of these operations from beginning to end, because I cannot take general remarks as evidence?—It is a wide question altogether.

10,633. You are the only witness I think we have had representing the employers who has not assured us that there is a great deal of dust generated in many of the operations of house-painting. You want

26 July 1911.]

Mr. JAMES M. ORR.

[Continued.]

to minimise that, and say that the dust generated is very slight, and that what dust is generated is innocuous. Now, I am afraid I must take you through all the processes. First, as regards dry rubbing down with sand-paper. I understand that this process is indispensable?—In certain cases.

10,634. Would you agree, as a master house-painter, to the prohibition of any sort of sand-papering?—I do not think I would.

10,635. Then I am quite right in saying that this process is indispensable in some cases?—I cannot see how it is possible to apply a wet rubbing down between coats, but rubbing down between coats is not injurious rubbing down.

10,636. That is your opinion. I do not suppose that a single member of the Committee would agree with you?—That may be.

10,637. Am I quite right in saying that this dry rubbing down is indispensable in some cases?—I think it is.

10,638. Now where dry rubbing down with sand-paper is indispensable, how can you prevent the lead worker from breathing lead dust?—They might use masks.

10,639. Do you think that your men would like to wear a mask?—I am certain that they would not, but if it was necessary they would have to.

10,640. Supposing that they refused to wear masks, what would you suggest as the alternative?—There is no real alternative.

10,641. Then supposing that the Home Office said, or this Committee said, that in their opinion the dust generated from dry rubbing down was highly dangerous, and that unless you could suggest some precaution to relieve the men from the evil arising from it, they would have to prohibit the use of lead, what would you say to that?—I would say that, if the Home Office laid down such a rule, we would require to adhere to it, but the quality of the painting would be very much poorer than it is now.

10,642. I do not think I need go further into the processes. I think you agree with me in this: that if, in the opinion of this Committee, the present conditions which prevail are highly injurious to the workpeople, we ought to insist on some remedy being introduced to relieve them from that evil?—I would say so certainly. We hold in Scotland that we have the regulations.

10,643. (*Lord Henry Bentinck.*) Does the number of your men that you have in your employment vary?—Considerably.

10,644. You take on, I suppose, in the busy season a great many more?—Yes.

10,645. Are you in close touch with the men that you take on? If they are off for illness do you examine into the cause of the illness, or what they are suffering from?—No. We are not in very close touch with them.

10,646. My point is that they might be suffering from some form of lead poisoning without you really knowing it?—They might be. There is quite that possibility.

10,647. Your men are insured, I suppose, by you?—Yes.

10,648. Do you pay lower premiums than the premiums that the English employers pay for house-painting work?—It depends on the company. We pay less than most of the English employers to the company we insure in. The companies' rates vary.

10,649. Do you get off cheaper than the English employer?—Yes.

10,650. You insure for less?—I think so.

10,651. Are you sure on that point?—Yes. As I say, companies vary. All the tariff companies have the same rate right over, but in Scotland the question of lead poisoning has never been raised by our insurance companies. No particular notice has been taken of it.

10,652. (*Chairman.*) How much less do you have to pay for the insurance of your house-painters than is paid in England?—I know that with many English companies 25s. and 30s. are being paid, and I know that in Scotland some pay 12s. 6d. I have heard of that.

10,653. What do you pay yourself?—Fifteen shillings, I think.

10,654. Do you pay 15s. for your house-painters?—Yes.

10,655. As against 25s. or 30s., with the English painter?—Yes. It is all a question of the company. It is difficult to arrive at the point you are at.

10,656. Do you get this low rate from a non-tariff company?—Ours is a non-tariff company.

10,657. (*Dr. Collie.*) Could you tell me how many men are permanently on your staff?—It is a little hard to say, but I would say about 40 to 50 are what we call our regular men.

10,658. A little less than half of your staff?—Pretty much. Our regular men are on practically all the year through.

10,659. How old is the oldest of those men?—I think about 65.

10,660. What is the average age of the 40 to 50 men?—I would say about 45 or so.

10,661. What would be the average age of working men on permanent employment?—I am really speaking father without knowledge. The men's ages I do not know.

10,662. I now want to know how you have studied the question of the freedom of the Scotch house-painter from illness. The first thing to study is the average age of the people you have in your own employment, in order to compare that with the average age of people in other similar employments. Of course, you are prepared to give us those data?—I was not aware that that was a question I should be asked, or I could easily have found it out.

10,663. You have given us a broad and very emphatic statement, so it is only fair to you to give you the opportunity of stating the facts on which that statement is based?—The facts are the absence of facts.

10,664. That is an unusual way of basing argument?—It is, but that is what I say. If one can say there is no illness, it is more emphatic than saying that there have been ten cases of illness.

10,665. But I want to know how far you have carried your investigations. The Chairman has already pointed out to you that there are other things besides absolute lead poisoning to which the influence of lead gives rise, and I want to know how far you have studied the question from that point of view?—My point is that there are other contributory causes affecting the mortality of the men apart from lead poisoning.

10,666. You have made a very emphatic statement, and I am bound to ask how you have come to the conclusion. I ask you first, What is the average age of the people you have in your employment? It is a simple point to ascertain. You have been giving evidence on this special point?—I am not prepared with definite data, as I say.

10,667. How much time has been lost by the various men in your employment, taking the 40 to 50 on your permanent staff?—Do you mean by illness?

10,668. Yes?—Some painters lose half the year, but not through illness.

10,669. I am asking about those of your permanent staff who are employed the whole year, as you have said?—I could not tell you of any quantity of time lost. It is the rarest thing to hear of a man being off work on account of illness—so rare that we have never thought of taking specific note of it.

10,670. But have you taken out any detail, because we have to study these points when we are considering the question of illness in occupations?—You mean how many hours a man has been off work through illness in ten years?

10,671. Yes?—I could not tell you that.

10,672. This is the bed-rock of the Inquiry into such a subject as this. Now you said that in Scotland in your opinion dust is not a cause of lead poisoning. Would you kindly quote your medical support for that?—I do not quote medical support, but I go back on the fact I have stated several times already.

10,673. But I want to know on what facts your statements are made. You surely will give us medical evidence to establish the point?—My point is this: I compare the number of deaths which are said to occur

26 July 1911.]

MR. JAMES M. ORR.

[Continued.]

in England with the number that are said to occur in Scotland, and I say that until I know how far the English deaths are the deaths of men who are not house-painters in our Scotch sense, I would draw the conclusion that it is due to less cleanly habits on the part of the painters' labourers and plumbers.

10,674. We shall come to all these points. If you will only answer the questions as I ask them we shall get on much faster. I want the basis of your statement and the medical support that you have for making the statement that lead poisoning is not caused by dust?—I have no medical support.

10,675. Dr. Alexander Scott has given great attention to occupational diseases. He is a physician of your own city. Have you inquired of him?—No. I have never heard of him. There is no physician of that name mentioned in the Glasgow Post Office Directory.

10,676. Your statement is a lay statement without medical support?—Yes.

10,677. Are you aware that consumption is one of the diseases the influence of lead gives rise to, apart from absolute lead poisoning?—I was not aware of that.

10,678. The Registrar-General shows that to be so, in his figures for England and Wales of people employed in lead occupations?—I take it to be so.

10,679. How is it that we find amongst Scotch house-painters that deaths from phthisis are in considerable excess?—I was not aware of that. I have not known a man of ours with phthisis.

10,680. In answer to Question 4007, before this Committee, I said: "In the Scottish society the incidence of plumbism is decidedly lower, that of Bright's disease somewhat lower, but that of phthisis decidedly higher. The figures are very close to those given by the Registrar-General for plumbers, painters, and glaziers." You cannot explain that?—I can. I think it is due to other causes altogether.

10,681. Will you suggest a cause?—The painting trade being considered a "light job," the less robust members of families are often put into it; and also I would say irregularity of employment might contribute to it.

10,682. How is that?—If a man is irregularly employed, he has less means of nutrition, and his system will not have the same power of resistance.

10,683. I follow your point. What experience have you had of the use of non-lead paints?—We have used them to some extent.

10,684. To what extent?—Not very largely. Many years ago we used Charlton white for a time.

10,685. Not in recent years?—We use Duresco, if you call that a non-lead paint.

10,686. That is a water paint?—Apart from that we have not used non-lead paints to any great extent for many years.

10,687. So you have really no experience on that point?—We had experience 20 years ago.

10,688. But not recently?—Not quite recently.

10,689. You have had no experience of modern non-lead paints?—No great experience of them.

10,690. You are unable to say whether they are as efficacious for your work as the paint you at present are using, or not?—We discarded them very largely because they were not as efficacious.

10,691. That is many years ago?—We have used them in the last four or five years.

10,692. I thought you said twenty years ago?—We used them at that time to a considerable extent, and discarded them. Since then we have not used them so much as before, because we have found them not so efficacious.

10,693. You have not made recent experiments?—Not recently.

10,694. You have no experience of how far they might or might not be valuable in replacing lead paints?—No.

10,695. You have said that you would rather have regulations, if something is to be done, than any form of prohibition or limitation?—Yes.

10,696. Can you suggest to me how regulations can be enforced in the house-painting trade? It is no use

passing a law if you do not look after it?—Masters require to lay down stringent rules and see them enforced.

10,697. We have found in the past that getting masters and occupiers to lay down stringent rules in factory work does not get them enforced. We have in the Factory Department, you know, Factory Inspectors?—Yes.

10,698. Perhaps you are outside their influence. Do you suggest that such Factory Inspectors should be appointed to look after the house-painting trade?—I do not see how it could possibly work. It is not practicable.

10,699. So that even if means, by regulation, could be devised for removing the dust, and for everything else, you do not consider that there is any practical means that could be adopted for enforcing them. First you do not think that they are possible, and if they are possible you do not think they could be enforced. That, I gather, seems to be the position?—Not altogether. There are regulations that are possible.

10,700. (Chairman.) The main regulations that I suggested to you, you said were impossible to carry out?—Some of them are.

10,701. (Dr. Collis.) Even those that you think could be carried out, you do not think could be enforced?—I see a difficulty in enforcing some of them. A Factory Inspector going to a factory would see that each rule is carried out. A similar inspector employed in the painting trade would have to go round to every job that the men were on. It might help to keep the men up to the mark.

10,702. Do you think it possible to carry out inspection in private houses?—That is one of the difficulties.

10,703. How much do you think such an inspection is likely to cost the nation?—I have no idea.

10,704. You cannot say whether it would probably cost the public a great deal more than any deterioration which there might be in employing paints which do not contain lead?—I am not in a position to answer that question.

10,705. If it was found that the cost was in excess of what the public might have to pay, due to the fact that non-lead paint is not quite as good as lead paint, what would you say?—If you put it in that way, there is no question that the cost to the public would be very much greater if they discarded lead.

10,706. People differ considerably on that point, and your experience on this matter does not seem to be recent. Are you aware of the fact that the Office of Works have, for the last four years, discarded all paints containing lead?—I say that four years is not a long enough period.

10,707. How long would you say?—Ten years.

10,708. You think that during ten years we ought to do nothing?—Not necessarily.

10,709. How long do you think we ought to stand still, and experiment?—I say that four years is not sufficient to justify making a change.

10,710. Do you think that during the ten years we should do nothing?—I do not say "do nothing."

10,711. What do you suggest we should do?—I suggest regulations of some kind. I would not discard white lead.

10,712. What form should the regulations take?—Something on the lines laid down, as far as they are practicable.

10,713. You have not admitted that any of them are practicable, or that those that are practicable can be carried out?—In Scotland we are at present carrying out a system of regulations which has so far proved considerably effective. I cannot accept the figures quoted here as being applicable to the house-painting trade at all, and therefore we are looking at it from two different points of view altogether.

10,714. Are you aware that cases of lead poisoning which occur among house-painters and plumbers do not have to be notified to the Home Office?—Yes.

10,715. In factories and workshops they have to be notified. You are aware of that?—Yes, I suppose they are.

26 July 1911.]

Mr. JAMES M. ORR.

[Continued.]

10,716. I daresay you know that the Scotch people are quicker perhaps than the English in taking up a point of law?—So they say.

10,717. That may account for the fact that we have received a certain number of voluntary notifications from people who have apparently mistaken the law, and think it safest to send in every case of lead poisoning to us, to be on the right side?—Yes.

10,718. Scotch people being quicker perhaps to notice the law do not send us as many. In 10 years we have had close on 2,000 (1,973 exactly) of these voluntary notifications with regard to which there is no compulsion whatever. In 1910 there were 232, of whom 197 were house-painters and 35 were plumbers. There were 5½ times as many house-painters as plumbers, and the witness who gave us that evidence said "This is about the relation of house-painters to plumbers which usually exists?"—My point is that we have no painters' labourers in Scotland at all.

10,719. We have to protect the labourer?—The large percentage is due to men who have no training as painters, and do not know what means to take to avoid risk.

(Chairman.) That is only a statement.

10,720. (Dr. Collis.) We have had 12 cases notified voluntarily from Glasgow in the last five years, but you have not been able to ascertain any cases, you tell us?—We asked and we found no case of death resulting from lead poisoning.

(Dr. Collis.) These are cases of illness that I am putting to you now. Information with regard to Scotland has not been asked for until recent years.

10,721. (Mr. Parsonage.) You ascribe the number of lead poisoning cases in England to painters' labourers. You make out that that is the difference with regard to the conditions?—I give that as one possible explanation.

10,722. Have you any knowledge of the extent to which painters' labourers are employed to do painting in England?—No, but I know that they do a lot of preparatory work.

10,723. That would be rubbing down, I take it?—Yes.

10,724. But your own statement is that there is no danger from the rubbing down?—No, I did not say that. I said that there was no danger in the particular kind of rubbing down that I spoke of.

10,725. What rubbing down is there where labourers are liable to a risk that painters are not?—If one sand-papers a door instead of using pumice stone, there is risk.

10,726. Do labourers in England sand-paper doors at all before they are painted? Have you ever seen them on old paint?—I have not seen them.

10,727. What knowledge have you to go on? You make an assertion, but I want to know on what you base that assertion?—I base the assertion on the fact that painters' labourers are employed in conjunction with painters, and those are very likely men who are not men of the same habits as painters.

10,728. You have no knowledge of the class of work that these labourers do? You would not expect a labourer to get lead poisoning if he was put to wash off a ceiling or strip paper off walls? Have you any knowledge that labourers in England do painters' work?—I have no definite knowledge.

10,729. You have no knowledge whatever that they do painters' work?—I have been told that they do painters' work. I have been told that they assist painters.

10,730. (Chairman.) What you have been told cannot be taken as evidence. We want to know your own experience?—If it comes to that, I never have worked in England.

10,731. It is not quite fair to come down from Scotland and tell us that lead poisoning is caused by the employment of labourers unless you can support your statement?—I had no other means of accounting for the figures.

10,732. (Mr. Parsonage.) You have no reason, but you are trying to give a reason. You have no facts on which to base your assumption, but you try to find

something? The facts are that the conditions in Scotland are not those in England.

10,733. Take Manchester. There is a standing agreement, which is strictly observed, and Mr. Sutherland will bear me out, that no labourer in Manchester is allowed to do any preparatory work of any description. He is not allowed to wash a ceiling or strip wallpaper or anything. A painter's labourer in connection with painting in Manchester is unknown, but there have been five verdicts of death from lead poisoning during the present year. One of these cases is a master painter. A labourer is not even allowed to handle a distemper brush in Manchester. That is an agreement between the master painters and the operatives?—What does the labourer do?

10,734. He assists with the scaffolding and prepares the men's meals, and so on?—Does he not touch paint at all?

10,735. He is allowed to do lime-washing. That is all that he is allowed to do. It is in a printed agreement. He does not touch paint?—Who keeps the shop? Who looks after the material?

10,736. He may sweep up?—That is my point. Then he is doing the very thing where he is most apt to meet danger according to you.

10,737. You have yourself said that there is no dust in the paint shop?—I have held all through that there are other things than dust which may induce lead poisoning; and this applies in a special degree to a man working in the paint shop.

10,738. Is it not ridiculous? Say one labourer on a job and 20 painters are employed; he sweeps up. Do you say that he contracts lead poisoning from that?—That is not my point. I do not personally think (I know I am against the medical evidence altogether) that lead poisoning is due to inhalation of the lead dust so much as it is due to dirty habits in regard to the fingers and finger nails, and a man working in a paint shop lading out paint or making it up or helping with paint, if he is not a careful man, will get his hands smeared with paint and may get lead poisoning.

10,739. You would attribute the death of the master painter in Manchester to dirty habits?—It may be. I have known dirty master painters. You put the question, and I must give the answer.

10,740. How do you account for some painters from Scotland going to London and getting lead poisoning? They use the same material?—The difference comes from the diet to some extent, and habits.

10,741. What do they live on different in Scotland from England?—They live on porridge in Scotland sometimes, and broth.

10,742. Would you suggest that one of the regulations should be that painters must eat porridge for breakfast?—I would, very gladly.

10,743. You would seriously suggest that?—Honestly, I would. A man comes down from Scotland, where he has been living on a particular kind of diet and drinking a particular kind of water. He comes to London, changes his whole method of diet, and drinks different water. His whole organism becomes upset, and he is more liable to any illness.

10,744. The rules in my society say that a man to join must have served five years at the trade before he is 21. We get applications to break that rule, and they are always refused. I do not say that a few do not get in who violate the rule. We have always any number of lead poisoning cases on hand. We have paid out no less than 4,800*l.* odd in 52 cases of paralysis from lead poisoning in six years. We only pay for paralysis. I could bring you a sheaf of doctor's certificates now, describing men as suffering from Bright's disease and other diseases. They have to be rejected. If we recognised them we could not meet the claims that come in. Our society is a painters' society with no labourers or plumbers. If we take in a man who has served his apprenticeship as a plumber and painter he has to give up the plumbing?—All I can say is that your experience is very different from Scotland, whatever the cause of it.

26 July 1911.]

Mr. JAMES M. ORR.

[Continued.]

10,745. You will not admit that there are any deaths from lead poisoning in Scotland?—I say that as a matter of fact we have no record of one in fifty years.

10,746. You have not, personally?—No, and we have inquired from the biggest employers in Scotland, men who have been in the trade for over fifty years, and not one of them can recall a case.

10,747. How much time do the men that you employ permanently lose in the winter?—Very little.

10,748. Do not they trouble to look for work in another shop?—We have an average of 40 men who are practically employed the year through.

10,749. That is a very different thing. You may have 10 in the winter and 80 in the summer?—No. The winter and summer staffs are different things. I was trying to give as nearly as possible the number of men regularly employed.

10,750. (Chairman.) I thought you said that the average number was 140?—No! 110, of whom about 40 may be called permanent "staff." We do not pay off certain men if we can avoid it. We call them our staff. We may have to suspend them for an odd week or so.

10,751. Sometimes it is two or three hundred?—It comes up to 200 sometimes.

10,752. (Mr. Parsonage.) What regulations do you carry out with regard to cleanliness in your shops? You speak of regulation?—The only regulation is that we insist on the men being clean and wearing clean overalls.

10,753. Every witness from the employers has stated that he insists on the workman bringing clean overalls on a Monday morning?—It is quite possible.

10,754. But you would not term that a regulation to prevent lead poisoning?—The wearing of overalls is a very important point.

10,755. Do you provide nail brushes?—Not nail brushes.

10,756. Do you provide towels?—Yes, sometimes.

10,757. And soap?—Yes, and there is always something besides towels that men can use.

10,758. What is that?—Scrim cloth.

10,759. And stuff that they strain the distemper through, and all that; in fact, anything that is on the job in that way. That is precisely the same as they do in England. You have no regulation that I can see that is not followed out here?—All I can say is that the result is very different.

10,760. (Mr. Gardner.) In speaking of rubbing down paint between coats, you said that paint could be rubbed down with sand-paper, so that there would be no dust?—Yes.

10,761. How could that be done?—By putting a little oil on the back of the sand-paper or wetting the sand-paper.

10,762. Is that generally done?—It is not generally done, but it can be done.

10,763. It can be done?—It is done.

(Mr. Gardner.) I have never experienced it.

(Mr. Parsonage.) I have never known it.

10,764. (Mr. Gardner.) With regard to your experience since the present Workmen's Compensation Act came into operation, so far as your association goes, no men have claimed for lead poisoning under that Act?—I have not heard of a single case.

10,765. I believe that you would be very astonished to learn that within the last eight years we have paid two death claims for lead poisoning in Scotland?—I am astonished.

10,766. And that we have quite a number of sick cases due to lead poisoning—Bright's disease and phthisis—due to lead as the primary cause?—I am not aware of it. It has not come before our association.

10,767. One member of your association, two years ago, had a claim for a death from plumbism. Are you aware of that?—I would like his name.

10,768. In Glasgow—Bryson. It was proved that plumbism was not the cause of death, although the man was suffering from it. The case was not reported to you?—No, there is no occasion to report.

10,769. There are quite a number of cases which have not come under your notice. Do you think medical examination of workmen at all practicable?—

A monthly examination is quite impracticable. I do not see how it could possibly be done with any assurance of success. If the onus were put on the operatives, so that they would require to produce their medical certificate when applying for work, it might be practicable.

10,770. (Mr. Sutherland.) You are very solicitous for the men in your shop. You have a character for that?—We try to be.

10,771. And your class of work is good general high-class work. Now do you think that in relation to that class of work it would be possible to dispense with dry rubbing down, which the Home Office authorities locate as the serious source of the evil. Do you think that it would be possible to submit to a regulation abolishing dry rubbing down?—It certainly would be irksome, I admit, but it is possible.

10,772. It would be irksome, but could the trade meet it in some way that would preserve the use of lead and still preserve the quality of the painting which follows from the use of lead?—I think they could.

10,773. Do you think that it would be worth trying?—It would be worth trying.

10,774. Do you think that that regulation would meet with opposition? If it was a question of the abolition of lead, or submission to regulation, and that was one of the regulations, do you think it would meet with opposition from the employers?—In the first instance it would, as any deviation from the accepted course meets with opposition.

10,775. I know that, but assuming that it became law, do you think that the employer would fall in with it, and see that it was enforced?—Decidedly, I would say so.

10,776. Now, with regard to dry rubbing down: in a great many cases the sand-paper is used merely to take the fine ribs off the surface of the paint. Is not that so?—Yes.

10,777. And not to cut the surface of the paint?—No.

10,778. So that in those cases, which form the great proportion of the process, the dust from dry rubbing down would be very small?—That is exactly my opinion.

10,779. The serious cases of dust from dry rubbing down would arise when you were cutting down sharp colour?—Yes.

10,780. But that does not form a great proportion of the painting work?—No.

10,781. Relatively a very small proportion?—A very small proportion.

10,782. Now with reference to insurance, the tariff rate (for this purpose we can only take the tariff rate) is the same in Scotland under the new Act as it is in England, 30s. less whatever rebate there may be?—It is quite possible.

10,783. Under the old rate, when lead poisoning was not included, the tariff rate was higher in Scotland than it was in England?—That may be. I am not in a position to say.

10,784. That points to the fact that lead poisoning in Scotland is not as serious as it is in England, because lead poisoning in England has sensibly affected the tariff rates?—I see.

10,785. (Chairman.) You only gave us a non-tariff office?—Yes. May I say that we have tariff companies in Scotland, and I think that you can get a fair basis of comparison.

10,786. Have not they made arrangements with the tariff companies in England for a uniform rate?—I do not know.

10,787. (Mr. Sutherland.) It is the common practice, is it not, for the men to have overalls, and for the men to provide them?—Yes.

10,788. It is the same in England in most shops. It is not necessary for us to insist on that, because the master already insists on it?—I would not employ men who had not overalls.

10,789. With regard to provision of meal rooms, did I understand you to say that it was impossible to get a separate meal room on a job?—No, I did not say that. What I did say was this: I thought that the Chairman meant that we should fit up a special meal room. You could easily arrange to have meals in a different room.

26 July 1911.]

MR. JAMES M. ORR.

[Continued.]

10,790. You agree that it is necessary?—Yes.

10,791. And also a separate room to hang the clothes, quite apart from the room where the work is being carried on?—Yes.

10,792. (*Chairman.*) I want to know in what way you could provide a room for meals in some cases?—The point is this: If the rule were made that a separate room must be found for meals, we would see that it was done. We would get another apartment. There has been no regulation ever made as to where a man took his meals. He might take them in the room where he was working; he might take them in the paintshop; or he might take them in another room. If it were thought for the health of the men advisable that the rule should be made that the men should not take meals in the work room, that could be observed.

10,793. Supposing that they are only painting one room?—That is the point.

10,794. (*Mr. Sutherland.*) If it was part of the regulations that they should have separate meal rooms, could they be provided?—I would say a separate place to take their meals. I do not like the term "separate meal room."

10,795. Could they be provided?—Yes.

10,796. (*Chairman.*) Could they be provided in almost every case?—Yes, I think so.

10,797. (*Mr. Sutherland.*) Could the provision with regard to separate rooms for hanging the clothes be enforced, if it was the rule? Do you think that customers would offer any objection, knowing what the law was, and the danger arising from the old practice?—If that were the law we should have to inform our customers and make arrangements.

10,798. You think that it could be done?—Yes. It is a question of adjusting ourselves to the new conditions.

10,799. (*Chairman.*) How could the rule with regard to meal rooms be enforced? How is the Home Office to know that the men are being protected in respect of those two points?—As a matter of fact, men generally get their meals in the kitchen of the house they are working in.

(*Chairman.*) It is not practicable in many cases. They would be laughed at if they wanted to go into the kitchen for such a purpose.

10,800. (*Mr. Sutherland.*) At most jobs there is provision for washing in the shape of buckets of water?—There always is.

10,801. Speaking generally, there is no difficulty in getting hot water?—Speaking generally; but in a new house, where water is not laid on, it is difficult.

10,802. But they can heat water?—Yes.

The witness withdrew.

Mr. G. CARFRAE examined.

10,803. (*Chairman.*) Do you attend here to-day as a representative of the Association of Master House Painters in Scotland?—Yes.

10,804. What is the nature of your business and where is it carried on?—House-painter in Edinburgh.

10,805. What is the average yearly number of painters employed by your firm?—About 100.

10,806. How long have you been in the painting trade?—Personally, 29 years.

10,807. Have you known any cases of lead poisoning or painter's colic?—None at first hand.

10,808. Have your men had occasional days of sickness possibly due to lead?—No case in all our experience that I can find out by asking old men.

10,809. Do you have a periodical medical examination of your men?—No.

10,810. If you have no such examination by a doctor, is it not possible that some of the men may be suffering from the slower and more insidious forms of lead poisoning?—It is possible.

10,811. You know, I presume, that lead poisoning frequently undermines the health without immediate violent symptoms arising?—Yes.

10,812. The incidence of lead poisoning is published month by month by the Board of Trade. Do you see the "Labour Gazette" published by them?—No.

10,813. Do you know that there were 284 deaths of painters, definitely certified as due to lead poisoning, in the last ten years?—No, I do not know that.

10,814. And that there is a definite increase in the death rate from lead poisoning amongst painters during the last six months?—It is the first I have heard of it.

10,815. These are English statistics. Scottish statistics have not been collected in past years, but with the same processes and the same materials, the risk must be the same?—Yes, if the processes are the same.

10,816. In addition to this, the death rates from Bright's disease and nervous diseases due to work in lead are very high?—I hear that for the first time.

10,817. There are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office?—That is also new information to me.

10,818. I am sure you will agree with me that if these figures are correct, all this sickness and death is very deplorable?—Certainly.

10,819. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I do know that.

10,820. That the use of white lead has been prohibited to an appreciable extent abroad?—I know that.

10,821. And that the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed. Do you know that?—I know that.

10,822. Do you not think it regrettable that this country should be behind other nations in this respect?—Decidedly.

10,823. Something must be done, either by regulating the work very closely or by restricting the use of lead?—Yes, where necessary. I may say that it seems to be more in England that the cases occur, than in Scotland.

10,824. But I have asked you the question, which you have answered, that, given that the materials are the same, and the processes are the same, there cannot be any difference in the two countries?—Well, Sir, I do not know whether I am in order in bringing it in at this point, but I think that the processes are different in England.

10,825. Perhaps you would kindly tell us in what way the processes are different in Scotland from England?—They use more oils in Scotland. In England, particularly in London, they use a very much smaller proportion of oil. They bring up their paint to what we call flat, turpentine being the principal medium for thinning it. It dries quickly and they rub it down, and they can get two and sometimes three coats on in one day. A process of that kind is almost unheard of in Scotland. Of course when there is very little oil, the rubbing down causes a dust that flies about. I have spoken to some of our men who have worked in London and know the conditions of labour there.

10,826. Do you think that the difference of putting more oil in the paint makes the men immune from the dangers of lead poisoning in Scotland?—Well, it prevents the lead floating about in the atmosphere to some extent.

10,827. You do admit that a certain amount of dust is generated in the process of painting?—Very little.

10,828. But there is some?—There is some.

10,829. Do you admit that the dust is highly injurious to the workmen?—Yes, if inhaled.

10,830. It is only a question of the quantity with you. You think that in Scotland there is less dust about than there is in England?—Yes, a great deal less.

26 July 1911.]

Mr. G. CARRERA.

[Continued.]

in Scotland, because with so much oil it does not float about so much in powder.

10,831. You no doubt realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—Does that apply to North and South Britain—all over the country?

10,832. Yes. The potteries of Glasgow and outlying districts are in effect precisely the same restrictions with regard to the use of lead as are the potteries in North Staffordshire; similarly, any regulations issued to the painting industry would apply equally to Scotland as they would to England?—I follow.

10,833. Are you aware of what the details of these precautionary measure would be?—To some extent, I have a certain number sent to me by a white lead works; that is all.

10,834. First of all there is the provision of overalls by the employer, who is responsible for seeing that they are regularly washed. Would you agree to that provision?—I would rather the onus were put on the men.

10,835. But that has not been done in other industries. The reasoning is this: if a dangerous element is allowed to be used in any particular industry, the employers must see that any dangers to the men which ensue in the course of the occupation are removed. Would you agree to any rule which the Home Office enacted, by which the employers should provide the overalls for the men and see that they are properly washed?—Decidedly, if it is made a regulation.

10,836. Secondly, comes the provision of a meal-room, care being taken that in no case whatever are any of the men allowed to take their meals in a room where lead is used. Would you agree to such a provision?—It would be extremely difficult to carry it out.

10,837. Again, in the pottery industry it is laid down that under no circumstances are the men to be allowed to take their meals in any place where lead is used?—I can understand that in a factory, but where you are sending men all over the country it is different.

10,838. I quite see the great difference, but I am only telling you what sort of regulations the Home Office would insist upon if lead is to be permitted to be used in the future. I want your kind assistance with regard to whether it would be practicable to introduce these various rules. The third is the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing, and where they will not collect unnecessary dust when not being worn. Would you agree to making a provision of that sort?—I agree with that.

10,839. Do you think that it is possible to do that?—I think it is possible. It is a little difficult, but it can be done.

10,840. The next is the provision of cloakroom facilities, so that clothing put off during working hours shall not, under any circumstances, remain in a room where lead is used.—It is practically impossible to carry that out.

10,841. You see, do you not, the danger which arises at once? Again, taking the pottery industry, no workman is allowed to have his outdoor clothes in the room where lead is used, because it collects on his clothes and he takes it home?—It is practically impossible to prevent that in the house-painting trade.

10,842. Now comes the introduction of proper washing accommodation—one basin or other utensil to every five men, the supply of hot and cold water, and soap and nail-brushes, and a sufficient number of clean towels?—If you leave out the hot water the rest can be managed, but you cannot always depend on getting hot water on jobs.

10,843. Would you agree that hot water is very much better to wash paint off the hands than cold?—It is not always necessary, if you use soap.

10,844. Take a cold winter morning, would not you prefer hot water?—Yes.

10,845. And so would the workmen?—Yes, if they can get it.

10,846. Provision would have to be made for the avoidance of dust?—Yes.

10,847. Some means would have to be devised for getting rid of any dust which the men might breathe?—Yes.

10,848. Would that be practicable? Let me give you an illustration. Is it practicable to provide means for removing the dust in sand-papery?—No.

10,849. You say that it is not practicable to avoid the dust in sand-papery?—No, it is not practicable to avoid the dust.

10,850. Now, with regard to the fumes from burning off and the spray which may be breathed in certain operations?—Are these supposed to be dangerous?

10,851. Yes?—You cannot avoid them I am afraid.

10,852. Are you aware that the Committee's attention has been called to the existence of poisonous emanations from liquid paint? Have you heard of that? As the paint is put on the surface, the vapours that arise from that are highly dangerous. Have you heard of that?—I can understand that they are, in a confined area.

10,853. Have you anything to suggest to us with regard to how men can be protected from those vapours?—It is principally where turpentine is used as the medium for thinning the paint. In a confined area I have experienced myself that it makes you slightly dizzy.

10,854. Have you anything to suggest to us as a means of removing that evil?—No, you cannot remove it, but I would not keep a man very long at it. I would have him relieved.

10,855. In addition, periodical medical examination of the workpeople, say once a month, would be insisted on at the expense of the employer. Would you agree to that?—It is adding another burden, and all these things only make painting work more expensive. That is the only thing against it.

10,856. The tendency of the present day is that the democracy are going to have fair play?—They will not have quite as much work.

10,857. That is a question which we are not here to inquire into, but what we are here to inquire into is the mitigation of the evils which unquestionably arise in this industry. Do you think that it would be practicable to have a monthly medical examination?—Quite practicable.

10,858. And that the employer should bear the brunt of it?—Yes, just in the same way as he has to pay insurance at the present moment.

10,859. Together with the payment of compensation to any worker withdrawn from work by the certifying surgeon's orders on account of doubtful health?—Yes. It is all practicable. The only objection is the question of expense.

10,860. Would you have any objection to the expense?—None whatever. It will affect everyone in the same way if it is made the law.

10,861. Taking all these points into consideration, would you say that you would prefer that the industry should be regulated by a special code of rules or that the use of lead should be very closely restricted?—If it lies between the two, I would certainly say that lead should be continued under a special code of rules rather than that it should be prohibited.

10,862. But you understand that this Committee have to report to the Home Secretary. Can we tell him that we are satisfied that a special code of rules would meet the evil? You have told us that in one or two instances rules which might be considered imperative are impracticable. Now what would you suggest we should do under those circumstances?—So far as Scotland is concerned, I do not see that any rules are necessary, but if they are necessary for one part of the kingdom and will be applied to the whole of the kingdom, then I should say, make up your code of rules and see that they are adhered to as far as possible.

10,863. But that would not be sufficient. We have to put it to the Home Secretary that a certain list of rules is first of all practicable; secondly, that they could certainly be carried out; and thirdly, that they would remove the evils which the Committee think exist. Now what sort of recommendation are we to

26 July 1911.]

Mr. G. CARFRAE.

[Continued.]

make with regard to the removal of dust which is generated in the process of sand-papering, and which all the medical evidence goes to show is one of the greatest of all the evils?—I say that you could make it a stringent rule that painters use more oil and other binding materials than they do in London now.

10,864. You have admitted that that would not entirely remove the dust?—Not entirely, but it evidently would mitigate the evil of lead poisoning.

10,865. But it does not remove it, and we have to remove the evil. It is no good our going to Parliament with a half-hearted measure. We are sitting here to present something to the Home Secretary for him to present to Parliament. The tendency of the people irrespective of party, is that they are going to see now that, if there is a real evil existing in any particular industry, that evil is going to be removed. All the best medical evidence of the country points to the profound evil of lead dust, and unless we can suggest its entire removal another Committee will be appointed to settle the question. Now I ask you as a practical man, what are we to do on the question of removing dust generated in the process of sand-papering and other operations?—I am afraid that it is beyond my power to answer that.

10,866. (Mr. Gardner.) Have you had experience of non-poisonous paints?—Yes, some.

10,867. Has it been extensive?—No, not very extensive.

10,868. Has that been of late years or some time ago?—Within the last ten years, I should say.

10,869. Right along?—Not continuously.

10,870. Have you found them satisfactory?—No.

10,871. What non-poisonous paints have you used?—Only zinc.

10,872. Has not that been satisfactory?—No.

10,873. (Mr. Sutherland.) Was it zinc oxide?—Yes. I have not found it satisfactory.

10,874. (Mr. Gardner.) Did you treat it as zinc or purely as a lead paint? Did you treat it as a medium that you had to give some special attention to, or was it used in the ordinary manner?—It was used in the ordinary manner for the sake of getting extra whiteness.

10,875. No special treatment?—No special treatment.

10,876. Do you think that medical examination of the workmen would be practicable?—I think that it is practicable.

10,877. If you send your men to a country job, as you do repeatedly, how are you going to get them examined every month. Would you send the doctor away after them to see how they were getting on?—In these out-of-the-way places, they would require to be examined by a doctor in the vicinity. As for the ordinary country job, the man as a rule comes home for the week end every second week, and if it is not very far away, every week.

10,878. How near at hand?—From jobs 60 to 80 miles away.

10,879. Do you think that it would be quite practicable to have them examined every month?—Yes.

10,880. What about the men who come floating in and floating out of the shop, starting at the beginning of the season and going on for a month or so and then going off? What would you do in those cases?—That is a matter of detail. Unless a man could show that he had passed the doctor he would not be taken on. He would have to carry his certificate with him.

10,881. Do not you think that it would be a very expensive procedure for the employers?—Yes, undoubtedly the whole thing is expensive.

10,882. You have no knowledge first hand of any cases of white lead poisoning?—None whatever.

10,883. I suppose you are aware that there have been deaths in Scotland from white lead poisoning?—I have heard that such a thing has occurred.

10,884. And that there are cases of illness?—I have only knowledge of one case at second hand, within the last 60 years, of illness.

(Mr. Gardner.) I am sorry to say that we have too many cases of sickness due to lead poisoning.

10,885. (Chairman.) You told me that you have no knowledge of the number of deaths in England?—No.

10,886. You have no knowledge with regard to any part of the country?—No.

10,887. (Mr. Parsonage.) You think that if more oil were used in London, that would cause less danger?—Decidedly.

10,888. Do you know why more oil is not used in London?—It is not speedy enough for getting two and sometimes three coats on in one day.

10,889. Have you had any experience of getting two or three coats on in one day in London?—Not at first hand. This is from men of my own who have worked in London, and have known cases of illness amongst their friends working with London decorators, and they have attributed it to that.

10,890. Two or three coats in one day?—Two or three coats in one day.

10,891. (Chairman.) What you hear from someone else is not evidence?—I cannot speak first hand.

10,892. (Mr. Parsonage.) Do you not think that the reason for using so much turpentine in London is on account of the atmosphere, and that if they used oil paint it would not dry?—No.

10,893. I can assure you that that is the reason. What would be the average number of painters that you would employ?—I think, taking all the year round, about 100.

10,894. What proportion of labourers do you employ?—Not above 2 per cent.

10,895. Not above two labourers to 100 painters?—No, not above two labourers to 100 painters.

10,896. Do those labourers do anything with regard to painting?—They may limewash a cellar occasionally, but they are generally just taking materials about.

10,897. They would sweep up the paint shop on the job and do that kind of thing?—No.

10,898. Have you used zinc paints on outside work?—Once.

10,899. Did you find it answer?—No, it was a failure.

10,900. (Mr. Sutherland.) Do you know any reason why oil paint should not dry in London?—None whatever.

10,901. Oil paint is used extensively in Lancashire, which is very humid, and has a less dry atmosphere than London?—I have used oil paint in London.

10,902. Do you think that it would be possible to dispense with dry rubbing down?—It would be possible.

10,903. Would it be a little more expensive?—Much more expensive.

10,904. Why do you like white lead? If the Home Office really enforce regulations or prohibition, and if the principal source of the evil of lead poisoning is due to dry rubbing down, do you think that painters would meet the case by some treatment that would give good work?—They would have to. It is possible, as I say, but much more expensive.

10,905. Why, as a master painter, do you prefer white lead?—Because it lasts longer, and it is more durable. It stands more washing.

10,906. And does not lead admit of better workmanship? You can brush out white lead to a fine surface, but zinc you have to lay on thicker?—I do not altogether agree with that. With zinc you require more coats.

10,907. Yes, you require more coats if you are going to brush it out thin, but even then you do not get the body, do you?—Not with the same number of coats.

10,908. No. As a matter of fact white lead lends itself better than does zinc to workmanship, does it not, of which Scotch painters are proud, like a good many English painters?—Yes.

10,909. And that will probably account for their preference for white lead?—I cannot say that it does.

10,910. What would you ascribe the preference for white lead to?—It is more economical to begin with, which appeals to the Scotsman. It lasts longer and you get a better job with less labour.

26 July 1911.]

Mr. G. GARFRAE.

[Continued.]

(Mr. Gardner.) Due to long knowledge of the material.

10,911. (Chairman.) If the use of lead were prohibited, in what way would it affect the painting industry?—It would make it more expensive, and there would be less of it done. That is all.

10,912. Do I understand you to say that the carrying out of these new rules would be very expensive?—Yes.

The witness withdrew.

Mr. W. F. DOBIE examined.

10,915. (Chairman.) Do you attend to-day as a representative of the Association of Master House Painters in Scotland?—Yes.

10,916. What is the nature of your business and where is it carried on?—In Edinburgh; house painter and decorator. That is how we speak of house painters in Scotland. That is nothing in the way of cabinet maker or upholsterer or anything of the kind.

10,917. What is the average yearly number of painters employed by your firm?—It varies from 100 to 150. About 100 on the average.

10,918. How long have you been in the painting trade?—From 40 to 45 years—about 43 years.

10,919. Have you known any cases of lead poisoning or painters' colic?—I have never heard of any fatal cases. I have been making careful enquiry lately from my foremen to find what information I could, and we have heard of three cases. One man was laid up for a week or two, and two others for a few days, and on enquiry I have discovered that these men were at a country job, where their diet was of a peculiar character, and that may have had something to do with it. It was said to be lead poisoning.

10,920. Have your men had occasional days of sickness possibly due to lead?—No, not that I know of.

10,921. Do you have a periodical medical examination of your men?—No.

10,922. If you have no such examination by a doctor, is it not possible that some of the men may be suffering from the slower and more insidious forms of lead poisoning?—It is quite possible.

10,923. You know, I presume, that lead poisoning frequently undermines the health, without immediate violent symptoms arising?—I do not know it. I will take that as a fact from you.

10,924. The incidence of lead poisoning is published month by month by the Board of Trade; do you see the "Labour Gazette" issued by them?—No.

10,925. Have you noted that 284 deaths of painters have been definitely certified as due to lead poisoning in the last 10 years?—No, I do not know about that. I should say that that does not refer to Scotland.

10,926. No, but I suppose you agree that we should not have a law passed to apply to England and not to Scotland?—It would be very hard lines on Scotland if the same necessity did not occur there.

10,927. But do you think that it would be possible to have a law prohibiting lead in England and not in Scotland?—It might be possible.

10,928. Would it not be very unfair to the English?—It might be rather rough on them perhaps, but it is possible.

10,929. Do you think that it would be a wise thing to do?—I think that it would be very unjust to prohibit it in Scotland when there is so little cause of trouble.

10,930. That is not an answer to the question. Do you think that it would be a wise and just thing to prohibit the use of lead in England and not in Scotland?—It is difficult to say in that case.

10,931. Are you aware that the death rate from lead poisoning amongst painters increased to an alarming extent in the first six months of this year?—No, I am not aware of that.

10,932. You say that in Scotland you have had very few cases of lead poisoning?—Very few. I have heard of no fatal cases, and I can only trace these three that I speak of. There was one other case that was called lead poisoning that I might mention—a

10,913. I do not think that you can answer this question. Might not the expenses of the new rules be as great as the cost of the extra paint that would have to be used if lead was prohibited?—It is impossible to answer that question. It would be a toss up which was the more expensive.

10,914. So that it would not matter, from that point of view, which you had?—If we were bound to have one or the other, no.

colourman of ours, who was in our employment for about forty years I think. During twenty-five years of that he was a colourman in the workshop making up colour, and it used to be said of him that his system was full of lead; but after leaving our employment he was a pensioner of ours for many years, and he died somewhere between 80 and 90.

10,933. I am not at all surprised to hear of good records, because in some of the potteries there have been no cases at all, and then quite unexpectedly without any warning a firm which has been immune has had a crop of cases. Now, the gravity of the danger is seen if you compare the figures for house painters with those for all lead industries under the Factory Act, in which there have been 20 deaths in the first six months of this year, and 19 in the first six months of last year. So that there has been an increase of one only in this instance, but in the house painters' trade there has been a large increase, and the deaths from lead poisoning in the house painters' trade are more numerous than in all the other industries where lead is used?—I cannot understand that at all. It certainly does not refer to Scotland.

10,934. Then, in addition to this, the death-rates from Bright's disease and nervous diseases, due to work in lead, are very high. There are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office. We have that from trade union returns and from other sources?—You say so, but I must say my own experience does not bear that out at all.

10,935. Are you speaking from experience of your own firm or for the whole of Scotland?—Only from the experience of my own firm and hearsay from other firms.

10,936. I cannot take that. I may tell you that in the course of the inquiry in the potteries, it was ascertained that, out of 500 potteries in England, about three-fourths of them had had no case of lead poisoning at all. The whole of the cases were confined to the other portion. So that it is quite possible that in your works you may have had no case of lead poisoning, whereas it may be fairly prevalent in other works?—But in the course of business that has been going on with my father and myself—60 years—there would be some tradition of lead poisoning if it had occurred.

10,937. Your works may be conducted on the most admirable principles. I am sure you will agree with me that, if these figures are correct, all this sickness and death is very deplorable?—Yes, if that is correct.

10,938. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes.

10,939. That the use of white lead has been prohibited to an appreciable extent abroad?—So I understand.

10,940. Do you not think it regrettable that this country should be behind other nations in this respect?—Not if the conditions in which the work is done are more favourable with us than elsewhere. Possibly other countries have done much the same as in England, and different from Scotland.

10,941. You agree that we ought to level up to other countries with regard to protecting our work-people?—That depends. I would say that you should

26 July 1911.]

Mr. W. F. DOBIE.

[Continued.]

not level up Scotland to other countries, because there is not the same necessity.

10,942. You agree that, if the figures are correct, we should level up to meet the evil?—Yes.

10,943. Something must be done, either by regulating the work very closely, or by restricting the use of lead?—I cannot accept either of those personally because I do not see the necessity for them.

10,944. I am speaking of the whole country?—I will take your statement, but I cannot give an opinion upon it.

10,945. Taking the figures which I have given to you as correct, something must be done to meet such a deplorable evil?—Yes, if the figures are correct.

10,946. That must take the shape of regulations and special rules protecting the workpeople, or the prohibition of lead?—Well, yes.

10,947. No doubt you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—Again I must speak for my own firm.

10,948. Will you kindly not speak for your own firm, but on the figures I am giving you?—As I say, if these figures are correct it might be necessary to do something.

10,949. But do not you think that it is absolutely imperative to do something?—Certainly, on these figures, if they are correct.

10,950. You may take it that these figures are correct; there is no question about the figures; the Home Office have had them analysed with the very greatest care?—That may be, but there must be some special conditions affecting those figures.

10,951. Perhaps you are not aware of the details of the precautionary measures to which I refer?—No.

10,952. First of all there is the provision of overalls by the employer, who is responsible for seeing that they are regularly washed?—As a matter of fact my workmen put on clean overalls every Monday morning. They require no supervision with regard to that.

10,953. Yes, but the Home Office would enact that the employers should see that the workpeople had on clean overalls from time to time, at least once a week, and that the employers should provide them?—The employer could not undertake that, because of the way in which the men are employed. For instance, workmen are employed from the very south of England to the very north of Scotland, and are scattered. It is impossible to supervise them.

10,954. How are you going to be sure that the provision of their wearing overalls is adhered to?—It could not be except as a regular practice among them. It is part of the training of an apprentice that he is taught to do no work without having overalls on.

10,955. Secondly, we come to the provision of a meal-room, care being taken that in no case whatever are any of the men allowed to take their meals in a room where lead is used?—That would all depend upon the customers.

10,956. Would it be possible to insist on such a rule being carried out?—In most cases it would be. In fact in most cases it is done.

10,957. But I want to know about the instances where it could not be done. What is the proportion?—I do not know that there is any case where it could not be done, except where men are working in a house doing only one room, say a drawing-room. If the owner of the house did not allow them to make use of another apartment, what could they do?

10,958. Then your answer is that you could not ensure a separate room being provided in every case?—No.

10,959. Then the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing, and where they will not collect unnecessary dust when not being worn. Could you insist on that provision?—I do not quite follow that. They wear the overalls over their outdoor clothing.

10,960. They take off their coats?—They take off their coats, but then they have a waistcoat and trousers.

10,961. I include the coat in outdoor clothing?—They do not have an overcoat. They have an ordinary coat and the waistcoat and trousers are touched by the overalls, and the overalls are left on the job when they go away.

10,962. Where do they leave the overalls?—They usually throw them down in a corner of the room where they are working.

10,963. With the dust that has been generated during the day and collected there?—Yes.

10,964. So that when they come in the morning they are liable to inhale the dust that is on their overalls?—Yes, if there is any.

10,965. Is there any possibility of providing them with a cloak-room for putting off their coats during working hours, so that they shall not under any circumstances remain in a room where lead is used?—That would be scarcely possible unless again, as I say, customers would allow the men to use some of the rooms in their houses for that purpose.

10,966. Then the introduction of proper washing accommodation; one basin or other utensil to every five men, supply of water both hot and cold, soap, nail-brushes, and a sufficient number of clean towels. Could that be provided for?—Hot water would not always be available, but soap and water are always provided as a necessity of the work.

10,967. And a sufficient number of clean towels?—Instead of towels, they use chamois skins as a rule for drying themselves.

10,968. Provided by the employer?—Yes; they are always at the work as part of the tools.

10,969. Would you agree, if the Home Office insisted on it, that a sufficient supply of clean towels should be provided for the workmen?—Yes, that could be done, but well-trained painters are trained from earliest apprenticeship to wash their hands after doing work before they start their meals.

10,970. Do they always do it?—Yes.

10,971. How do you know?—Have you seen them doing it?—Often.

10,972. In every case?—I have seen them time after time.

10,973. Mr. Sutherland and I the other day, in Manchester, saw three or four men wiping their hands on their handkerchiefs?—Quite likely.

10,974. Is not that a very great evil?—Yes, that is very bad.

10,975. How are you going to ensure that other men shall not do that?—The only way that you can ensure it is by training the apprentices.

10,976. The men that we saw were trained men?—Badly trained evidently, if they did that.

10,977. Can you ensure their all being well trained?—Yes, you can ensure their all being well trained, but you could not always ensure that they would not do that. There might be exceptions.

10,978. Provision would have to be made for the avoidance of dust. Some means would have to be devised for getting rid of any dust which the men might breathe. Is it practicable to provide means for removing the dust in sand-papery?—I do not think that there is any appreciable amount of dust in sand-papery. Whenever you come to the preparation of hard work, water and pumice stone are used. The only time when sand-paper is used is between the coats, and there is necessarily a softness which prevents there being actual dust.

10,979. Is the practice of sand-papery different in Scotland from what it is in England?—I do not know. I could not say what it is in England. Between the coats we smooth the surface preparatory to the next coat being put on, and there is always a certain amount of adhesion in the material in the half-dry state, and most of the dust adheres to the sand-paper.

10,980. Do you maintain that there is practically no dust in sand-papery?—Very little.

10,981. What do you mean by "very little"?—It is difficult to explain. As I say, most of it adheres to the sand-paper itself. So much so that if you see a painter

26 July 1911.]

Mr. W. F. DOBIE.

[Continued.]

rubbing between the coats he has to renew the sand-paper very frequently, because it gets clogged up and loses its efficiency. You can pick up on a job any number of pieces of sand-paper that have been thrown aside because filled up. The dust is of that character that it cannot float about very much.

(*Chairman.*) In England the employers have admitted that the dust in dry sand-papery is very considerable. I think Mr. Sutherland would say it is appreciable.

(*Mr. Sutherland.*) There is an amount of it. There is bound to be some.

10,982. (*Chairman.*) Should you say it is different in Scotland from what it is in England?—I should not think so.

(*Mr. Sutherland.*) I should not think so.

(*Chairman.*) Then the Home Office would insist on some means being provided to prevent that dust from coming in contact with the men.

10,983. (*Mr. Sutherland.*) There is a point which Mr. Carfrae made which relates to Scotland which has not been made before, and I think it is an important one, and that is the larger quantity of oil in the paint. What do you think about that?—I think that that is a very important point. If you talk about that there is one very important point to my mind that makes probably a very great difference between England and Scotland, and that is the quality of the oil. We are very particular in Scotland about using the very purest of oil, with great elasticity and adhesive qualities. There is a great deal of oil in the market which has not those qualities, and it breaks off short, and possibly there is more dust.

10,984. (*Chairman.*) Then there are the fumes in burning off and the spray which may be breathed in certain operations. How do you propose to get rid of them?—It is quite easy to do without burning off. I was not aware that there was anything injurious in burning off.

10,985. Could you insist on no burning off being done in the future?—Yes. If it is injurious, it could quite well be done without. There are numerous solutions now-a-days which take the place of the lamp, and can be quite well used instead.

10,986. Are you aware that the attention of this Committee has been called to the existence of poisonous emanations from liquid paint?—I am surprised to hear it.

10,987. How would you deal with such an evil?—It is impossible to deal with it. Might I go back for a moment to the so-called dry polishing?

10,988. Do you mean sand-papery?—Yes. I would like to point out that the time occupied by an ordinary workman in sand-papery is a very small proportion of the time occupied in the painting, and the time occupied in painting is a very small proportion of the time a man is occupied. The other part of his time is generally spent in paper hanging and size-colouring and other things.

10,989. In addition to the precautions that I have suggested, a periodical medical examination, say once a month, would be insisted upon, at the expense of the employer. Would you agree to that?—If that was made compulsory, then of course one would have to agree to it. It would come back on the public. The customer would have to pay for it in the end. That would not matter.

10,990. Together with the payment of compensation to any worker withdrawn from work by the doctor's orders on account of doubtful health?—That would come under the present Employers' Liability Act.

10,991. (*Mr. Sutherland.*) No?—Would it not?

10,992. (*Chairman.*) In the pottery industry the certifying surgeon has the power to suspend a man up to three months, because in the certifying surgeon's opinion the man may be likely to contract lead poisoning, and the employers have agreed for a period of three months to pay half wages. Would you agree to anything similar?—One would agree to any of these things, because, as I say, they are covered by insurance, and the customer has to pay, so it does not much matter.

10,993. Do you think that the cost of these regulations would be very excessive?—I should think they would be. They would add to the present burdens.

10,994. That would mean appreciably extra cost to the public?—Undoubtedly.

10,995. Now supposing that lead were prohibited, would that mean that the substitute would cost more than the lead paint?—Yes, for outside work.

10,996. And the public would have to pay more in that case too?—Yes.

10,997. So that it is a choice between two evils, the public being the carriers of the burden in each case?—Yes.

10,998. Does it matter which of the two burdens he has to carry—the burden of extra cost in administrative matters or the extra cost of the substitute?—I think that it comes to the same thing in the end. I think it would mean prohibition each way. Those administrative proposals would be so impossible to carry out that it would simply mean not using lead at all.

10,999. Do you think that on the whole it would be better to prohibit the use of lead than have the regulations?—I do not think that either is necessary.

11,000. I know, but of the two what would you say?—But I cannot admit it.

11,001. Will you put yourself in the position of the Home Office, with Parliament looking on anxious to protect the workpeople in this industry where the incidence of lead poisoning is terrible—I will not say in Scotland?—I cannot answer that. I cannot put myself in the position of the Home Office there. It seems to me an impossible position.

11,002. You can put yourself in the position of realising that this Committee is sitting for a specific purpose, and trying to produce a remedy for an admitted evil. I ask you whether, taking the figures to be correct, you do not think that Parliament has to do one or the other—either make rules to prevent the evil or prohibit the use of lead?—The rules are impossible to carry out.

11,003. So you mean to say that the employers would have no option but to go in for prohibition?—That is all. There is no other option to my mind under those conditions.

11,004. (*Dr. Collis.*) With reference to the point which you have made, that you consider that there is no lead poisoning worth considering in Scotland, would it astonish you to hear that a great many of the English employers who have given evidence before this Committee have said that they have no knowledge whatever of the occurrence of lead poisoning in the trade in England?—I would not be surprised to hear that.

11,005. Notwithstanding the figures that we know, of deaths sent to us by the Registrar-General which have occurred in England?—Well, I cannot understand those figures. As I say, they puzzle me altogether. I cannot understand them under ordinary conditions. They seem to me to require some explanation.

11,006. You understand that each one of these cases of death is a case upon which an inquest has been held, and the cause of death more closely inquired into than any other cause of death except deaths from accident, which the Registrar-General has knowledge of? So that it is very difficult to throw any doubt upon the cause of death in these cases?—I cannot understand how it is possible that under ordinary conditions of painting work there should be so many deaths.

11,007. That is a matter for us to inquire into, how it is possible; but the fact remains that these deaths have occurred, that is to say deaths the cause of which in every case has been carefully inquired into, because it is part of the law that an inquest is held upon any case of poisoning. I would suggest to you that the English employers who have given evidence here seem to be equally ignorant with yourself as regards the occurrence of lead poisoning in their trade among their workmen?—I cannot account for it either way.

11,008. The population of Scotland, I think, is only about one-eighth of that of England, is it not?—I could not say the exact figures just now, but I will take your statement for that.

26 July 1911.]

Mr. W. F. DOBIE.

[Continued.]

11,009. If there have been 983 deaths in England and Wales in 10 years there would be only one-eighth of that—about 45 deaths—in that same 10 years in Scotland if the incidence was the same. That only gives between four and five deaths per year, which, since the numbers themselves are few, might lead to the fact that it had not come to your attention?—It is quite possible.

11,010. So that the incidence in Scotland may possibly—I do not say it is—be equally as great as that in England?—That is quite possible.

11,011. Certain other illnesses, besides lead poisoning as such, are associated with the influence of lead. Would you allow that if those illnesses are present in excess in any community, that would be some evidence that the influence of lead is present in that community? What I mean is this: We find on examining statistics of deaths of people exposed to lead that there is an excess (apart from the deaths from lead) of deaths from Bright's disease and from consumption?—Is that caused by the lead?

11,012. The conclusion is, as it is associated with this class of employment, that there is some relation between the two?—Of course, I must accept that, as a statement.

11,013. When we come to examine the deaths among the Scottish Society of Painters, we find that the number of deaths from Bright's disease is higher than normal, and that consumption is decidedly higher than normal, and that the calculated figures of deaths which have occurred in the society are very close to those given by the Registrar-General of England and Wales for plumbers, painters and glaziers. The conclusion, then, which we seem to be justified in drawing is, that both classes, being exposed to the same influence and showing the same excess of deaths from certain causes, are being affected in the same way by lead?—But how can glaziers be affected by lead?

11,014. It happens that the Registrar-General gives them as a class all together. He does not separate them for England and Wales. He puts plumbers, painters and glaziers all together, so you have to take his figures unseparated. That is the point. I quite agree with you that, with regard to glaziers, they are a minor quantity of the whole number. I am only drawing your attention to the logical conclusion—or rather what seems to us to be the logical conclusion we must draw from these figures—that in Scotland the influence of lead in painting is not different from its effects with regard to England and Wales?—You speak of Bright's disease. I have no recollection of any workmen of mine ever being affected with Bright's disease, for instance. I must not say that it has not been so, but I have no knowledge of it; and I come very much in contact with the men when they are ill. I always hear about their illness, and I try where I can to assist them in any illnesses they have. So I do not think it is possible that I should not know. I usually know what is the matter with any of my men when they are away ill.

11,015. The statement which I read is made on an analysis of 305 deaths which occurred in the Scottish Society of House and Ship Painters in the course of ten years. The figures are small, I will allow, but for what they are worth they point in the same direction as those we have had for England?—I got my foreman to enquire at a society that he was connected with—the Shepherds. It is a friendly society. They say that they have only had two cases of painter's colic in 15 years, and those were not fatal cases but illnesses. They have had to pay for illness for only two painters in 15 years, and there are 30 painters in the society.

11,016. That gives a certain incidence even then. You do not know, I presume, the ages of those 30, or how long they had been exposed to this in their trade?—They would be all ages.

11,017. It makes a considerable difference whether a man has been a long time in the trade or newly exposed?—It is a very old society. There must be men of all ages.

11,018. That gives us two cases in 450 members per year. That is a definite attack rate. It is low in a sense, but still it is 44 per cent. even on those

figures. So they are not so small as they first appear, when you begin to work them out as the attack rate. In the Potteries the attack rate is about 1.4. So that even your figures give an appreciable attack rate, although it may not to you at first sight seem great. I only wish to bring your attention to these points. So that it is possible that the influence of lead in producing illness may be going forward in Scotland to an extent that has not been at present disclosed?—That might be possible.

11,019. (Mr. Parsonage.) You say that painters usually use chamois skins to wipe their hands with?—Yes.

11,020. Those are the skins you send on the job for washing the paint with?—For all washing purposes.

11,021. They get a lot of lead in those from rubbing down with pumice stone and water and then drying the door off with the skins. Nothing carries dirt or keeps dirt more in it than a chamois leather does?—They are always washed thoroughly.

11,022. It is about the most dangerous thing they could use, I should think?—After the use of soap and water?

11,023. Yes. Do you consider painting a healthy occupation?—Yes.

11,024. Will you tell me why it is that the Hearts of Oak, one of the largest friendly societies in the country, refuses to take house painters in?—I did not know that. I am very much surprised to hear it.

11,025. It is a fact. That is a peculiar thing, is it not?—Very peculiar.

11,026. If a man wanted to get into the Hearts of Oak—a painter—he would go in under another occupation. Many go in as paper-hangers?—But a house painter and a paper-hanger are the same.

11,027. He would call himself a paper-hanger. They do not know the difference. We know it, but they do not?—I am surprised to hear that.

11,028. That was the fact. I do not say that it is so now?—I can understand the painter's business being an unhealthy one under certain conditions. Take a ship painter painting such a vessel as the "Lusitania" or "Mauretania," where there are hundreds of small state rooms, and ceilings and walls are all painted together in a confined atmosphere for days and days and perhaps weeks at a time. That I can understand would be unhealthy; but the ordinary conditions of a house-painter's work, where he is doing either colouring of a ceiling or a cornice, or putting papers on the walls or painting woodwork, are not unhealthy. Besides that, the rooms are, as a rule, well-ventilated and airy apartments, and the conditions under which the men work (I am speaking for my own business, I admit) are essentially healthy.

11,029. (Mr. Gardner.) If painting in a state room on board a vessel with white lead paint is dangerous, what sort of space would you require to work in for it to cease to be dangerous?—It is more the confined nature of the space they are working in, and the want of ventilation and fresh air that are the trouble. We know perfectly well that the fumes of turpentine, and the fumes of varnish even more so, where there is absolutely no lead, and the fumes of enamel, which is made of zinc and gum, cause headache and that sort of thing in a confined area. There is no lead in it, and yet nothing affects the atmosphere more than varnish does. In our own place I see a lot of varnish being used, and I feel the effect of it in a headache way, and there is no lead in varnish whatever.

11,030. (Mr. Sutherland.) There is a small quantity in varnish, but it is infinitesimal in the boiled oil that they use for varnish?—They use manganese driers entirely now.

11,031. Litharge?—They do not have lead.

11,032. Have you tried any leadless paints?—I have used zinc paint very freely.

11,033. What is your experience of it?—It is an excellent paint. I have usually used it with a preparatory coat or coats of lead. I have finished with zinc. But there is this difficulty—that you cannot produce a flat paint with zinc. It is impossible to get a zinc paint flat. The nearest you can get to it is

U 2

26 July 1911.]

Mr. W. F. DOBIE.

[Continued.]

what you know as an egg-shell gloss. You cannot get a dead flat.

11,034. Have you used Lithopone?—No.

11,035. Charlton white is Lithopone?—Yes, I have used that.

11,036. (*Chairman.*) Are you aware that the Office of Works have introduced a formula for painting both for inside and outside work, which they tell us is highly satisfactory after a trial of four years?—That depends upon what their standard of satisfaction is.

11,037. They paint all kinds of buildings from Buckingham Palace to, let us say, a labour exchange. Would not that influence you in your statement that leadless paints are not efficacious?—You can get a perfectly pure white effect with leadless paint, but I think it is necessary to have a foundation of lead to start with.

11,038-9. But would not you say that what is good enough for Buckingham Palace is good enough for any of His Majesty's humble subjects?—You would think so, but I know I have seen painting at Windsor Castle that I would not like to see turned out of my establishment. I do not know Buckingham Palace.

11,040. You believe that you get better work, as workmanship, with white lead?—With the combination.

11,041. But with lead?—Yes, with lead and zinc. I like to finish with zinc paint very much indeed, and for certain purposes it is exceedingly satisfactory, more especially where it used with enamel, because it is so white and keeps its colour.

11,042. Do you think that you could not get as good work if white lead were abolished?—I think not. I am certain you could get no dead flat surface. The reason is this: that to make zinc to a suitable consistency for working you have to add so much oil to it. As you know, the more oil you add the more gloss there is, and the more turpentine you add the flatter the paint is. With lead you can add a sufficient amount of turpentine to get a dead flat surface.

11,043. (*Mr. Parsonage.*) Could not you substitute varnish for the oil and so get the flat?—The varnish makes it glossy.

11,044. Yes, but it would harden the paint and answer the purpose if you took a smaller quantity of varnish compared with oil, and you could use more turpentine?—But there are certain decorative effects, if you want to produce that dead flat, which you could not get in that way.

11,045. (*Mr. Sutherland.*) Have you had any experience with zinc paint for exterior work?—Different kinds of reds and greens and oxides, but I do not think that anything is so good as lead for the purpose, if mixed with good oil. That is a very important point. You get an india-rubbery elasticity that makes a skin. In enquiries that I have been making, my foreman was telling me (I do not know whether this is admissible, because it is second-hand information and not my own knowledge) that, at a job he was working on, they were doing some outside work with white lead and they got instructions to do some more outside work of the same character. Their white lead was finished and they used zinc white for the remainder of it, and when he went back to that job some years afterwards he found that the lead paint had stood very much better than the zinc. But, personally, I have no experience of zinc paint for outside work.

11,046. You know that the technique of working with zinc paints is very distinct from that of working with lead paints?—Quite so. With lead paint you get a stringy elastic character in the lead, whereas with the zinc it is more of a globular character and shorter and does not form the fine skin.

11,047. In the use of zinc, you have to apply it much thicker than lead paint; consequently you cannot get the fine brush work?—Yes.

11,048. For situations where sulphurous acid and gases abound, and humid atmospheres, zinc paint, unless specially protected with varnish, as is done by the Office of Works, would disintegrate?—I do not know sufficient of the chemical action to say that.

11,049. The Dutch Commission, in reference to this matter, emphasises the point that in all situations like railway stations and manufacturing centres, where

there is a lot of sulphurous acid in the atmosphere and humidity, lead is very much better than zinc?—The humidity I can understand—the moisture—but I could not speak of the action of chemicals.

11,050. That was demonstrated. Now with reference to the ignorance of employers in regard to the ravages of white lead, roughly the number of deaths represents one in 9,000 of the employes taking the employes as 250,000 right throughout the Kingdom. Twenty-eight deaths per annum represent one in 9,000 employes, so you are not surprised that a great many employers are ignorant of the seriousness of the mortality due to lead poisoning?—No.

11,051. As the Chairman said, our members came up with very much the same experience as your own. Large numbers of them in a long experience had not had any cases in their own shops. Now, do you think it possible to dispense with dry rubbing down with sand-paper?—Not to make a good job. You can dispense with it, but it is at the sacrifice of the quality of the work.

11,052. There is one of the most important of the evils, so far as we know. Would it seriously affect the quality of the work? Do you think that if dry rubbing down were abolished, the master painters could not find some other way of meeting the case and getting up a nice surface?—I do not know. I do not think there is any possibility of getting the fine surface necessary previous to enamelling or varnishing or flattening without dry rubbing down.

11,053. In most cases of dry rubbing down with sand-paper, you do not rub down to cut the surface?—No.

11,054. You take the superfluous nibs off?—Yes, the rough top and any brush marks there may be.

11,055. In normal cases you do not get much dust from that?—No, I do not think so. As I say, the paint is scarcely hard, and therefore clings to the sand-paper, and does not come off in dust.

11,056. (*Mr. Parsonage.*) If it clogged the sand-paper, you would say, "It is not hard enough to do yet." You would allow it to stand over until the following day?—It might be too soft. There is a state in which you can sand-paper where it is not hard enough for pumice stone.

11,057. (*Mr. Sutherland.*) That is common experience in rubbing down, is it not?—Yes.

11,058. Overalls are used by employes now without any sense of injustice on their part?—Every painter in my employ, man and boy, wears overalls.

11,059. And in every good shop it is the same?—In every good shop it is the same.

11,060. If it were the law, do you think that your customers would respond, and give your workpeople separate rooms where they could have their meals and hang their coats?—It would be very difficult in many cases, but it would be possible. The customers would be obliged to do it. They would complain very much, as they do sometimes if the men want to go into the kitchen to boil their tins with their food. If he finds them walking in the garden at the meal hour the customer grumbles. He is very inconsiderate sometimes, and often forces men to do things that we do not approve of.

11,061. If there were a law established to meet the case of this excessive death and sickness, do not you think that the public would realise their responsibility in that respect?—They would have to.

11,062. (*Chairman.*) What do you mean by "they would have to"?—They would have to give facilities for a separate room.

11,063. It is not proposed to issue special rules for the public?—If we were doing a drawing-room in a house, there would be a table in the centre of the room where the men would keep their paints and materials. We would say to the customer: "You must give us another room in the house for our men to take their food in," and they would have to do it.

11,064. Apropos of your answer to Mr. Sutherland with regard to the use of zinc paints for producing flat work, we have been told that zinc paints in oil can be treated in such a way as to cause the oil to float. The

26 July 1911.]

Mr. W. F. DOBIE.

[Continued.]

oil is poured off, and turpentine and gold size added. The resulting paint, in the opinion of the witness I am speaking of, was quite satisfactory for flat painting. Have you tried that?—No, I would not imagine that it would be so, because you would not have the adhesive quality with the turpentine, and if you add the gold size you bring back the glossy nature again.

11,065. (Mr. Sutherland.) If the prohibition of white lead included other compounds of lead, it would carry with it all yellow chromes and reds?—Yes, and that will lead to more adulteration than we have at present. They try to make out just now that barytes is a good basis for striking colours on. I for one always demand them to strike them on lead. It will make a grand excuse for adulteration.

The witness withdrew.

Mr. E. GUEST examined.

11,069. (Chairman.) Do you attend to-day as a representative of the Association of Master House Painters in Scotland?—I do.

11,070. What is the nature of your business, and where is it carried on?—House painting business, exclusively carried on at 1191, Argyll Street, Glasgow, and 3, Kensington Terrace, Ibrox.

11,071. What is the average yearly number of painters employed by your firm?—About 30.

11,072. How long have you been in the painting trade?—Thirty-seven years in the trade altogether. I was a trained apprentice for six years.

11,073. Have you known any cases of lead poisoning or painters' colic?—No.

11,074. Have your men had occasional days of sickness possibly due to lead?—Not as far as I am aware of.

11,075. Do you have periodical medical examination of your men?—No.

11,076. If you have no such examination by a doctor, is it not possible that some of the men may be suffering from the slower and more insidious forms of lead poisoning, without your knowledge?—That is quite possible, but we have always taken very great interest in our men. If they are off a day we usually ask the reason, and we have never had the slightest indication of such trouble.

11,077. You know, I presume, that lead poisoning frequently undermines the health, without immediate violent symptoms arising?—I have been told that, but I have had no experience.

11,078. The incidence of lead poisoning is published month by month by the Board of Trade; do you see the "Labour Gazette" issued by them?—Yes.

11,079. Have you noted that 284 deaths of painters have been definitely certified as lead poisoning in the last ten years?—I have, and I have always been very much surprised because of the entire absence of information on that point myself.

11,080. Do you know that in every case a post-mortem examination has been made by independent doctors, and that their certificate says "lead poisoning"?—I do not dispute the post-mortem examination and the result, but I say this, from a knowledge of working in Ireland as well as in Scotland, that the conditions in Scotland are very different. If you got the results from Scotland, the percentage would be very much smaller than in England or Ireland.

11,081. Are you aware that the death rate in the first six months of last year shows an alarming increase?—No, I am not aware of it.

11,082. I am not surprised to hear that in your business there are no cases of lead poisoning, because in some of the potteries they have had no cases at all, and then quite unexpectedly, without any warning, a firm which has been immune has a considerable crop of cases?—There is no analogy to be drawn between the conditions of labour in a pottery and the house-painting trade in Scotland.

11,083. From the figures which I have read out to you, the gravity of the danger is seen, is it not?—If the figures are right, then I would say it is a serious condition of affairs.

x 7790

11,066. It goes further than that? It restricts the scale of colours?—Undoubtedly.

11,067. We cannot get the corresponding colours from a zinc base at all, and those that we can get have not the same staining power, and they are very costly?—I should not imagine that you can strike a lemon chrome from zinc.

11,068. You can strike a chrome, but it has no staining power. It evaporates directly. Do not you think that that would seriously restrict the decorative aspect?—It is a very serious difficulty. Up to the present time our experience has been with white work or slightly tinted off the white. It has not gone beyond that. We have not any other experience, but I can quite imagine that what you put to me may be so.

11,084. If you compare these figures with those for all lead industries under the Factory Act, in which there have been 20 deaths in the first six months of this year, and 19 in the first six months of last year, you will see that there has been an increase of one death only in this instance; but in the house-painters' trade there has been a large increase, and the deaths from lead poisoning in the house-painters' trade are more numerous than in all the other industries where lead is used?—I can only speak for Scotland.

11,085. I am speaking of the figures that we have. Are you surprised to hear what I have just quoted?—I am very much surprised indeed, so far as I know the trade in Scotland, that there should be anything like an increase, because I think the conditions in Scotland have improved considerably during the 37 years that I have been in the trade.

11,086. In addition to this the death rates from Bright's disease and nervous diseases, due to work in lead, are very high?—I suppose I must take it from you.

11,087. There are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office?—I can only say I am surprised at that condition of things. It has never been brought home to me. Some of our men have been for over 20 years in our employment.

11,088. I am sure you agree with me that all this sickness and death is deplorable?—Yes, and if preventible should be prevented.

11,089. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, I am quite aware of that, especially in France and Germany and Holland.

11,090. Do you not think it regrettable that this country should be behind other nations in this respect?—But I do not admit that we are behind.

11,091. Please remember the number of deaths I have given. There are no restrictions obtaining in the house-painting industry in this country?—If my memory serves me rightly the condition of things in France that called for legislation was very much more serious than ever it has been in this country.

11,092. I suppose you would agree that we ought to use every means in our power to protect the workmen in this country?—Yes.

11,093. Something must be done, either by regulating the work very closely, or by restricting the use of lead?—Yes, I agree that something should be done.

11,094. No doubt you realise that if the free use of lead is allowed to continue the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—Yes. I think that reasonable precautions would eliminate the evil.

11,095. Are you aware of the details of the precautionary measures which are in practice in other lead industries?—I am not familiar with them, but I have an idea.

11,096. I will give you an outline. First of all, there is the provision of overalls by the employer, who is responsible for seeing that they are regularly

U 3

26 July 1911.]

Mr. E. GUEST.

[Continued.]

washed?—That would be almost impossible in our trade, because of the casual nature of the employment, because of the men being employed at considerable distances from the workshop, and outside of the workshop, and because of the objection from the men's point of view to using overalls that have been used by other tradesmen.

11,097. Secondly, comes the provision of a meal room, care being taken that in no case whatever are any of the men allowed to take their meals in a room where lead is used?—That state of things does not exist so far as either of my establishments is concerned, and we give the men facilities for getting their food cooked.

11,098. In your own establishments?—Because of the fact that we prohibit smoking on account of the danger of fire, the men immediately go outside the premises after they have taken their food.

11,099. But where do they eat the food in your place?—We have, in both of our shops, a small apartment, apart from the general paint room, where there is a fire.

11,100. What about when they are working outside?—We have never had any difficulty whatever in getting a suitable place for our workmen outside. I have heard objections from other people.

11,101. You have been very fortunate in that respect?—Our men have been very fortunate in that respect and we have been fortunate too. I never heard of any lady or gentleman objecting to giving reasonable facilities to tradesmen.

11,102. Have you heard of any cases outside your works where men could not get a separate room?—I heard of a case where a lady objected to the men taking their food in the kitchen, but I came to the conclusion that she was not a lady or she would not have objected.

11,103. Then the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing, and where they will not collect unnecessary dust when not being worn?—You see that we are in a different position altogether from an ordinary workshop, where the work is being done continuously in the workshop. The outside job for the time being is the work room. In that matter I think an obligation might be laid upon the men to provide weekly overalls, to be under their own care and custody.

11,104. I am asking now about the provision for keeping overalls in a place where no lead is used?—It would not be a serious difficulty if the men were at the shop, but there is no work in our workshops. They work away from there.

11,105. It is a difficulty when they are away?—There is no difficulty whatever.

11,106. I do not understand your answer?—The point is: Is it desirable that the men's overalls should be kept in a separate department from the actual paint room?

11,107. Separate from the room where they are working?—I do not see any difficulty in carrying out a regulation of that kind.

11,108. Next, the provision of cloak-room facilities, so that clothing put off during working hours shall not, under any circumstances, remain in a room where lead is used?—There should be no difficulty in carrying out a regulation of that kind.

11,109. How would you ensure such a regulation being adhered to?—I would put an obligation on the men to carry it out.

11,110. How would the Home Office know whether it was carried out?—I do not see how you could carry it out.

11,111. It is impracticable?—I think it is. I do not see how you could enforce the recommendation. Some of our jobs we do not visit once a week.

11,112. Now the introduction of proper washing accommodation: one basin or other utensil to every five men?—There, again, you have difficulty. Just now I have about 60 men employed; I do not think that there would be an average of a dozen of those men coming to the shop at all for weeks, and when they do

come they are only there for a few minutes in the morning.

11,113. I quite see the difficulty. You cannot control it?—We cannot control it. I quite agree that if you could get the men to carry this out systematically it would be beneficial to them and beneficial to us too.

11,114. Then the supply of both hot and cold water, soap, nail-brushes and a sufficient number of clean towels. Could you ensure those being provided?—As a rule we always provide towels and soap.

11,115. "As a rule" would not do. I want to know whether there would be no question about their being supplied?—There would be no question about it.

11,116. How would you ensure the rule being observed?—The only rule would be that every job should be equipped with soap and towels, but how you are going to force the men to use them is quite a different matter altogether.

11,117. Then provision would have to be made for the avoidance of dust; some means would have to be devised for getting rid of any dust which the men might breathe?—The painter is only called in, you see, because there is dust. Primarily, the reason why he is called in is because a thing has got dusty and dirty.

11,118. I am referring to lead dust?—I beg your pardon. I have heard a good deal about this dry dust, and so on, but I cannot follow it in Scotland after 37 years' experience. I can follow it in Ireland.

11,119. We are dealing with the industry as a whole. I ask you what means can be devised for eliminating the dust that the men breathe?—I really do not see. It must be taken as a condition of the trade. There is other dust besides lead dust which is almost as noxious.

11,120. Do you answer that you can devise no means to get rid of the dust?—Really I could not. I wish I could.

11,121. Then the fumes in burning off, and the spray which may be breathed in certain operations. How would you deal with those?—I do not think that it would be a great hardship to abolish the burning-off lamp altogether. There is an ever increasing number of liquid substances for removing paint which seem to answer the purpose.

11,122. You are probably not aware that the attention of this Committee has been called to the existence of poisonous emanations from liquid paint?—No, I am not aware of that.

11,123. If it is the case, how would you propose to protect the workmen from the noxious vapours that arise?—Well; again I go back to saying that I have no knowledge of that.

11,124. I am not asking you what your knowledge is, but how can the workers be protected from this risk?—I do not see how it can be avoided at all. Somebody must mix the paint. It is impossible to mix it by machinery.

11,125. I am speaking now of a man who is painting a wall. We have had evidence to show that emanations arise from putting lead paint on to the wall?—Yes, oxidation takes place. Without that the paint would not dry.

11,126. That is harmful to the workman, and how would you meet the difficulty?—As long as you paint, you cannot stop it.

11,127. Then, in addition to what I have mentioned, a periodical medical examination, say once a month, would be insisted upon, at the expense of the employer. I ask you two questions on this point; first of all, whether the employers would bear such expense, and secondly, whether they could enforce such a regulation?—We could not enforce it unless you laid down the law on the matter, and made it compulsory for us to do so.

11,128. Supposing it was one of the new regulations, would you bear the expense?—Yes, willingly, if I thought it was going to effect any useful purpose.

11,129. Could you undertake to see that such a rule was carried into force? I want to know whether it would be possible for you to be certain, taking into consideration the jobs all over the country, and your men being away from you, and bearing in mind the

26 July 1911.]

Mr. E. GUEST.

[Continued.]

fact that you would be liable to a fine, and probably serious trouble, if it was not carried out, that it would be carried out?—The difficulty might be removed if the Government appointed special doctors in special districts, to whom the men could go to get a certificate. If we employed a particular individual, he might be considered to be prejudiced. Another point is that our men might be away in the country, and at a great distance from the place of examination. If the Government appointed statutory officers all over the country, who would be accessible to the men, I see no difficulty whatever.

11,130. The Government do appoint the certifying surgeons?—My point is whether they would be numerous enough to be accessible.

11,131. You see difficulty in that respect, that the men may not be near enough to the certifying surgeon, to be certified?—It might mean a very great additional expense, besides the cost of examination. You could not reasonably expect a workman to come a number of miles for examination without being paid for his time.

11,132. I see the difficulties that you refer to in that respect. Then there is the question of paying compensation to any worker withdrawn from work by the doctor's orders on account of doubtful health?—I am afraid that that would prove a great hardship to the men in this way: that whenever an employer got a certificate of doubtful health of an individual workman, he would be very likely to discontinue that man, and the man himself would find, I believe, great difficulty in getting employment. That is to say, he might be suffering from something else altogether apart from lead poisoning, which might make him more susceptible.

11,133. But putting the man's position aside for a moment, would you as an employer agree to pay compensation under such circumstances?—Yes, but I would immediately take steps to get rid of all the delicate men in my employment in my own interest.

11,134. Taking all these points into consideration, would you say that you prefer that the industry should be regulated by special rules such as I have foreshadowed, or as an alternative, that the use of lead should be prohibited?—I think that in the meantime regulations would be better for everybody concerned. I am still impressed with the infinitesimal damage that is done.

11,135. But it will not be sufficient for you to make that general statement. You have told us that most of these regulations are impossible to carry out?—Yes, but there are regulations which have been suggested that might be carried out that I believe would be beneficial.

11,136. I am not speaking of what you consider sufficient, but of what the Home Office would most assuredly insist upon if lead is allowed to be used in the future. You have said that in the majority of cases it is impossible to carry out the rules, and I say that if that is the case and the Home Office insist on those rules the alternative would be prohibition?—A modification of those rules, I think, would be a very great help.

11,137. But there would be no question of modification, I think. This Committee is sitting to deal with a very serious evil. We have to report to the Home Secretary, and the Home Secretary has to put before Parliament our Report, which must contain either a prohibition of lead or such restrictions in the way of special rules that we can be certain that the men will not be injured?—If there are two alternatives only, prohibition or those rules without any modification whatever, I would take the rules and regulations in the meantime and wait hopefully that the Home Office would give us a solution of the difficulty.

11,138. That is not sufficient. We are a body of practical men, and we have to recommend to the Home Secretary, after consultation with the employers and workpeople and the medical authorities of the country and other experts, a practical solution of the difficulty. It is no use our recommending as a practical solution regulations that you and other employers tell us cannot be carried out?—I would most respectfully suggest

that, if the Home Office make regulations, they will tell us how they are to be carried out.

11,139. But I am afraid that you do not see the seriousness of the position?—I see it and appreciate it.

11,140. We have heard of the most alarming condition of the workpeople employed in house painting. I am not saying whether it applies to Scotland or not. The mortality rate has increased in the last few months. We are sitting here as an impartial body to devise some means to meet this evil. The suggestions that I have made to you as to probable rules which the Home Office would enforce, you tell us are impracticable?—I beg your pardon. I did not say that they were all impracticable.

11,141. You have told us that it is impracticable to insist on the overalls. You have told us that it is impracticable in some cases to have a meal-room. You have told us that it is impracticable to have any device for getting rid of dust. You have told us that it is impracticable to enforce these rules?—I think my evidence was rather to the effect that I thought it was desirable that the men should have clean overalls every week.

11,142. I do not want to waste your time or the Committee's time, but I shall have to go through the whole of these rules again, I am afraid, because you have given the answer with regard to certain regulations which the Home Office would consider necessary, that you think it would be impossible to carry them out. Now, I ask you, in view of that, what are we to do? Are we to prohibit lead altogether, or are we to put forward a lot of rules which you say cannot be carried out if they are issued?—I prefer to take the regulations.

11,143. But do not you see that that is not a serious answer. You tell us in one breath that the regulations cannot be carried out?—I do not see how they can be carried out.

11,144. Then, what is the use of playing with the Committee by saying that you would rather have regulations when you say immediately after that they cannot be carried out?—I am very sorry if you think I am playing with the Committee. I am very serious, and I am speaking with long practical experience.

11,145. Would you kindly answer the question. You see my difficulty. Your evidence has to be dissected. What can we say about it? First, "Mr. Guest" has said that, if these figures are correct, the evil "must be dealt with. As a humane man," he said, "it must be combated." Then, I went on to ask: "How is it to be combated, by prohibition or regulations?" and he replied, "That the regulations could "not be enforced"—Some of them.

11,146. Some of the most important ones cannot be enforced. Then, I come to the point of what I am to say as your conclusions on this very grave question?—First of all I say that the conditions regarding England and Ireland in the painting trade are totally different from what they are in Scotland.

(Chairman.) I will not take up the Committee's time any further.

11,147. (Dr. Collis.) Could you tell us exactly how the conditions are different in Scotland from what they are in England?—I would put it rather more regarding Ireland, because I have an experience of Ireland, and only a very casual one of England. I have six years' experience of Ireland.

11,148. You have stated that there is a difference between the way in which it is carried on in England and in Scotland, so I presume that you are prepared to say what the difference is?—In England there is a very much larger proportion of flat work with turpentine than there is in Scotland. There is a great deal more oil work in Scotland than there is either in England or in Ireland.

11,149. How do you think these differences affect the health of the workpeople?—In rubbing down, with sand-paper, a flat surface done with turpentine, there would be a very much larger preponderance of dust than there could possibly be with an oil paint.

11,150. With regard to the emanation of volatile lead compounds, to which the Chairman drew your attention?—Again, there, I think, there would be a

26 July 1911.]

Mr. E. GUEST.

[Continued.]

very much larger amount of evaporation with turpentine paint than there would with oil. Then, again, in Ireland they have a lot of workmen whom they classify as whitewashers or whiteners. These men do all the whitewashing and practically all the preparatory work before painting. Now, in Scotland the painter does all the whitewashing and all the preparatory work for it, and all the preparatory work for the painting. He may be one week without doing any painting at all, and the next week he may be painting for so many days or all the week.

11,151. Your contention is not that the danger while he is occupied is less, but that he is exposed to the danger for a less period?—Yes.

11,152. (Mr. Sutherland.) Compared with Ireland you mean?—Yes, compared with Ireland.

11,153. (Dr. Collis.) The danger may be there and illness may be occurring due to the influence of lead to which your attention in Scotland is not being drawn, because it does not produce the symptoms of lead poisoning, although it may be at the same time undermining the constitution or weakening the health of the workmen?—That is quite true.

11,154. Are not we coming back rather to the same point?—It comes back to this, that we all admit that lead is of a poisonous character, and, more or less, substances are given off that are detrimental to health.

11,155. What experience have you had of the use of paints which do not contain this poisonous substance?—We have experimented and we have carried out work, and we never could get the covering properties in any of the substitutes, nor yet could we get the protective character for outside work.

11,156. How recently have you carried out these experiments?—Two or three years ago.

11,157. What substances have you used?—Charlton white and zinc white.

11,158. For interiors and exteriors?—Yes.

11,159. Do you not find it valuable for interiors?—Some people pin a good deal of faith on its non-discolouration under the fumes of gas. In one particular instance we had a very large ceiling all ready flatted for the finishing coat. It was suggested that we might try zinc white. We had to give two coats where one coat of lead would have made a suitable job, and better in every way than zinc white.

11,160. Was the zinc used in the same way as the lead?—Not the same way exactly, but by the very best method. It was steeped overnight in varnish to break up the globules, and allow it to mix. In fact, extra precautions were taken to ensure that it would be satisfactory.

11,161. We have had a good deal of evidence placed before us by people who have given time and attention to the subject of zinc and other paints which do not contain lead, and which they, for their respective purposes, have used and found as effectual, and in many cases more effectual, than paints containing lead. This evidence is not confined to what has been placed before this Committee, but is the evidence also given by experts before the Swiss inquiry into the subject. Do you not think that the opinion of these experts ought to be considered?—Certainly.

11,162. And it is possible that, if lead ceased to be used, the paint trade would find that the work done by these experts was of great value, and that they could do work as effectively as to-day?—Climatic influence has a great effect upon paint, and we find ourselves that we have sometimes to adapt ourselves to the particular climate or particular exposure of the paint. So far as Scotland is concerned, I am quite positive in my own mind that zinc white would never justify its existence against white lead. If you take France or Switzerland, they have a very much clearer atmosphere and a very much drier climate, I think.

11,163. Do not you consider the conditions, at any rate, of England are as adverse as anything that you will find in Scotland?—I do not think so.

11,164. Do not you think that the air of Scotland is as pure as the air of England?—Well it has agreed with me very well. I think there is a distinct difference in the climate of Scotland. We have a good deal of foggy, misty weather.

11,165. We are not without that in England?—No but it is quite a different fog from ours.

11,166. Take Manchester for instance?—I have been in Manchester, but even there the conditions are not quite the same.

11,167. Are the conditions better in Manchester than they are in Scotland?—I do not know. I have travelled a good bit, and I am bound to say that I think the climate of Scotland puts one of the severest tests upon paint that we can get anywhere.

11,168. I am not in a position to judge of its effect upon paint, but London is not without its reputation for fogs?—I know.

11,169. Do you think that a paint that can be successfully used here might not have some success even north of the border?—Well it might. As I say, circumstances alter cases. We have in Scotland to diagnose the case as we find it, and sometimes we find that one varnish, for instance, that will suit on one job will not suit on another.

11,170. That experience is not unique. We have had evidence given us by very large users of paint in England, for instance, the Office of Works, that for four years they have been able to do entirely without lead in their paints both for external and internal work, and are pleased with the results?—How many coats and what was the price per yard?

11,171. They say that the price was no dearer, and if anything a little less?—That has not been my experience.

11,172. Your experience is not so great as theirs?—I would not put my experience against theirs. I do not know what their experience is. I can only speak for myself.

11,173. I only wondered whether such evidence as we have had would in any way affect you in choosing between the two alternatives which have been placed before you, and whether the difficulty will be as great as you anticipate?—On that point I would like to say that we had, some years ago, two tenements of equal size. We finished the first tenement with white lead, and we kept an accurate record of the cost of the work both in material and time. We were persuaded to try Charlton white on the next tenement, and we found that both the time and the material were very much in excess of the first, and the work was not so satisfactory.

11,174. Your workmen are not so used to using the one material as the other, I presume?—There is really not much difference in that respect—not all that difference.

(Dr. Collis.) There seem to be two schools of thought on that point.

11,175. (Mr. Gardner.) With regard to the regulations, at the present time men have not reasonable facilities for taking food on their jobs away from the room in which they are painting?—I have never known any great difficulty. I have never known any great difficulty, in fact. I speak as an apprentice, as a journeyman, and as an employer for 23 years.

11,176. In a business such as yours, you do not find that the men working in a house get the use of another room to take their food or for keeping their overalls. They have to be kept where they work?—That is one of the difficulties about the overalls, but as far as the food is concerned we have never had difficulty about getting into the kitchen for food.

11,177. Have you never known food handed in when men are working at painting a bathroom?—I only speak of our experience. I would be very indignant if I knew that such a thing happened.

11,178. In an ordinary tenement, a painter has only access to one room to keep his material and food and clothing. Regulations would require another room, and that is a difficulty, is it not?—The usual practice, so far as tenements are concerned, is that they give you a house for a workshop.

11,179. One room?—No; it is a house.

11,180. Not always. I do not suppose that a great many employers supply towels and soap to the men for washing?—I can only speak for myself. I am very anxious to see that regulation. I spoke to a man last week about not keeping himself clean.

26 July 1911.]

Mr. E. GUEST.

[Continued.]

11,181. As a general rule, what do you say?—As a general rule, in Scotland, the men are exceptionally tidy and clean.

11,182. With regard to your experience of non-lead paints, I admit that Charlton white may be a very unsatisfactory material to work with, but do not you think that if the employers were to experiment a little with some of the other compounds and treat them away from white lead altogether, they would get better results than they have got?—I am not at all prejudiced in favour of white lead. I would like to see it abolished, but I can only speak from experience.

11,183. (*Mr. Parsonage.*) Why would you like to see it abolished?—Because of this incipient danger.

11,184. But you do not know of that danger, you say?—I said I never knew any of the men to suffer.

11,185. But you accept the evidence?—Yes. If we could get anything like a substitute we should be delighted, but those we have tried have not the covering power, and a number of them are the very opposite from white lead, as you know. The more you work with white lead the finer the surface, but the more you work with some of these substitutes the more corded and rough the surface gets.

The witness withdrew.

Colonel R. J. BENNETT examined.

11,190. (*Chairman.*) Do you attend to-day as a representative of the Association of Master House Painters in Scotland?—Yes.

11,191. What is the nature of your business and where is it carried on?—Painters and decorators, at 50, Garden Street, Glasgow, and Wellington Chambers, Ayr.

11,192. What is the average yearly number of painters employed by your firm?—About 150.

11,193. How long have you been in the painting trade?—Over 50 years.

11,194. Have you known any cases of lead poisoning or painter's colic?—Not in our establishment.

11,195. Have your men had occasional days of sickness possibly due to lead?—No, not that I know of.

11,196. Do you have a periodical medical examination of your men?—No.

11,197. Is it not possible that some of them may be suffering from the slower and more insidious forms of lead poisoning without your knowledge?—That is so.

11,198. You know, I presume, that lead poisoning frequently undermines the health without immediate violent symptoms arising?—I believe so, but I have no experience of it.

11,199. Do you ever read the "Board of Trade Labour Gazette"?—Occasionally.

11,200. Have you noted that 284 deaths of painters have been definitely certified as due to "lead-poisoning" in the last 10 years?—No, I have not.

11,201. Or that the death rate during the first six months of this year has increased to a very appreciable extent?—I have not noticed that.

11,202. You say you have had no cases in your own works?—No.

11,203. I am not surprised to hear that, because in some of the potteries they have had no cases at all, and then quite unexpectedly, without any warning, a firm which has been immune has a crop of cases. Are you aware that the cases of lead poisoning in the house painting trade are more numerous than in all the other industries where lead is used?—No.

11,204. Are you surprised to hear that?—I am.

11,205. In addition to this, the death rates from Bright's disease and nervous diseases due to work in lead are very high?—I have no experience of that.

11,206. And there are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office?—I am surprised to hear it.

11,207. I am sure you agree with me that all this sickness and death is very deplorable?—Very.

11,186. (*Mr. Sutherland.*) I take it that, if regulations were decided upon, the muster painters in Scotland would enforce them. The obligation would be upon them?—I am quite certain that you would get the loyal support of the Associated Masters of Scotland.

11,187. I did not quite catch what you said to Mr. Gardner. You were saying something about the reediness of zinc paints. Do not you think that the substitution of zinc paints for lead paints would deteriorate the quality of the workmanship amongst painters?—Undoubtedly. My experience of those substitutes is that the quicker you can get over the ground the better. If you lay on the paint at once with one brushing, it is far better than going back two or three times.

11,188. Putting it on thickly you mean?—Yes, and because of its transparency or want of body you have to put it on very much thicker. It forms into a skin, and would eventually result, I daresay, in a great deal more dry scraping than you have just now.

11,189. That is a remote contingency, and would not come on for some years after, but it is a contingency which, as practical painters, you have to look to?—Yes, and it would be very much more liable to blistering, I think.

11,208. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I have heard so.

11,209. That the use of white lead has been prohibited to an appreciable extent abroad?—I have heard so in France.

11,210. Do you not think it regrettable that this country should be behind others in this respect?—Certainly, if it were so.

11,211. And that something should be done either by regulating the work very closely or by restricting the use of lead?—I think by regulation.

11,212. Have you had any personal experience with paints which contain no lead or very little lead?—Yes, of zinc white.

11,213. What period would that experience cover?—Perhaps 15 years.

11,214. When did you make your last experiments with leadless paint?—Two years ago, but not alone. It was mixed with lead—50 per cent. of lead.

11,215. Have you ever used any leadless paints in their entirety?—Duresco and various others.

11,216. Duresco is a water paint?—It is a water paint.

11,217. Have you used ordinary oil paints which are leadless?—I have used them for outside railings.

11,218. Have you found them satisfactory?—No, they have not been satisfactory.

11,219. Are you aware that the Office of Works and others have told us that they have used leadless paints with entire success for some years past?—No, I have not heard so.

11,220. Would that affect your opinion as to the suitability of leadless paints?—If I inspected the work, I could tell you. I would require to see it.

11,221. No doubt you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—I believe that that would be necessary in England, but I do not think it would in Scotland.

11,222. Do you think you could differentiate between England and Scotland in this respect?—Yes.

11,223. Do you think that the employers of labour in England would welcome that innovation?—I do not think so.

11,224. Do you think it is practicable? Do you think, as a business man, it would be a practicable thing to do?—The result would be that the Scotsman would do all the work in England.

26 July 1911.]

Colonel R. J. BENNETT.

[Continued.]

11,225. Now, are you aware of the details of the precautionary measures which obtain in other industries?—No.

11,226. First of all, there is the provision of overalls by the employer, who is responsible for seeing that they are properly and regularly washed. Would you, as an employer, agree to that?—As a matter of fact the men do that now. My own workmen do it.

11,227. Would you agree, as an employer, to provide overalls and see that they are properly washed?—I think not. That would be a matter entirely for the workmen.

11,228. Would you guarantee that provision should be made for a meal-room, so that in no case whatever could any of the men take their meals in a room where lead is used?—I cannot say that, for this reason: that every new house we go to is a new workshop, and we are not there, you see. In 90 per cent. of these houses that we go to provision is made in some part of the house for the men to have their meals.

11,229. Would you agree to the provision of a proper place to keep the overalls, where they will not contaminate food or out-door clothing, and where they will not collect unnecessary dust when not being worn?—I could not agree to that because of the exigencies of the trade. It is scattered from John o' Groats' down to Exeter.

11,230. Next, could you provide cloak-room facilities so that clothing put off during working hours shall not under any circumstances remain in a room where lead is used?—I could not say so.

11,231. Would you agree to introduce proper washing accommodation—one basin or other utensil to every five men?—That is already done in my shop.

11,232. But with regard to outside work I mean?—Outside, they always have water in the house.

11,233. Would you agree that they should have one basin or other utensil for every five men?—They have far more than that now.

11,234. And a supply of hot and cold water?—Sometimes we are prohibited from using fires in a house. People do not want us to, so I could not undertake to supply hot water.

11,235. Would you agree to the supply of soap, nail-brushes, and a sufficient number of clean towels?—That is a matter for the workman. Most of my men carry them.

11,236. But could you, as an employer, obey a regulation of the Home Office to that effect?—Certainly, if it was a regulation.

11,237. Then provision would have to be made for the avoidance of dust; some means would have to be devised for getting rid of any lead dust which the men might breathe. Would you agree to that?—I do not see that there is much lead dust.

11,238. Is it practicable to provide means for the removal of dust from sand-papering?—Only by the ventilation of the room.

11,239. By exhaust draught?—Opening the window.

11,240. That would not do, because you might get a contrary wind that would blow the dust in the men's faces. Could any means be derived for local exhaust draught to carry away the dust which the men generate in the course of their work?—It would add considerable expense, which the customer would have to pay.

11,241. But would it be possible, say, in sand-papering this wall, to provide any apparatus by which the dust could be carried away?—In 99 per cent. of cases you do not do that to the wall.

11,242. But would it be possible, in sand-papering this wall, to provide any apparatus by which the dust could be carried away?—There is nothing but the opening of the windows. If there is a regulation, perhaps something will be found.

11,243. At the moment you cannot suggest anything?—No.

11,244. Do you think it is possible to deal with the dust in the way that I have suggested?—Yes, at considerable expense, which the customer would have to pay. This seems to be the crux of the whole matter, and in Scotland, where we do as fine work as any part

of the country, we do not experience this which seems so fatal in London. Regulate the trade so that no one who has not served his apprenticeship to the trade will be allowed to work at it and you will, if not cure, at least considerably lessen the evil.

11,245. Now, there are a certain amount of fumes in burning off and spray which may be breathed in certain operations. How would you get rid of those?—I have no experience of that. In 99 cases out of a 100 we use a liquid for burning off. Ammonia will burn off quicker than any lamp.

11,246. You are probably not aware that the attention of this Committee has been called to the existence of poisonous emanations from liquid paint?—I know that by your asking me here.

11,247. Can you suggest any means by which those noxious vapours could be removed from the workmen?—Yes, by making a regulation to do away with the burning off; but again I say, in the hands of trained workmen there is no fear.

11,248. I am speaking now of the ordinary painting of a wall. There are certain vapours which arise from the actual painting operation, and I want to know whether you can suggest any way by which the workmen would not come into contact with those vapours?—No, not at the moment.

11,249. Do you think it would be possible to obviate this danger by any form of rule?—It might. Every day we are bringing out inventions for other things, and if a few minds were giving attention to it it might be done.

11,250. I suppose it would be rather an expensive operation?—Clearly.

11,251. In addition to this a periodical medical examination, say, once a month, would be insisted upon at the expense of the employer. Would you object to that?—I think the men would.

11,252. But would you object?—I do not see why we should pay. If we did, we should add it to our bills.

11,253. A further expense to the British public?—Yes, which they object to. They think the painter's bill is high enough already.

11,254. Then there is the question of the payment of compensation to any worker withdrawn from work by the doctor's orders on account of doubtful health. Would you agree to pay that?—We are insured and the insurance companies would pay that.

11,255. But it would be another charge on the employer?—Certainly.

11,256. (Mr. Sutherland.) It would not be covered by your present policy?—If we had to pay more, we should have to charge more. At present we think we pay plenty and we never have had a case.

11,257. (Chairman.) I have given you very briefly a few regulations which the Home Office would probably enforce if they continue to allow the use of lead. In reply to those suggestions I have made, you have told me that many of them could only be carried out at very great expense?—Yes.

11,258. Would it be possible to enforce such regulations? How could you enforce such regulations amongst your own men? How could you be quite sure that the rules were observed?—That would be a difficulty. We have, say, at the present moment 60 workshops. It is not as if the men were all in one place like men at a mill or soldiers in a barrack yard. Our work is so scattered through the country that we have not control except by the foreman in charge.

11,259. Is it not practically impossible to enforce such a set of regulations?—I do not know that it is quite impossible, but it would certainly take some education. It might take a few years.

11,260. Now, taking all these points into consideration, would you say that you prefer that the industry should be regulated by special rules such as I have foreshadowed, or, as an alternative, that the use of lead should be prohibited?—Regulation by special rules, certainly. You cannot do away with white or red lead so long as the Admiralty insist on its use in all these specifications.

11,261. Are you quite sure that these rules could all be observed; for instance, on the question of

26 July 1911.]

Colonel R. J. BENNETT.

[Continued.]

removing the dust?—I have told you that they might be observed at great expense, which the customer would have to pay.

11,262. Now, what is the objection to using leadless paints?—I have had no experience of them, except mixed.

11,263. If lead was prohibited, what harm would ensue to the trade?—In a very short time it would disappear, I should think.

11,264. I have told you that the Office of Works have used leadless paints for the last four years to their entire satisfaction. Why should not that system of painting be universal throughout the country? Against that, I would tell you that I washed a ceiling a few weeks ago that my father painted in 1847, and the ceiling and cornice were as fine as the day they were painted.

11,265. But I want you to realise, if you kindly will, that we are sitting here to deal with a very serious evil?—That is so.

11,266. And we have to recommend to the Home Office some means by which this evil can be combated. Now, I want to know how we are to combat this very serious evil. You told us that the question of removing dust is very nearly impracticable. Most of the other witnesses have said that it is impossible. You say you think that it might be done in some years?—Yes.

11,267. Now, what are we to recommend the Home Office to do with regard to this evil? None of you gentlemen, if I may say so, have brought forward any possible solution of this very great evil. Now we must do either one of two things: we must either recommend the prohibition of the use of lead in the future, or we must say that the employers have come forward and have made certain suggestions, taking the processes seriatim, by which, in our opinion, the evils can be removed. You have made no suggestions?—Where there is electric light in a house you could apply a fan by putting in a plug.

11,268. But where there is no electric light, what would you do?—We would have a difficulty which would have to be overcome by some invention such as could be carried about.

11,269. Do you think it would be practicable for us as a Committee to say to the Home Secretary, "Lead should be used as before. The employers are going to think over inventing some means by which the evil can be removed"? Do you think the Home Secretary would accept that or that Parliament would accept it?—I think not.

11,270. Then what are we to do? I ask you as a business man and a humane gentleman to deal with this very serious problem?—It certainly seems a very serious evil, but after 50 years' experience, we have not it, in Scotland.

11,271. I am not talking about your experience, but about the cases of lead poisoning presented to us by the Registrar-General. Is there any practical suggestion but prohibition?—I would much rather have regulations.

11,272. But if it is impossible to introduce regulations to remove the evil, have we any alternative as a Committee than to recommend prohibition?—That is a matter for the Committee to consider. I could not take it on myself to say. I would say regulation instead of prohibition.

11,273. You would not be surprised, I suppose, if under the circumstances, we did recommend prohibition of the use of lead?—They would certainly be surprised in Scotland.

11,274. I wish I could get you to focus your mind on the situation as it is presented to us here. We have to deal with this evil; none of the employers representing either England or Scotland have brought any practical suggestions before us which can remove the evils which undoubtedly exist, and I ask you what are we to do under the circumstances? Is there any other alternative but prohibition? You have admitted that if we presented a report to Parliament with no recommendations it would not satisfy either the Home Office or Parliament. Then is there any other

alternative but prohibition?—It is a very serious matter.

11,275. You do not like to commit yourself?—No, I cannot commit myself.

11,276. But you have nothing to recommend with regard to removing the evil?—No, I have no experience. I don't admit the evil if you confine the business to trained and efficient workmen.

11,277. (Dr. Collis.) You consider, I understand, that if the regulations which have been suggested could be carried out, they could only be carried out at considerable expense?—That is so.

11,278. Which expense would fall on the public?—That is so.

11,279. Do you not think it likely, considering the extra expense that having a house painted with lead paint would throw upon them, people would themselves promptly and immediately stop asking for lead and choose what would then be much cheaper, lead substitutes like zinc?—I have no experience of the substitutes at the moment.

11,280. But I am speaking of the public. Do you not think that the public would then choose a cheaper way of having their houses and places decorated and painted?—We are doing that to a large extent at the moment. Over 30 per cent. of the ceilings, walls, and cornices now are being done with water paint—Duresco, and so on.

11,281. When it was found that the price of oil paints containing lead was rising still higher and higher, do you not think that the public would then cease to ask for them or to have them used?—Yes. At the present moment it is not cheaper to use these other materials.

11,282. You have already suggested that, if the regulations came into force and were practicable, that would add very considerably to the amount of money that the public would have to pay?—Yes.

11,283. That would make the use of lead paints more expensive?—Yes.

11,284. Do you not then think that the public would cease to ask for lead paint and use the substitutes?—It might be so.

11,285. Then what is the good of drawing up regulations?—I am thinking of the public. They would require their premises done three times or four times for the once that they have them done now, and everybody is glad to get painters out of the house. They are glad to see the men, but as glad to get them out.

11,286. But your statement is not in accordance with those given to us by the experts, who have given many years to studying paints which do not contain lead?—Well, I have no experience.

11,287. If their suggestion is correct, the durability and permanence of zinc paints is closely to be compared with the durability and permanence of paint containing lead, and the expense of applying lead paints when such regulations as you have thought might be introduced were applied, would be so much greater that surely the public would promptly cease to ask for or allow lead paints to be applied?—But I have said, or tried to say, that these paints are only of value when they have 50 per cent. of lead in them. Zinc paint is of no earthly use itself.

11,288. The evidence placed before this Committee is diametrically opposed?—Diametrically opposed to my own experience?

(Dr. Collis.) Yes.

11,289. (Mr. Sutherland.) Your preference for lead is not only for its permanence but for the quality of the work which you can do with it?—Yes.

11,290. Your particular work and that of most of the gentlemen who have been before us here is marked by a high quality of workmanship, and you are of opinion that you could not get such work, which also implies permanence, with zinc paints?—I think not.

11,291. And you think that the public would prefer the cost of the regulations being added to the cost of the work done with lead paint to having an inferior article like zinc paint?—That is so, and it would save the trouble of having the house turned out half a dozen times instead of once in ten years.

26 July 1911.]

Colonel R. J. BENNETT.

[Continued.]

11,292. (Chairman.) Half a dozen? Your estimate has gone up. You said just now three or four times as much painting would be required with zinc as compared with lead. Is not that rather an extravagant estimate?—Then say three or four times.

11,293. (Mr. Sutherland.) Do not you think that, if the regulations are enforced, you could make the foremen of your different jobs responsible for seeing them carried out?—Clearly, just as they would have to be responsible for any other part of the work.

11,294. In ordinary sand-papering there is not much dust?—Very little.

11,295. In sand-papering a wall like this between the coats, the dust would hardly be appreciable?—Yes.

11,296. It is just to take off the extreme top surface?—Yes. As a matter of fact walls like this or ceilings would not be sand-papered.

11,297. The rubbing down concentrates on the wood-work where there is going to be a fine finish?—Yes.

11,298. Could not that be done by the wet process, by ground pumice and water?—It is done in many cases, but you cannot do it where work is hurried. You want time to do it. The paint must harden. Time is a factor. But it could be done.

11,299. Two or three gentlemen have told us to-day that in Scotland you put less turps and more oil in the

paint. Do you think having more oil reduces the risk from dust?—Undoubtedly.

11,300. You think that the public and the trade would gain by these regulations rather than by the abolition of lead?—Yes.

11,301. In quality of work and permanence?—Yes.

11,302. (Chairman.) Do you think, taking into account the fact that you find it extremely difficult at this moment to make any suggestions about the removal of dust, and so on, that the regulations would be as beneficial to the men as the prohibition of lead?—I think so.

11,303. Do not say that without thinking over it. This evil exists and the figures are appalling, and you can make no recommendation for removing some of the great evils. I ask you whether you think regulations would be as beneficial to the men as the prohibition of lead?—I think that the public would suffer.

11,304. But do you think that it would be as beneficial to the men to have regulations which you say you cannot enforce, or some of which you cannot enforce, as it would be to have prohibition? You admit that you cannot think of any means of combating the evil?—No.

The witness withdrew.

Mr. R. L. ANDERSON examined.

11,305. (Chairman.) Do you attend to-day as a representative of the Association of Master House Painters in Scotland?—I do.

11,306. What is the nature of your business, and where is it carried on?—House painting and decorating, in St. Vincent Street, Glasgow.

11,307. What is the average yearly number of painters employed by your firm?—The average number is 30 to 40.

11,308. How long have you been in the painting trade?—33 years.

11,309. Have you known any cases of lead poisoning or painters' colic?—None.

11,310. Have your men had occasional days of sickness possibly due to lead?—Not to my knowledge.

11,311. Do you have a periodical medical examination of your men?—No.

11,312. Then how do you know that some of the men may not be suffering from the slower and more insidious forms of lead poisoning?—I have no report.

11,313. You do not know?—I really do not know.

11,314. I presume you know that lead poisoning frequently undermines the health, without immediate violent symptoms arising?—I believe so.

11,315. Have you ever read the Board of Trade Gazette?—No.

11,316. Have you heard that 284 deaths of painters have been definitely certified as due to lead poisoning in the last 10 years?—Yes, I believe so.

11,317. And that the mortality rate increased very largely in the first six months of this year?—Yes; I believe there have been more recently.

11,318. But you have had no cases of lead poisoning in your own business?—No cases that I have heard of.

11,319. I am not surprised to hear that at all, because in the Potteries we know of a large number of employers who have had no cases of lead poisoning at all, and all of a sudden without any warning a large crop of cases has arisen. Now, do you know that the number of deaths from lead poisoning amongst house painters is greater than in all the other industries where lead is used?—I hear you say so, but I have not statistics to compare.

11,320. In addition to this the death rates from Bright's disease and nervous diseases and consumption due to work in lead are very high?—I believe so, but it is all quite new to me.

11,321. There are also a very large number of non-fatal cases, most of which are never recorded, as they are not required to be notified to the Home Office?—I believe so. That refers, of course, to Returns made on England and Scotland.

11,322. I am speaking of the whole country?—Precisely.

11,323. I am sure you agree with me that all this sickness and death is deplorable?—It is very deplorable.

11,324. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I understand so.

11,325. Do not you think it is regrettable that this country should be behind other nations in this respect?—Yes, I think it is.

11,326. Something must be done, either by regulation or by restricting the use of lead?—I think so.

11,327. Now, have you had any personal experience with paints which contain no lead?—No, none, beyond the water paints, and they are not included in that denomination.

11,328. Have you heard that the Office of Works and others have used leadless paints with entire success for some years past?—I believe so.

11,329. No doubt you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead?—I believe that that is so.

11,330. Are you aware of the details of those precautionary measures?—No, I do not know what they are.

11,331. Let me give you a few of them, and then you will understand what I mean. First of all, there is the provision of overalls by the employer, who is responsible for seeing that they are regularly washed?—It is quite unknown in my business in Scotland for any men to work without overalls. That is to say, a man who comes to me and asks for a job would not be permitted to start work without wearing overalls.

11,332. Do you provide the overalls yourself?—No.

11,333. Do you see that they are washed?—No.

11,334. Do you know whether they are washed every week?—If on going round my works I see a man not properly clean, I check him personally, or tell the foreman to look after him. As a rule the overalls are washed every week.

11,335. You do not know that of your own knowledge?—No.

11,336. They may have an accumulation of lead on them which would be very harmful?—It may be so.

11,337. If the Home Office introduced a rule that employers should provide overalls, and should be responsible for seeing that they were regularly washed, do you think there would be any difficulty in its being

26 July 1911.]

Mr. R. L. ANDERSON.

[Continued.]

carried out?—There would be difficulties which seem to be overlooked. The difficulties are that we take on men on Monday morning and by Friday night they might be paid off and other men taken on. Trade fluctuates.

11,338. In a former Committee, we agreed that it was the multiplicity of small dangers added together that caused the great evil in the operations, and we looked upon the question of overalls as being one of the important things?—I do not think in Scotland there is any danger of lead-poisoning occurring through carelessness on that particular point you have mentioned of overalls, because the men are very careful. If a man is slovenly he is spoken to.

11,339. You think there would be objections to employers providing the overalls, and seeing that they were washed once a week under the supervision of the employer?—I think there would be great difficulty.

11,340. Now on the question of the provision of a meal-room, would you agree that in no case should the men be allowed to take their meals in a room where lead is used—where they come into contact with lead, either dry or mixed?—That would be impracticable outside. In my own shop no man is allowed to take his meals in the workshop. He might require to have his meals in a room that has been painted a day or two before.

11,341. The difficulty would be outside; I quite see that. Then there is the question of the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing?—It would be very difficult in our trade.

11,342. Could you provide a cloak-room so that clothing put off during working hours shall not under any circumstances remain in a room where lead is used? The men take their coats off and put them in the room where the paints are mixed or where they are working. I have seen it myself?—The customers would not allow you to run all over the house, so what are you going to do?

11,343. Then there is the question of washing accommodation. The Home Office would insist probably on levelling this industry up to other lead industries, and that would mean one basin or other utensil to every five men, supply of water both hot and cold, soap, nail-brushes, and a sufficient number of clean towels. Could you insist on those being provided?—In some cases it could not be done. I might explain, also, that in my place the foreman has instructions to see that every man who is having food at the job washes his hands. Soap is supplied and he gets cold water or hot water. I tell my foremen and my men constantly, when I am round, that they must be tidy in their work.

11,344. Now with regard to dust, provision would have to be made for the avoidance of dust. Some means would have to be devised for getting rid of any lead dust which the men might breathe. Would that be practicable in work amongst house painters?—I am prepared to say from my knowledge and experience that there is not sufficient lead dust comes off properly prepared paint to do any man any harm.

11,345. Would you go so far as to say that it did him good?—No. I would not say that it would do him any good.

11,346. Is it practicable to provide means for removing the dust caused by sand-paparing?—If it is there, it must descend to the ground in the usual form of dust. There is no way that I know of of taking it away.

11,347. Are you aware that the attention of this Committee has been called to the existence of poisonous emanations from liquid paint? Let me describe what I mean. In painting a wall with lead paint certain vapours arise from the paint which are noxious to the men who breathe them. Is there any means of carrying those away?—Simply by opening the windows.

11,348. That might mean blowing it more into a man's face?—Not sufficiently to do him any harm, in my experience.

11,349. I am not asking you whether there is any danger, but is there any means of removing the vapour,

if it is dangerous?—Only by opening the windows, as I say. I do not know of any other means.

11,350. That might make it worse?—It could not make it worse.

11,351. In addition to those regulations, a periodical medical examination, say, once a month would be insisted upon at the expense of the employer. Do you agree to that?—No. It is an expense that I should be very unwilling to bear.

11,352. Would you agree to the payment of compensation to any worker withdrawn from work by the doctor's orders on account of doubtful health?—No.

11,353. Then in your view, to sum the whole question up, would you say that you prefer that the industry should be regulated by special rules such as I have foreshadowed—not one or two that you may think would be applicable—or as an alternative that the use of lead should be prohibited?—Special rules.

11,354. Do you withdraw all that you have said about these special rules, regarding the inexpediency or the impossibility of enforcing these rules and the objection you have yourself to some of them?—Not these rules.

11,355. I am referring to these rules?—I say it is impossible to apply them.

11,356. We are told that these rules are the only rules which will mitigate the evils which the men have to encounter?—I do not agree to that.

11,357. What are we to do as a Committee?—Are we to prohibit lead?—I do not think I should, from my experience.

11,358. Are we to let the men go on suffering?—I hold that they are not suffering.

11,359. But you cannot get away from these figures?—I have not the statistics before me.

11,360. You said just now that you thought that this deplorable state of affairs should be remedied, and I ask you shall we remedy it by the prohibition of the use of lead?—No.

11,361. Shall we remedy it by these rules as I have given them to you?—No.

11,362. Shall we let the men go on suffering?—No.

11,363. Then what are we to do?—Make some conditions that can be carried out and still be sufficient.

11,364. What are they? We shall have some interesting information if you will tell us what is in your mind?—I can prove this to demonstration: I have been in business for 33 years and my father started business in 1842.

11,365. If I may say so with all respect, I do not want any evidence about your own firm?—I cannot speak of anyone else.

11,366. Would you put yourself in our position? We are here to deal with this admitted evil and you agree that something must be done?—If the conditions that I adopt in my business were carried out, these evils would be reduced to a fraction.

11,367. What are they?—The men are told to clean their overalls, and I see that it is done.

11,368. To your own knowledge does your foreman see in every case that the men have clean overalls every week?—They must be clean every Monday morning.

11,369. You know that from your own knowledge?—I know that from my own knowledge.

11,370. Is a man asked whether they have been cleaned?—No; but if they are not clean and it is noticed, he is checked.

11,371. What is done?—He has to get clean ones. If he is not a good respectable man, he is paid off.

11,372. What is the next thing?—A foreman is told that before a man eats he must wash his hands. If the man is careless there is no obligation on my part further. If he is feeling unwell the foreman sends him off work at once.

11,373. You have cases sometimes of a man being unwell?—It is reported to me at once.

11,374. You said just now that you knew of no cases?—Not of lead poisoning.

26 July 1911.]

Mr. R. L. ANDERSON.

[Continued.]

11,375. I asked you whether you knew cases of men occasionally off for sickness. You said no?—I misunderstood you.

11,376. There are cases where men do not feel very well?—Yes; they may be out of sorts and lose a day's work. They may have a cold.

11,377. It is nothing to do with lead, you think?—Not as far as I have ever heard. My shopman has been with us for 20 years. I asked him before I came away what he did. This lead poisoning was absolutely new to me a few months ago. He said, "I come in at six and work till eight." He goes away for an hour and has breakfast and comes back at nine and works till 12. He goes away home at 12 and has dinner. He works when he returns from 1 to 5.30, and then goes home. I said, "What do you do about washing your hands?" He said, "I have plenty of soap and water and wash whenever I think necessary, and I keep my nails clean." He has been among the paint for over 20 years, mixing paint, but taking no food where the paint is. He has not lost a single day's work from illness in the 20 years.

11,378. I could take you down to the Potteries and show you hundreds of men with a similar record, and I could show you others who have had lead poisoning?—Under these conditions?

11,379. Under precisely the same conditions?—I cannot believe it.

11,380. (Dr. Collis.) Are your suggestions summarised in washing the hands and wearing clean overalls?—Yes.

11,381. And they begin and end with those two provisions?—Yes.

11,382. How do men get clean overalls?—They are washed.

11,383. Where?—At home.

11,384. How do they take them home?—In their hands or in a little bag. Many of them carry little bags. Or they take them home at the end of the week rolled up under their arms.

11,385. I suppose that the overalls must be dirty or they would not require washing?—They are dirty—yes.

11,386. And they take them home in these small bags?—Those who have bags do. Those who have not, roll them up.

11,387. How do they bring their food to the works?—In a paper parcel as a rule. A man brings a little tin with his tea.

11,388. Does the paper parcel ever by chance get into the bag?—He does not take his bag home every night. He would take it home on Saturday only. I never knew a man take his bag away every night.

11,389. Does he never bring his food back in the bag that he takes his overalls in?—He might.

11,390. Is there not possible means of contamination there?—I do not think so.

11,391. Why not?—Because the overalls do not contain much lead. If they contain any at all, it is not sufficient to do him any harm.

11,392. That is your opinion?—That is my opinion, and it is my experience. I can prove it by figures. I have had no case of lead poisoning.

11,393. Turning then to the question of figures, you say that you have no knowledge of the cause of sickness, even though only temporary, among your men?—Yes.

11,394. Do you have doctors' certificates to state what these sicknesses are due to?—No.

11,395. A man does not know what is the matter with him, as I daresay you know, unless he is specially diagnosed medically?—A man is ill and off work and if he starts work again better I ask no further questions.

11,396. So you have no knowledge at all of what the sickness may be due to?—None whatever.

11,397. It may be due to indigestion caused by food contaminated in his bag by the dust from the overalls?—It may be, but I have no knowledge of it.

11,398. You have no knowledge at all of illness among your workpeople unless there is a severe attack of lead poisoning?—I know what the symptoms of lead poisoning are—the dropping of the hands, for instance.

11,399. That is only in the most pronounced cases. That occurs after many years?—Men are ill and off

for a day or two, and then resume work, and no lead poisoning has ever been reported to me.

11,400. That may be so. The doctors are not called upon to notify to the Home Office the occurrence of these cases. They are outside the factories, so that there is no responsibility placed on the doctor to make a pronounced and definite diagnosis of the illness in these cases. As regards the amount of sickness, even though temporary, amongst your men, have you compared it with sickness amongst other men in other trades?—No, I have no knowledge of that.

11,401. So that you do not know whether it is in excess or the reverse?—I have no figures to work on.

11,402. So that it may be in excess as far as you can tell. What is the age of the oldest man that you have employed on your permanent staff?—61 or 62.

11,403. Are there many others close to that age?—Half a dozen between 45 and 50.

11,404. How many altogether are there on the permanent staff?—Between 30 and 40 on the average.

11,405. That does not give a very high average age. What happens to the old painters after they are 60? Most of us expect to live over 60 you know. It is a sort of general hopefulness that we have?—I am thinking of a number of my former foremen, that is foremen in my father's time, who have been with me till they died. An old foreman died at 74. He had been with us for 55 years.

11,406. Do you have many people die as old as that?—Half a dozen, about 60 to 65, were with me till they died. I could get the exact figures for you if necessary. I kept all the old foremen on, and most of them died at about 60 to 65.

11,407. Have any died younger?—Occasionally one or two.

11,408. You know that the average age at death of the agricultural labourer is 67?—I will take that as correct. I do not know to the contrary.

11,409. Your men, even on your own showing, hardly come to that age?—67 is a good average.

11,410. The average age of a painter is 48 to 49?—I would like to ask what is the average age of clerks. My men are healthy as far as I can gather, and they are off work very little.

11,411. But all these points are comparative. I know that it is a difficult subject, and it is a subject that can only be investigated by comparing people in other trades, the age, constitution, and the average age at death, and until we have made such an inquiry it is difficult for us to take as absolute evidence the statement you have made that there is no illness, particularly among your men. Do you follow my point?—Yes.

11,412. We wish to get all the information we can. We ask for these details, when you say that there is no illness to speak of, because only upon such an inquiry can the statement be well based?—In every business and every profession there is a certain amount of illness.

11,413. Precisely, and they want comparing?—I do not know what the comparative tables are. I have never seen them. I speak from my own experience.

11,414. Everything is comparative. A statement is no good unless there is something else to compare it with?—What you have put to me is interesting. I hear what you say, and I take it as correct, but I have no evidence to the contrary or for.

11,415. We are searching for evidence. We are bound to search the facts which witnesses give us to see how they are based?—I can only say that the majority of my men who have behaved themselves and who have done good work, and who have been good servants to me, have lived to over 60 years of age, and remained in my employment. I can only give my personal experience.

11,416. (Mr. Parsonage.) Have you had any experience of using zinc paints and leadless paints?—Very little experience of leadless paints.

11,417. You cannot speak of them with regard to either durability or quality?—Very little. I was brought up in the good old school—nothing was better than white lead.

11,418. (Mr. Gardner.) You would not like to leave it?—No, I would not like to leave it. It is good and

26 July 1911.]

Mr. R. L. ANDERSON.

[Continued.]

easily washed and durable. I have used enamel composed of zinc white. I have used it on window sashes where I wanted them to be preserved from the damp. I have found that the enamel, where it came in contact with water through the sweating of the windows along the bottom sill of the window has all peeled off, and dried up, whereas the priming coats of lead below were quite sound. From my experience and what I have been taught as the fundamentals of my trade, there is nothing better than white lead known as a preservative.

11,419. You do not think an enamel is a preservative?—No.

11,420. Not even when applied on lead?—No. It goes when it gets exposure to the weather.

11,421. Taking a door finished in flat and a door finished in enamel, which would last the longer?—The door painted in flat.

11,422. Would it last equally as long?—It would last better probably. I am speaking of outside work.

11,423. I am speaking of inside work. They use very little enamel outside, you know?—It is used outside.

11,424. Very little. You would not say that, on a door inside, the flat would last as long as the enamel?—Inside the enamel wears better. Outside the flat paint would wear better.

11,425. The paint outside would not be flat. It would be oil colour. So there is no comparison at all. We want to have things perfectly right. Will you admit that enamel lasts a lot longer inside than flat, where it is used?—Yes.

11,426. And flat is not used for outside?—Not for the finishing coat.

11,427. No. It is oil colour outside?—Yes.

11,428. (Mr. Sutherland.) With regard to the point of dust in rubbing down with sand-paper, there is not much rubbing down on walls, is there?—Very, very little.

11,429. Where would you say that the rubbing down with sand-paper concentrates? Where is it most used for?—Windows and doors—woodwork.

11,430. Where?—The woodwork of the rooms.

11,431. Where particularly?—The doors and window sashes.

11,432. The amount of dust that would arise in a room with an ordinary door is not sufficient to demand exhaust apparatus?—No.

11,433. I do not know whether you are aware of it, but the point you suggest in reference to Mr. Parsonage's query corresponds with the experience of the Dutch Commission, that where zinc white was used on window sills and ledges, it did not last as long and did not answer as well as white lead. That was ordinary zinc white with ordinary oil, and certainly where enamel was used there would be a greater protection than just oil and zinc white. So that really confirms the final conclusions of the White Lead Commission of the Dutch Government, which was a very exhaustive inquiry. Your preference for lead paint is because it is very much better as a paint?—Yes. It is the best known article.

11,434. As a paint and as a protection?—As a paint and as a protection.

11,435. You can do better brush-work with it?—Very much better.

11,436. (Mr. Parsonage.) But you say you have never tried the other, and know nothing about the other. How can you speak of the relative qualities of a thing when you admit that you have never tried it?—We have tried it.

11,437. (Mr. Sutherland.) Zinc white?—Yes, when we were compelled to put it on, and that is the impres-

sion it has made on me. We put it on ironwork in laboratories, to stand the fumes of chemicals.

11,438. What result did you get?—It stands better than lead.

11,439. In certain laboratories where certain acids are generated, it stands less than lead?—The architect specified that it should be put on. I seldom use it for the reason I have given, because I have been trained to understand that white lead is the best basis.

11,440. If lead was prohibited, and that carried with it lead compounds, all the yellows and greens and reds which we now get (like Brunswick green and variations), and all the yellow chromes and all the variations of reds would practically be annihilated?—And disappear.

11,441. Yes. Do not you think from a decorative point of view that would be a serious loss?—It would be a very serious matter for the public.

11,442. You know that there is no substitute that is at all available commercially (when I say that, I mean that can be provided at a reasonable price) for these yellows which control the greens, and for the reds?—I know of none.

11,443. You would have to content yourself with natural earths and oxides for your reds, and with zinc chrome for your yellows, which is a very poor stainer, and would make a very indifferent green?—Yes.

11,444. So from an artistic and decorative point of view it would be a loss?—A very serious loss.

11,445. (Chairman.) I suppose you agree that we could not have legislation and special rules for England without their applying to Scotland?—I see no reason why.

11,446. Do you think that English employers would welcome such an innovation? Do you think it would be fair to the English employers to prohibit the use of lead in England and not in Scotland?—It is for this Committee to say from the statistics that they get. I am not here to deal with that, if I understand your question.

11,447. (Mr. Sutherland.) The effect would be that you would not be able to come into England if we were only using zinc paints and you were using lead?—If a Scotch painter came to England he would have to conform to the conditions of England.

11,448. (Chairman.) But do you think it desirable to differentiate between Scotland and England in a general law of this kind?—Surely you do not?—From what I have seen of the figures I see no reason for any legislation whatever for Scotland, but from the figures that you have given me, I think there is good reason for very serious legislation in England.

11,449. If regulations were enforced, however stringent they were, would you prefer them to the abolition of white lead?—No.

11,450. You would prefer the abolition of white lead to those stringent regulations?—Yes. Might I ask whether you have any statistics with reference to Scotland alone?

11,451. (Dr. Collis.) No. We have figures from the Scottish Painters' Society, but we have not a return from the Registrar-General for Scotland?—All the cases from England, Scotland, and Ireland are together, I suppose?

11,451A. There are practically no Scotch cases in our figures at all, because we have not asked for them. They only represent England and Wales?—It would be a very good thing to have those tabulated. It would be a hardship to put on to Scotland certain conditions, which will be serious to the trade, which are not necessary.

(Dr. Collis.) The position would only be exactly the same as in England.

The witness withdrew.

## SIXTEENTH DAY.

Thursday, 27th July 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. M. HOLZAPFEL examined.

11,452. (*Chairman*.) Do you attend to-day as the representative of the North-East Paint and Oil Trades Association?—Yes.

11,453. What is your own business?—Specialities for ships, particularly ships' bottoms—composition for ships' bottoms.

11,454. Is your business confined to specialities for ships?—Almost exclusively. We are enamel manufacturers and varnish makers.

11,455. Do you grind both lead and zinc paints?—We grind zinc paints, but not lead paints.

11,456. Have you a large trade in leadless paints?—In various paints.

11,457. Are they all leadless paints?—All leadless except so far as lead is contained in oil or varnish—in the boiling of oil or varnish.

11,458. In what form do you use lead at all?—Litharge, for using with boiling oil or boiling varnish—or red-lead for boiling oil or varnish.

11,459. Do you add lead in any form in your works?—No, not to the paints.

11,460. Is your trade in enamels increasing?—Yes.

11,461. Are enamels all leadless?—Ours are all leadless.

11,462. What are they mostly built up from?—Mostly from white zinc, because it is nearly all white enamel that is used.

11,463. Why is it that you never use lead in any of your paints?—Our business has grown up without lead. Lead has been mainly the competitor against us. It is not used by us.

11,464. Have you found your experience perfectly satisfactory with paints that contain no lead?—Yes.

11,465. Has your business been a progressive one?—Largely.

11,466. And you have no inclination to revert to lead whatever?—No; but I am alluding to ship paints.

11,467. Principally for ships' bottoms?—Principally for ships' bottoms, and also the interior of ships and the sides of ships.

11,468. (*Lord Henry Bentinck*.) Would you mind describing to the Committee the process of grinding zinc paint? Is there a dust arising from the process of grinding?—Yes, certain dust arises, but that can be obviated very largely by having it in a closed vessel, and getting it into a tank in which oil is contained with the stirring arrangement, and then grinding it.

11,469. Thus, I suppose, none of the zinc dust gets into the lungs of the workers?—Very little.

11,470. Do you consider it necessary to protect the workmen against dust?—We have to protect some of our workmen against dust, because we use mercurial, copper, arsenical and other poisons in some of our compounds.

11,471. In the grinding of the pure zinc, I mean?—No.

11,472. You do not consider it necessary?—No.

11,473. You have found that zinc dust has had no ill-effect on the health of the workmen?—Not in our paints.

11,474. (*Dr. Collis*.) Do you make any other paints besides enamels?—Yes, compositions for ships' bottoms,

in which these poisons are used which I described just now, and different specialities for ships. We make a special paint for engine rooms, a special paint for the top sides, a special paint for the boot tops, a special paint for the holds, and for the decks and different things like that.

11,475. All these paints which you are mentioning are not enamels?—No. We make enamels as well as paints. I draw a distinction between the two.

11,476. And they contain no lead?—They contain no lead.

11,477. You make your paints entirely for use on ships?—No, also for land use. Enamels we make for land use—for house-painting or railway painting and so on.

11,478. But do you sell any paints which are not enamels for use on land?—Yes, but they are liquid paints, ready mixed paints, varnish paints.

11,479. For what purpose are they used?—They are used for various purposes—bridge-painting, house-painting, and also for decorative purposes.

11,480. Do you know whether they have been used much on the exteriors of houses and buildings?—No, not to a large extent.

11,481. Are you able to say whether they have been satisfactory where they have been used?—Yes, I believe so. I believe they have been satisfactory.

11,482. Your non-enamel paints, that is, the zinc paints which are not enamels, are used on board ship you say on the top sides and exposed to the weather?—Yes.

11,483. And do they stand well?—Yes, they stand all right.

11,484. Do they compare favourably, from the point of view of price, with paints which contain lead?—Yes.

11,485. What is the difference from the point of view of price?—Some of the paints are cheaper; for instance, oxide of iron paints, which we use, are cheaper than lead. Oxide of iron, as a rule, is a cheaper article than lead; and the black colour, as a rule, is cheaper than lead.

11,486. And the white colours?—For the white colours we use zinc.

11,487. How do they compare for price?—I think that they are dearer.

11,488. Do you know to what extent?—White lead is about 19*l.* per ton, zinc is generally about 22*l.* a ton. That is about the proportion.

11,489. You mean mixed paint?—No, the zinc or lead.

11,490. But I want to know as regards the paint as you send it out, because, weight for weight, zinc paint is so much bulkier than lead that it does not represent the same amount of paint, gallon for gallon?—I should say that the difference would be very slightly in favour of zinc.

11,491. Gallon for gallon?—Gallon for gallon, because zinc is so much lighter specifically.

11,492. It is not fair to quote prices by weight, but only by the gallon of paint, I think. You cannot give absolute figures?—No, I did not prepare myself to give those figures.

27 July 1911.]

Mr. M. HOLZAPFEL.

[Continued.]

11,493. (*Mr. Sutherland.*) Your other painting business is quite a small side line compared with your general ship paint business, is it not?—The same paints that are used for ships are also used for houses. We manufactured these compositions originally for ships, and they have been gradually introduced for land purposes.

11,494. That is a comparatively recent development, is it not?—Yes, a more recent development.

11,495. And your enamels are a recent development?—Yes, they are a recent development.

11,496. The paint you use on ships, you say, are mixed with varnish?—Yes.

11,497. Why?—In order to make them adhesive. They are mixed with special varnishes in order to make them waterproof, and others again in order to make them soluble in sea water in a certain ratio. The varnishes are made so that they become soluble in sea water in a certain ratio. These paints have to be acted on by sea water in order to free their poisons.

11,498. I am not speaking about ships' bottoms?—I am speaking of the ship composition.

11,499. I am not concerned with that. I am speaking about the top paints. You put varnish in those?—Yes, those are made with varnish in order to make them washable.

11,500. Is that the only reason—to make them washable?—And to make them last longer—to get a certain hardness.

11,501. That implies that zinc paints have not the same permanency as lead—that without the varnish they would deteriorate, and to make the zinc paint permanent you have to add varnish to it?—Yes.

11,502. But you have not to do that with a lead paint to give it permanency?—No. Lead acts on oil differently from zinc.

11,503. That is really an admission that the lead is better as a general paint base than zinc?—Yes, that is so.

11,504. It also implies that the addition of varnish adds a considerable cost to it?—Yes.

11,505. So that the 3% per ton distinction between the two products in the raw state would not exhaust the difference in cost?—No. I am not comparing varnish paints with oil paints. When I was talking about zinc paints and lead paints, I assumed that both were made with the same base of varnish which we use.

11,506. That is so far as your own experience is concerned?—Yes.

11,507. Do you come to represent your own firm?—No; our association in Newcastle.

11,508. What association?—The Paint, Oil, and Varnish Association.

11,509. But they do not confine themselves to zinc paints, do they?—No. We have lead grinders amongst the members of the association.

11,510. You are not adverse to the use of lead, are you?—By no means.

11,511. You consider it good?—I think that lead for certain purposes is necessary, although I have fought it all my life.

11,512. You have fought it?—Fought against it.

11,513. But you think that for certain purposes it is necessary?—Yes, for certain purposes it is necessary.

11,514. (*Chairman.*) Would any serious difficulty arise if lead was prohibited?—I think so.

11,515. Can you tell us in what way?—The decorative trade, I think, would be upset altogether.

11,516. What do you mean by "upset"?—It could not adapt itself to paints which are entirely without lead.

11,517. Simply for decorative purposes you think it would not be so efficient?—I do not think that you could find a suitable substitute to do what is required in the decorative trade.

11,518. What do you mean by "what is required"?—For instance if you paint in a room and do not use lead and have not the drying action of the lead on the oil, you might have the paint wet for a week. Dust would get on and everything would get dusty, and you could not make a satisfactory job of it.

11,519. But supposing that the natural lead in zinc oxide was still allowed to be used?—Zinc oxide?

11,520. Yes. Supposing the trade were allowed to retain the natural lead which is to be found in zinc oxide?—But there is no lead in zinc oxide.

11,521. Yes, there is, when it is made by the direct method?—Perhaps 1 per cent.

11,522. More than that—sometimes up to 4 per cent.?—We have never found 4 per cent. in our white zinc—never. We have found, perhaps, up to 2 per cent. at the most.

11,523. What zinc white do you use—German, Dutch, or English?—I think we use mostly the Belgian and American.

11,524. Would not that natural percentage, between 1 and 4 per cent., be sufficient to act as a drier?—No.

11,525. What percentage do you consider would be necessary to act as a drier?—I should say 10 to 15 per cent. of lead in the paint to make it act as a drier, at least.

11,526. Have you used manganese driers?—Yes, I have used manganese driers.

11,527. Are they as efficient as lead?—Yes, for certain purposes they are.

11,528. Do you think that it would be absolutely impossible, if this Committee prohibited the use of lead, to find a substitute for lead as a drier?—No, it would not be absolutely impossible. I could not say that.

11,529. Supposing that the Committee reviewed the position, and they found that the health of the workpeople was so much affected by the use of lead that it became absolutely necessary to make a prohibition, do not you think that the painting world would find substitutes for lead and go on comfortably?—I think that the whole of our system of decorative painting would have to be changed in that case.

11,530. Would that be very harmful?—I should say so.

11,531. In what way?—You could not possibly, for inside work, obtain an article to satisfy the requirements of the trade which would dry sufficiently quickly unless you used lead.

11,532. Your evidence now is diametrically opposed to that of the majority of the master house-painters we have examined, because they have generally agreed that, for inside painting, zinc would be quite sufficient. Not necessarily zinc oxide, perhaps zinc sulphide, or lithopone. I am speaking of non-poisonous paints generally. I am not confining myself to zinc oxide. Do you mean to say that there is no non-poisonous paint on the market that will do for internal work?—It is going a little too far to say that.

11,533. Have you any great experience in house-painting?—I have had a good deal of experience, because we supply house-painters also, and I have come continually against lead paints.

11,534. Have you had experience yourself, direct, with regard to house-painting?—No, not personally.

11,535. You are speaking now from the inference you have drawn from the people who have bought your paints?—Yes, I have the experience of our researches.

11,536. But have you had any practical experience of the painting of houses inside and outside?—Not beyond that I get my houses painted regularly, and look after them and see how it is done.

11,537. What houses?—My own dwelling-houses and my offices.

11,538. But not otherwise?—Not otherwise.

11,539. You are speaking generally now from what you have heard from master house-painters?—We have made very far-reaching researches in reference to all these questions, because we keep a large staff of chemists, and we experiment in reference to all these questions, and have done so for years.

11,540. (*Mr. Sutherland.*) We have no native sources of supply of zinc?—No, I believe not.

11,541. So that, if white lead was prohibited, the painting trade and the paint manufacturers would be entirely dependent on supplies from foreign countries for its continuance?—Yes.

11,542. Do not you think that that would be a serious matter for the paint grinders and paint manufacturers?—Yes. May I speak a moment without a

27 July 1911.]

Mr. M. HOLZAPFEL.

[Continued.]

question? I have been asked, "Is it possible to do away with lead?" Of course, in a case like that nothing is impossible. You can always adapt yourself within a certain radius, within a certain efficiency. I do not see why it should be contemplated to dispense with lead.

11,543. I am not asking about that?—That seems to be the inference from the question.

(*Chairman.*) It is contemplated.

11,544. (*Mr. Sutherland.*) In case of the contingency arising of white lead being prohibited, we should be dependent entirely on outside sources for the supply of a material which represents a very important trade?—Yes. May I make an observation? Very many ships use red lead for inside painting. Every four years a survey is held, and during these surveys the paint has generally to be removed to examine the surface of the iron or steel. The removal of the paint is done by hammering. The holds of the ship are one mass of lead dust then, and the men are working dry after day in this mass of dust. I think if a restriction is intended for the use of lead, that would be a case where restriction should be imposed. It is not in the application, but in the removal where the danger is, because those men, if they had to do that continually, would very quickly suffer from lead poisoning, but fortunately for them they are not always doing this work. Sometimes they work outside, and underneath the ship's bottom, and so they have sufficient variation of work to be somewhat protected against lead poisoning. In many cases, or in most cases, there is a chance of the lead working out of the system, before fresh doses of poisoning set in.

11,545. (*Chairman.*) What have you come to tell us specially to-day?—I had three headings on which I offered to give evidence. I had the heading of "The effect of applying oils and varnishes containing lead compounds, and the removal of these coatings." Then I had "The mixing of lead paints and their application on board ship." Then I wanted to speak on the perishable nature of lead paints and the removal of lead paints by mechanical means. Those are points which I have more particularly under my observation.

11,546. (*Mr. Sutherland.*) What is the first?—"The effect of applying oils and varnishes containing lead compounds, and the removal of these coatings."

11,547. (*Chairman.*) I do not think that that is germane to this inquiry?—Very well.

11,548. The point of this Committee is to inquire what remedies can be introduced to mitigate the evils which ensue from painting houses and other things with lead paint.

11,549. (*Lord Henry Bentinck.*) Perhaps you were going to speak of the evils attendant upon that?—I should like to speak upon that. I consider that most of the lead poisoning that we have to contend with is in the sand-papery of coats of lead that have been applied, in order to prepare for the next coat. An enormous amount of dust is created through that, and that is partly inhaled and partly swallowed.

11,550. (*Chairman.*) We have been told that the quantity of dust generated from sand-papery in some cases is very small. Would you say, generally speaking, that that is not so?—No; it cannot be so. You have a comparatively rough surface before you commence sand-papery, and after the sand-papery is done, you have an absolutely smooth surface. I should say by sand-papery you remove 25 per cent. of the surface.

11,551. (*Mr. Sutherland.*) Are you referring to ships?—No; I am speaking generally there. I think that sand-papery of lead paint should be prohibited, and you should use pumice stone and give sufficient time to dry, so that the wet process can be used.

11,552. (*Chairman.*) Would any harm be done to the surface if you insisted on it all being rubbed down in a wet state?—No, I do not think so, not if the coat has sufficient time to dry.

11,553. (*Lord Henry Bentinck.*) That would increase the cost?—It would increase the cost and increase the time. It is not a very pleasant thing to contemplate.

11,554. (*Chairman.*) Do you think it possible to introduce any contrivance in the shape of an exhaust draught to remove the dust that is generated?—I do not think it is.

11,555. I am afraid to ask these questions, because from what you have told me you have had no direct experience in house-painting, and so on?—No, I am not a house painter; I am a manufacturer.

11,556. But could you speak positively as to the feasibility of abandoning all dry rubbing down?—Yes.

11,557. You think that it is quite possible?—Yes, quite possible.

11,558. But more expensive?—It would be more expensive. It takes a longer time. If it is rubbed down in the wet, time must be allowed for it to dry.

11,559. Have you any idea what extra expense would be incurred?—I could not give an estimate of that.

11,560. What length of time would you have to give?—You will have to give another 24 hours for each coat.

11,561. Is it practicable to give an additional 24 hours for each coat?—I see no reason why not. You have to submit to the painter so much longer.

11,562. (*Lord Henry Bentinck.*) Whether you prohibit lead or whether you add to the time, you are putting a burden on the customer, are you not?—Yes; you are increasing the cost in any case.

11,563. Then there is very little difference, whichever you do, I should think?—Perhaps so.

11,564. (*Chairman.*) It might prolong the painting of the house two or three weeks. Is that a desirable thing?—Not two or three weeks. If you put on four coats that will be about the most that a house will take. If you gave each coat an extra 24 hours to dry, it would not be three weeks.

11,565. But you do not paint the whole of the house simultaneously?—No.

11,566. You take room by room. If you had a delay of 24 hours in one room, and a delay of 24 hours in the next, would not you prolong the painting time indefinitely?—That is a matter of arrangement of the work.

11,567. Is not that a practical difficulty?—I should say that four or five days would be the minimum amount of delay, but you can spin it out as much as you like if you do not arrange your work properly.

11,568. Is there any other subject you would like to speak on?—One suggestion that I should like to make is this; in house-painting where leads are used, a large amount of poisoning will no doubt obtain through the finger nails and absorption.

11,569. Do you think so?—Yes, I think so.

11,570. You are entirely mistaken on that point?—I think it is bound to be absorbed.

11,571. No, it is not. You ask Sir Thomas Oliver of your town, and he will tell you that that is not correct?—Well, I spoke to him some time ago—it may be two years ago—and at that time he was under the impression that absorption would take place.

11,572. (*Mr. Sutherland.*) You were going to say something about mixing paint. Do you mean with regard to the mitigation of the perils of lead poisoning?—That is what I wanted to refer to.

11,573. To reducing the danger of lead poisoning?—Yes. Red lead, for instance, is mixed in a dry state. You cannot keep red lead moist. You must keep it dry, because it hardens the oil. On board ship they are very careless. They have a barrel of red lead. They take it out with a trowel, or whatever they have, and throw it into a bucket, and pour a little oil over it, and dust continually arises while they mix it. That is a source of danger which perhaps may not come within the scope of this inquiry. But it certainly exists.

11,574. Is not there a red lead that is supplied moist?—No; you cannot have it.

11,575. I thought there was. I do not know the maker, but I understood so?—I never heard of one.

11,576. (*Lord Henry Bentinck.*) I am not quite clear where your paints are applied?—Are they applied in the open air? I do not mean only to ships; I know all about those. Are they applied to public buildings in Newcastle and to iron?—Yes.

11,577. Stations?—Tramway posts and railway stations.

27 July 1911.]

Mr. M. HOLZAPFEL.

[Continued.]

11,578. Inside railway stations?—Yes, inside railway stations.

11,579. Do they stand the action of sulphuric acid?—Yes.

11,580. What is the atmosphere of Newcastle like?—Well, pretty thick.

11,581. Sulphurous?—Yes.

11,582. You find that it does not suffer from the action of the bad atmosphere of a railway station, for instance?—No, I cannot say it does. We have not painted a railway station at Newcastle, so I cannot speak from experience there.

11,583. You have painted railway stations?—Yes, but not at Newcastle. We supply to railway companies, but I cannot say what station it is used for.

11,584. Are your paints largely used in Newcastle for outside work?—Fairly largely.

11,585. Do they last as well as other paints?—Yes, I think so.

11,586. Your only fear about zinc paints, then, is for the inside decoration?—Yes.

11,587. Because of its drying property?—Yes.

11,588. Do you think if you were given two years' time, you could invent something which would make it dry?—I do not know.

11,589. Your scientific persons, I should think, could manage that?—My chemists have worked on this now for many many years, upwards of twenty years some of them, and none of them has thought it would be possible to do away with lead paints.

11,590. (Chairman.) They must be very much behind the times?—I do not know, that ours are behind the times.

11,591. The Office of Works for the last four years have used leadless paints for decoration and everything, for inside and outside work, from Buckingham Palace down to a prison. Now, if they can do it, why cannot your chemists do it?—I do not know what they have done. Does the question of colour come in at all.

11,592. No, it is not a question of colour?—Or of preparation?

11,593. No. You say your chemists have tried for many years to find a substitute for lead and have not found it. I tell you the Office of Works have not only found one, but are very pleased with it in every form, both with regard to its efficiency and cheapness?—I am glad to hear it.

11,594. Do not you think that that ought to weigh very much with us?—Yes. In that case we must be behind the times.

11,595. (Lord Henry Bentinck.) You can get any gradation of colour and quickness of drying in enamels?—Yes.

11,596. It is only when people want a dull surface that the difficulty would come in?—Yes. You can make enamels without any lead at all.

11,597-8. And they have the quick-drying qualities of the lead paint. The hardship would arise when anybody wanted a dull surface?—Yes.

11,599. (Mr. Fell.) Have you ever used or supplied any paints for carriage work?—No, never.

11,600. Not for tramways?—We supplied some to the Newcastle Tramways Company for enamelling the cars.

11,601. That is all enamel, not paint?—That is enamel not paint. All our enamels are free of lead.

11,602. Have you had any difficulty in producing certain colours with zinc? Take chromes, for instance?—We have only a comparatively small range of colours in our business, and those colours have all been adapted without lead. We have never tried some of these very fine gradations where lead paints may be needed. We only supply certain standard colours of paints quite outside of that.

11,603. Have you done that because there has been a difficulty?—We made up our minds from the start that we would not go into these very fine gradations, because the atmosphere in Newcastle is not sufficiently clear as a rule. You would not be able to see them. The light is not good enough. So we have confined ourselves to standard colours. If anyone wants to grade colour we leave that to other manufacturers to supply.

11,604. (Mr. Mason.) Can you give us any idea as to what colours cannot be produced without the use of lead?—No, that I cannot do. I cannot go through the range. There are hundreds and hundreds of colours that are made. Some are made with lead; some are made without lead. I am sorry I cannot answer that.

11,605. (Mr. Parsonage.) Have you any personal knowledge of the time it takes for zinc paint to dry on interior work?—No. I never apply the paints myself, so I cannot speak from personal experience of applying them.

11,606. What do you speak from with regard to its taking a week to dry?—I am speaking from the reports which I received with reference to the different paints.

11,607. Different zinc paints that have been used?—Paints with varnish can be made to dry within an hour, if you like, but as you make the varnish dry quicker you do it at the expense of the lasting properties. You can make a white zinc dry in any time you like by adding varnish to it, and you can make a varnish dry within an hour if you want to, but you do it at the expense of the lasting property. If you want to have a lasting paint you must have a considerable amount of oil in the paint. The lead acts on the oil much more rapidly than the zinc. With lead you get a very much more quickly drying material than if you use zinc.

11,608. (Chairman.) The Office of Works in their formula use linseed oil and turpentine. They have given evidence here to the effect that that formula has proved just as efficient both with regard to durability and finish as a former formula they used which contained lead?—But I am speaking about the drying now. With regard to cost, I quite agree, it would not be higher. Zinc is so much more voluminous and spreads further.

11,609. What do you say to the evidence we have received? What is your explanation of what I have just told you?—I say it is a physical impossibility that two paints, one mixed with lead and another, the same mixture, mixed with zinc, can dry equally quickly.

11,610. Do not you think that the Office of Works would have brought that forward as a very strong objection to the use of their formula, if they had proved to themselves that the drying property is so inefficient that it takes considerably longer time to paint with the different paints?—That I cannot answer.

11,611. (Mr. Sutherland.) Do you know the Office of Works formula?—No.

11,612. If varnish enters largely into it, that would really sustain your point?—Yes, that may account for it.

11,613. (Lord Henry Bentinck.) In other words, the lasting quality of the paint as used by the Office of Works cannot be as great as other paints made without varnish?—You will get no end of contradiction on this. You cannot get two men to mix paints alike, and everybody's idea of what a paint ought to be is different.

11,614. (Dr. Collis.) May I on this point read the answer of Mr. Patterson, of the Office of Works? "It was soon discovered that when zinc oxide was mixed with refined boiled linseed oil with the usual thinners and a trace of litharge and borate of manganese driers, such paints dry quite well." There is no reference to any varnish there?—You have litharge. You have lead.

(Dr. Collis.) But that amount of litharge requisite for driers, it is not proposed to remove. There is no mention of any varnish in that answer of Mr. Patterson.

11,615. (Mr. Gardner.) You told us that the paint you manufacture is largely a leadless paint?—Yes.

11,616. And largely used for shipwork?—Yes.

11,617. And it is quite satisfactory?—Yes.

11,618. There is no more severe test of paint than painting on board ship. I suppose you agree to that?—That may be.

11,619. You supply paint for the skin of a vessel?—Yes.

11,620. Is that an oxide of iron paint or zinc?—For inside use it is oxide of iron paint.

X 2

27 July 1911.]

Mr. M. HOLZAPFEL.

[Continued.]

11,621. Where do you use the zinc paints on board?—Mainly in the engine room and for deck work.

11,622. They are zinc paints?—They are zinc paints.

11,623. A zinc paint in an engine room must stand a severe test?—No, I do not think the engine room is at all a severe test. I think the severe test is in those parts of the vessel which are exposed to the weather. They are exposed to sunshine when they go south and then to cooling.

11,624. It is a severe test for zinc paints on the bulwarks and deckhouses to be exposed to the sea air, the action of sea water and the sun?—Yes.

11,625. It stands quite satisfactorily?—I must draw a distinction there. It stands quite satisfactorily, but a ship is generally painted once a year if not oftener. It is supposed to stand six or eight months.

11,626. You would not get the same amount of action in the inside of a house or the outside of a house

as you get in a ship?—You cannot get such a severe test.

11,627. One year on a vessel would be equal to half a dozen years in an ordinary place?—I cannot say how it would compare, but the test is severe.

11,628. Take the inside of an engine room. You get strong heat and steam?—No, not steam in an engine room.

11,629. I have seen a tramp steamer engine-room full of steam, and you have the sun beating down?—It lasts three to four years. It is washed down.

11,630. It is a severe test?—In an engine room it is not so severe—not much more than in a house. There the difference is very slight.

11,631. Your paints have been very satisfactory so far?—Yes.

11,632. You have had no complaints?—No.

The witness withdrew.

Mr. A. W. WILLIS examined.

11,633. (Chairman.) Do you attend here to-day as a representative of the London Colour, Paint, Oil, and Varnish Trades' Association?—Yes.

11,634. Do I understand that at a meeting held at the Cannon Street Hotel on the 19th July, authority was conferred on you and other gentlemen representing the London Association to speak generally in the name also of the Hull Paint and Colour Manufacturers' Association?—Yes.

11,635. The Liverpool and District Paint, Colour, and Varnish Manufacturers' Association, and the Scottish Oil, Colour, Paint, and Varnish Trades' Association, as well as your own Association?—Yes.

11,636. Was a similar authority also conveyed by letter from the North East Paint and Oil Trades' Association?—Yes.

11,637. I understand that you are instructed to speak, in the first instance, regarding the amount of capital invested in the manufacture of paint, colour, oil, and varnish?—Yes. It is estimated that a capital of nearly ten millions is employed in the industry throughout the country.

11,638. Can you tell me what proportion of that capital is essentially confined to the manufacture of paints having a white-lead basis?—It is impossible.

11,639. To what extent would the employment of that capital be affected by an increased demand for zinc or other non-poisonous paints as contrasted with lead paints?—It would certainly increase the demand for zinc paints, because, in white, that is the only alternative.

11,640. My question goes further than that. To what extent would the employment of that capital be affected by an increased demand for zinc or other non-poisonous paints as contrasted with lead paints?—It is thought that if zinc were used instead of white lead and the lead products are to go with the white lead, then it would upset the manufacture of colours, and there would not be as many varieties of colour made. It would be impossible to make such a variety of colours, and consequently there would be less employment. Work would be reduced in volume.

11,641. Would it not be possible to utilise the same machinery and plant generally in grinding zinc or other non-poisonous paints?—I prefer that Dr. Crow should answer that. I am not a technical man.

11,642. Very well. Can you give me figures showing the extent to which you, as a grinder and manufacturer of paints, not concerned in the actual production of white lead, would be affected by a general change from lead to non-poisonous paints?—I am not in a position to answer that question.

11,643. Now, I understand that you wish to speak with regard to the cost of meeting the requirements of the Home Office in regard to Special Rules?—Yes. Of recent years there has been investigation made, and new regulations have been formed, which have put all grinders of white lead to considerable expense,

and in some instances I understand that the expenditure has run into thousands of pounds.

11,644. I understand that that expense has been incurred in introducing appliances to protect the workpeople?—Yes, to protect the workpeople, with beneficial results. I have figures in favour of it here.

11,645. The results have been beneficial to the workmen?—Yes, beneficial to the workmen.

11,646. Have you found the adoption of such precautions has resulted in a considerable decrease in the risk of lead poisoning?—Yes; the official figures say so. In white-lead works the average for ten years up to 1909 was 129.5 cases with 3.1 deaths; in 1910 only 34 cases with one death. In paint grinders the average for the ten years was 42.2 with 0.7 deaths. Last year there were only 17 reported cases with one death. That speaks very strongly in favour of the effect of regulations to benefit the workmen.

11,647. What deduction do you wish the Committee to make from your statement that you have made great expenditure in protecting the health of the workpeople in the use of lead?—In the first place the benefit of regulations, and in the second place that we look upon it as an industry that should be represented before your Committee, not only for its size but because they have always been ready to conform to any requirements which would benefit the working-man.

11,648. Do I understand you to mean that, because you have complied with the Home Office request that you should introduce adequate protection for the workpeople, you have thereby reduced the number of cases by approximately two-thirds, and that that ought to be borne in mind in any regulations the Home Office make in dealing with the subject of this inquiry of ours?—No, I do not suggest that.

11,649. Then what is the point?—I put it here that the fact that we are an important industry forms a claim for the fullest consideration of the case from our point of view.

11,650. Then, because you are a large industry, you want this Committee to take that into consideration in any action they may take in limiting or prohibiting the use of lead, is that the point?—That is the point.

11,651. We shall take that into consideration. I understand that you are instructed to speak in regard to the suitability of white lead and other white pigments for general decorative purposes?—Yes.

11,652. What do you wish to say on that?—The paint grinders wish to say that in their experience white zinc is not as suitable, especially for outdoor work, and is not as reliable as white lead. It will not wear as well. It will perish sooner, especially in this country, where, taking London, it is estimated that there is sulphur corresponding to 600,000 tons of sulphuric acid discharged into the air in one year. That has a marked effect upon zinc paint. I happen to have some boards here that were exposed in Hull, where the atmosphere is very similar to that of London. This was there for

27 July 1911.]

Mr. A. W. WILLIS.

[Continued.]

three years. Here is genuine white lead, here is genuine white zinc paint, and here is a mixture of white lead and zinc, and they are all reduced with the same thinnings (*producing some specimens*)?—It happened to me in my office. It has been there now for over six months.

11,653. (*Mr. Sutherland.*) How long was it exposed?—For three years.

11,654. (*Lord Henry Bentinck.*) Would you explain it a little more. The white-lead paint apparently has worn off altogether?—No; that is good. It is discoloured by the air. The white zinc has perished to a very great extent. *This is the mixture of the two.*

11,655. How much lead?—Two-thirds lead to one-third zinc.

(*Chairman.*) I do not think that this proves anything, because we do not know how you may have mixed them. We have against that testimony the evidence of the Office of Works, who have used zinc paints for the last four years both for inside and outside, and have found them satisfactory. We could not judge whether that was a fair experiment unless we knew exactly the formula of each paint.

11,656-7. (*Mr. Gardner.*) You did not treat the zinc in any special manner?—No; we used ground zinc.

11,658. (*Mr. Sutherland.*) And you used the same medium?—The same medium.

11,659. (*Chairman.*) There are a number of non-poisonous substitutes for white lead at present on the market?—Yes.

11,660. Have you made exhaustive trials of any of them?—Yes, in addition to zinc oxide, we have tried zinc sulphide. Zinc sulphide is no use for exterior work. It changes colour in the sunlight.

11,661. The Office of Works have succeeded in obtaining a formula, which is perfectly satisfactory. How do you account for the fact that you have never heard of it. Are they not great buyers of paint?—The Office of Works, I presume, are large buyers.

11,662. One of the largest buyers, I suppose?—No, by no means.

11,663. Not one of the largest?—Oh, dear no. I should put the Admiralty down as the largest buyer.

11,664. But the Office of Works are very large buyers?—Yes.

11,665. And should not their conclusions be received with great respect?—I do not know the conditions under which the experiments were made.

11,666. It is not experiment. It is actual work in their buildings. In their evidence they said that they had painted Buckingham Palace, the Government buildings, and small offices, and so on, and for four years this formula has been used with satisfactory results. Is not that a very important piece of evidence for us to consider?—Yes, it would appear so. It is impossible to judge without knowing further the way in which it was used.

11,667. It was used in the ordinary way, and they used it instead of white lead, and they found it as a substitute for white lead eminently satisfactory both with regard to durability and with regard to its cost. I think that you might mention that to your society and see what they have to say about it?—Yes, I will report it.

11,668. Has your society ever made any strenuous attempts to find a substitute for lead for use in paint?—We are always doing that.

11,669. But are you wishful to find a substitute?—Yes.

11,690. If you found a substitute for lead, would not your objection as to imperilling the capital of your industry come into play?—The whole trade grinds a large quantity of zinc.

11,671. I understand that one of your main points to-day is to ask us to consider the fact that you have invested a large amount of capital in the lead industry, and that you have been careful to observe the Home Office rules and regulations. You wish us to bear that in mind?—Yes.

11,672. Then you say that you have made very great experiments to find a substitute for lead. If you did find a substitute for lead, would not the point arise that

you would be injuring your own capital?—Yes. I should not accept on behalf of the trade the evidence of the Office of Works.

11,673. I did not ask you that. Please do not deal with that. You say that you have tried to find a substitute for lead for some considerable time?—Yes.

11,674. If you succeeded in finding a substitute for lead, would not you by your own act be imperilling your own capital that is invested in the industry?—No, because speaking as a grinder only, and not as a lead corroder, it would not make a great difference to the grinders whether they ground white lead or a substitute.

11,675. But I am asking you to speak for your association. You have made a statement to us that you want the Committee to take into consideration the fact that you have invested an immense amount of capital in this business?—Yes.

11,676. You say, "We have carried out the Home Office rules; we have been the means of greatly mitigating the evil of lead-poisoning in this industry; do not forget it; do not imperil our capital." That is what you have asked us, is it not?—No.

11,677. Then please state what you did mean?—It was a justification for appearing before you to represent our side of the case, particularly with regard to lead products, which is the strongest point with us.

11,678. But what is the deduction we are to make? I do not understand your point?—We have the two in combination, not only white lead but lead products.

11,679. May I ask you this: Do you mind, as an industry, from the capital point of view, whether lead is prohibited in the house-painting trade?—No.

11,680. Your association are not manufacturers of white lead?—No, we are not manufacturers of white lead.

11,681. But you represent manufacturers?—No, grinders.

11,682. They are two distinct industries?—Lead corrodors form the other section of the trade. We represent the houses who buy their dry lead and grind it. We are none of us corrodors.

11,683. (*Lord Henry Bentinck.*) To your association then, it is a matter of utter indifference whether white lead is prohibited or not?—Yes, from that point of view.

11,684. (*Mr. Gardner.*) You are interested in lead compounds for tinting purposes?—I am only speaking now of white lead, not lead products.

11,685. (*Chairman.*) Why do you draw special attention to the immense amount of capital you have invested in the business?—As a justification for appearing before you.

11,686. To give evidence?—Yes, to give evidence.

11,687. And only on that account?—Yes, that is it.

11,688. Then I quite agree. That is most proper?—With reference to the suitability of white lead and other pigments for general decorative purposes, with a view to correcting or confirming their own opinion as to the relative cost, body, covering power, and durability of white lead as compared with zinc white and other substitutes, representatives of the Paint Manufacturers' Associations have made inquiries of certain representative decorators and coach-builders in different quarters of the kingdom, and here is a summary of the 350 replies received. May I read those to you?

11,689. I do not think I can take this unless I have the names of the firms?—The names are all here.

11,690. We have heard a great many of these gentlemen?—Since we started this we found that you had had several painters before you.

11,691. Do I understand this to be a summary that you have made of the letters?—A summary of the replies.

11,692. We must consider very carefully whether that shall be put in as evidence. I do not know whether there is any precedent for evidence being tendered by proxy. I have never heard of evidence being accepted in this form, because there is no opportunity for cross-examination. I am much obliged to you for the trouble you have taken in getting this evidence. You will leave the replies with us?—Yes.

27 July 1911.]

Mr. A. W. WILLIS.

[Continued.]

11,693. (*Dr. Collis.*) I do not understand which years you quoted with reference to lead poisoning in the paint and colour industry?—1900 to 1909 inclusive.

11,694. You know when the regulations came into force?—I am not quite sure.

11,695. In 1907, in January. In 1909 there were 39 cases with two deaths?—Yes.

11,696. That is the only year of the whole 10 years that you have chosen in which there are two deaths?—It does not follow that they were contracted that year.

11,697. I am taking your figures. There are only four years of the whole 10 which are higher than that?

(*Chairman.*) It is not very material.

11,698. (*Dr. Collis.*) No, it is not very material; but, having regard to the expensive appliances which you have installed, we expect a greater reduction in the future. We are not blaming the paint and colour manufacturers for a moment?—I am only drawing your attention to the facts. In 1908, the year after the introduction, the cases were reduced to 25.

11,699. In 10 years there were 422 cases?—Yes.

11,700. We expect a reduction to follow. Forty-two is the average for the whole 10 years, and in 1909, the last year of the 10 which you have, the number is 39; 1909 also happens to be the only year of the whole series in which there are two deaths?—Lead poisoning is cumulative.

11,701. Why should there be a rise up to 39 cases?—In all these things there are variations. Some of these cases may have been recurrent cases.

11,702. Sufficient time has not elapsed, since the bringing in of the regulations, to give you or ourselves an opportunity of seeing the value of them?—To bring the cases down to 17 from an average of 42 is significant.

11,703. (*Chairman.*) Among house-painters, the average yearly number of reported cases is 197.3 and 38.3 deaths, and in 1910 there were 232 reported cases and 35 deaths?—Yes.

11,704. They have gone up?—Yes; showing considerable room for regulation and education of the boy at school. He should be taught that when he is handling lead or lead products he has to be careful of lead poisoning, and regulations should be exhibited in workshops. We think that those would be very valuable means of educating the men, even if they were not always carried out.

11,705. How would you propose to get rid of the dangers arising from the dust that is generated in rubbing down, and dust and splashes in other operations?—There is no dry white lead used by painters, speaking broadly.

11,706. How would you propose to get rid of the dust that is generated in dry rubbing down?—By the use of respirators.

11,707. Have you ever known a respirator that would do?—Mr. Carson is prepared to show you a respirator which has been used.

11,708. But supposing that the men would not wear the respirators?—I think that they should be subject to a fine; I think that that would soon make them use them, especially when it was pointed out to them that it was for their own benefit.

11,709. (*Dr. Collis.*) You have referred to the money which has been expended by the paint and colour trade in setting up the appliances for carrying out the Home Office regulations?—Yes.

11,710. Those appliances have to be maintained, have they not?—Yes.

11,711. And they cost money for maintenance?—Yes.

11,712. Exhaust fans have to be kept running, and they have to be kept painted to preserve the fan?—Yes.

11,713. Medical examination has to be paid for?—Yes.

11,714. Although you have expended a large amount of capital, you still have considerable expenses in maintaining the regulations?—Certainly.

11,715. Which you would avoid if you were not grinding lead paints?—I think that we should still use them to prevent certain dust getting absorbed by the worker.

11,716. We should not object to your using them, of course, but my point is that the Home Office regulations would not call upon you to continue to spend money in that direction. You would not have the regulations as at present drawn, so there would be a saving as far as the legal requirements go?—Yes, in the upkeep.

11,717. So that although you had to spend money in the past, if there was a prohibition of lead you would actually be saved something?—Yes. We do not look on that as very important.

11,718. No, but since you raise the question of the money expended, it is a point that, I presume, has also to be taken into consideration, is it not?—Yes.

11,719. Do you wish to speak yourself in respect of respirators, or do you leave that to Mr. Carson?—I leave that to Mr. Carson.

11,720. (*Mr. Sutherland.*) Do you know the paint formula of the Office of Works?—No, I have no knowledge of it.

11,721. You have never tendered?—No, not direct, since they have had a new formula out.

11,722. Do not you think it an extraordinary thing that the manager of a department in the Office of Works should have solved this question of substitutes satisfactorily?—Yes, I do.

11,723. When paint manufacturers have been striving for a long while to find a satisfactory substitute, do not you think it an extraordinary thing that the Office of Works should have succeeded where the manufacturers have not?—Yes. I do think it most extraordinary that they should have found out what other painters have been unable to find out.

(*Chairman.*) Sir Henry Tanner encouraged them for years. They have been experimenting for 12 or more years, and were most zealous and determined, and they have achieved this result.

11,724. (*Mr. Sutherland.*) Do not you think that any firm who found an effective substitute for white lead would readily scrap all their machinery and make this substitute, if it was as good as white lead as a paint base?—Yes, if it was as good under all circumstances, they certainly would.

11,725. Would not they make a great fortune out of it?—No doubt they would.

11,726. So that the point that the Chairman was seeking to bring out would be answered by that reply?—Yes.

11,727. Any firm that could find a basic substitute for white lead that would give all the qualities of white lead, would make an immense fortune?—Yes.

11,728. You do not know of any such substitute?—No, we have not found one yet.

11,729. You would not say that zinc white, good basic material that it is, has the qualities of white lead?—No; the trade maintain that it has not.

11,730. It needs to be fortified by the addition of varnish?—That improves it, but that will not do under all circumstances.

11,731. But for outside work?—It helps.

11,732. With special oils?—It would not be equal in our opinion to white lead then for outside work.

11,733. So that there is a very marked difference between the two as a base for paint?—Yes.

11,734. You know that a large number of paints that the Office of Works specify are proprietary paints. You would not compare those with a base paint like a white lead paint. It would not be fair, would it?—No, I should say not. I do not know what they contain.

11,735. Two or three well-known firms have been before us and said they supply the Office of Works and make their paints according to the Office of Works formula, but you would not accept that as a basic paint like you would accept white lead and linseed oil?—No.

11,736. It is a special formula to which are added special things to give it the lasting qualities which they claim for it?—Yes.

11,737. (*Mr. Fell.*) Does your association prepare paints for coaches, tramcars, and motor cars, and that sort of thing?—Yes.

27 July 1911.]

Mr. A. W. WILLIS.

[Continued.]

11,738. Have they experienced any difficulty in preparing certain colours?—Dr. Crow will deal with that.

11,739. (*Mr. Gardner.*) As paint grinders, when you put out new material on the market, such as some of the water-paints, you do not expect a painter to use them as he would ordinary white-lead paint. You would expect him to use special precautions and prepare them in a special manner before he puts them on a wall or uses them in a room?—Yes, he has to follow out the instructions usually given with the particular article.

11,740. But when zinc is issued, you do not issue any special instructions?—No. Zinc is usually supplied like white lead, in a stiff paste, and the painter mixes it up to his own requirements. It is only when it is mixed specially, ready for use, and sold under a proprietary name that it comes under a different category.

11,741. The painter in getting zinc gets it like white lead and uses it as white lead. He gets no warning: "This is not white lead, and you must prepare it in a special manner in order to get a satisfactory result?"—A painter should know the difference between white lead and white zinc, and he mixes the paint according to the work that it is for. If it is for inside work, he mixes it in one way; if it is for outside work, he mixes it in another way.

11,742. But how could a painter know, if he has had no experience of zinc, the difference between white lead and zinc when preparing it for use. No intuition would teach him how to do it. He must learn how to use the material?—The master painter is the man who teaches him.

The witness withdrew.

Mr. K. K. CARSON examined.

11,749. (*Chairman.*) Do you attend to-day as a representative of the London Colour, Paint, Oil, and Varnish Trades' Association?—I do.

11,750. Have you the same authority as Mr. Willis to represent certain provincial associations as well as your own?—I have.

11,751. I understand you are instructed to speak mainly in regard to precautions which may be taken for mitigating the evils of lead poisoning?—Yes.

11,752. In the first place, do you advocate the supply of ready-mixed paint to painters?—I think that it would be a distinct advantage if the painters were to buy their white-lead paint in a ready mixed form, but if they will not do that, I think it would be very advisable that they should employ one man specially for mixing, and not allow all their staff of painters to mix separately and then take the paint to their jobs. I think that that is a great source of danger.

11,753. Do I understand that you consider the mixing of paint by painters themselves to be a dangerous operation?—I do, unless they keep themselves clean.

11,754. Do you consider the handling of dry white lead, without proper precaution, to be a grave source of danger?—I should say certainly with painters, and there is no necessity at all for them to be supplied with it.

11,755. Do you advocate, then, the prohibition of the sale of dry white lead?—Absolutely.

11,756. Do you consider that the wearing of overalls by painters should be made compulsory?—Certainly.

11,757. And that the overalls should be washed periodically?—At least once a week if the men are in regular employment. If they are jobbing men, the overalls ought not to be used for more than seven or eight days.

11,758. And they should certainly be removed during meals?—That I consider is a very essential point.

11,759. This would of course involve the provision of a suitable place to deposit the overalls?—They can usually hang them up, I think, where they are working; they would be quite safe. There is generally a room that is idle.

11,743. But the master painter does not know any better than the workmen, when he gets a new material. He has been accustomed to white lead all his life, and unless he is told by the grinder or the manufacturer: "This is a new material and it requires special treatment," how is he going to give it that special treatment?—But he has not had the new material yet. White-zinc paint is not a new article. It has been before the public and been used by painters for very very many years. It is not a new article.

11,744. No, it is not a new article, but it is quite a different article from white lead, and I suppose you will take it from me that not 50 per cent. of painters use it?—Very likely not, especially the lower-class painter. The high-class painters would all know the value of zinc, and how to mix it, because they would want it for special decorative work.

11,745. Do you sell much bleached boiled oil to painters?—Nothing in comparison with dark boiled oil.

11,746. Do not you think that you could do a much larger trade by recommending it for use with zinc?—My firm always do recommend it.

11,747. I have been making inquiry among a number of master painters, and 75 per cent. of them have never heard of bleached boiled oil; it never is inquired for and they do not know what it is used for. I am speaking of large firms. I think that the grinders should go into that question a little bit, and recommend it for use with zinc?—We recommend the use of bleached boiled oil in our printed instructions.

11,748. When you send it out for use?—Yes.

11,760. In a room where lead is used?—It would not matter at all if the paint were dry.

11,761. What about the dust?—There is no dust from lead after it has been put on.

11,762. But I am referring to the droppings on the floor that are kicked up?—That would not hurt at all.

11,763. Why not?—It is all mixed with oil, and it oxidises the same as on the wall. No dust can possibly come from lead which has once been mixed with oil.

11,764. Except when it is dried up?—When it has dried up, it is not powder.

11,765. (*Lord Henry Bentinck.*) What is the object of washing one's hands then?—They eat with dirty hands very often, and they absorb it through the mouth.

11,766. They do not absorb it in a wet state, but in a dry state?—They can absorb it if it is mixed in oil or if it is in dry powder, equally.

11,767. (*Chairman.*) I understand you to say that you advocate overalls being hung up at night in the rooms where they have been at work?—Not at night. I think they ought to have a proper room for the purpose—but while they are taking their food, I mean. They may be away on a job.

11,768. Would you advocate a rule prohibiting overalls being left in any room where work is being done?—Certainly, over night.

11,769. Or in the daytime?—It depends on how long the work has been done.

11,770. Would it not be better to prohibit it altogether?—I quite agree. You cannot be too careful, I admit.

11,771. Do you consider it essential that the employer should always provide his painters with a supply of water for washing?—Most essential—and and soap.

11,772. And hot water?—Cold, preferably.

11,773. Why is not hot water better?—Hot water tends to open up the pores rather than cold.

11,774. You do not put that forward seriously as an objection?—No; it has been said to me by men who have experience.

11,775. Is it not more reasonable to say that without hot water you cannot clean your hands properly?

X 4

27 July 1911.]

Mr. K. K. CARSON.

[Continued.]

—Yes, to a certain extent, I think it is, but I have had that put to me. I think it does not very much matter either one way or the other.

11,776. You advocate also a supply of soap and towels?—Certainly; that is very essential.

11,777. A regulated number of towels, I suppose?—Yes, certainly.

11,778. Do you consider that a certain time should be allowed to the men for washing purposes before each meal time?—I do.

11,779. Out of the employer's time?—Certainly.

11,780. You recognise that the breathing of lead dust in the process of dry rubbing-down is a serious danger?—I certainly think it is.

11,781. What precautions do you recommend in regard to this danger?—The use of a suitable respirator, in my opinion, or prohibition altogether. This is a form of respirator that we have used for some 60 years or at least 40 years (*producing the same*).

11,782. To take your alternative suggestion first, could you prohibit dry rubbing-down altogether?—I see no reason why not. There is a lot of prejudice in the trade against it, I admit.

11,783. Do you believe in trade prejudice?—To a certain extent. I believe it is essential to dry rub down new work but not old work.

11,784. Would you prohibit it entirely?—If you prohibit it, they can do nothing else but use the wet process. I certainly think it should be prohibited, but I think that that respirator would practically answer very nearly the same purpose as prohibition.

11,785. (*Lord Henry Bentinck*.) Is it used by the paint-grinders?—By the men who pug, who put the dry white lead to the oil. The grinders do not use it. It is not necessary.

11,786. (*Mr. Sutherland*.) Is that respirator efficient?—Absolutely. I may tell you that for the last 40 years we have only had one case of lead poisoning that I know of. It was lead colic rather.

11,787. (*Chairman*.) How long would you like to wear that respirator yourself?—I have worn it for an hour or two at a time very often.

11,788. Do you like it?—No, I do not like it.

11,789. I have never seen one that anybody would like to wear?—There are some that are ordinary plain canvas or linen bags which are very efficient.

11,790. The best I have ever seen is a piece of wet sponge worn across the mouth and nostrils?—That would be useful. There are lots of different forms.

11,791. The evidence we have had in other Committees proves that there is no respirator that a man will wear?—They have to wear them. You must make the master-man responsible in the first place.

11,792. But suppose the men will not do it?—I would sack them; that is all.

11,793. I want you to take a kindlier view than that. If the State allows you to use a dangerous element like lead, you must protect the men and you must not greatly inconvenience them in protecting them. If you do greatly inconvenience them, you must not talk about sacking them?—I do not consider that it is a great inconvenience. It might not be very comfortable for them, but they are not wearing them all day long. It is only for a short time.

11,794. How many hours a day would a man wear a respirator?—Not once a week in the ordinary way. He is not dry rubbing-down all the time.

11,795. Would you have a time limit, that it should not exceed so many hours a week?—I should not think that necessary.

11,796. I want you to put forward something practicable?—I see what you mean. He has to finish his job, and it depends upon how long the dry rubbing-down will take.

11,797. Can you speak with any authority on the time that a man would occupy in dry rubbing-down?—No.

11,798. I cannot pursue that point then. Do you advocate a regulation forbidding the smoking or chewing of tobacco while working with white lead?—I think that that is a great source of danger. The men have dirty hands and take a cigarette up full of lead,

or they chew tobacco, and they will absorb a certain amount of lead.

11,799. Do you consider that the periodical medical examination of painters is desirable?—I think it is essential.

11,800. And that the employer should bear the cost of it?—Certainly.

11,801. You have outlined a number of very useful precautions which might be taken. Do you consider that these would remove the danger of lead poisoning?—I think that they would reduce it at least 75 per cent. if they were properly carried out.

11,802. Would it be possible to carry them out?—I see no reason why not.

11,803. Have you thought them all out from beginning to end?—I can see no real difficulty. You always get opposition at first.

11,804. But how would you be sure that the rules were being enforced?—You would have medical inspection so many given times a year. That would be one thing.

11,805. Let us take the medical inspection first. Supposing the Home Office were to say that they were to be examined once a month?—I do not think that they would need to be examined once a month.

11,806. You are not a doctor?—No.

11,807. Do not you think that the Home Office would have to have them examined at the same periods that they adopt in other industries?—I do not think that the painter would have the same risk as a man would have in our own business.

11,808. But the incidence of lead poisoning amongst house painters is greater than in all the other lead industries put together; so the Home Office would never agree to have less stringent rules than in other industries?—But our industries are dealing with lead, more or less in a powdered form, whereas the house painter never touches it in a powdered form. The painters' trade is not nearly so dangerous, I should say, as lead grinding.

11,809. There are more deaths per year among house-painters?—Because there is more carelessness.

11,810. I should think the Home Office would not be inclined to introduce, and I do not suppose this Committee would be inclined to recommend, less stringent rules in the house-painting trade than obtain in the other lead industries?—I see your point.

11,811. I want to know, first of all, how you propose to enforce the medical examination once a month of painters all over the country?—I think that once a month is rather more often than necessary.

11,812. Would you answer the question?—They could have the men summoned at given times and the doctor could go there.

11,813. Have you thought it out in a practical way? Men scattered all over the country might be miles away from a certifying surgeon. There would be the expense of the man's journey if he was in some country district in the North and had to go to Sheffield, say, to be examined?—When men are away on jobs it would be a rather difficult matter.

11,814. Are they not very frequently away on jobs?—Yes, very frequently.

11,815. Then do not you see practical difficulty in the way?—Say, on Saturday, when they are paid, or on Monday, they could easily come up in a group or a body. It would be an extra expense to the master-men, slightly, but I think they would willingly go to that expense rather than have cases of lead poisoning.

11,816. With regard to washing, for instance, how would the Home Office know that soap and towels and all the other things are always there for the men?—They could have a few inspectors to go round occasionally.

11,817. How many inspectors do you think would be required to have any practical effect?—There are 230,000 painters, roughly.

11,818. How many jobs are there in operation at the same time that would have to be inspected?—It is very difficult to say.

11,819. If you had to come up and give a report to the Home Office on this, how many inspectors do you think you would say would be wanted?—I think you

27 July 1911.]

Mr. K. K. CARSON.

[Continued.]

could get through very well with about 50. You see once you take the point up and you find flagrant cases, you make people frightened and they will not continue. They will be much more careful. You have only to drop on to people a few times. That is my own personal idea.

11,820. Have you any idea what it would cost the State?—None whatever.

11,821. It would cost a large sum every year, with travelling expenses?—You would probably be able to reduce the cost afterwards when you found that things were working well.

11,822. But you know what human nature is. If the pressure is removed we forget all about the pain, and if you removed the pressure of the factory inspectors there would be chaos?—I think that a little teaching and a little moral persuasion would go a very long way with these people.

11,823. Do you seriously think you could inspect a great range of man scattered on jobs all over the country?—No, but what I do feel is that if the greater number of those men were examined at the shops and various painting places over so often, you could tell if they were in a fit state to work in lead or use lead. Some men are far more prone to lead poisoning than others. Some can stand it a great many years and others cannot stand it at all.

11,824. You have admitted that the great evil in this industry is the dust?—Yes.

11,825. How would you ensure any rule being carried out by which the workmen would wear respirators and so avoid the dust?—I think that the employer would certainly see that a thing like that was carried out. It ought to be his duty to see to that.

11,826. But how could he do it? If he is situated in a town, how could he see that his scattered men carried out these regulations?—You would put the onus on the foreman on the job. That is what I would do.

11,827. Would you suggest that the foreman should report to the employer every week as to how the men have behaved themselves?—Yes, he would report any violation of the rules.

11,828. And should that be reported to the Home Office?—That is a matter for the Home Office.

11,829. I do not want any vague evidence?—I think that would be a very good suggestion, if there are any violations of the rules.

11,830. (*Lord Henry Bentinck*.) I suppose your men are more or less in your own hands—concentrated?—Yes, they are concentrated.

11,831. You cannot speak with much authority as to the possibility of enforcing these regulations when the employment is very much scattered?—No. One could not give the same surveillance quite, I suppose, but still you could make your foreman responsible for your orders being carried out, and for rules and regulations being carried out if they are the law.

11,832. (*Chairman*.) I notice in your proof you say that, in collecting statistics, some distinction should be made between first attacks of lead poisoning and repeated cases?—Yes. It occurs to us that a large number of the reported cases are recurrent.

11,833. This is already done by the Medical Inspectors of the Home Office?—As it is cumulative it might go on for five or ten or twenty years. That is the trouble.

11,834. The present system is that if a man is attacked and he suffers another attack within 12 months, it is not put down as two cases?—But if it occurs in 15 months it is put down as two cases.

11,835. If he gets lead poisoning three times at intervals of more than a year, it is put down as three cases?—I think that the man ought to have a cross put against him. He should be ear-marked, and if he is subject to lead poisoning to that extent, he should find another mode of employment, because it is those particular men that add to the death-roll in the trade. There is no question about that.

11,836. (*Lord Henry Bentinck*.) It is not their fault?—It is not their fault, but they are not fit subjects for the work.

11,837. (*Chairman*.) You would agree that if a man is injured to that extent, he should be compensated by the employers?—That is a matter for the Government.

11,838. But should the employer be asked to compensate?—I would not express an opinion on that.

11,839. Do you consider that the chipping off of lead paints is dangerous, for example, in the holds and peaks of ships?—Yes, certainly, when they hammer.

11,840. What would you suggest to remove the danger?—Using a detergent or pickling. It would not hurt on iron at all.

11,841. Should the chipping off of old lead paint on ironwork be forbidden?—It would not matter much if it were in the open, outside, and if they wore respirators of some kind, but in a close hold it ought to be prohibited.

11,842. You speak here to-day on behalf of your association?—Yes.

11,843. I should like to inform you that the large preponderance of employers who have been before us have stated that such rules as you have put forward very fairly would be impossible to carry out?—Yes, I know.

11,844. And they have gone further and many of them said they would prefer prohibition to enforcement of such rules?—They always do kick a lot. We said, first of all when these regulations came to us, that we could not carry them out; it would be impossible; but we find we have to do it.

11,845. I only said that in contradistinction to the evidence which you put forward?—I know there is a great deal of talk; they cannot do this and they cannot do the other.

11,846. I put that statement forward in view of the evidence and the replies, referred to by Mr. Willis, from this large number of firms. In examination and cross-examination they have finally admitted—or most of them—that they prefer prohibition to the infliction of rules, because they would find it impossible to carry the regulations out. I dare say that a large number of these gentlemen who have written statements would hold a similar view if they came before us and were cross-examined?—I cannot speak as to that.

11,847. Would it not be possible to utilise the same machinery and plant in grinding zinc or other non-poisonous paint which you now use for lead?—The same machinery could be used.

11,848. (*Lord Henry Bentinck*.) Do you advocate a monthly medical examination of the men?—I do not advocate it monthly; I advocate the examination of the men. The Chairman suggested monthly.

11,849. If a workman was found to be suffering from lead poisoning, he would be liable to lose his job?—Not until it was a recurrent case, I think.

11,850. If he was found to be suffering from lead poisoning, do you think that the employer would renew his engagement if he recovered?—Certainly I think so, as they have done before.

11,851. He is insured, and if he is liable to be a charge to the employer, is he likely to be employed?—I should say so, but really I cannot answer for employers.

11,852. (*Dr. Collis*.) In reference to a point I did not quite understand in the answer you have just given, you said that men should be ear-marked when they had an illness?—Yes.

11,853. If a man is ear-marked, you say he should not come back into the trade?—Only if he is ear-marked many times; that is to say, if it is really serious. It is a matter for the doctor to say if he is a fit subject to continue to use lead or not; it ought to be left to the doctor. Because he has had a small attack of lead colic, there is not necessarily great danger.

11,854. You said serious cases?—If it keeps on recurring, he has no right to continue to work in lead.

11,855. You have shown us a respirator?—Yes.

11,856. Have you ever worn it and done work?—Yes, certainly.

11,857. Much work?—Yes.

11,858. For how long?—At least two or three hours.

27 July 1911.]

Mr. K. K. CARBON.

[Continued.]

11,859. Were you a bit out of breath before the end of the time?—No, I have not been seriously inconvenienced.

11,860. Did someone else put it on after you had worn it?—No. We always keep our own "muzzles," as we call them.

11,861. You have one for each man?—Yes.

11,862. If a man has a bad cold or an attack of influenza, and is away for a week or ten days, as must happen, what happens to the respirator meanwhile?—It is locked up in a certain place, I believe. My foremen control all that sort of thing.

11,863. When he comes back, what then?—It is given to him.

11,864. He re-infects himself with influenza, or whatever it is?—They always change their wools.

11,865. But that does not disinfect the velvet or the respirator itself at all?—I do not know whether we use formalin or not.

11,866. I should condemn the respirator. It holds residual air, and there is the danger of infection—two of the chief things that are said against respirators. I daresay this stops dust; but to be a satisfactory respirator it must be capable of being disinfected, and it must not impede breathing?—I do not think it will impede breathing.

11,867. I had it on for about five minutes, and it did?—You are not working.

11,868. No, except with my brains, I hope. You do not remember the first introduction of these respirators?—No, they have been in use for 60 years.

11,869. Have you had trouble in getting your men to wear them?—Not a bit.

11,870. Do they use them regularly?—Yes.

11,871. Not intermittently?—They only use them when they are on lead.

11,872. Are they on lead continuously?—Certain men are off and on continuously.

11,873. They do not work for half an hour on and two hours off?—Not necessarily. They might work for two hours and have the rest of the day off.

11,874. Usually they work straight ahead?—Yes.

11,875. It is a fairly long piece of work?—Yes; on making inquiries I find we allow our men to periodically remove their respirators and breathe in the open air.

11,876. We are given to understand that the dry process of rubbing down paint in houses is short and intermittent employment?—That is a matter for the decorator more, is it not?

11,877. Even if you have respirators in factories under the eye of the master and foreman, and possibly the factory inspector, who may catch them, how are you going to make painters wear them for similar short and intermittent jobs; the man may be 20 miles off in a private house with no master present and no foreman present, and it being a private house, which is an Englishman's castle, no inspector can enter?—It is very difficult.

11,878. Do not you think that it would be practically impossible to inspect under the circumstances?—It would be impossible in that case, but a painter would look after his own interest.

11,879. You have some knowledge of men?—I have.

11,880. Knowing human nature is what it is, do not you think it is impossible? You are not makers of dry white lead, but buyers?—Yes, buyers.

11,881. Is all that you use made in England?—Not all.

11,882. Have you any idea of the amount that is not made in England and the amount which is?—Do you mean of what we use or of what is used generally?

11,883. Taking yourselves and the trade as a whole?—I could not tell you.

11,884. It is rather necessary to know, because it has been suggested that the non-use of white lead might throw people out of employment in England?—It undoubtedly would.

11,885. So it is necessary, therefore, to know the proportion that is imported from abroad and the amount that is made at home?—There are probably some figures to guide one in that respect.

11,886. But you are not in a position to say?—No.

11,887. What foreign white lead you buy, you buy dry?—Yes.

11,888. If it could not be bought dry?—It might come straight in and go through a dealer.

11,889. (Mr. Sutherland.) You think that the lead industry, and what follows on it, is of sufficient value to bear the restrictions which the Home Office might put upon it both with regard to the decorator and the paint manufacturer?—I think so.

11,890. You perhaps do not know that most painters come in at the very outside once a month. That is part of their working rules. They are seldom longer away from home, so the operative painter could go to the medical officer once a month and be examined. That would not present the difficulty that you thought of?—No.

11,891. Do you think that the operative painter could be got to wear that respirator?—I would not say that particular form.

11,892. You have no idea of the amount of time occupied in rubbing down on a job?—I have no idea.

11,893. Many painters would go for two or three weeks without doing dry rubbing down?—I should think so.

11,894. Even if they were compelled to wear a respirator, which would only be needed in special cases, it would not be a great hardship?—In my opinion, no.

11,895. (Chairman.) You seem to minimise the risk of dust causing the dangers that the men are confronted with. How do you account for the deplorable prevalence of lead poisoning?—Dirty hands and absorbing lead through the mouth. Eating and smoking with dirty hands, to my mind, are the greatest dangers.

11,896. (Mr. Kinggate.) I notice that you lay great stress, as a great many do, on the dirtiness of the painter or the man who uses the lead. I would like to know what knowledge you have of the ordinary coach-maker's shop with regard to that?—I have no knowledge of coachpainters' shops.

11,897. You only speak from hearsay?—I am not talking particularly of coach-painting, but of general painting.

11,898. What is your knowledge with regard to general painting?—The men, as I see them, very often are covered with much more lead on their hands than they should have.

11,899. Do you know that they do not wash when they have meals?—A great number of them do not wash.

11,900. You know that that is so?—Yes.

11,901. With regard to medical examination of the workers, how many times would you think that a man should be certified as suffering from lead before he should be compelled to leave his trade?—That is a question that I do not think I am in a position to answer. I am not a medical man. I think a medical man should decide a point like that.

11,902. You have said that a man should not be allowed to continue to work at his industry if he has recurrent lead poisoning?—Yes, in other words if he is endangering his health permanently.

11,903. But does not working in lead endanger the health of every man?—A great number of people never suffer at all from it.

11,904. How do you know?—I have been in and around lead for the last 24 years myself, and have never suffered at all.

11,905. I have been in it for more than 35 years, so I know something about it. Perhaps it might be news to you that there are hundreds of cases that are never reported. Men are periodically off, but not certified as suffering from lead poisoning. If you had strict medical examination, and these men were examined, they would be found every time to be suffering from lead. How many times should they be certified before being discharged from their employment?—It entirely depends, in our opinion, on the condition of the men.

11,906. If a man's health is impaired, which it is by the use of lead, what would you say? What would you do with the workman?—(No answer was given.)

27 July 1911.]

Mr. K. K. CARSON.

[Continued.]

11,907. (*Chairman.*) (To the witness.) Would you rather have the question postponed for Dr. Crow?—Yes.

11,908. (*Mr. Kinggate.*) You say you would not allow them to work at their industry, so what should be done with them? They may have been apprenticed and their fathers may have paid a heavy premium?—If they are going to suffer they should get some other employment. It would be wise.

11,909. (*Chairman.*) Do not you think that if they have been injured to that extent, they should be compensated by the people who have injured them?—That is a matter for the State to decide. I would not like to express an opinion on that.

11,910. (*Mr. Robins.*) Is it your opinion that the painter of to-day is far more intelligent and healthier in his habits than 20 years ago?—Yes, emphatically yes.

11,911. Then how do you account for the greater number of cases of lead poisoning during the time that he has been more intelligent and more cleanly?—There are more painters now, I take it, than there were 20 years ago. You may get more cases, but are the percentages higher?

11,912. The percentages are higher than they were 20 years ago notwithstanding the extra intelligence of the man and his extra cleanliness?—It does not always follow that because a man is intelligent he is clean, but I should have thought that they were cleaner than they were. Cases were probably not so carefully reported 20 years ago as they are to-day.

11,913. I am sorry you have the impression that you have expressed of the working-man. You have no knowledge at all, I presume, of painters in a coach-making shop?—No.

(*Mr. Robins.*) I can guarantee that, taking any paint shop you like where a painter has been painting, no doctor would certify any man in the shop as entirely free from the influences of lead poisoning in his system. You can generally tell, if the men are standing outside without their aprons which are the painters.

11,914. (*Mr. Parsonage.*) What personal knowledge have you of house-painters, when you say they do not wash their hands before meals?—I do not say they all do not wash their hands, but a number do not.

11,915. What percentage do you know of painters who do not take the trouble to wash their hands?—I could not give you any percentage; it is impossible.

11,916. Is it not a slander on the workmen to make a statement like that without being able to give some authority for it?—I think it is quite a known thing that the washing arrangements are not carried out as they ought to be in every case. I do not say that most of the men do not wash; they certainly do.

11,917. Would you say that the workmen, where washing accommodation is provided, refuse to wash their hands?—No, I do not say that.

11,918. Would you blame the employer for not providing proper accommodation for washing?—The employer certainly should provide proper accommodation.

11,919. Do you think that he does at the present time, and allows a reasonable time for the workman to wash his hands?—No doubt a great number of employers do.

11,920. Would you blame the employer equally with the men for their not being cleanly?—I think that every employer ought to look after his men.

11,921. You are employed in lead works, and you say you have had no lead poisoning although you have been in it for 24 years?—Yes.

11,922. Have you handled the lead?—Not in recent years.

11,923. Do you ascribe your immunity from lead poisoning to your own personal cleanliness?—No.

11,924. Do you admit that even the most cleanly man can still take lead poisoning?—Certainly.

11,925. Then cleanliness is not the main point?—I still beg to differ.

11,926. With regard to these regulations, would not the employer be equally ready to evade the regulations as the workman, seeing that it was to his interest to evade them in order to get the work done?—I see no reason why.

11,927. You would put the penalties on the employer?—I think he ought to see that any regulations are carried out.

11,928. What effect would you expect these regulations to have on the trade with regard to the quantity of painting work done?—I do not think it would alter the quantity in any way.

11,929. (*Mr. Gardner.*) As one preventive of lead poisoning you advocate ready mixed paints?—Yes.

11,930. Do you think that the fumes arising from the mixing of paints are a cause of lead poisoning?—No.

11,931. Then what is the cause?—They get the lead on their hands, and in work they may stroke their mouths and absorb a certain amount of lead through the mouth. That is my only point. They should keep their hands as clean as possible.

11,932. A man mixes paint on a job in small quantities. He does not get his hands dirty?—If they use due care they need not do it.

11,933. Would it be practicable to mix all paints in a workshop? Each coat must be treated in a different fashion?—I admit that.

11,934. If there is no danger except that of getting dirty hands?—Cleanliness to my mind is the great thing.

11,935. You advocate the supply of water and towels and soap?—Yes.

11,936. If a man does not wash his hands it is because he does not get facilities?—Very often.

11,937. Very often it is very difficult for employers to provide these. On one job there will be 20 men and on others only three. Some may last a week and some only a few hours. Is it not most difficult to carry out regulations?—I think they can always arrange to have water and towels and soap on a job. We have a lot of difficulties in business, but we usually surmount them.

11,938. You are different because your men are gathered under one roof and not scattered about?—In nearly every place where there is a painting job there is water laid on.

11,939. Not always?—In nearly all. There is usually a pump or something to which to take a bucket.

11,940. With regard to the chipping off of scale, do you think that it would be practicable to scale the paint off the skin of a ship with a solvent?—Do you mean outside or inside?

11,941. Inside?—I think so, certainly.

11,942. How are you going to protect the deck underneath?—That is the great difficulty with a pickling solvent. You could use a spirit solvent which would not hurt the deck in any way.

11,943. If I want to scale the 'tween-deck of a ship, how am I going to protect the decks underneath if I use a solvent?—If you used a spirit solvent you would not require to. If you used a pickling solvent it would be perhaps difficult.

11,944. You have to clean off the skin?—Yes.

11,945. These are some of the practical difficulties. Chipping is bad?—Chipping is bad, most decidedly. You come back really to the use of a respirator. You can stop this danger.

The witness withdrew.

Mr. J. K. CROW, D.Sc., examined.

11,946. (*Chairman.*) Are you Examiner in paints, colours, oils, and varnishes at the Technological

Department of the City and Guilds of London Institute?—Yes.

27 July 1911.]

Mr. J. K. CROW, D.Sc.

[Continued.]

11,947. Do you attend to-day as a representative of the London Colour, Paint, Oil, and Varnish Trades Association?—Yes.

11,948. Have you the same authority as Mr. Willis to represent certain provincial associations as well as your own?—Yes.

11,949. I understand that you are prepared to speak specially in regard to the manufacture of yellows, greens, and reds?—And also the lead contents of driers, oils, and varnishes.

11,950. Do you maintain that the use of lead compounds in relatively small proportions is essential in such paints—yellows, greens, and reds?—In some proportion.

11,951. That is to say, in relatively small proportions?—In some cases, I think, in large proportions.

11,952. What proportion of lead compounds do you consider necessary in yellows?—Well, sometimes a high percentage is required. In some of the colours that are used for lining in the coach trade, where just one single line of colour is required on another, as a general rule a chromate of lead is employed in those cases, in which the percentage of lead metal would be from 60 to 80.

11,953. Is that lining a very small part of the painting of a coach, an infinitesimal part really?—It is infinitesimal, but for beauty it is necessary.

11,954. Have you anything else to suggest about yellows?—With regard to zinc yellows, a zinc yellow would hardly be suitable for lining purposes, because it has not sufficient opacity. Its staining power is only equal to a lead chrome that is reduced to a fifth of its strength by an adulterant.

11,955. You were telling us about the proportion of lead compounds in yellow paint, and you told us the amount of lead contained in the yellow paint that is used for lining. In what other yellow paints is it used?—For ordinary yellow chrome paints, mixed kinds, say 10 to 20 per cent.

11,956. Is the painting of the lines on a coach with yellow paint essential?—It is a matter of taste, I suppose. Some people like yellow, and some other colours.

11,957. Now you are going to tell us the effect of painting the lines with non-poisonous paint, are you not?—Yes. Zinc chromate would not answer, because it has only one-fifth of the opacity of a corresponding lead chromate.

11,958. What effect would that have on the coach?—It would be an inadequate colouring, that is all.

11,959. It would not be sufficiently strong, you mean?—It would not be sufficiently strong.

11,960. The line would not be?—The line would not be.

11,961. It would be a faint yellow line instead of a strong one?—Yes, transparent I would rather say.

11,962. Has nothing been found to mix with the lead chromate to make an effectual and lasting line and equally opaque?—A lead chromate is very strong, and even a 50 per cent. strength one might perhaps cover sufficiently well, but I know of no other colour except cadmium yellow, and that is excluded by the price.

11,963. Is there any danger to the workmen in painting the lines?—I should say not.

11,964. Is there any scraping down beforehand?—No.

11,965. Or any sand-papery?—The coach would have to be prepared for that, as for any other colour, but there would be no special preparation.

11,966. So that the workmen who put on the yellow lines would not run any risk with regard to dust?—None whatever.

11,967. Have you anything to say about preparing the paints?—That is done in our works under supervision. They are always ground in fine mills.

11,968. (Mr. Sutherland.) The paint is generally supplied in a tube, is it not?—It is generally supplied in a tube.

11,969. And the man just squeezes out what he wants?—Yes. It may possibly be supplied in larger packages.

11,970. (Chairman.) What proportion would the paint in the yellow line be to the paint on the whole of the coach?—That is rather a poser. I would say a thousandth part of the area, as a shot. It is really too minute to estimate.

11,971. Have you given me all the proportions of lead compounds that you consider necessary in yellows?—Yes, I think so. I think you asked me if I had anything else to say about yellows. The only other point I was going to impress upon you was that yellows made from chromates of lead possess every possible variety of shade from an extremely pale lemon down almost to a red, and there is no other basis on which similar colours could be made at present with the same opacity.

11,972. Could not zinc chromate be used equally well instead of lead chromate?—No, it certainly could not, only under special circumstances.

11,973. What are those special circumstances?—Occasionally as a distemper, for instance, a zinc chromate is of value; that is to say, not in oil but water colour.

11,974. (Mr. Gardner.) Do you mean for scene painting?—Yes.

11,975. Size colour?—Yes.

11,976. (Chairman.) Is it a question of the cost of zinc chromate?—Yes, it is, to a large extent.

11,977. In other respects would it be equally efficient?—No. You can get no zinc chromate that has the opacity of lead chromate of a corresponding shade.

11,978. I believe you have some exhibits of these yellows?—I have an exhibit to show you the staining power, the colouring power, of a zinc chrome compared with a lead chrome (*producing a specimen*). There is the pure zinc chrome. At this end it has 20 parts of zinc to one of lead chromate. Here is a similar one done with a lead chromate. That is a lead of similar appearance reduced. The cost of the two respectively is 36s. manufacturing cost for the zinc, and 9s. for the lead.

11,979. But if it is so infinitesimal in amount, the increased cost would be equally infinitesimal, would it not?—Yes, but for a pure yellow paint the difference is enormous. These are only to show you that this chrome, which is only one-fifth pure, is as strong as the genuine pure zinc chrome.

11,980. For what are these yellow chromates used?—For yellow paints, generally, for decoration. In that case they are not very often entirely genuine. In answer to a previous question, I stated that a good yellow for a yellow paint contained from 10 to 20 per cent. of lead. The remainder is chrome, as chromic acid, and barytes, or something of the kind.

11,981. If lead was prohibited in all paints, and the prohibition applied equally to yellow paints, it would simply mean that instead of getting that effect you would get that (*indicating two exhibits*)?—Yes.

11,982. (Mr. Sutherland.) What is the cost?—The cost of the lead chromate and the zinc chromate is practically the same, but a lead chromate can be reduced to a fifth of its strength, and yet have the same staining or covering power as the zinc chromate.

11,983. (Chairman.) Do I understand that the lead chromate is four-fifths cheaper?—Yes, as a paint.

11,984. The net price would be four-fifths lower than the zinc chromate?—It would be one-fifth of the zinc chromate.

11,985. (Mr. Sutherland.) You have just told us that the lead chromate and the zinc chromate are identical in cost to begin with, but that the lead chromate has five times the staining power of the zinc chromate?—Yes.

11,986. And it gives you a greater variety of shades?—Yes. I will put in some other chromate shades (*producing some further specimens*).

11,987. Are those all lead chromates?—They are all lead chromates.

11,988. Is that the only shade you can get from zinc?—Something very near that.

11,989. (Chairman.) Cannot you get a variety of other shades with zinc?—Not many—very few. They are within a very small range of tints.

27 July 1911.]

Mr. J. K. CROW, D.Sc.

[Continued.]

11,990. What would be the comparison between the tints with lead and with zinc?—To speak roughly, there would really be only one tint for the zinc chrome. The variation of colour in manufacture of zinc chromate is so very little that it is practically all one tint.

11,991. (*Mr. Sutherland.*) What is the proportion of one to the other?—One to 10 in the second instance, and 1 to 20 in the third.

11,992. You practically get down to a pure cream?—Yes.

11,993. (*Chairman.*) What is the average amount of lead in the chromates?—Anything from 60 to 80 per cent.

11,994. I suppose in using lead for painting a coach or carriage, or anything of the sort, there would of necessity be dry rubbing down?—In between coats, I understand, they must have it on account of the nibs.

11,995. Is not that a highly dangerous operation with a large percentage of lead in the paint?—I hardly think so. The dry cutting down is, as far as I understand it, confined to the removal of the slight inequalities on the surface. It is not intended to absolutely cut half the coating away the same as the wet cutting down. It is only to remove a nib or two.

11,996. I suppose a certain amount of dust is generated?—Possibly there might be a little.

11,997. Could you suggest any means by which that dust could be done away with, for instance, by exhaust draught?—No. I do not know whether it could, but I would like to put in a statement from the Chairman of the Health Department as to the toxicity of lead chromate and lead carbonate. Lead chromate is not so poisonous as lead carbonate according to this.

11,998. How much soluble lead would there be in 6 per cent. of lead in a lead chromate?—Soluble in what menstruum?

11,999. A quarter per cent. hydrochloric acid?—Possibly it might dissolve a little, but I think so very dilute hydrochloric acid has hardly any action on lead chromate. I might mention the work of K. Beck and P. Stegmüller.

12,000. What is the purport of the statement of the Chairman of the Health Department to which you refer?—The object was to ascertain for the German Government, I understand, whether the colours used in the manufacture of toys were harmful to children who sucked them, and to see whether the chromates and sulphates of lead which are used were equally as dangerous or less dangerous than white lead.

12,001. What result have they arrived at?—They give the milligrammes of lead that go into solution in dilute hydrochloric acid.

12,002. That is the point that I was asking you about. (*A document was handed to the Committee.*) You have nothing else to say about that?—No, nothing more about chromes.

12,003. With regard to greens, most of these are made up of a yellow colour to which varying proportions of Prussian blue are added, are they not?—That is the general method.

12,004. Would all that you have to say about zinc chromate and lead chromate for yellow colours apply equally to the manufacture of greens?—Yes, practically.

12,005. What are the exceptions?—Green is a much more widely used colour than yellow, and is generally sold in a rather more reduced condition. The percentages of lead in greens, on account of the blue that is added, are reduced compared with the percentages of lead in yellows.

12,006. What amount of lead would you consider necessary to make a complete green colour?—Some of the best greens contain about 20 per cent. to 25 per cent.

12,007. I think you may take it from me that the Home Office would not agree under any circumstances to allow any paint with such a high proportion of lead in it, if there is any risk of generating an appreciable amount of dust, unless precautions are introduced to get rid of that dust?—That is for them to deal with.

12,008. Do you think it would be possible to introduce precautions to get rid of the dust?—That

would be in cutting down. The danger from dust is infinitesimal.

12,009. I have been informed in reply to an inquiry that there would probably be 18 per cent. of soluble lead in a lead chromate, which you say contains over 60 to 80 per cent. of total lead?—Well, I do not know the strength of the acid used, and I have never tried to experiment. The same remarks with regard to price apply to greens as apply to yellows, and I have some exhibits here of the greens.

12,010. Would the same remarks apply with regard to zinc chromates in green colours as the remarks you have made about yellows?—Yes.

12,011. Do they precisely agree?—Not quite, but very nearly.

12,012. What is the difference due to?—The difference is due to the addition of the blue.

12,013. What proportion of lead would you use in a lead chromate for green colour?—The usual commercial greens that are used for paints average from 3 to 5 per cent.

12,014. (*Mr. Sutherland.*) Ordinary Brunswick green?—Ordinary Brunswick green, commercial qualities.

12,015. If a decorator ordered a hundredweight of Brunswick green of the best quality?—A suitable quality to cover in one coat would contain 5 per cent. of lead metal.

12,016. (*Mr. Gardner.*) The same thing applies to your chrome. You gave us 60 to 80 per cent?—But that is not as you put it on the market. In the market chrome paints, the quantity would be from 10 to 20, as I said. Chinese blue is an extremely strong colour, and therefore you do not require such a percentage of colouring matter. You must take that into consideration. I have a pure zinc green here made with zinc yellow and Chinese blue, and a similar green made with chrome yellow and Chinese blue to get them as near as possible for staining colour. One cost 5s. and the other cost 10s.

12,017. (*Chairman.*) Which cost 5s.?—The one made with pure zinc. A similar green can be made with lead chrome costing 10s.

12,018. (*Mr. Sutherland.*) That is bare manufacturing cost?—Yes, that is bare manufacturing cost.

12,019. Lead chromate would probably yield at least 14 to 18 per cent. of soluble lead in the 60 to 80 per cent. of which you spoke?—It depends entirely on the concentration of the hydrochloric acid. Very dilute hydrochloric acid will hardly act on it at all.

12,020. We are talking about the test which the Home Office has accepted in other industries, which is known as the Thorpe test. It has existed for years, and you probably know it?—Yes.

12,021. That is the commercial chrome the proportion of chromate of lead is enormously reduced?—It is only 10 to 20 per cent.

(*Mr. Sutherland.*) Then it would come under 5 per cent. with the Home Office test of solubility.

12,022. (*Chairman.*) With regard to the cost of the lead chromates as compared with the cost of the zinc chromates, I understand that the lead costs 10s. as against 5s.?—Yes.

12,023. Would that apply to all the chromates?—Yes. That would be about the relative cost.

12,024. Now with regard to reds, why do you say that the use of a small proportion of lead compound is essential?—There are some red colours that we cannot get without more than a small percentage—something like 90 per cent.

12,025. In what form do you use the lead?—Orange or red lead is used.

12,026. We have had evidence to the effect that it is easy to dispense with lead in making red colours?—I am afraid that that evidence was not given by a colour maker. We have reds that have no lead in them. I have exhibits of an aniline dye made with lead and of one without. If you hold them up to the light you will see the reason why lead is necessary (*producing two specimens*). The lead is just to give opacity, and to get some of the shades that are asked for. It is impossible without a considerable percentage of oxide of lead.

27 July 1911.]

Mr. J. K. Crow, D.Sc.

[Continued.]

12,027. What are the relative prices of the lead chromate and the zinc chromate in reds?—We do not use any chromates in reds, because an orange lead, as it is called, an oxide of lead, or a red lead, answers the purpose just as well at less than half the price.

12,028. Are these reds which you speak of very important colours?—Yes; they are used largely by agricultural implement makers, and for wagons and post office vans, motor-cars, and so on, and signals. They all contain a large percentage. The post office reds mostly contain lead oxide.

12,029. In your opinion would it be impossible to substitute some other ingredients for lead?—It would with our present knowledge. You could not get the same colours.

12,030. But could not you get colours that would be quite good enough?—That depends on the customers' requirements.

12,031. Supposing that he could only get certain colours, he would have to be satisfied?—Supposing he were a manufacturer of agricultural implements, for those they use large quantities of red colour, and the basis of the red colour is lead. If he wanted a certain red and could not get it in England, he would buy American undoubtedly.

12,032. But would the question of the colouring of agricultural implements be an important feature for this purpose?—I am afraid it is a very important feature.

12,033. Why?—We could not carry on business unless we supplied what our customers wanted.

12,034. But would it be important from the point of view of the purchasers of the agricultural implement?—I think so, or they would not be so particular about our supplying exactly the same shade every time.

12,035. Is there at the present moment a large importation of foreign agricultural implements?—I do not know that it is very large. It is considerable, but I could not say how large.

12,036. You are afraid that, if lead is prohibited in red paints, it might seriously affect trade in England by inviting competition from abroad?—Yes, I should say so.

12,037. Do I understand you to mean that the competition would come in in the shape of the agricultural implements themselves, or from the fact that Americans would send in the paints to be applied?—The Americans would send in the goods if the paint was not allowed to be applied in this country. American paints would be under the same laws as the British paints, I take it. Americans, by the way, are particularly good at making everything that they turn out look very smart, and the smartness would be enhanced.

12,038. Are there any other uses that you can think of for red paint?—They do not occur to me at the moment.

12,039. I understand you consider that a small proportion of lead compounds is absolutely indispensable in making driers for paints, boiled oils and varnishes?—Yes.

12,040. Why do you make this statement?—From experience.

12,041. Are not manganese borate and manganese linoleate largely used as driers?—Yes.

12,042. We have been told that these manganese driers are more efficient than lead driers?—I have seen that statement in advertisements too.

12,043. But have you any practical experience?—Manganese linoleate and borate dry very well in warm weather, but they cannot be relied upon to dry in the autumn and winter and spring in the English climate.

12,044. Have you made trials of these manganese driers?—Thousands. We make them ourselves.

12,045. Even if you find the use of lead in driers to be desirable, what proportion of lead would be introduced in the form of driers into the paint?—Do you mean into a ready mixed paint, mixed up in oil and turpentine, and the usual thinners?

12,046. Yes?—That depends entirely on the pigment used. Some are very bad driers and some are very

good. A black paint, for instance, would require very much more drier than white lead.

12,047. If, then, it should be decided to restrict the amount of lead in paints to not more than five per cent. of the dried material of the paint, would not that allow an ample margin for the use of such driers as you recommend?—Yes, quite so, as a drier.

12,048. Do you wish to speak of the difficulties which you believe would arise in making alterations in the standards of various paints, colours, oils and varnishes?—It would naturally cause tremendous difficulty.

12,049. What difficulty do you refer to?—We should have to alter all our tint cards, and get them reprinted.

12,050. That is not a very serious thing?—It is good for the printing trade, but is very difficult for us.

12,051. The first difficulty you put to us is the expense which would be incurred in printing your advertisement sheets of colours?—Yes.

12,052. What other difficulties are there from your point of view?—A good many of the shades would be altered with zinc, and it would be a gamble as to which shade we should use. We should have to find out what the customers required.

12,053. But if you had exemption, say, for two years before lead was absolutely prohibited, would not that be sufficient time to enable you to set your house in order, so to speak?—It would assist, of course.

12,054. After two years would not most of these difficulties be removed?—We could not prepare the same colours as we had before.

12,055. But the difficulties that would ensue in consequence of the change that had taken place, would disappear practically after two years, I suppose?—The internal difficulties no doubt would disappear, but the cost of the colours would be very much greater. We could not get the same greens at the same price, and we could not get the yellows at the same price.

12,056. The purchasers of these new colours, I understand you to mean, would have to pay a higher price?—Yes.

12,057. These purchasers would be absolved, if lead was prohibited, from a very great deal of expense incidental to the carrying out of the special rules which the Home Office would issue, so that in the long run there probably would not be much difference to them?—I was thinking—if you do not mind my saying so—that, if paints are increased in price very much, the demand for them will diminish, and in consequence there will be less work for those who make them and those who use them, and the labour employed will be less.

12,058. The Office of Works have a formula which they say is quite satisfactory?—I have not seen that formula.

12,059. They have given evidence of it before us?—I have not heard of any independent authority saying that their statements were correct.

12,060. But they use the paints. They demonstrated the practicability of their position by using leadless paints entirely?—Have they no leads in their driers?

12,061. Not exceeding 5 per cent.?—That is a very different matter.

12,062. Supposing that this Committee agreed on prohibition, in preference to a stringent code of rules which would be very expensive to the industry, and were to allow up to 5 per cent. of soluble lead in all paints, would not that be a very good solution of this very grave question?—It would only be a partial solution. I do not say that any perfect solution is possible.

12,063. You see the difficulties that we are in?—Yes.

12,064. We have to report to the Home Secretary, and the Home Secretary has to put our recommendations before Parliament as to what means can be introduced to greatly mitigate, if not entirely remove, the dangers incidental to the house-painting trade?—I did not come prepared with evidence about that.

12,065. (*Dr. Collis.*) What would be the respective values of a gallon of white lead paint and a gallon of

27 July 1911.]

Mr. J. K. Orow, D.Sc.

[Continued.]

white zinc paint (I do not mean after thinning down) made ready for use as issued by yourselves, one the oxide of zinc, and the other the sulphide of zinc, and also lithopone?—I should think that the gallon of zinc paint would cost a third more than the lead at present market rates.

12,066. I have put to you three forms?—I am not aware of zinc sulphide being used. I have not seen pure zinc sulphide used.

12,067. Could you tell me on this point whether it would be possible to fortify the colours obtained with zinc chrome, with lead chrome up to 5 per cent. solubility?—It would depend on the tint.

12,068. What is the effect on the tint of mixing lead chrome with zinc chrome?—If you had a very pale lead chrome, the zinc chrome is somewhat soluble in water, and has an effect on the lead chrome and changes its colour slightly.

12,069. There is decomposition and change of colour?—Slight change of colour with the very palest quality. Where the colour descends more into the yellow from the primrose, this effect would not be visible.

12,070. It would only be visible with the pale yellow colours?—Yes.

12,071. The pale colours you can already obtain with 5 per cent. soluble lead chrome?—Yes.

12,072. So we have only to consider the strong chromes?—Yes.

12,073. It has been suggested that 20 per cent. of lead chrome roughly represents 5 per cent. of solubility. How much extra zinc chrome would have to be added to keep the dense colours?—If you added the remaining 80 per cent. of zinc chrome you would get the same strength, then, as with a 36 per cent. lead chrome.

12,074. By using this amount of lead chrome, then, you would reduce the cost to an appreciable extent of a paint, the main part of the pigment of which was zinc chrome?—You would not reduce the cost, because the materials that you would use in a lead chrome paint containing, say, 20 per cent. of chrome would not be nearly so costly as the zinc chrome replacing it.

12,075. But more than 20 per cent. of the pigment would be replaced by the cheap pigment, would it not?—I do not follow you.

12,076. If you are allowed a 5 per cent. solubility in your pigment, it is not necessary to use in that pigment pure zinc chrome. To the extent of 5 per cent. solubility, which is practically 20 per cent. lead chromate, you can use lead, and only as regards the remaining amount is it necessary to use zinc chrome?—I do not follow why it should be necessary at all to use the zinc chromate.

12,077. You said that you cannot get the colour with only 20 per cent. of lead chromate?—You cannot get the best colour.

12,078. Can you obtain the other qualities?—You mean the opacity?

12,079. The staining power—by adding zinc chromate?—You would get the equivalent of a lead chromate containing 36 per cent. of lead chrome. If you added the whole of the remaining 80 per cent. zinc chrome as a constituent of the colour, you would only add a fifth of its value as lead chrome, and you would only get 36 per cent.

12,080. Thirty-six per cent. of opacity and staining power, and you want to get much higher?—Yes.

12,081. You would not get what you wanted?—No.

12,082. To what colours would that apply?—It would only be applicable to the lining colours.

12,083. Those lining colours are almost innocuous in their use?—Yes.

12,084. So that, with 5 per cent. solubility, you can obtain practically all the necessary colours except just these few that you mention. Am I right in understanding you to say that?—Yes, practically, that is so. I would not say it is universally so. There might be some tints in which some of the darker lead chromes are not so strong as others. The darker lead chromes have not as much opacity as the pale ones, and it might not be possible in those cases.

12,085. But it would be possible to obtain the majority of them?—The pale ones, undoubtedly.

12,086. Certainly, and the deeper colours are practically only required for lining?—Yes. Only those that you require for lining would be excluded.

12,087. That is the practical position?—Yes, that is probably the position.

12,088. So that you say from your technical knowledge that as regards these colours required for lining, if you have to supply them, you will have to have an exemption from such a suggestion as the limitation of lead to 5 per cent. solubility?—Yes.

12,089. And if you had that exemption for those purposes, you could practically produce all the tints and colours that you produce to-day?—Yes; if we are allowed the limit that you suggest, which brings it to about 20 per cent. of lead chromate.

12,090. On this matter you only speak subject to careful analysis of the lead chromate with regard to solubility. If that is the solubility of lead chromate, that is your opinion as a technical expert?—Yes, provided the percentage of soluble lead is as you represent it.

12,091. Exactly. I had better ask about reds. How far is it possible to obtain the requisite reds with oxide of iron?—You cannot get the tints.

12,092. You could not get the tints, even if you fortified with oxide of lead?—No. The vermilion-colour reds are of a delicate tint, and the least proportion of a brown in them, as in the oxide, destroys the delicacy of the colour.

12,093. You cannot get the brilliancy with iron?—No; there is no oxide of iron that I am acquainted with that will help you in that.

12,094. Aniline dyes, you say, do not give the requisite opacity?—No, they do not give the requisite opacity.

12,095. Could you get the opacity with aniline dyes if they were fortified with lead oxide?—That is how it is usually obtained in the trade. That is the usual way of getting it.

12,096. You use the anilines associated with the lead oxide?—Yes.

12,097. What is the smallest proportion, then, of lead oxide that you can strike your colours with?—That is almost impossible to say.

12,098. It varies with different ones?—Yes, it varies. If you had 2 per cent. of aniline dye, you would want more red lead to produce the opacity than you would if you had 5 per cent. of aniline dye, because the aniline dye itself has some slight opacity.

12,099. If you were limited to 5 per cent. solubility, so that you had to increase the amount of aniline dye as far as possible, still adding the lead to give you opacity, would you be able to produce colours of commercial value?—No, you would not. It would not do.

12,100. It only leaves you with 5 per cent. when dealing with litharge?—Yes.

12,101. How many tints would it be impossible to obtain?—Here is one that it would be impossible to obtain. Here is one with the lead and one without (*producing some specimens*).

12,102. Is it impossible to obtain either?—It is impossible to obtain *this*. You would not get the shade and the opacity.

12,103. Would the thing fail with the brighter reds?—Yes.

12,104. With the darker reds would you succeed?—Yes, with the darker reds, but it would be more expensive.

12,105. Your point is that these brighter shades are used on agricultural implements?—Yes, and motor-cars.

12,106. Agricultural implements, I think, would be the most important?—Yes.

12,107. If the requisite colours could not be produced, the foreigner might get an advantage?—He would get a pull, undoubtedly.

12,108. Do you think that is a sufficiently strong reason for our holding our hands in regulating the industry?—You would be handicapping the English makers.

27 July 1911.]

Mr. J. K. Crow, D.Sc.

[Continued.]

12,109. How far can vermilionettes be used?—These anilines are vermilionettes.

12,110. Vermilion itself is more expensive still?—Yes, and just as poisonous, I take it.

12,111. No; it is not, curiously enough. It is too expensive to use, I suppose?—Yes.

12,112. (Mr. Sutherland.) What is the present market price of vermilion?—About 2s. 8d. or 2s. 9d. a pound.

12,113. As against what for vermilionettes?—Anything from 3d. to 6d.

12,114. Do you think, in view of what you have told us with regard to these tints, that it would assist if the law of the land were that only 5 per cent. soluble lead should be present in paint, and if, where it was shown, as you are pointing out to us to-day, that certain of these tints cannot be obtained without a higher percentage of lead, there should be exemption, always presuming that the workpeople are guarded in their use?—Would that entail any responsibility on the manufacturer for selling them to the right people?

12,115. It would entail upon the manufacturer giving the name to the authorities of the person to whom these paints were sold, so that we could watch them in their use?—That would be rather awkward, I think. They are often sold to colour merchants who re-sell them retail to users.

12,116. We should have to follow them to the colour merchant?—There would be a lot of following-up required.

12,117. But we should have only a small amount of material to follow up?—I hope not. At present a large quantity of vermilionettes is sold with a much higher percentage of lead than you are speaking of.

12,118. That is so, and we should have to follow that. That would be quite different from following up the users of white paint, and every other form of paint?—I do not think it would be workable in practice. I do not see how it could be done.

12,119. (Chairman.) That would be for the Home Office to decide, would it not?—Yes.

12,120. (Dr. Collis.) Would it give you such latitude that you think that the trade would not be interfered with from your point of view? The user would have to get permission to use such paint?—I am afraid it would not be practicable.

12,121. (Chairman.) This is an alternative to special rules?—Should we be prohibited from selling these colours abroad? You are not looking after the foreigner?

12,122. No. This is not an international inquiry. This is a very important point, because it would practically mean that the users of lead paint would be exempt from all these tiresome regulations, and the object of this Committee is to simplify matters as much as possible, and if it were laid down that no one was to use more than 5 per cent. of lead except on certain occasions, and on those occasions the permission of the Home Secretary must be obtained, you would have the thing simplified?—Yes.

12,123. The same thing obtains to-day in the spirit trade. No one may sell spirits without a permit. The permit may go through a dozen hands?—Speaking for my own firm, I would rather have that than be stopped from making them altogether.

12,124. That is the point?—I am speaking entirely for my own firm. I am not at liberty to speak for the association on that point.

12,125. You might put that to your association, because it seems to be the simplest solution. Then you could confine the dangerous operations to a very small area, and the rules would only apply to those instead of to all the work. Instead of having to have all your men medically examined, the only people who would have to be medically examined would be just the few men who handled these things?—I see the advantage.

12,126. You would narrow it down to a few tints?—I follow. For my own part, I have been a zinc advocate for many years as far as possible, but I am sorry to say that I have not been able to agree to some of the statements made.

12,127. (Mr. Sutherland.) As representing the decorating trade, I would like to know how far the limitation of lead, such as has been indicated in the questions put to you, would curtail your range of colours?—With the limitation to 20 per cent. of chromate of lead in the yellows, it would not limit the range, provided allowance was made for the fine colours which have to be genuine for lining, and purposes of that kind—what we call artists' colours, and so on.

12,128. They do not come under the terms of our reference, I think. They are applied at a later stage, and there is no dry rubbing-down on the yellow itself, so that it does not affect it?—With regard to the yellows, it would not seriously limit the range of shades.

12,129. (Chairman.) I think that on the principle you agree with us. In your mind it is a question of making some practical suggestion that can be carried out?—If a practical suggestion can be made which will give us the same range of colours as before, very well.

12,130. (Mr. Sutherland.) We shall hear about that from your association. Another point arising out of the questions of Dr. Collis, which arose out of the testimony of a witness the other day, is this: can zinc sulphide by itself be used as a paint without the addition of sulphate of barium?—It can be used, but zinc sulphide by itself is more expensive to make, up to the present, than zinc sulphide in company with sulphate of barium.

12,131. Has it a good covering power?—It has a good covering power. Unfortunately, like most of the sulphides, it is oxidised and converted into soluble salts when exposed to the air and damp.

12,132. (Dr. Collis.) Lithopone is thrown down in solution. The paint referred to, which you are speaking of, is a mixture of zinc sulphide and barium sulphate not so thrown down in solution?—Practically there is not much difference whether it is thrown down or not. As long as it is in intimate mixture, and then afterwards is heated in a furnace, that gives the body to it. Zinc sulphide, though suitable indoors, is unsuitable out of doors, on account of its being oxidised to zinc sulphate, which is dissolved out by rain.

12,133. (Mr. Mason.) Zinc is obtained entirely from abroad, is it not?—Yes, I believe that is so entirely.

12,134. Is there an open market for it, or is it in the hands of a trust?—I understand a powerful combine has control of almost the whole of the zinc oxide output.

12,135. Do you suppose that when the powerful competitor, lead, is removed from the field, zinc will increase in value?—It seems natural, with a very powerful combine like the Zinc Oxide combination, as there are no zinc mines to speak of in this country, and as zinc oxide is chiefly made direct from the ore, in distinction to white lead, which is made from blue lead.

12,136. (Dr. Collis.) It is made from the ore?—Yes, but I have not explained it quite clearly. You do not follow me. I am afraid that we should be rather in a cleft stick with regard to it. They may raise the price and we could not avoid it. There is certainly that fear, I think.

12,137. (Mr. Sutherland.) We have no natural resources of our own?—No. Some mines might be discovered later on, and be bought up by anybody who was quick enough to see them before the Zinc combination saw them, but he would have to get up very early in the morning to do that.

12,138. Is it a very huge combination?—Yes; it embraces the whole of the Continent and America.

12,139. (Dr. Collis.) Does it embrace all the makers of spelter?—I do not know that it does. I cannot speak with accuracy on that point, but I know that it is a very large combination indeed.

12,140. There seems to be no reason against making zinc white with spelter, and it is so made by the indirect method?—Yes.

12,141. Unless all the spelter manufacturers are within that combine, the combine do not hold the world?—Those that I know about are in the combine.

27 July 1911.]

Mr. J. K. CROW, D.Sc.

[Continued.]

12,142. Broken Hill is not in the combine?—No, not yet.

12,143. And that is one of the biggest zinc mines in the world?—We do not know how long it is going to be so.

12,144. But as it is to-day, I mean. We are making zinc from Broken Hill ore in England to-day. Unless the combine can buy all the zinc in the world, it is an open market?—I should not think that the proposition is a possible one. I should fancy not.

12,145. I might just as well buy all the lead mines and increase the price of white lead. The thing is purely imaginary?—Such a thing might happen.

12,146. (Mr. Mason.) As a practical proposition, do not the prices of lead and zinc vary together?—Not always.

12,147. (Mr. Kinggate.) With regard to the opacity of yellows, you were speaking of the picking out on carriages and fine lining. Could not the difficulty be obviated by going over twice?—Yes.

12,148. With white lead it is the same. It has to be done over twice. There is no opacity in white lead?—I would not like to say that there is no opacity in white lead.

12,149. But not sufficient for picking out. If you had a blue ground, for instance, and you had a picking out line upon that, with white lead you would have to go over it twice?—Yes.

12,150. The same thing would follow with zinc chrome?—Yes.

12,151. You would get opacity by two coats?—Five.

12,152. For a simple line?—I could not say for certain, because I have not tried it, but I know that the opacity of lead chrome is five times as great as that of zinc chrome.

12,153. I am not speaking of the body. I should have thought two coats would be quite sufficient for lining?—I have not made the experiment.

12,154. Now, speaking of the cost of vermilion and ordinary reds, what would be the difference in cost in painting a motor-car?—I do not know.

12,155. It would be very small indeed?—I do not know how much they use.

12,156. Say 3 lbs. of vermilion to paint a motor-car entirely?—You would not get the same shade.

12,157. I am only speaking of cost now. When you come to consider the price of a motor-car, the difference between the ordinary reds and vermilion is exceedingly little, with regard to price?—If only 4 lbs. were used it would be only 8s. difference, or something like that.

12,158. It is not really prohibitive. It would not make much difference in the value of a 1,000l. motor-car?—No.

12,159. (Mr. Sutherland.) It would make a difference on a farmer's cart?—Yes.

12,160. (Mr. Kinggate.) They use ordinary red?—Then there are agricultural implements.

12,161. You spoke of the smartness of the American vehicle. Do you say that the American vehicle is smarter than the English?—I was not referring to motor-cars, but to the general smartness of everything that the Americans do. I was speaking of agricultural implements.

12,162. I thought you were speaking of motor-cars, and speaking generally?—No. I was not making a reflection on the English.

(Mr. Kinggate.) I understood you to say that they were smarter in regard to getting up, but I should have to contest the point that the motor-car from America is smarter than the English made one.

12,163. (Mr. Robins.) In the course of your evidence you were dealing with yellows made from zinc. Only within recent years has yellow been made from zinc, I believe?—I have made it for 30 years.

12,164. At the present time the demand is not much?—No, it is not much.

12,165. Would you consider that the making of yellow from zinc is in the experimental stages, or has it come to the end of the rope?—Nothing has come to the end of the rope, as far as that goes, but general knowledge as to the manufacture of zinc chromes is fairly accurate now.

x 7790

12,166. Is there an improvement on what there was thirty years ago?—Very little improvement.

12,167. But there is a little?—I should not think so. There may be an improvement with regard to cheapening, but there is no improvement in the body or the colour of the tints.

12,168. You do not think it is possible that, with further research, there will be improvement?—I could not say that. It is impossible to say in science what improvements may happen.

12,169. Have you a knowledge of carriage painting?—No, I am not a coach maker.

12,170. What led you up to the remark that, in painting a carriage yellow, there would be a very small amount of dust from the sand-papery?—I do not think that I made the statement.

12,171. (Chairman.) I understood you to say that?—The dust in laying on, do you mean?

12,172. (Mr. Robins.) In sand-papery?—I did not speak of sand-papery.

12,173. There would be no dust in laying on, because the colour would be liquid?—Yes, that is the point.

12,174. (Chairman.) I asked you whether, in the operation of painting with a yellow chrome, there would be much dust in sand-papery?—I think I said that it did not matter which colour was put on, whether it was a chrome or not. That did not enter into the question. The dust would be the same whatever colour was used.

12,175. I suppose that there is a considerable amount of dust in sand-papery?—I do not know; I have no experience.

12,176. (Mr. Robins.) Not knowing anything about the coach trade, you spoke specially of the lining colours. The quantities of lining colour that would be required on a carriage, if it was picked out with a broad line and a fine line, would range from about 4 to 8 ounces on any carriage. To-day not one out of 50 carriages or motor-cars is picked out with fine lines. With regard to zinc white, if a man is lining white (and I have come in contact with a good many men) he prefers zinc white to line with instead of lead. If you use lead for picking out and fine lining, the picking out line always has to be done twice. If you use lead you always have to add a very small proportion of ultramarine blue. If you pick out a fine line with zinc white, you have to do it twice just the same, and you add a little ultramarine blue at the same time; so you have the same relative value. There is another advantage, and that is that the white lead stands high above the surface. I say that zinc white is far superior from my own experience.

12,177. (Mr. Parsonage.) One question with regard to the suggestion that has been made once or twice to-day with regard to the cornering of zinc, all of it belonging to a foreign combine. Were you referring to the Zinc Corporation?—I would not like to say the Zinc Corporation.

(Mr. Parsonage.) That is a British Company, and the main place where they get the ore they treat is Broken Hill, Australia. I know that this is put forward as a strong argument, but I do not think there is anything in it. I think it is a bogey that zinc could be cornered in that way, because the most powerful corporation dealing with zinc at the present time is a British Corporation.

12,178. (Mr. Gardner.) What proportion of lead is there in patent driers?—Some specifications call for white lead alone with manganese salts. It runs up to 70 or 80 per cent.

12,179. The ordinary commercial stuff?—With those it goes down very low sometimes.

12,180. As ordinary painters, we are dealing with the ordinary commercial stuff, and it is a very low proportion?—Yes, 5 or 10 per cent., or something of the kind.

12,181. I take it that the position of paint manufacturers is that they are not quite so much interested in the grinding of white lead (the, would require to grind something), but in the question of tints. You hold that if lead compounds were done away with, you would require to reorganise your whole works

Y

27 July 1911.]

Mr. J. K. CROW, D.Sc.

[Continued.]

and machinery?—The present machinery would be available.

12,182. Then it is simply a question of adapting that?—Yes, organisation.

The witness withdrew.

Mr. J. SCOTT examined.

12,184. (Chairman.) Do you attend to-day as a representative of the Association of Master House Painters in Scotland?—Yes.

12,185. What is the nature of your business and where is it carried on?—House painter, 249, West George Street, Glasgow.

12,186. What is the average yearly number of painters employed by your firm?—80 or 90.

12,187. How long have you been in the painting trade, approximately?—I have been connected with it all my life, practically.

12,188. Have you known any cases of lead poisoning or painter's colic?—I used to hear about them a lot when I was a boy, but the only case that I have known was that of a man who works lead in the shop. He was off 2 or 3 days. That is about 20 years ago. I have never heard anything of them since.

12,189. Have your men had occasional days of sickness possibly due to lead?—Only one man, and he is not a painter.

12,190. Do you have a periodical medical examination of your men?—No.

12,191. If you have no such examination by a doctor, is it not possible that some of the men may be suffering from the slower and more insidious forms of lead poisoning?—I do not think it is probable.

12,192. But it is possible?—Everything is possible.

12,193. You know, I presume, that lead poisoning frequently undermines the health without immediate violent symptoms arising?—I presume so.

12,194. So it is quite possible that some of your men may have been away for what has been thought ordinary sickness, when it may have been incipient lead poisoning?—Honestly, I do not think so.

12,195. Now the incidence of lead poisoning is published month by month by the Board of Trade. Do you see the "Labour Gazette" issued by the Board of Trade?—I cannot say that I have read it.

12,196. Have you heard that 284 deaths of painters have been definitely certified as due to lead poisoning in the last 10 years?—I have heard so.

12,197. And that the increase in the death rate from lead poisoning among the painters in the first six months of this year is considerable?—I suppose that is so.

12,198. I understand that you have had no lead poisoning in your works at all?—None—unless you take that man who was off for half a week.

12,199. Are you aware that in the Potteries a large number of the works have never had any case of lead poisoning whatever?—I do not know anything whatever about the Potteries.

12,200. Are you aware that the cases of lead poisoning in the house-painting trade are more numerous than in all the other industries put together where lead is used?—Unless you have statistics, I do not know it.

12,201. You may take it from me that that is the case. In addition to that, the death rate from Bright's disease and nervous diseases and consumption due to work in lead are very high?—I did not know that.

12,202. There are also a very large number of non-fatal cases most of which are never recorded, as they are not required to be notified to the Home Office. Are you aware of that?—Really, I do not know of that.

12,203. I am sure you agree with me that all this sickness and death is deplorable?—Certainly. All sickness and death is deplorable.

12,204. Do you know that this deplorable evil has attracted the most careful attention in most foreign countries?—Yes, I know that.

12,183. You think that the percentage of soluble lead, which is in all these stainers, with the exception of the bright reds, is a very small quantity?—It is not very great. Of course, there are exceptions.

12,205. I suppose you agree that something must be done—taking these figures as correct—either by regulation or by prohibition, to meet the evil?—There is an undoubted evil, and I think that regulation might mitigate it.

12,206. Now, have you had any personal experience of paints containing no lead?—Yes.

12,207. How long ago is it since you made any serious experiments?—I have seen them within the last week.

12,208. Have you used leadless paints very much in your business?—Yes, but we stopped using them alone. Latterly we have mixed them with lead.

12,209. When did you last, on a large scale, use leadless paints in your business?—Without a lead basis?

12,210. Yes?—We have not done it for 20 or 25 years.

12,211. Have you found the leadless paints satisfactory?—No.

12,212. Then your experience of the unsatisfactory condition of leadless paints was 20 years ago?—No. I examined some last week.

12,213. But you said your own personal experience of the use of these paints, on a large scale, was 20 years ago?—Yes, on a large scale, but not on a small scale.

12,214. What sort of work have you done, on a small scale, recently?—We have tried some green-houses and we have tried a ceiling with lithopone, and tried it outside.

12,215. By your own workmen?—No, not by our own workmen.

12,216. What have you had done by your own workmen?—Nothing of any great extent.

12,217. Then your own personal experience with leadless paints was 20 years ago?—Yes, on any practical scale, unfortified by lead.

12,218. The Office of Works and others have told us that they have used leadless paints with entire success for some years?—I cannot say anything about that.

12,219. The Office of Works have made very zealous experiments and trials for the last 10 years, and, at last, after a great many failures, they have hit upon a formula which they introduced four years ago, which has proved entirely satisfactory. Do not you think it would have been very much better if some of the large employers of labour in Scotland had done the same thing, and had gone on experimenting until they had found something?—At Hartwood Asylum, 10 years ago, we did a room entirely with Durresco, and gave it a coat of varnish, and it is standing, but when you come again to use that material you will find a very different state of matters. Many things which do at one time when you come to repeatedly work upon them form a bad basis.

12,220. But you have not been very zealous in making your attempts to find leadless paints?—No, I cannot say that I have been zealous.

12,221. My point is that the Office of Works have, and they have been successful, and perhaps if you had been a little more zealous you might have been equally successful?—I could easily be successful the first time.

12,222. But the last four years they have been successful all the time and are perfectly satisfied?—I have one that has done for 10 years, but it will not do repeatedly.

12,223. They have got a formula which is entirely satisfactory after repeated trials?—It has only stood four years. You want 20 years.

12,224. You think 20 years?—I would not say that. If you took a thing and, two years after that,

27 July 1911.]

Mr. J. SCOTT.

[Continued.]

submitted it to a repainting, and, when it was actually hard again, submitted it to repainting, you would see what was going to be its use for general purposes.

12,225. You have told us that you have not made any really serious attempts to find leadless paints yourself for a considerable number of years, and yet you come here to tell us to-day that lead paints are absolutely essential?—I believe so.

12,226. Although you have not made any trials to find a substitute?—No. We are only painters, not manufacturers.

12,227. But you have not attempted to find a substitute in all these years?—No, we have not.

12,228. If the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workmen handle lead. That you understand, do you not?—Yes.

12,229. Are you aware of the details of these precautionary measures?—No, I could not say that I am.

12,230. First of all there is the provision of overalls, which are to be found by the employer, who is responsible for seeing that they are regularly washed?—They are found at the present time by the men, and they are properly washed.

12,231. Would you agree to the provision which I have just put to you?—I would not.

12,232. Secondly comes the provisions of a meal-room, care being taken that in no case whatever are any of the men allowed to take their meals in a room where lead is used. Is that possible in all cases?—I think so.

12,233. You think that in all cases the men could have their meals in a separate room?—That would be a standing rule and must not be broken. If it were the rule it would have to be kept.

12,234. Could you see that that rule was enforced?—I believe that I could if it were the law.

12,235. Then a provision of a proper place to keep the overalls, where they will not contaminate food or outdoor clothing. Would that be possible?—I should think so.

12,236. Where are the overalls kept to-day when they are not being used?—Anywhere about the job.

12,237. And so they are in places where they could contaminate food?—No, I do not think so.

12,238. But if they are left all over the job they must collect a great deal of dust, and dust is the serious evil that has to be contended with?—I do not think that they would collect more dust, there, than a man walking along the street in them would collect on them.

12,239. I am speaking of lead dust?—They will not collect lead dust.

12,240. I have seen men with clean overalls, and seen them wipe their hands on them, and they have splashes on them, and all those splashes dry and come to dust?—I think it would be whiting.

12,241. But I am speaking of paint, not whiting?—Painters use whiting.

12,242. But I am speaking of paint. I will not labour the point, because you do not admit, I understand, that any dust of any sort is collected on the overalls if they are left about the job?—Not if they are properly put aside on a shelf or in a press or something of the sort.

12,243. Are they always put aside on a shelf or in a press?—They are usually put in the best place.

12,244. Do you know for yourself that they put them in a press?—Yes, sometimes.

12,245. Do your foremen report that that is the practice?—No.

12,246. Then how do you know?—I go about myself on the jobs.

12,247. You have seen them always put away very nicely?—I cannot say I have seen them put away very nicely, but they are usually put in the cleanest place. There is no lead dust in the paint-shop.

12,248. Is there none?—No.

12,249. Are they always kept in the paint-shop? Are they not kept sometimes in the room where the men are working?—Yes.

12,250. They would collect dust in that case, would they not?—I do not think it would be lead dust.

12,251. But that is the very dust that is impregnating the room. There is the rubbing down; would not the dust collect on the overalls then?—It is not often you will see lead dust about a room from the rubbing-down.

12,252. Then as to the introduction of proper washing accommodation; one basin or other utensil to every five men, supply of water both hot and cold, soap, nail-brushes, and a sufficient number of clean towels. Could you ensure that such a provision was carried out?—With regard to one basin to every five men, would it not be better to have a provision that every man should have proper facilities? I would not like to have to refuse a job because there was only one basin and the men had to wait their turn. Suppose I was away 10 miles and there was only one basin in the house?

12,253. The rule would be not less than one basin or other utensil for every five men, and you would have to obey it. There is no question of being 10 miles away. Could you always provide hot water?—We should have to do it, if it was not there.

12,254. But if it was not there, what would you do?—You would take sticks and make a fire.

12,255. Then provision would have to be made for the avoidance of dust; some means would have to be devised for getting rid of any dust which the men might breathe. Could you ensure that provision being carried out?—Yes, lead dust.

12,256. How would you, for instance, arrange to collect the dust in dry rubbing-down with sand-paper?—There is practically no dust generated.

12,257. I know there is dust?—In exceptional cases there may be dust.

12,258. I have seen the work done myself and you cannot rub down a dry wall without generating dust. I want to know how that dust is to be collected?—I would not object at all to the prohibiting of dry rubbing-down on old work.

12,259. Would you object to the prohibition of dry rubbing-down altogether?—Yes.

12,260. How are you to collect the dust that is generated where dry rubbing-down is allowed?—If there was dust perceptible to the naked eye, I should object to dry rubbing-down, but in the majority of cases, from the way in which the paint is put on in Scotland, with a coat of white paint, the dust is practically collected in the sand-paper.

12,261. But we are not dealing with Scotland only. How is this Committee to deal with cases where there is a considerable amount of dust created by the sand-papering process. Is it not impossible to devise any scheme?—I can only say that if dust is perceptible, it should not be allowed.

12,262. But I can tell you that there is a large amount of dust in sand-papering in England, and I ask you can you suggest any means for getting rid of that dust?—Could the men wear respirators?

12,263. Have you ever seen one that is comfortable to wear?—No.

12,264. Then could you insist on that?—If we had to.

12,265. This Committee is formed to decide whether the Home Office should allow in future the use of a very dangerous element, namely, lead; and, if permission is given for the continued use of it, to devise some precautions to relieve the men from the evils which ensue; and I ask you what do you suggest as a remedy for removing the dust which is generated by sand-papering a surface?—There is really none.

12,266. I must really ask you to answer the question, otherwise I shall not go on with my examination?—Very well, then; use respirators.

12,267. But you cannot expect a man to wear an uncomfortable respirator. Supposing that the Home Office do not agree to a respirator, is there any other means that you can suggest of removing the dust?—I have heard some people speak of electric fans.

Y 2

27 July 1911.]

Mr. J. SCOTT.

[Continued.]

12,268. But can you suggest anything yourself?—Really I cannot.

12,269. I did not expect that you could, but I wanted to get an answer. Then, in addition to this, a periodical medical examination, say once a month, would be insisted upon, at the expense of the employer. Have you any objection to that?—I think it is pretty often. I do not see much need of it once a month.

12,270. Lead poisoning amongst house-painters is more prevalent than in the whole of the other lead industries put together. The rule in the potting industry is that each person employed in lead has to be medically examined once a month. The Home Office is not likely to go back on that and make a longer period for an industry where the prevalence of lead poisoning is even higher. So I ask you whether you would agree to such a provision as I have cited?—I would not if I could help it.

12,271. But supposing it was the law of the land, would you object to it?—I would object, if I could; but if it was the law of the land, I would need to obey it.

12,272. Would you object if the medical examination was going to be of great value to the workpeople?—No. If I thought that, I would not object for a moment.

12,273. I was sure that was in your mind; that is why I pressed for an answer. Then with regard to paying compensation to any worker withdrawn from work on the certifying surgeon's orders on account of doubtful health, would you agree to that?—Yes.

12,274. But this is in doubtful cases where a man has not contracted lead poisoning, but who, the doctor thinks, is likely to. Would you be prepared to give compensation if he were suspended in such circumstances?—If the man contracted it in the course of his employment, certainly.

12,275. Suppose he has not contracted lead poisoning actually, but the doctor thinks he may get it if he is allowed to continue in the work?—What would you pay him—half wages?

12,276. Yes. Would you agree?—[No answer.]

12,277. Taking all these things into consideration, would you prefer that your industry should be regulated by special rules such as I have foreshadowed, being quite sure that they could all be carried out, the employer being responsible for their being carried out? Or would you prefer that lead should be prohibited?—I would rather answer that question in this way; I would rather say that I believe, in the interest of our trade and the public, it would be better that the regulations were there than that lead was done away with.

12,278. Would you agree to seeing, in all cases, that these regulations were carried out, and to becoming responsible for them, and, if they are not carried out, standing the penalty?—Yes; if they were the law I should have to; but I should object very strongly to some of them.

12,279. Would it be possible to carry them out?—Some of them could be carried out.

12,280. The Home Office look upon the question of removing the dust as one of the most essential things. How would you get away from your answer that you do not think there is any possible means of doing it?—If that is imperative I must say that I think respirators would be about the only thing, and the men would have to use them for all the time.

12,281. I do not think that that would be accepted. If your employers would come forward and make suggestions for the total removal of all the evils, that might be considered as an alternative to prohibition; but if you cannot come forward with such recommendations to us, the Committee must seriously consider whether lead will not have to be prohibited?—Do you suggest that our association should debate on this question and send up their opinion in writing?

12,282. If the evidence is going to be anything like what they have given during these last two days, it will not be of any use, because no one has had any practical suggestion to make about the removal of dust. I would rather ask the individual members, but I think we have taken all the evidence from the employers that we can get?—You put it like this: you are either to abolish dry rubbing-down altogether or you are to do away with lead. Is that the form that it takes?

12,283. I would go further than that, and I would say that you have, in every case where the Home Office considers there is danger to the workmen's health and life by being engaged in various processes in this industry, to provide a reasonable and a practicable precaution which we are satisfied can be carried out. If you cannot do that, then it is a question whether we shall not have to prohibit the use of lead. Unless you can do that, it is no use coming here like some gentlemen who have said it is quite easy. We must have a demonstration of how it is to be done?—But really I do not see any real practical difficulty in anything but this dry rubbing-down.

12,284. I see difficulty in this—that I cannot see how you can enforce the regulations to the satisfaction of the Home Office. Your individual promise is sufficient, but in a large number of cases the individual promise would not satisfy the Department?—I think you have an organisation that would see those things carried out.

12,285. No, we have not?—I think that the workmen have.

12,286. I do not think that the workmen have?—You can do very little outside the rules but what it is reported here.

(Chairman.) You would want an army of inspectors to enforce the rules which are essential for protecting the workmen in this industry, and even then I do not think that you would cover one-hundredth part of the ground.

12,287. (Mr. Sutherland.) In the normal way of rubbing-down, there is no dust?—If you get a very reedy bit of wood, which may be once in a hundred times or once in a thousand times, you might in the first coat get dust; but otherwise there is none.

(Chairman.) It may be so in Scotland, but it is not so in England.

12,288. (Mr. Sutherland.) You object to providing overalls because the men already provide them?—I do.

12,289. You would not take on a man in your shop unless he came with overalls?—I would presume, when I took him on, that he had overalls, and if he did not appear in overalls I do not think the men would let him on the job.

12,290. (Mr. Gardner.) I suppose that you are rather astonished to hear of the prevalence of this evil of lead poisoning?—Yes.

12,291. And that painters are subject to Bright's disease, consumption, and nervous troubles more than men in other trades?—I have known lads who were threatened with consumption and who attributed their cure to being made house-painters, because of the outside work it gave them.

12,292. But the returns show us that there is more phthisis in our trade than in any other trade, and that the average age of our men is some eight years lower than the average age of adults throughout the kingdom, so that it is necessary that something should be done?—I think if you did anything to give them work in the winter time you would save twenty lives from natural decay to one you would save by preventing lead poisoning.

12,293. That would mean forwarding a recommendation to the Home Secretary to have all the Government work done in the winter season?—If you will.

The witness withdrew.

27 July 1911.]

Mr. J. R. DONALD.

[Continued.]

Mr. J. R. DONALD examined.

12,294. (Chairman.) You attend to-day as a representative of the Association of Master House Painters in Scotland?—That is so.

12,295. What is the nature of your business and where is it carried on?—House Painter, 622, Eglinton Street, Glasgow.

12,296. What is the average yearly number of painters employed by your firm?—About 20.

12,297. How long have you been in the painting trade?—40 years.

12,298. Have you known any cases of lead poisoning or painter's colic?—Yes, but nothing of any importance; very very few.

12,299. Have your men had occasional days of sickness, possibly due to lead?—Not to my knowledge.

12,300. Do you have a periodical medical examination of your men?—No.

12,301. Then how do you know that some of them may not be suffering from the slower and more insidious forms of lead poisoning?—There has never been any indication in any way from doctors or anyone else, and no signs of it, to my knowledge.

12,302. You know, I presume, that lead poisoning frequently undermines the health, without immediate violent symptoms arising?—Yes.

12,303. So it is quite possible that they may have suffered from lead poisoning without your knowledge?—I do not think so. It could not be much, at any rate, if anything.

12,304. Do you ever read the "Board of Trade Labour Gazette"?—No.

12,305. Do you know that 284 deaths of painters have been definitely certified as due to lead poisoning in the last 10 years?—No, I did not know that.

12,306. Or that the increase of lead poisoning in the first six months of this year has been very considerable?—No, I was not aware of that. I hoped that it was decreasing; I did not know that it was increasing.

12,307. You have had no cases in your business at all, to your knowledge?—Not in my employment, no; I have never had such a thing.

12,308. Do you know that some of the Potteries are in the same satisfactory position, and that some of the potteries have been quite immune from lead poisoning cases, while their next door neighbours have had a crop of cases?—I did not know that, but I know in the Potteries they sometimes suffer from lead poisoning.

12,309. Do you know that the figures of lead poisoning in the house-painting trade exceed those of all other trades put together?—No, I did not know that.

12,310. And, in addition to this, the death rates from Bright's disease and nervous diseases, due to work in lead, are very high?—I was not aware of that.

12,311. And that there are also a very large number of non-fatal cases most of which are never recorded because the Home Office do not require them to be notified?—No, I was not aware of that.

12,312. I am sure you will agree with me that all this sickness and death is very deplorable?—It is; there is no doubt about that.

12,313. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I am aware of that.

12,314. Do not you agree that something must be done, either by regulation or by the prohibition of lead, to meet this evil?—Yes, it would be much better if something were done.

12,315. Have you any personal knowledge of paints which contain no lead?—Some of our pigments contain no lead.

12,316. Have you had any general experience in using paints which contain no lead?—Yes; we always use them.

12,317. On a large scale?—I do not know what you might call a large scale. We use them in proportion to the number of men we have. Sometimes a demand may take place for a great amount of white lead or a non-poisonous paint.

x 7790

12,318. How much of the work you perform is done with white lead?—It is a difficult question to answer. We will go through 4 or 5 tons a year.

12,319. How does that compare with the amount you use of leadless paints?—That is much smaller.

12,320. How much?—25 per cent.

12,321. Do you mean that 25 per cent., or a quarter of your work, is done with non-lead paints?—That is about it. I could not say exactly.

12,322. (Mr. Gardner.) Are you including Duresco with non-lead paints?—It is a non-lead paint.

(Mr. Sutherland.) But it is a water paint, not an oil paint.

12,323. (Chairman.) Have you found the non-lead paints satisfactory?—Non-lead paint will never fill the place of white lead paint, in my opinion.\*

12,324. In what way is it inferior?—Want of durability for one thing, and want of covering power for another.

12,325. Is non-lead paint cheaper or dearer?—I think if anything, zinc white is dearer. In fact, I know that it is dearer. The circumstances arise where you have to use it. That is why I use it.

12,326. You never use it if you can help it?—Sometimes it is specified.

12,327. If it is not specified then you would use lead paint, as a matter of course?—Yes; lead is the basis of our business practically.

12,328. You have not found the leadless paint satisfactory?—Not when it is compared with white lead for durability.

12,329. Do you know that the Office of Works have a formula for leadless paints, which they have used for the last four years with very excellent results? They have experimented for many years and after many reverses they have succeeded in obtaining a formula which they say now is first-rate?—I do not know their formula. Have they tried it in the Glasgow atmosphere?

12,330. I understand that they have tried it all over the country?—The Glasgow atmosphere is very severe on anything of that kind.

12,331. Now I want you to realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the observance of precautionary measures of the same kind as those which are observed in other employments where the workers handle lead. Are you aware of the details of these precautionary measures?—I have heard them spoken about, but I do not know them exactly.

12,332. Let me give you a few of them. First of all there is the provision of overalls by the employer, who is responsible for seeing that they are regularly washed?—The men supply their own overalls in Glasgow.

12,333. Would you have any objection to supplying them yourself, and seeing that they were properly washed every week?—I do not know. If it was compulsory, I should have to do it, but I am afraid it would be a very peculiar job. You might supply a man with a new suit of overalls on Monday morning, and he might leave you on Monday night. What are you going to do in that case? There is some consideration necessary there.

12,334. Then with regard to meal-rooms, is it possible always to provide that men working in lead should have a separate room in which to take their meals?—That is also a very difficult problem, I am afraid. They generally take their meals in an empty room in the house.

\* Since giving my evidence I have made very careful inquiry into the manufacturing of paints and pigments in London, and I am now convinced that white lead can be done without. I desire to add this footnote to my evidence, because my opinion has been changed in consequence of the practical results with leadless paints which have come under my notice in the last few days, and have confirmed the small but successful experiments carried out last year by my sons and myself in Glasgow.

(Signed) JOHN R. DONALD,  
31.7.1911.

Y 3

27 July 1911.]

Mr. J. R. DONALD.

[Continued.]

12,335. They cannot always take their meals in an empty room in the house, can they?—Yes, they can if it is empty; sometimes, of course, houses are occupied while they are being painted.

12,336. There are occasions when it would be absolutely impossible to provide a separate room?—You could not in some cases.

12,337. Now, next, the provision of a proper place to keep the overalls where they will not contaminate food or outdoor clothing. Is that always possible?—Yes, that is pretty well done as it is. There is not a place set apart for it, but the men are pretty careful in that way themselves.

12,338. Could you always provide a separate room for the men to keep their outdoor clothing while they are at work?—No; that would be almost impossible unless some arrangement was made.

12,339. Now the introduction of proper washing accommodation; one basin or other utensil to every five men, supply of water, both hot and cold, soap, nail-brushes, and a sufficient number of clean towels. Is that always possible?—I am afraid that that would also be difficult. There is always soap supplied to every job. There is no question about that.

12,340. And sometimes the men provide their own pocket-handkerchiefs to wipe their hands on?—I have seen them do that.

12,341. One of the most important provisions is with regard to the avoidance of dust. Some means would have to be devised for getting rid of any dust which the men might breathe. Do you think it is practicable to devise any such system?—Dust arising from what?

12,342. Dust arising from sand-papering?—I would not like to say that there is no dust, but there is very little. It is impossible for dust to rise from sand-papering.

12,343. It would save your time if I told you that in England there is a considerable amount of dust, and we have to deal with the trade throughout the United Kingdom. Now I ask you, as a practical man, is it possible, where dust is generated in the process of sand-papering, to devise any means by which it can be carried away?—Most of the grit that comes off sticks to the face of the sand-paper.

12,344. Kindly answer the question. Making the assumption that what I have put to you is the case, can you suggest any means by which the dust can be removed?—No, not at present.

12,345. Then medical examination. A periodical medical examination, say once a month, would be insisted upon at the expense of the employer. Would you agree to that?—I should require to obey it, if it

was put into force, but I do not know how even the men would take it themselves.

12,346. Would it not be very difficult to carry out?—Yes, because men might for months never be near the shop. They might be out of the town altogether. There are many things to be considered there.

12,347. I quite agree. I am not putting this forward by any means on the assumption that it is easy to do?—There would be difficulty in carrying it out.

12,348. Would you agree to pay compensation to any workers withdrawn from work by the doctor's orders on account of doubtful health? That is to say, supposing the doctor examined a man and said to him, "You are very poorly to-day. I suspend you for a month. You have not lead poisoning, but if you are not careful you will get it"; would you pay that man compensation up to two or three months?—No, I do not think so.

12,349. I am going to put this one last point to you. This Committee has been established to deal with what you have agreed is a very deplorable evil?—Yes, that is right enough.

12,350. We have, as practical men, two alternatives. The first and simplest is to agree to prohibit the use of lead in the industry altogether. The second is to provide precautions to deal with every incident of danger which arises in house-painting operations. Now if the employers come to us and give us very definite and very precise suggestions for the removal of these various evils, then this Committee will very carefully consider them, provided that the employers can concurrently show us that these rules can be carried out—not merely that the rules can be established, but that they can be established and carried out. Now, I ask you, as a practical man, whether you think it is possible under the circumstances to carry out these rules which I have suggested in their entirety?—That would require very careful consideration, at any rate.

12,351. Would you prefer such a code of rules, with all the expense and trouble and irritation which attach to it, or the abolition of lead?—I think the regulation. It would be detrimental to the trade to stop the use of lead entirely. It would be a very serious matter, that, for us.\*

12,352. Do you think you could show us that every incident in house-painting operations which involves danger can be removed?—They could be lessened.

12,353. But I am talking about removal?—I could not guarantee removal.

12,354. If you cannot put forward practical suggestions to us for the removal of these evils, you will not be surprised if the Committee make up their minds to prohibit lead?—I suppose that is the alternative.

\* See, however, the witness's footnote to 12,323.

The witness withdrew.

## SEVENTEENTH DAY.

Wednesday, 1st November 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

LORD HENRY BENTINOK, M.P.

Mr. E. L. COLLIS, M.B.

Mr. A. L. C. FELL.

Mr. C. L. MASON.

Mr. C. KINGGATE.

Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary*).

Mr. W. ROBINS (a member of the Committee) examined.

12,355. (*Chairman*.) Have you been making practical test with zinc white and white lead for lining purposes?—Yes.

12,356. Do you produce comparative test boards?—Yes.

12,357. What conclusions do you draw from the tests?—I draw the conclusion from the tests that zinc

white is much easier to handle in the pencil to put a line on, and that with regard to wear it is better; it retains its colour, and further, that the varnish on the surface damages the appearance of the zinc white less than it does white lead.

12,358. Have you had any practical experience of its durability?—I have had practical experience of

1 November 1911.]

Mr. W. ROBIN.

[Continued.]

durability with regard to a car that had been standing in sulphurous fumes; the work which was done with white lead had gone yellow, and that with zinc white had retained its colour.

12,359. Do you know of your own personal knowledge how long the test has been made of zinc white in these lines?—I have used it on and off now for over two years.

12,360. Have you made careful observation of the vehicles which have been painted with this zinc white?—Yes, and it is satisfactory. It retains its colour on the fine lines of motor cars. The specimen marked "P" is pure white lead; the other has a small portion of blue in to retain its colour on account of the varnish.

12,361. (Mr. Fell.) How long had that car been standing in the sulphurous fumes?—It was standing in the shop only about a week, and it altered its colour.

12,362. You have had no experience with zinc white out in the open air, have you?—Only with regard to cars being painted with zinc white, grey, and so on,

from zinc white, the base of the colour being zinc white.

12,363. How long had those been out in service?—I have seen cars out twelve months, and not alter colour. I have had cars painted myself with greys made from zinc white as a base.

12,364. (Chairman.) Are you confining your evidence to the lines?—No, the general appearance of the colour. With regard to the colour of the lines, I have seen cars in zinc white that have been good two years after.

12,365. With these narrow lines?—With these narrow lines.

12,366. (Mr. Fell.) There is no difficulty in applying them?—No, there is no difficulty in applying them. They are lighter in pencil. They work better.

12,367. Is that one coat or two coats?—With both of those, any painter is obliged to use two coats if he lines with white, whether white lead or zinc white. Those are both applied with two coats as an ordinary painter would do. Neither white lead or zinc white will be solid with one coat.

Mr. WILFRED READMAN (104, Bramshot Avenue, Charlton, S.E.) examined.

12,368. (Chairman.) Are you the foreman painter at the London County Council Tramways Car Repair Depot at Charlton?—Yes.

12,369. How long have you held that position?—Since July 1908.

12,370. What experience have you had in painting?—My experience in the painting trade dates back from leaving school in the year 1892, when I was apprenticed to my father, who is still in the business at Stockton-on-Tees as a painter and sign writer.

12,371. Will you give details of your experience from your apprenticeship to 1908?—During the latter years of my apprenticeship, I worked for the trade as a writer to Messrs. Burrell and Wilkinson, coachbuilders, also of Stockton: I left Stockton in 1900 and commenced for Messrs. Maple & Co., London, on general painting and sign writing. I returned to Stockton in the spring of 1903, and again worked for my father. In the following June I took up my position as foreman painter to the London United Tramways, Chiswick. Here I dealt with 340 electric tramcars, and 10 horse cars annually, together with motor cars and tower wagons. I left the London United Tramways in December 1907, and commenced for the Wallpaper Manufacturers, Limited, of Darwen, Lancashire, as a representative for their enamels and paints department. I left their employ in June 1908, and commenced, as stated above, for the London County Council.

12,372. What number of vehicles do you deal with in the London County Council Car Depot?—The number has increased to 1,397 electric cars for 1911, 81 horse cars, 20 carriages and broughams, 8 motor cars, 5 steam lorries, and 7 petrol lorries.

12,373. Will you describe the process of annual renovation of electric cars?—The car is thoroughly washed down and smoothed with pumice stone and water, all bad parts are touched in with paint, and filled with stopper.

12,374. What material has been in general use for stopping?—The stopper until recently has been made as follows: dry white lead, gold size, and turpentine.

12,375. How is that rubbed down?—This in all cases has been smoothed down with pumice stone and water.

12,376. What is the next process?—The light-coloured parts of cars are given two coats of cream; the waist panels are glazed with lake body colour. Gold lines, transfers, &c., are saved where good, bad parts repaired, lining, &c., is also made complete.

12,377. Is the whole of the outside of the car then given a coat of finishing body varnish?—Yes.

12,378. Is anything done to the roof?—The outside roof is given one coat of paint made up from white lead.

12,379. What is done to the insides?—The insides of most cars are washed and re-varnished; floors,

platforms, staircases, &c., being given one coat of lead colour.

12,380. What are the exceptions?—The only exceptions to this are subway cars, which are painted inside.

12,381. Is any dry rubbing down done?—In the whole of the processes there is little or no sandpapering of work in a dry state.

12,382. What experiments have been made with non-lead paints?—Experiments dating from March of this year up to the present time have been conducted, zinc white having been used in place of white lead.

12,383. What has been the result of those experiments?—These experiments show that, generally speaking, the former material can be satisfactorily employed; so far, at all events, as a paint pigment is concerned, experience has been too short to form a definite opinion.

12,384. Does that answer relate to paints only, or to stopping material also?—Zinc white is used altogether for stopper.

12,385. Now, will you tell us how you deal with new work?—All outside work on car body is given one coat of white lead paint before moulding headings, rails, panels, &c., are fixed. When these are fixed, the portions of car to be coloured Midland red receive four coats of priming.

12,386. Of what does the priming consist?—It is made up from white lead, vegetable black, and driers thinned out with turpentine and a little linseed oil.

12,387. Does the filling come next?—Yes, five coats.

12,388. Of what is the filling made?—It is made from slate filling powder, white lead, gold size, and turpentine.

12,389. How is the filled surface rubbed down?—With pumice stone and water.

12,390. What finishing coats are given?—Two coats of lead colour tinted with Indian red. Then three coats of Midland red, one coat of Midland red varnish colour, one coat undercoating body varnish, lined and lettered gold, one coat undercoating body varnish, and two coats finishing body varnish.

12,391. How are the window frames treated?—The frameworks of drop and sliding lights are filled with patent wood filler, and given one coat undercoating body varnish, and two coats finishing body varnish.

12,392. How is the interior of the car finished?—The whole of the interior of the car, as well as all seats, are filled with patent wood filler and given three coats of hard drying body varnish.

12,393. Portions of your cars are finished in light colours; how are those treated?—The outside upper portion of car, which is finished cream colour, is given one coat of lead colour, one coat of white and three coats of cream colour, is lined and varnished, one coat

Y 4

1-November 1911.]

MR. WILFRED READMAN.

[Continued.]

undercoating body varnish, two coats finishing body varnish.

12,394. How do you paint the outsides of dashes and staircase stringers?—Two coats of lead colour, three coats Midland red, one coat Midland red varnish colour, lined and gilded one coat of undercoating body varnish, and one coat of finishing body varnish.

12,395. How do you treat car floors and similar parts?—Car floor, platform, insides of dashes, staircase treads and risers, and steps are given three coats of lead colour.

12,396. With what is the roof painted?—Outside roof is given four coats of white lead paint.

12,397. How is the roofing canvas bedded?—With a thick paste of white lead on roof boards, which have previously received two coats of lead colour.

12,398. How is this work done?—This thick paste of white lead is spread with a stiff brush and palette knife on the roof boards, and the canvas is drawn tight over and pressed down with a piece of wood, so that the lead is pressed through the texture of the canvas forming one solid mass.

12,399. You have told us that there is no sandpapering of priming coats?—No; the four coats of priming lead colour are put on in the usual way, and are not sandpapered or smoothed in any way.

12,400. Nor of filling coats?—The filling up is also applied without any sandpapering of coats.

12,401. When is the stopping applied?—The pinholes are stopped after the application of the first coat of filling.

12,402. Is the fifth or last coat of filling faced down?—When the fifth coat is dry, the whole is faced down with pumice stone and water, and when dry given one coat of lead colour.

12,403. Is that coat of lead colour also rubbed down wet?—This coat is also faced down with pumice stone and water and given another coat of lead colour.

12,404. Is the second coat lead colour again treated similarly?—No; this is sandpapered before the first coat of Midland red is put on.

12,405. Why do you use sandpaper on this coat?—The reason for using sandpaper as against pumice stone and water is that it is quicker, and also that many of the parts can be got at more easily with flexible sandpaper than would be the case with pumice stone.

12,406. Are the coats of Midland red sandpapered?—No; the coats of Midland red, being made of finely ground colour, do not require to be smoothed between coats.

12,407. How is the work finally prepared for varnishing?—Previous to the first coat of varnish being put on, the work must be sponged down with water and dried off with a chamois leather—this allows the varnish to take more freely.

12,408. Is the first varnish coat flatted?—Yes. When this first coat of varnish is dry, it is flatted down with pumice dust, and a piece of cloth or felt in water.

12,409. And, similarly, for later coats of varnish?—The lining and gilding is then done, and a second coat of undercoating body varnish given. This and the following coat of body varnish is flatted before the final coat completes the car.

12,410. By whom is the mixing done?—All colour, stopper, &c., is mixed by the colourman so that none of the other employees do any mixing whatever.

12,411. Do you consider that this reduces the danger?—This takes away a lot of the danger of mixing by hand.

12,412. Have you found any special difficulties with zinc white?—In our experiments with zinc white we have found some difficulty in getting a lemon yellow to take the place of lemon chrome.

12,413. For what purpose do you use lemon chrome?—Lemon chrome? Lemon chrome is used to tint the white to a cream colour; cream colour we find to stand the atmosphere of London much better than any other light colour; it cleans up well, and is not discoloured by repeated application of varnish.

12,414. Can you not use lemon chrome in this way with zinc white?—Yes; several cars have had the whole of the light colour painted out with cream colour

made up from zinc white, lemon chrome and raw sienna, and these have been checked and are being carefully watched. We have also painted eight or ten new roof covers entirely with cream colour made of zinc white.

12,415. Is this satisfactory?—Some of these have come in with cars for renovation after being in service about two months, and they show no signs of alteration of colour, though of course this length of time is insufficient to prove anything.

12,416. Such a paint would contain less than 5 per cent. of lead material, would it not?—It would contain less than 5 per cent. of lead material.

12,417. Have you seen anything of other works where leadless paints are used?—In connection with our experiments with zinc white I was instructed to visit Bradford Tramways, where zinc white has been used entirely in the place of white lead for over three years; also the Midland Railway Company of Derby, where they have used zinc white entirely for over seven years.

12,418. Do you think that white lead could be dispensed with?—I am fully convinced that white lead can be done away with entirely in a paint shop or coach body shop.

12,419. Do you consider that all coach makers could dispense with white lead?—I do consider that all coach makers could dispense with white lead.

12,420. (Lord Henry Bentinck.) Is your only objection to zinc white that it is difficult to make chrome yellow properly?—Chrome yellow is a difficulty.

12,421. Is that your only difficulty with zinc white?—That is our only difficulty.

12,422. You say it is difficult to tell whether zinc white is satisfactory after only a few months' trial. Have you only had it in use a few months?—Only from March of this year.

12,423. Why did you begin to use it in March?—Because of instructions from my higher officials.

12,424. Have you any idea why they instructed you?—No other idea than from a health point of view. We have had one or two cases of lead poisoning.

12,425. Is your percentage of sickness rather high from lead poisoning?—No; on the other hand, it is low.

12,426. Your percentage of sickness is low?—Very low.

12,427. But from lead poisoning I meant?—The percentage from lead poisoning is exceptionally low.

12,428. But, still, you have had two cases lately?—Yes.

12,429. Do you think that influenced your committee?—I take it that has influenced the committee.

12,430. (Chairman.) Have you known of many lead-poisoning cases?—I have this particular case in mind, and one since. I have been very fortunate in not seeing many. The only authentic instance of lead poisoning which has come immediately under my notice is that of a brush hand who was attacked in January of this year at the Central Repair Works of the London County Council at Charlton. This man was employed to my knowledge for nearly three years on inside work of cars, namely, mostly washing down and varnishing. The only lead that he used was on outside roofs, floors, and platforms.

12,431. Was he a careful man?—I always found him clean and careful in his habits, and was more than surprised when I heard that he was attacked with lead poisoning. He recovered about two months ago, and is at present at work, but outside the painting department.

12,432. Have you had any other cases of lead poisoning?—Yes, one case since. In this particular case a man, aged about 33, was employed in the paint shop of the London County Council at the Central Car Repair Works, Charlton, and must only have had a slight attack, as after five weeks' absence from work he resumed his employment as a painter in the above shop, conditionally as per the London County Council medical officer's report.

12,433. How many men are employed in your department?—One hundred and forty-nine total.

1 November 1911.]

Mr. WILFRED READMAN.

[Continued.]

12,484. Do they all come into contact with lead?—Yes, unless you except the labourers who do the sweeping of the shop.

12,485. No doubt the working conditions at your place are admirable?—The working conditions in the London County Council paint shop are good in every way. The heating and ventilating is effected by means of steam heaters, each equipped with a motor-driven fan capable of displacing 2,000 cubic feet of air per minute. These draw their supply of fresh air from outside the building and deliver it either heated or cooled as required, at about 2 feet from floor level. There are 18 of these heaters which have a total capacity of 36,000 cubic feet of air per minute. This combined capacity is sufficient to change the whole of the air in the paint shop three times every hour.

12,486. What temperature do you maintain in winter?—The shop is heated and maintained at a temperature of 60 degrees Fahrenheit during the winter months.

12,487. What lavatory accommodation have you?—The shop is equipped with wash basins, hot and cold water, and each man employed in the painting is supplied with a nail-brush. Clean towels are renewed daily.

12,488. How often are the floors cleansed, and by what method?—The paint shop floor is swilled down with water daily to prevent dust.

12,489. Are you prepared to put in a schedule showing the amount of each kind of paint used?—Yes.

12,440. (Mr. Mason.) What would you replace white lead with for bedding roofs?—I would replace it with a mixture of zinc white and, say, an oxide of some sort.

12,441. Have you ever tried any such material?—I have not actually tried it. I have seen it in use.

12,442. And, as far as you know, successfully?—As far as I know, successfully.

12,443. Where was that?—At Derby, at the Midland Railway Company's works.

12,444. What would you use for bedding lights?—We do not actually use any white lead in bedding lights in any case.

12,445. What do you use?—Rubber. Light frames are simply varnished before the glass is fixed in. In all cases a coat of paint also is applied; it may be either zinc or white lead.

12,446. Surely you do not find this keeps out the weather?—Yes. If you paint the rebate before the glass is put in, with rubber, it keeps the weather out.

12,447. That is wet when you put the glass in?—Not necessarily.

12,448. For jointing what do you use?—For jointing at present we use white lead. I do not see anything against using zinc white in the place of white lead for that or for canvas, as I mentioned previously.

12,449. Of that you have no personal experience?—No personal experience.

12,450. (Chairman.) Have you seen any cars or carriages dealt with in that way?—I have seen the joints prepared for fixing with zinc white in place of white lead, or this mixture which I mentioned, which is zinc.

12,451. Where have you seen that?—At the Midland Railway Company's works.

12,452. (Mr. Mason.) You have seen it done successfully, as far as you know?—Yes, as far as I know. I was told that they could not notice the difference as regards the work standing.

12,453. (Dr. Collis.) I would like to ask you, with regard to the re-painting of coach-work, why is the painted surface of coach-work renovated? Is it because the paint has all worn away, and you have to re-paint, or for what reason?—If it is not worn away by cleaning down, renovation, viz., touching up and re-varnishing will keep it in such a state that it never does get actually very bad.

12,454. So that the pigment of which the paint itself is made is not so important as the covering material and the varnish with which it is protected. Is that so?—That, practically is the case. Much of the work is not coated with white lead, and would not be

in any case coated with it. The varnish is really the most important.

12,455. So that, whatever may be the respective values of white-lead and zinc-white paints in other branches of the painting trade, in the coach-painting trade it is not important, because it is the varnish which is the life of the paint that is put on?—Yes.

12,456. So that, with regard to the coach-painting trade, would you be able to say that you are the more convinced that white lead may be replaced by other pigments?—Yes, quite so, because white lead is used to a great extent only for the foundation of work.

12,457. And that foundation, you think, could be replaced by other pigments?—Yes, it could in those instances I have mentioned.

12,458. With regard to the difficulty of obtaining colours, when you use lead chrome to make the lemon colour what is the usual proportion of lead chrome then used, if you are mixing it with white-lead paint?—I could not say offhand, but for 1 cwt. of lead (I am giving the approximate amount), say, between 7 and 14 lbs.

12,459. That would be a pale lemon?—Yes, a pale lemon. That varies. The strength of the yellow varies, so that I could not give the actual weight; 4 lbs. in some particular case it might be. It depends altogether on the strength of the staining.

12,460. Have you any experience at all of the way in which dust can be removed locally in factories?—I have not had experience with any plant of that description.

12,461. You cannot say whether you think it would be possible to remove any dust which is caused in rubbing down various parts?—No, I have not had experience with any machinery or anything of that sort.

12,462. (Mr. Mason.) Do I understand that you never burn off your coaches at all, or trumcars?—It is very seldom that a job is burnt off. The dash plates occasionally, where damaged, are burnt off. We have been experimenting with a paint remover, but not altogether satisfactorily. We find the blow-lamp is quicker and more effective than the paint remover.

12,463. Do you find that by applying or continuing to apply new coats on the top of old ones the paint stands perfectly satisfactorily?—Perfectly satisfactorily.

12,464. How often do you paint?—Once a year. Do you mean paint the whole coach right through, or renovation?

12,465. How often do they come into the paint shop?—They come into the paint shop once a year.

12,466. (Chairman.) To be renovated?—To be renovated.

12,467. (Mr. Kinggate.) With regard to the fixing of mouldings, they are put on with white lead, I presume?—They are put on with white lead.

12,468. You said they received a coat of lead colour before the mouldings were fixed. They are generally fixed with white lead?—Yes, a thin coat. The mouldings are fixed, and put on wet with the lead.

12,469. There has been no experiment with regard to other compounds used for that purpose?—No; I have not experimented in jointing at all.

12,470. You would attribute the immunity from sickness in the works to excellent ventilation, and other things in connection with cleanliness?—I would. The men may have worked in a variety of shops that I have no knowledge of, and the lead poisoning may have been contracted before they came under my notice.

12,471. You would agree that there is general lowering of the vitality of men working in lead, apart from serious cases of lead poisoning?—Yes.

12,472. Men have very frequently illness not attributed to lead poisoning, but which is caused by that?—Yes.

12,473. The appearance of the painter would tell you that he is suffering from something of the kind?—Yes.

12,474. It would be a great benefit to the health of the workers if you could possibly abolish the use of lead?—It would, I agree.

1 November 1911.]

MR. WILFRED READMAN.

[Continued.]

12,475. You, as a practical man, think it is possible to be done?—I do believe it could be done away with in our particular trade.

12,476. The most important point is keeping the vehicle well varnished?—It is, undoubtedly.

12,477. It is more important even than the pigment?—It is, undoubtedly.

12,478. (Mr. Robins.) In your answer to Mr. Mason, you said you would apply coats of paint over the old surface?—I do not quite understand.

12,479. Did you mean to infer that you would not remove the old paint before you applied new?—No, I would not if the surface of the paint was good, which it usually is, in my particular experience.

12,480. It is more frequent that you touch up and varnish rather than re-paint?—Yes, it being an annual business.

12,481. But in all cases of re-painting you do not remove all the old paint?—No.

12,482. In the case of a perished article you would?—Yes, a perished article.

12,483. That would be done by rubbing down wet, I presume?—No. I should put the blow-lamp on and burn that off.

12,484. Could not another method be applied instead of the blow-lamp?—I have tried paint removers and they are slow in comparison. If you want to remove about three coats of paint without filling up anything underneath, a paint remover does it quite well; but if you have many coats of filling up, and such like, and the coating is pretty nearly one-sixteenth-inch thick, the paint remover is too slow. It takes a lot of soaking.

12,485. I take it that it is a question of cost against the health of the worker?—I do not see anything that is unhealthy in burning off.

12,486. The fumes are unhealthy?—They may be, but it is for such a very short time that a blowlamp is used, and not regularly day after day, as with other work.

12,487. What you burn off produces dust in a very few hours?—No doubt there is a little dust, but we do not allow it to remain. It is taken up as soon as it is scraped off.

12,488. But there is a little?—There is a little.

12,489. (Dr. Collis.) The reason why you renovate your cars every year is, I believe, because you are under statutory obligation to do so?—That is the reason.

12,490. In your experience, do other people who paint coaches and who are not under such an obliga-

tion allow a longer period to elapse before their carriages and cars are renovated?—Yes.

12,491. And do you think that with them the question of the pigment of the paint would be more important than it is to you?—I think it would be more important.

12,492. Have you had much experience in an ordinary coach-building shop?—Yes, in coach-building generally, but, being a writer more than a coach-painter, I have not been working on the coach-work.

12,493. Not when it has first come in?—No, not on the actual coach-painting so much as sign writing and writing on coaches, and fine work, and so on.

12,494. Are you able to express an opinion as to how far coaches and carriages come in with the paint pigment itself destroyed before they are renovated?—The outer surface indicates whether it should be painted again or not. I quite agree that the better pigment underneath would certainly last longer than if there were an inferior thing put under the varnish.

12,495. In your experience, carriages and cars come in to be re-painted with the pigment of the paint below the varnish itself wasted and destroyed in some cases?—Yes, right down to the bare wood in many cases.

12,496. Have you used zinc white for writing and fine lining at all?—I have used it for both.

12,497. Do you find any difference in applying it over white lead?—It is slightly different in use, but it is equal to white lead. In lettering two coats of a well-ground zinc are quite satisfactory.

12,498. Could it be applied as easily and freely by a man used to working with lead as by a man used to working with zinc paints?—I do not see any difference.

12,499. (Chairman.) You said that white lead could be dispensed with in the coach-building trade?—Yes.

12,500. I suppose, with regard to operations of which you have had no actual personal experience, you base that answer on what you have seen at other large works such as the Midland Railway Company's works at Derby?—Yes.

12,501. Entirely?—Yes.

12,502. That would apply to the fixing of mouldings and to the bedding of canvas?—Yes.

12,503. Do you find zinc white takes longer to mix and prepare?—I do not find any difference between that and white lead.

The witness withdrew.

Mr. WILLIAM AWCOCK (278, Hertford Road, Lower Edmonton), examined.

12,504. Are you one of the representatives giving evidence on behalf of the United Kingdom Society of Coachmakers?—Yes.

12,505. What practical experience have you had in the coach-painting trade?—During 44 years.

12,506. Have you worked at railway coach and tramcar painting, or only at carriages and motor-cars?—Only at carriage and motor-car painting.

12,507. Have you known many cases of lead-poisoning amongst coach-painter?—Yes. I know five that I should say were special cases. I know plenty of others, ordinary cases, that come under daily notice.

12,508. You know of five special cases and a great many others, not severe cases. Is that what you mean?—Yes, men who are affected by lead.

12,509. How many other cases do you know?—I should say, speaking from experience, probably at least a hundred.

12,510. Covering what period would that be?—Forty-four years.

12,511. Have you had any personal experience of the ill-effects of lead?—No, it has not affected me.

12,512. But in your opinion this lead poisoning evil is very extensive in your trade?—Yes; I think it more or less affects 50 per cent. in the coach-painting trade.

12,513. That is a very bold statement. Have you any facts to give us on that?—I want to explain that in this way: The men are affected by the use of paint; they simply go home and take a dose of castor oil or something of that kind, and keep plodding on, you see.

12,514. But on what do you base that statement that 50 per cent. of the men are affected by the lead?—Nearly every man that I know has been affected by the use of lead paint. His health has been affected in various ways.

12,515. But we must have facts. Have you anything to show the Committee that that statement is correct?—No. It is only my opinion.

12,516. On what have you formed that opinion?—Merely on personal experience in the paint shop.

12,517. By your general observation?—Yes, by general observation.

12,518. How many men have you worked with in the different shops you have worked in?—I could not tell you. I have been in about 34 shops.

12,519. Can you give us approximately what number of men you have worked with?—An average, I should say, of 15 in each shop.

12,520. Do you tell the Committee that out of those 15 men at least seven of them have, to your certain knowledge, been affected?—In my opinion they have been.

1 November 1911.]

Mr. WILLIAM AWCOCK.

[Continued.]

12,521. Have they made any personal complaint to you about it?—No. You simply see it in daily contact with them, and you take no notice of it as far as that goes. A man has been working with dry white lead stopping and so on, and feels queer: he goes home; he is not very well; he comes back again after a day off, and goes on. He may not be engaged on that same work for some little time.

12,522. Are you prepared to answer questions with regard to each of the processes in detail?—Yes.

12,523. First, as regards the body-makers, are they exposed to any risk?—Undoubtedly.

12,524. Does the carriage-maker come into contact with lead?—Yes. Every piece of ironwork that he puts on the carriage he has to lead.

12,525. When the carriage-maker has completed the work of fitting-up, is the article ready to pass into the painter's hands?—When the carriage-maker has done—yes.

12,526. The first coats of paint applied are termed priming coats, are they not?—Yes.

12,527. How many coats are generally applied?—About four coats of lead colour.

12,528. Does the priming contain lead?—Yes; it is lead.

12,529. Is sandpapering done between successive priming coats?—Generally.

12,530. In what shop is this generally done?—In nearly the whole of the trade.

12,531. Is it done in the body-maker's shop?—Some of it is done in the body-maker's shop. If a body is ready you send the painter up to give it a coat of lead colour. It is not the general practice to strain lead. Lead contains skin. When a painter goes up again to give it another coat he runs a piece of paper over it to make it smooth, and it also gives a better grip to the next coat put on.

12,532. So that the body-makers and carriage-makers are frequently exposed to dust made by the painter?—Undoubtedly. He is standing at the side of the bench.

12,533. Do you regard the breathing of this dust as one of the most serious dangers of the industry?—Undoubtedly.

12,534. Can it be replaced by a wet rubbing process?—Not in that case.

12,535. Why not?—Because of the thinness of the colour that is put on. You would probably be rubbing through to the wood. By the dry process of sandpapering if you touch the wood it has no ill effects, but water would cause the grain to rise and spoil the panel.

12,536. Is it generally possible to use any form of local exhaust apparatus to remove the dust?—I do not think so, but that is more a question for an engineer.

12,537. Then how is this danger to be overcome?—By finding a substitute in place of white lead. That is the only thing that I can suggest.

12,538. Is the next process what is generally known as filling?—Yes.

12,539. About how many coats are put on?—About five. If it has a very rough grain like ash you give it an extra coat.

12,540. Does the filling material contain lead?—It ought not to. Some do and some do not. With patent filling, a kind of slate material; there is no necessity to put lead in.

12,541. There is no rubbing down between the successive coats of filling, is there?—Just previously to putting on the last coat of filling, you very often pass a piece of sand-paper over it to remove any odd piece of material that may be hanging about the panel.

12,542. Is stopping generally done after the last coat of filling has been applied?—Yes.

12,543. What is the stopping material made of?—Dry white lead and gold size.

12,544. By whom is the stopping material mixed?—In the place where I am now by the foreman. It is very often mixed by the man who has to use it.

12,545.—Do you consider that the mixing of white lead and gold size is attended by danger?—Yes, because it has to be mixed on a stone. You put it in

a heap; a man stands over it and beats it and naturally dust is rising up all the time.

12,546. How is the rubbing down done after the application of the filling coats?—By pumice stone and water.

12,547. Is it ever done dry, for example, with sand-paper?—No. You would not get a proper surface if you did.

12,548. What is the extent of the danger in the rubbing down after the application of the filling and stopping?—Simply this: the water is charged with the paint that you are rubbing off the panels. You may get an inch of stuff at the bottom of your pail which is simply a mixture of pumice stone and lead filling.

12,549. In what way is there any danger in that?—Only that the man is being smothered in it. He may be using that and his hands are practically clean to all appearances, but the water is charged with lead and he may sit down and have his lunch without washing.

12,550. He gets water charged with lead splashed on his clothes?—On his hands.

12,551. And he rubs his hands on his clothes?—Yes; and he may rub it on to his food.

12,552. Does he ever wash his hands in this dirty water?—Oh, yes; he thinks nothing of that.

12,553. Why does he not wash his hands with clean water in the lavatory?—A lavatory is not always provided.

12,554. Do you know any cases where men have used this lead water to wash their hands when lavatories were provided?—No, I do not. You see the lavatory may be all right enough, but it may be in the paint-shop.

12,555. But do men use this lead water because there is no other accommodation for washing their hands?—If a man is in the body shop, he may have a long way to go to get to the paint-shop, where he has lavatory provided for him.

12,556. Does not the man know the risk he runs in washing his hands in such water?—I daresay he does, but I think familiarity breeds contempt, very often.

12,557. I hope the men will wake up to the seriousness of the position and help us if rules are provided to obviate all these dangers. Are the wheels and the carriage underwork treated differently from the body?—Yes.

12,558. In what way?—They have three coats of oil lead colour, and then they generally have two coats of Presto lead colour; that is dry white lead discoloured with a little vegetable black and mixed in gold size and turps. The work is then sandpapered.

12,559. Does this produce dust of a poisonous nature?—Yes; that is the worst part we have to deal with. It is only just bound, you see. There is a sufficient amount of gold size put in it to bind the colour which the men have to sandpaper down.

12,560. Is it necessary to sandpaper in every instance by this process?—There is no other way.

12,561. This, then, is also an extremely dangerous process?—Yes. A liquid filling that we used to use in a shop I worked at, Valentine's wood filling, was put on with a wet rag. We got it from America.

12,562. Is it impossible to use wet methods of rubbing down in this work?—Yes, I think it is. You could not rub wheels down in that way.

12,563. It is impossible owing to the prevalence of curved surfaces?—Yes. There is hardly a straight piece of wood in a wheel.

12,564. Is it practicable to apply local exhaust ventilation generally?—I do not think so.

12,565. After the rubbing down of the filling has been completed, what is the next operation?—Coating with a lead colour; in some cases two coats, but generally one. Then it is faced again with pumice stone and water.

12,566. Is the work then ready to be painted the desired finishing colour?—Yes. It is then ready for the ground, or whatever is put on.

12,567. Is the carriage then ready for varnishing?—Yes, after the proper colour is on.

12,568. Do your answers apply equally to carriage-building and to the manufacture of motor-car bodies?—Exactly the same.

1 November 1911.]

Mr. WILLIAM AWCOCK.

[Continued.]

12,569. Do you consider that the introduction of motor-cars has had any effect on the dangers of the employment?—No, I do not think it has.

12,570. Do you mean to say that the motor-cars have simply taken the place of carriages?—That is it.

12,571. Can you tell us anything with regard to fixing canvas or moleskin on the roofs of closed vehicles?—Different shops have different methods. In some cases they use japan and white lead mixed.

12,572. Is that a dangerous process?—You only get it on your hands; that is all. I do not look upon it as particularly dangerous in the case of roofs.

12,573. Have you anything special to say with regard to tram-car and railway work?—I have never had any experience.

12,574. Are there any other processes in coach-painting which involve the formation of a spray or vapour of thin particles of paint?—No, I do not know of any.

12,575. You have now told us all the operations in which there is serious risk of lead-poisoning in coach-building work. Is it, in your opinion, impossible to remove these dangers except by prohibiting or closely restricting the use of lead?—I do not think it is possible to get rid of the danger, unless you get rid of the lead entirely.

12,576. Now, there are no doubt many processes in which the workman cannot avoid getting his hands soiled with the material he is using?—In every process he is bound to get his hands soiled.

12,577. Is adequate washing accommodation provided by most employers?—That is a question I could not answer.

12,578. What is your own experience in the shops you have worked in?—In my own experience I have been very fairly treated, and I should say yes.

12,579. Are nail-brushes and hot water available as a rule?—No, not hot water.

12,580. Do you think hot water very important?—Yes, it is, but it is not provided. We usually use horse-hair in the place of nail brushes; the painter prefers it; it gets the dirt off a good deal better than a nail-brush.

12,581. Is time allowed to the men for washing before leaving off work for meals?—No. I have known cases where men have been discharged or threatened with discharge, for washing their hands. I will give you an instance in the case of the London County Council. A body-maker was found washing his hands after using white lead, and although they were supposed to have the time, he was threatened with being discharged if he was found doing it again. A complaint was sent to Mr. Fell, and Mr. Fell had notices put up in the shops stating that men were to be allowed to wash their hands immediately after the use of white lead.

12,582. Is the food often kept and eaten in the workrooms where lead is being used?—Yes.

12,583. Are meal-rooms provided in any cases to your knowledge?—I know of one, Hooper's, in Chelsea, but I do not know of any others.

12,583a. You say that you have worked in 34 shops?—Yes, and I have never found one that did it.

12,584. In the whole of the 34 that you have been employed in, you have not found one where they provided a mess-room?—No.

12,585. Are the Committee to understand that in all those cases it has been imperative for the men to have their food in some part of the place where they come in contact with lead dust, or to go outside?—Yes. In our case we go to the smith's shop, but that is about the only place in the shop that is free from lead. Otherwise, you have to go outside.

12,586. Do the men have the use of a cloak-room?—No. You hang your clothes up where you are working.

12,587. Do you mean that the men hang their clothes up in the room where they work?—Yes.

12,588. Do the painters wear overalls while at work?—No.

12,589. Do I understand that all the dust that they come in contact with settles on their daily clothes?—Yes, and they take it home with them.

12,590. Can you tell us what are the usual hours of work for coach-painters?—It varies in different shops from 53 to 54 hours a week. Fifty-four is usual.

12,591. Do you think that a restriction of the hours of work in lead processes would have a good effect?—Yes, I do. I am always in favour of the restriction of hours.

12,592. Speaking not from the point of view of pleasure, but from the point of view of health, do you think that it would be a good thing?—Yes, I do.

12,593. Have you noticed any alteration in the hours of employment as the result of the development of the motor-car industry?—There is a slight shortage in the motor-car hours. They, generally work 53, whereas in the coach-makers' shops they work about 55.

12,594. Has not a good deal of overtime been introduced since motor-cars came into being?—Yes, undoubtedly.

12,595. Would you say that overtime has been very marked in most of the shops you have been working in?—No, not in my own experience. I know that it has been very much so in other large factories. I know a man who worked every Sunday for twelve months, and then he wanted a Sunday off, and he got discharged because they wanted him at the shop on Sunday.

12,596. (Dr. Collins.) You say that you have had knowledge of a considerable number of men who have had illness due to lead, in the course of your experience. Could you say, speaking generally, whether these men were the most careful, or the least careful, of the men who were working with you as regards personal cleanliness?—This is what I referred to in the first instance. A case of a man came under my notice when I was an apprentice. He was not careful in any way. His name happened to be "Painter," and he suffered from dropped hands and paralysis generally, which were caused by lead poisoning.

12,597. But, taking it as a general thing, do you think that the men who have been very careful with regard to personal cleanliness have still suffered at all from the effects of lead?—I find it in both cases, but I think that men are, if anything, more careful now than when I first came into the trade.

12,598. But you do not think that this additional care has removed the tendency to illness?—No, I do not.

12,599. I suppose it has been your bad fortune to work with men addicted to alcohol. Could you say, from your experience, whether they have shown any greater tendency to be ill than other men have done?—I have not noticed any difference.

12,600. Lead-poisoning, then, seems to attack all and sundry without regard to care in diet or care in cleanliness?—Yes, it does.

12,601. (Mr. Fell.) You have told us a good deal about the dangers of white lead. Have you had any experience with zinc white, or anything of the sort?—I have used zinc white.

12,602. Did you find any difficulty in the application of zinc white?—No.

12,603. None at all?—It is a better colour.

12,604. For the same number of coats do you get as good an effect?—Yes.

12,605. And you find there is no difficulty in application?—No; I find no difficulty whatever.

12,606. Do men take to it as easily as they do to white lead?—Yes, and the working of a colour depends on the way in which it is mixed. A good man mixing colours knows exactly what is going to be done with them, and therefore he would not have any difficulty in applying them.

12,607. There is no more difficulty in mixing zinc paint than there is in mixing lead paint, you think?—No.

12,608. Do you know anything about the lasting properties of zinc paint?—No.

12,609. You do not know whether it lasts as long as lead paint?—No.

12,610. You get carriages and so on sent back to your shop for renovation, do you not?—Yes. It is

1 November 1911.]

MR. WILLIAM AWCOCK.

[Continued.]

very seldom that you get a carriage that is painted white. White, as a rule, is simply a matter of picking-out and finè lining. In that case I have found zinc white keep its colour much better than white lead, which always discolours in a very little time. If I gave a panel a coat of white lead now and another coat next week, the first coat would be already discoloured.

12,611. But, apart from discoloration, what is the lasting property of zinc paint?—My experience is only confined to white-picking outlines. They last equally with white lead.

12,612. Do you find a greater tendency to powder with zinc white than with white-lead paint?—My experience, as I said before, only lies in the application of a picking-out line. I could not go any further than that.

12,613. (Mr. Mason.) To what class of shop do your answers apply?—Motor shops and coach shops.

12,614. Of a better and higher class, do I understand?—Yes.

12,615. From the early part of your evidence, I gathered that painters are frequently in the habit of having a day off owing to the effects of white lead?—Yes.

12,616. How much time would an average painter lose in the course of a year?—It would be rather difficult to say. He may lose four or five days.

12,617. That would not be a very frequent loss of time?—He has a day off, and very often he will not tell you what he is away for.

12,618. But how many days does he lose in a year?—I should say an average of five. It may be four or five days.

12,619. I gathered from the early part of your evidence that a painter frequently has a day off?—I call it frequent.

12,620. Five days in a year?—Yes. You are asking me for an average, you see. One man may have a great many days off, and another man may be like myself and go the whole year through without. In striking an average like that, you may have one man who is affected by colic or something of that sort pretty frequently, and you may have another man, or two men, not affected at all. Therefore the average may not amount to much when you come to strike it.

12,621. How would this loss of time compare with that in other trades, blacksmiths, for instance?—I could not tell you. I am talking of the time that a man is off when he feels ill. I am not talking of the time he is off when he is making a holiday. A man may be away with nothing the matter with him. He simply has a day or two off.

12,622. But can you classify the days he has off in any way?—Only by when he comes back and says he has been queer or not well.

12,623. (Chairman.) We want to know whether the absences from ill-health in your industry amongst the men are more frequent than they are in other industries which are not dangerous trades?—The absence of men from the paint shop is undoubtedly more frequent, in my observation, than in any other branch of industry.

12,624. (Mr. Mason.) You have no figures, I take it, to back that up?—I have no figures. If I had known I was coming here, I would have taken observations the last year or two.

12,625. How long have you been in your present shop?—Six years.

12,626. Could you give us any figures with reference to that?—Yes.

12,627. Would these men who came back, having suffered from sickness, claim compensation?—No, not always. I have a case of a man named Byrne who belonged to our union. Two years ago he was coating a chassis ready for the show. It was a bit rough on the sides. It was stopped up. Some quick-lead colour was put on, and the stopping put on the top. He sand-papered it. After working at it he went home ill, and was away about a fortnight, but he made no claim. He came back still ill. He still complained of his chest. He left the job, and he died about nine months ago. He never got over it. I do not know whether that case was ever reported as a case of lead poisoning,

but undoubtedly it was working on that chassis that killed him.

12,628. Then I judge from what you say that there are a great many more cases of lead poisoning not reported than there are cases actually reported?—That is my opinion.

12,629. Now to what, as the result of your experience, do you attribute this alarming increase in lead poisoning?—Simply to the floating dust of the lead from the method in which it is used.

12,630. Is there any difference now in regard to the floating dust or the method in which lead is used from the time when you first started lead painting?—No; it is the same old method.

12,631. The increase in lead poisoning has been enormous in the last 10 years?—There may be an increase in the use, but there is no difference in the method.

12,632. If you increase the use of lead you must in like manner increase the number of painters?—You may do so, but very often it happens that you may be increasing the use of a material in a shop without necessarily increasing the number of painters who use it. So much depends on the demand that the customer makes for a certain class of goods which necessitates the use of certain materials which otherwise might not be used at all.

12,633. Do you suggest that now a man applies more white lead in the course of a year than he did 20 years ago?—I would suggest that he applies more dry white lead than he used to. At one time the bulk of the coach-painting was oil colour always, but now you have to get your work done quickly; people are in a hurry to-day; the employer is in a hurry, and very often the man is in a hurry, with the result that he uses more presto colour, more dusty colour, than he used under the old system of coach-painting.

12,634. More presto is used now than 20 years ago, you think?—Yes, more than I have ever known before. At one time it was looked on as a crime to use presto colour on a panel, but they do it now.

12,635. It was practically unknown in those days?—A painter would refuse to do it. He would say it would not last, but it is used now. I have seen now carriages painted with presto colour, but when I first went to the trade it was all oil colour. It is the increase of quicker methods of working that has caused the increase in the use of presto, and the consequential increase in the dust.

12,636. Do you put it down, as Mr. Fell suggests to me, to general speeding up?—Yes. It is general speeding up very much, and the worker suffers.

12,637. (Mr. Robins.) And the work suffers?—Yes.

12,638. (Mr. Mason.) You were speaking of white lead in a bucket of water. Do I understand from you that white lead is highly soluble in water?—What I said was this: that in rubbing down, the white lead is mixed with the filling that is put on the body, and as soon as ever a man begins to rub down, he is rubbing down white lead and filling, and it mixes in the water, of course, at once. Therefore, if a man is a little bit careless, he may have half a pailful of white lead and filling, and by the time he has done rubbing he is fairly floating in it.

12,639. How many buckets of water would he use in rubbing down?—It would be according to the size of the body.

12,640. Take the average small body, even a small two seater?—He would want four at least.

12,641. Do you tell me that he does not empty the bottom of the bucket out at all when he takes his second bucketful?—But does he go for the second?

12,642. How can he get it, if he does not go for it?—He will do with the first very often.

12,643. You said a minute ago four buckets?—I say the man needs four, and should use four, but I do not say he does it.

12,644. How do you suggest, if the working painter does that sort of thing, anything that any employer can do will do anything for his good?—I do not think his employer troubles his head as long as he gets the job done.

1 November 1911.]

Mr. WILLIAM AWCOCK.

[Continued.]

12,645. (*Chairman.*) Mr. Mason means, if that is an illustration of the carelessness of the men, what guarantee can this Committee have that the men will be more careful in observing other rules which are introduced for their benefit?—I think that you might do a great deal by educating the men, more than has been done, to the danger of lead, by a better system of factory inspection.

12,646. (*Mr. Mason.*) Your evidence rather shows that the men are more careless than we had imagined here?—I say that in certain cases it is so. You asked how many pails of water a man should use, and I told you that sometimes there is difficulty in procuring water. A man has to go a distance for it, and, rather than go a distance for it, he will put up with what he ought not to do. Water is not always available in every part of the factory.

12,647. (*Mr. Kinggate.*) I think that what you intended to convey by your statement, about 50 per cent. being ill through the use of lead, was that all who work in lead are more or less affected by its use, and that it generally lowers the vitality of the men?—Yes.

12,648. And many of them, though they are never off from work, will suffer from the effects of lead?—Yes; that is my opinion when I say 50 per cent.

12,649. Many men continually suffer from lead, but never lose a day's work?—No. They feel ill.

12,650. They continually purge themselves in order to keep at work?—Yes, with castor oil, and so on.

12,651. Therefore, any statistics as to the average number of days lost by painters would not in any way convey the full effect of the use of lead?—No, I do not think they would.

12,652. I think you said that washing facilities were generally provided, but is that so?—It has been so lately. I do not say it has always been the case, but lately they have been pretty fair with regard to that in paint shops. It has generally been after the factory inspector has had a look round and has ordered it.

12,653. This improvement, speaking with regard to London, is of quite recent date?—Yes.

12,654. It is quite usual in big West End shops for men to have only a pail to wash in?—Yes, and towels are not provided.

12,655. I have been in large shops in the West End, and they have had no provision for washing of any description?—Soap is generally provided now, and washing bowls sometimes, and towels more frequently than they used to be. Generally speaking, in an ordinary wheelwright's shop the employer provides soap, and the men use their leathers for washing their hands, and the pails which they use in their work. In that case as a rule, someone goes and gets a pail of clean water when they wash at one o'clock, but in between times they might use the water they use in their work. At meal-times they would get clean water.

12,656. There are no meal-room facilities, or facilities for keeping clothes apart from where they are working, generally speaking, in coachmakers' shops in London?—I have never found it the case yet.

12,657. In your experience, has it been a usual thing to put canvas on roofs with japan without the use of lead?—Yes.

12,658. Do you think it possible to put it on with japan without the use of lead?—Yes.

12,659. Is it durable?—Yes, but it has to rest a bit. The canvas is of rather a coarse nature, and lead helps to fill up some of the grain of the canvas, and that is why it is introduced. White lead thickens the japan a bit, and helps to make a more solid surface under the canvas. When we had leather we only used japan, and never anything else. Some shops use an ordinary trimmers' paste, and that is equally good.

12,660. The putting on of leather on a brougham is by paste?—Yes.

12,661. With regard to the causes of death, you said that at any rate two recent deaths in London have taken place from lead, and the certificate has not stated that it has been the cause of death?—Yes.

12,662. Were the men two personal acquaintances of yours?—Yes. Gerald Byrne, whom I mentioned,

was one, and J. Shapley was the other. He suffered from lead and went blind.

12,663. He died from hæmorrhage of the brain?—Yes. He had 50*l.* from our union, and he died shortly after; in fact, in about a week after he had the money.

12,664. The medical certificate did not state directly that it was caused by lead?—No.

12,665. It gave the cause of death as hæmorrhage of the brain in the case of Shapley?—Yes.

12,666. The other was heart disease?—Shapley always said it was the lead that made him ill, and undoubtedly whenever he used it he was ill. If he was sandpapering a little body all over, he would always go home ill.

12,667. The Board of Trade Returns in the "Labour Gazette" do not in any way convey the evil effect of lead, you think?—I do not think so.

12,668. Men are continually suffering from lead where no report is made, and there are a number of deaths from white lead which are not attributed to white lead?—No; simply because they are not caused directly by lead poisoning. A man has been suffering for some time previously with other symptoms, perhaps.

12,669. The reason why you cannot speak with regard to the permanency or durability of the substitute for white lead is because the employers have not allowed you to use that material?—No, they have not provided it. It may be a question of cost.

12,670. The object of lead is to stop up the pores of wood in the first instance?—Yes.

12,671. Could other methods be adopted for that purpose apart from lead?—Yes; you have to adopt other methods when you have a varnished car. The filling will bite on that equally as well as it will with lead.

12,672.—Why is lead generally used with filling?—There is no reason at all.

12,673. Does it give a better surface when it is rubbed down?—No.

12,674. Is it not harder?—No. If I use patent filling, as it is sent in from Harland's, I get an equally good surface. I think that lead has a tendency to rot—I mean it has a more rotten feeling under the stone when you are rubbing it.

12,675. You think that filling can be used without lead?—Yes.

12,676. The general view is that lead is required?—The manufacturer of the patent filling tells you what I say—that it can be done without lead.

12,677. But it is your experience that it can be done?—Yes; I have used filling without lead with equally good results.

12,678. (*Mr. Robins.*) How many days, in your experience as a painter, would pass without at some time during the day painters complaining of feeling ill, putting aside the four or five days away of which you have spoken?—There is always someone feeling ill.

12,679. With that experience, do you consider that the painter of to-day is far more intelligent, cleaner, and better in his methods altogether than the painter of 15 or 20 years ago?—Yes.

12,680. And yet to-day we find that he is still complaining day by day in the workshops of his health and of his feeling bad?—That is because of the increased quantity of presto lead that is used.

12,681. That is daily experience?—Yes. In a shop of 15 or 20 men someone is sure to say he does not feel well, and if you find out what the men have been doing, you will probably find that they have been using presto lead or something of a dusty nature.

12,682. Although it might happen that none of those men would absent themselves from work for a month or two or three months, they would be suffering day by day?—The men using this presto generally are men whose wages are low. The painter's labourer and the brush hand in some cases are using this presto stuff, and they cannot afford to lose time. As long as they can potter along they will do so.

12,683. You attribute this, then, to the use of white lead?—Yes, I attribute it to the use of lead.

12,684. With regard to men rubbing down and being dirty in their habits, would not this be the

1 November 1911.]

Mr. WILLIAM AWCOCK.

[Continued.]

exception rather than the rule?—Yes. It is not everybody who does rubbing down. As a rule, you have a special class of men who take that, and our work is divided and subdivided. One man fills up, another man rubs down, another man puts on the best coats, and another finishes, but in all cases they come into contact with lead.

12,685. My experience of the painter's labourer, and it is a long experience, is that he is far cleaner to-day and is more careful about the water that he washes in?—Yes, he is more careful.

12,686. Where there is a dirty man, he is pulled up about it?—He would get the sack.

12,687. Then what you say about washing in the dirty water in the bucket is the exception rather than the rule?—Yes. In dealing with deaths, I have had occasion lately to go through the deaths of the members of our union in 40 years, dividing them up into body-makers, painters, and so on. I find that the painters have the shortest lives and the smiths live longest.

12,688. (Dr. Collis.) Will you put in a table of those statistics?—Yes; I will send it on to the Secretary.\*

\* See Appendix XIV.

The witness withdraws.

Mr. T. R. ATKINS examined.

12,689. (Chairman.) Do you attend to-day to give us information regarding a new paint material?—Yes.

12,690. Are you the inventor of it?—It was invented by me in conjunction with a chemist named Mr. Wynne, with whom I am now associated in the manufacture of the paint as a business concern. He is a Cambridge graduate in science. After leaving college he was connected with the Lithopone Works in Germany.

12,691. What is the composition of the paint?—Oxide of antimony, practically.

12,692. Is it to be used as a substitute for white lead?—Yes.

12,693. What is its covering power as compared with white lead?—It is far greater than white lead. I have brought down a small board on which I have black lines painted, and one coat of the stuff applied on the top of the black. Any gentleman who has had practical experience will realise that white lead will not obliterate quite in the same way with one coat. (The witness produced a small board.)

12,694. Was it mixed to the same consistency as an ordinary coat of white lead?—Yes; otherwise it would not have been a test. It was mixed half and half linseed oil and turpentine, with no patent driers. If you put a lot of driers in, you are working on driers to a certain extent.

12,695. Can it then be used to give body or covering power to zinc white?—Yes; it will amalgamate very well indeed with zinc. I am hoping to get it a little bit better, because it is not really a very good white yet. That is one difficulty with my stuff. It will not compare with zinc white for inside use, for drawing-rooms, for instance, but mixed with zinc white you get the covering power plus the purity of white.

12,696. Can you get a perfect white, then?—Yes, you can get a perfect white.

12,697. What knowledge have you as to its durability?—I have here a board (producing same) that was painted in February of last year. That was before I had my stuff quite as good a colour as it is now. It is exactly the same pigment. That was painted with one coat on a piece of plain board, and exposed on the gate of my temporary works up to the end of November, and it had sun and rain and everything on it.

12,698. That is not considered by experts to be anything like a sufficient time to test its durability?—An expert would be able to see whether that showed any signs of shivers or shakes or anything of the kind. It was very roughly done.

12,699. Does it adhere readily?—Yes; if any gentleman will scrape it a little bit, he will see the wonderful adhesiveness of it.

12,700. (Mr. Mason.) Is this board varnished?—No, only one coat of the stuff, and no varnish at all—just one coat with linseed oil and turpentine in combination. The board was about the place before it was painted. I painted it as a test board. It was handy, and so we used it.

12,701. How does your paint compare with white lead for price?—That is rather a commercial point as to what we shall charge for it later on, but our idea is to make it for about 1l. or 30s. a ton under the price

of dry white lead. We shall only apply it to wholesale men, that is to say, paint grinders. We shall in no case sell it to the actual consumer, so that we shall not be cutting into the trade in any way.

12,702. Have you satisfied yourself as to the non-poisonous character of your paint?—Yes; there is no question about that. I have inquired of a great many experts about it.

12,703. Have you had it tested to be quite sure that there is no lead in it?—There is a certain ore that we may be using in some cases that has a small percentage of lead which we cannot get out. In our process we get rid of nearly all the lead. If we use an ore with some antimony and some lead in it, we do not get rid of quite all. We might have 1 or 2 per cent., but as a matter of fact my colleague, Mr. Wynne, does not think of using any more of the ore in which there is any lead.

12,704. Can you demonstrate beyond question to this Committee that in no case would the amount of lead exceed 1 or 2 per cent.?—I can absolutely guarantee that we shall not send it out if it goes beyond that. We are making a point of that.

12,705. Has your paint been tried by firms in the trade?—Yes, by eight or ten of the good firms.

12,706. When did they begin to use it?—They have tested it in their works in a small way, and have had a few pounds of it.

12,707. Only in an experimental way?—Only in an experimental way. We do not supply the trade at present. When we start supplying the trade we must do it in a large way.

12,708. Have these firms that have made these experiments written any satisfactory testimonials?—I have one letter only; that is from Hills, of Manchester.

12,709. Who are they?—They are a firm in the paint trade who do a very large paint trade. They say: "Dear sirs, With reference to the samples of 'antimony white tested by our late Mr. Hill some months ago, we find that in addition to the exceptional covering power and good body, the metal and wooden panels show no deterioration in the chemically-laden atmosphere with which we are surrounded. We consider the pigment highly suitable for many purposes such as constructional iron, coal trucks, &c." You would not call that a high-class trade. They are very large users of paint stuffs for heavy work.

12,710. Messrs. Hill's testimony is that it is very good for rough work?—Yes; that is the chief work for which they require it.

12,711. Have you any evidence to give us that it has been used for more highly finished work?—I have not.

12,712. Have you any testimony from any other firm?—No, I have not. Most of the other firms do very high-class work. I might read out the list of the people who have tried it.

12,713. It does not matter about the list of people who have tried it. We want people who have found it suitable?—All these firms have said: "We think you have a big future in this, Mr. Atkins, and directly you have got it on the market we shall be

1 November 1911.]

Mr. T. R. ATKINS.

[Continued.]

" prepared to give you an order. We cannot say more than that."

12,714. Have you that in writing?—No, I have not, but that is what they have said.

12,715. Are you now embarking considerable capital in the manufacture of this new paint?—Yes. My colleagues and I have spent in our experiments about 3,000*l.*, and now we are making a fairly large company of it.

12,716. Are you proposing to erect large works?—Yes; in fact we have the plans out. Everything is ready.

12,717. Have you made a series of experiments yourselves to show clearly, without question, that this paint of yours will be suitable for every kind of work?—Yes; we are absolutely certain of that.

12,718. Suitable for coach-building?—Yes.

12,719. And motor-car bodies highly finished?—Yes.

12,720. House-painting inside and out?—Yes. If the colour is not quite suitable for the house decorator who wants to do a very highly-finished drawing-room pure white, he will body up with this stuff, and he will finish off with one coat, as he does now, with zinc white. You never find a first-class decorator finish off with white lead in a drawing-room job. He will always put his zinc white on the top as the last coat.

12,721. Are you erecting the works in England?—Yes, down the river.

12,722. On the Thames?—Yes.

12,723. You think that you have found a substitute that the trade has been looking for for many years?—I do honestly think so. I have put in three years' hard work on it.

12,724. (*Dr. Collis.*) Is the material from which you make the antimony oxide all imported?—Some of it occurs in England, but what we get from Cornwall is not specially good stuff. We are not anxious to use it if we can help it. We shall get the greater part of it from Australia.

12,725. You mentioned that some of the ores give you a product which contains a small percentage of lead?—Yes.

12,726. Is there a difference between the antimony oxide with that small percentage of lead and the pure antimony oxide without it, with regard to its covering property?—No. We should not be able to detect any difference with 2 per cent. without chemical inquiry.

12,727. (*Chairman.*) Have you patented this?—No. It is a secret process.

12,728. (*Dr. Collis.*) We have been told that a zinc pigment prepared from ores containing a small proportion of lead is better than a pigment prepared by the indirect method?—Clearly so, because with every ounce of lead in zinc you must have a better body. Zinc has practically no body. From the point of view of the decorator it has not any body at all, really.

12,729. (*Chairman.*) That is rather contradicting what we have had in evidence?—I have had thirty years' experience of selling paint all round England, and from Belfast to the Channel Islands.

12,730. (*Dr. Collis.*) The point is that in covering property it does not gain by the small percentage of lead?—No; it weakens it if anything; it does not gain.

12,731. What is the colour of antimony sulphide?—I do not know. I am not a chemist.

12,732. Is it a white or black?—In its native state it is grey.

12,733. It is an important point?—I am not a scientific man. I am only the selling man. I know very little indeed about chemistry. My part of the experiment consisted of shovelling on the ore and working like a navvy and shovelling on coke for days at a time.

12,734. Lead carbonate is white, and lead sulphide is black. One of the objections to lead carbonate as a paint is that when exposed to sulphur fumes it discolours?—Yes.

12,735-6. Zinc oxide is white, and zinc sulphide is white. Would not antimony show any greater tendency to discolour than the zinc oxide?—No. Antimony is not affected by sulphur fumes in the same way that lead is. We claim that for our stuff.

(*Dr. Collis.*) That answers the question, though you have no chemical knowledge.

12,737. (*Mr. Mason.*) How does your price of 30*s.* a ton less than lead work out, having regard to covering power?—We consider that our covering power is better than that of lead. We are only taking price for price. We are not going into whether it would be cheaper to do a job with one or the other. A man is going to pay 30*s.* a ton less for ours.

12,738. If I buy 30*s.* worth of your stuff, can I do more painting with it than I can with 30*s.* worth of white lead, or *vice versa*?—You could do infinitely more with mine.

12,739. (*Chairman.*) I understand it is cheaper, and goes farther?—That is so.

12,740. (*Mr. Mason.*) Do you sell it as a paint itself, or to mix with other paints?—Ours is a pure raw material which will be sold to paint manufacturers, as we call them. We shall not grind it or do anything but sell it as a raw material. They will grind it at their own mills.

12,741. What do you suggest they should do with it when they have bought it?—You are asking a delicate question now. They will do what they are prompted to do. I will answer that in this way: my stuff will take as much sulphate of barium or barytes as white lead. A man who wants to make a cheap paint can put his barytes into it exactly in the same way as he can with dry white lead.

12,742. It is not a substitute for barytes?—No. Barytes will adulterate my stuff as it will the other. In France they are using a lot of antimony in the Chantillon process. It is whiter than mine. By a special process they are throwing the antimony fumes that they get together with barytes in solution practically in the same way as they do in making lithophone with the zinc. They get a very nice white stuff, but it has not anything like my covering power, because the barytes has rather killed it. I have tested it. The paint manufacturer does not want an article already adulterated. He knows how to adulterate if he wants to, and it is not for me to tell him.

12,743. (*Chairman.*) What is the purport of your evidence given to this Committee?—I take it rather that I am in the position of being able to suggest a solution if white lead is considered to be in any way detrimental. I am coming in as a man who has something that he claims to be the only solution of the difficulty.

12,744. You mean to say that you claim that antimony will take the place of white lead?—I claim that it will absolutely take the place of white lead.

12,745. By mixing it with zinc oxide?—If they want a perfectly pure colour. The colour on the board that I have produced to you will not do for all work, but if they want a perfectly pure colour they can get it in that way. There are many cases where some other colour than a perfectly pure one would be good enough.

12,746. (*Mr. Robins.*) How many coats has this board had?—One coat.

12,747. (*Mr. Kinggate.*) Would there be any poisonous effect to the workman from using antimony?—No, not at all. It is practically non-poisonous. I do not mean to say that a man could make a meal off it.

12,748. (*Mr. Robins.*) It is free from lead entirely?—Yes. I should like one of you gentlemen, if you would, to use a penknife on that board, and it will give you a little idea of its adhesiveness.

The witness withdrew.

1 November 1911.]

Mr. R. J. CORNETT.

[Continued.]

Mr. R. J. CORNETT (550, Manchester Road, Bolton) examined.

12,749. (*Chairman.*) Are you one of the representatives giving evidence on behalf of the United Kingdom Society of Coachmakers?—Yes, I am.

12,750. What practical experience have you had in the coach-painting trade?—I have been in the trade since 1876. As an apprentice, I served my time.

12,751. Have you worked at railway coach and tramcar painting, or only at carriages and motor-cars?—Both private carriages and tramcars.

12,752. Have you known many cases of lead poisoning among coach painters?—Yes, many, very many.

12,753. Can you give us any idea of the numbers?—I know personally a matter of about six cases in Bolton, and they resulted in death in two cases, and the men having to leave the trade altogether in the other cases.

12,754. Is that eight cases in all?—Six cases I would say.

12,755. Any others?—There are others, but not of coach painters that I have known.

12,756. Are those six cases the only ones that you have come in contact with?—There are many that I have known to be cases of lead poisoning through being an official of the United Kingdom Society of Coachmakers, from death certificates that have come in, but I am speaking now of cases I have known from my own personal observation. In fact I have been affected by it myself. I have practically left the trade owing to the effects of lead. I have tried to get into another business. I am not very much better now, but rather better. I know of a case of a body-maker who had to leave a very good berth. He was a tramcar builder earning good wages, and worked for Messrs. Holden & Co. of Bolton. He had to leave the trade although he was earning very decent wages for that district—anything from 2*l.* 5*s.* to 2*l.* 10*s.*, and up to 3*l.* a week sometimes. He had repeated attacks of this, and the doctor told him ultimately that he must leave the trade entirely.

12,757. I think that is enough about that case. In all only six cases have come under your personal observation?—Yes.

12,758. During the 34 years you have been in the trade?—No, I am not going to say that only six have come under my personal observation. I can give my father.

12,759. What period would these six cases that you have mentioned cover?—Within the last 20 years I should say.

12,760. Are you at work in a coach painting establishment now?—No, I am not.

12,761. Why did you leave?—I left because the lead was taking so much effect on me. I left that trade to commence working in textile machine works at Bolton, with the object of getting away from the lead and its effects. It would have killed me if I had stayed in the confined air of coach-making. I believe the atmosphere is poison.

12,762. Did any of the other men you were in contact with ever show signs of ill-health from being in lead?—Coach painters only do you mean?

12,763. Coach painters only?—I would not like to go further than the six that I know of. There are others.

12,764. How many coach painters do you think you have come in contact with during your connection with the trade, taking the men who have had to handle lead paint?—I should say 70 or 80 different men.

12,765. Out of 70 or 80 different men that you have come into contact with, six have suffered from severe lead poisoning?—They have had to leave the trade, and two deaths have occurred out of those six.

12,766. Are you prepared to answer questions regarding each of the processes in detail?—Yes, pretty much. I can take different cases.

12,767. First as regards body-makers. Are they exposed to any risk?—Yes.

12,768. Does the carriage-maker come in contact with lead?—Yes.

12,769. Does he use white lead all the time he is putting the parts together?—Yes, the body-maker and carriage-maker generally do.

12,770. When the carriage-maker has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

12,771. The first coats of paint applied are termed priming coats, are they not?—Yes.

12,771*a*. How many coats are generally put on for priming?—Three or four.

12,772. Does the priming contain lead?—Yes, always.

12,773. Is it practically all lead?—It is practically all lead, especially the first two coats.

12,774. Is sand-papery done between successive priming coats?—Yes, on all occasions.

12,775. In what shop is this generally done?—Generally in the paint shop.

12,776. Is it ever done in the body-makers' shop?—Yes, it is occasionally done in the body-makers' shop, between the first and second coats. It is frequently done, in fact.

12,777. So that the body-makers and carriage-makers are frequently exposed to dust made by the painter?—They are.

12,778. Do you regard the breathing of this dust as one of the most serious dangers of the industry?—Yes.

12,779. Can the sand-papery be replaced by a wet-rubbing process?—No, hardly; it could not.

12,780. Why not?—Because there is such a small surface or such a small quantity on the first coat that it would be almost ridiculous to wet so near the timber. It would tend to raise the grain.

12,781. Is it generally possible to use any form of local exhaust apparatus to remove the dust?—I believe it would be.

12,782. Do you from your own personal knowledge know of any form of local exhaust apparatus to remove the dust generated in these processes?—I do not know of any process in use in a paint shop.

12,783. But you say that you think it is possible to invent something to remove the dust?—Yes.

12,784. What causes you to say that?—I have seen dust-removing processes working in mills, taking the cotton dust away, and I think that the same means could be adopted in the paint shops as are adopted there.

12,785. Would not that be a very costly operation? Probably you cannot answer that question?—No, I cannot.

12,786. Is the next process what is generally known as filling?—Yes.

12,787. How many coats are generally put on for filling?—I used to use seven.

12,788. Does the filling material contain lead?—Yes, about one quarter of the amount of slate powder.

12,789. There is no rubbing down between the successive coats of filling?—No, I do not know that there is.

12,790. Is stopping generally done after the last coat of filling has been applied?—Stopping is very often done before the first coat of filling is put on. The nail holes are stopped with white lead mixed with gold size, and any perforation, or any scratches, or anything like that, stopping is again used after the rubbing down.

12,791. By whom is the stopping material mixed?—Generally by the painter; I would say by the painter.

12,792. Do you consider that the mixing of white lead and gold size is attended by danger?—Yes, I do.

12,793. Why?—Because you have to use dry white lead, and there is dust arising from it. You have to beat this stuff up, take all the lumps out of the white lead, and the consequence is that a certain amount of the powder arises from the stone where the powder is beaten up.

12,794. It would be possible in that case to have exhaust apparatus, would it not?—Yes, it would.

1 November 1911.]

Mr. R. J. CORNETT.

[Continued.]

12,795. How is the rubbing down done after the application of the filling coats?—It is done with pumice stone and water, or with a prepared stone that there is.

12,796. Is it ever done dry with sand-paper, for example?—Yes. I have used what we term a sand-paper filling, made up solely of white lead, gold size, and turpentine, and a little lamp black put in. Entirely a dry process is used in some places I believe to-day.

12,797. But very rarely, I believe?—Rarely, now, but it is used.

12,798. What is the extent of the danger in the rubbing down after the application of filling and stopping?—Very considerable. During the time that I was rubbing down, if I may say so, we used to put a mask over our faces, over the nose and mouth, and after a person had rubbed a large surface you would see a black line completely round *here*, the eyes would be filled, and you would see it all about the neck. Dry rubbing is very dangerous, in my opinion.

12,799. Does that answer apply to bodies only?—No; the under-carriage and the wheels are treated in the same manner; in fact, I might almost say that there is, if anything, more danger with the under-carriage, because all the rubbing that is done on the under-carriage, and the wheels, is all dry rubbing—no wet rubbing.

12,800. I suppose that this dust is of a poisonous nature?—Yes, undoubtedly.

12,801. Is it impossible to use wet methods of rubbing down in this work?—It would not do. It would be too costly altogether to the employer. It is too lengthy.

12,802. After the rubbing down of the filling has been completed, what is the next operation?—Generally a couple of coats of lead colour.

12,803. Is the work then ready to be painted in the desired finishing colour?—Yes, after that.

12,804. Is the carriage then ready for varnishing?—Yes, after the finishing colours are put on.

12,805. Do your answers apply equally to carriage-building and to the manufacture of motor-car bodies?—Yes.

12,806. Can you tell us anything in regard to the fixing of canvas or moleskin on the roofs of closed vehicles?—There is great danger there. As a matter of fact, in Sheffield, I believe, they use no less than 75 lbs. of lead to cover the top of a car. It is a very dangerous process. The trimmers are sometimes affected, because they are called on the scene to stretch the canvas.

12,807. Have you anything special to say with regard to tramcars and railway work?—I consider that that is more dangerous than private carriages.

12,808. Why?—Because there is the interior work of these vehicles that has to be dealt with. The consequence is that the men during the time that they are painting inside are inhaling all the foul gases and the poisoned atmosphere. It is very dangerous.

12,809. Have you any reason to believe that there is danger from the smell or fumes arising from white lead paint?—Yes, I believe that there is great danger arising from that.

12,810. What makes you think that?—As a matter of fact my father was a foreman painter, and I saw the effects of it myself. He had no occasion whatever to handle paint; he had men to mix the paint; nevertheless it was in the shop that he was working in, or in his office, and there was no reason whatever (he was there 23 years) why he should touch paint, but he died from the effects of lead poisoning. Cerebral hæmorrhage, I think, set in at the finish. He had kidney disease, and the doctor certified that it was owing to lead. When I was an apprentice boy, I was set to paint my employer's office. I was only about 15 at the time. I could not tell what had come over me during the time I was painting the roof. I was practically drunk. I fell off the ladder from the effects of the smell of the paint. I have felt the effects of it when I have been inside a room where lead colours were being used. I believe that if you intend to allow lead to go on it would be wise to have it entirely isolated—that is, the priming coats—from the other departments altogether. That would tend to protect to some extent the other men's health.

12,811. Have you felt distinct ill-effects from the smell of the paint where there has been no possibility of your coming into contact with any lead dust?—Yes, I have.

12,812. Since the instance you gave us of, when you were 15 years of age?—Yes. I have it in my system now, and feel the ill-effects every time I use lead.

12,813. You have told us that, but I want to know whether you have had any ill-effects from the smell of paint where there has been no possibility of your coming into contact with lead dust?—Yes, I have.

12,814. Have you had those ill-effects frequently?—Yes.

12,815. Now you have told us of the operations in which there is serious risk of lead poisoning in coach-building work. Is it, in your opinion, possible, to remove these dangers except by prohibiting or closely restricting the use of lead?—I do not think that it is possible to remove the danger unless white lead is done away with altogether.

12,816. Now there are many processes in which the workman cannot avoid getting his hands soiled with the material he is using, I suppose?—Yes.

12,817. Is adequate washing accommodation provided by most of the employers?—In many cases it is.

12,818. Is it invariably the case?—Yes. It is the men's own fault if they do not get it, but I do not say that in every case it is provided for them. I cannot say that.

12,819. Are nail-brushes and hot water always available?—No; in many places they are not available.

12,820. Neither?—Neither.

12,821. Do you know of any places where hot water is available?—Yes, I know where it is available. It is in the car shed at Bolton, and also in one of the employer's places there.

12,822. Is it frequently the case that the men use hot water?—No, it is more often cold water.

12,823. Is time allowed to the men for washing before leaving off work for meals?—In most places it is.

12,824. Is food often kept and eaten in the work-rooms, where lead paint is being used?—Yes.

12,825. Are meal rooms provided in any of the factories that you know of?—No, not generally provided.

12,826. Do you know of any where a mess room is provided equipped with suitable seats and tables, and properly warmed in winter?—Only in the railway works.

12,827. Do the men have the use of a cloak-room?—Yes, some of them.

12,828. Do you know of many cases where the men have to put their ordinary clothes in the rooms in which they are working?—I should say that in most cases in the smaller shops that takes place.

12,829. Do the coach-painters wear overalls while at work?—Generally not; they have aprons.

12,830. How are they kept clean?—It is very rarely that the aprons are changed, except when replaced with new ones.

12,831. Do the men take them home to be washed from time to time?—The painters do not; the body-makers do each week, and the carriage-maker does.

12,832. When you say that the aprons are seldom cleaned, you mean to say that the workmen wear these dirty aprons for long periods together?—Yes. The painters' aprons are generally of a black glazed material.

12,833. Is there not some danger of dust arising from a dirty overall, and might not this dust be easily breathed?—Yes, there is danger from that.\*

\* With reference to questions 12,829-12,833, the witness sent the following note, under date 13th December 1911:—

"Coach painters do not as a rule wear overalls, one reason being that they are usually made of a coarse dust-carrying material with a 'nap' on. Many coach painters have two aprons of black glazed calico or linen. One is used for preparatory work, the other for finishing work. The reason for this is, in the finishing processes it is of the utmost importance they should be clean and that the air should be disturbed as little as possible; loose or flabby garments, such as jackets or overalls would disturb any dust there might be about more than tight-fitting garments."

(Signed) ROBT. J. CORNETT.

1 November 1911.]

Mr. R. J. CORNETT.

[Continued.]

12,834. Can you tell us what are the usual hours of work for coach-painters?—Generally 53 per week.

12,835. Do you know of many cases where overtime is worked amongst coach-painters?—Yes; in the summer time it is done in most private shops.

12,836. Is the overtime very excessive?—In some cases three to four hours per night.

12,837. Would it be desirable to have periodical medical examination of workmen by a surgeon with powers to suspend from employment in lead processes?—No, I do not think it would be desirable.

12,838. Why?—Well I do not think it would be quite fair to the men, and it would neither prevent or cure lead poisoning.

12,839. What would the medical practitioners find out?—They might find that there was some lead in their system. That is all that they could find out, as a general rule. I must say this on behalf of my fellow workmen: it would not be fair to them, I think.

12,840. Would it be advantageous to the men if they were medically examined from time to time?—Compulsorily?

12,841. Yes?—I do not think that it would. The men know when they feel the effects of lead.

12,842. But might it not have the effect of stopping what might prove to be a serious case of lead poisoning if it was checked in time?—I do not think that a medical man could check any case of lead poisoning if the man had to continue at the trade.

12,843. No, but if the man was medically examined, and the certifying surgeon said that a continuance in lead work would be detrimental to his health, would it not be better for the man that he should be stopped from working in the industry?—He would have to stop working at the trade altogether if he was compulsorily examined and the Government Medical Officer said that he was to, but it would be unfair to the man.

12,844. Do you think that it would be fairer to the man to let him go on heaping up the evil?—A man has to earn his livelihood, and he has given the whole of his time to a trade. We have to take those risks. It is unfortunate that we have to, but nevertheless there it is.

12,845. Have you had any experience of the use of coach painting materials which are entirely free from lead?—Yes, I have.

12,846. What are they?—They are the oxides. There is the yellow ochre. That was largely used in the old days. They do not do it now. Then there are the red oxides and zinc whites.

12,847. Have you had any practical experience in the application of these substitutes for lead?—Yes.

12,848. What has been the result?—Latterly I have gone into the zinc white, and my first experience was somewhat of a failure. I got some zinc white and mixed it with raw oil, and put it on some doors. I find to-day that it is all powdering off—washing off when it gets wet. But since then I have had some samples that I asked for sent to me by Griffith's of Liverpool. "Fordite" is the name of the stuff.

12,849. We have heard of that?—It is excellent stuff. (Witness produced samples.) That is white lead exposed to the effects of sulphuretted hydrogen. That is red lead. This is zinc white exposed to exactly the same conditions (producing some samples).

12,850. What practical experience have you had in applying that zinc white to work?—I have been at it for the last five years.

12,851. But I mean applying this particular paint? Not this particular one, but I have been testing different things. This I have had in hand within the last 18 months (producing another sample).

12,852. What have you been painting with that paint?—I have been painting some window sashes outside, and doors. I have been trying that specially.

12,853. As a private experiment?—Yes.

12,854. And has it proved to be a success?—Yes, it has proved to be a success.

12,855. What other instances can you give us of the use of non-lead paints?—I have used ochres for bodying up with—yellow ochre, and I have used them when we

have been getting dark grounds up. I have used both the ochre and the Indian red.

12,856. For what colours have the ochre and Indian red been used?—The ochre has been used largely when we have been getting a yellow or a green ground. The Indian red has been used for getting browns.

12,857. Have you given any lengthy trials to ochre and to zinc oxides?—Yes, for the last seven or eight years I have been trying these.

12,858. With what results?—Very good results.

12,859. Have they all been as good as lead?—Yes.

12,860. With regard to durability and colour, how do you find it?—I want to be cautious about the durability. The zinc oxide has not been exposed outside sufficiently for me to say absolutely that it is as good as lead. I would like to give it further exposure before I could say that. Most painters are very conservative about lead.

12,861. (Mr. Fell.) Have you used these leadless paints on any tramcar work or ordinary carriage-work?—Yes, I have used them, but not on tramcars or carriages.

12,862. Have you found them quite satisfactory?—Yes, so far as durability is concerned.

12,863. For what length of time have you had the leadless paints in use?—I have only had them for about the last eighteen months.

12,864. Have you, during the last eighteen months, painted any carriages or tramcars with that paint?—No, I am not allowed to. The employers will not get it.

12,865. You have not had any experience of it in the ordinary course of work?—No.

12,866. Have you seen any "Fordite" on carriages or tramcars about the country?—Yes, I have, and it has turned out very well. It has only been exposed about two years.

12,867. But that would be sufficient, I take it, to test it?—It seems to have stood very well.

12,868. It was paint covered with varnish?—Yes, it was paint covered with varnish.

12,869. Is it necessary on this under-carriage work and wheel work to rub down between coats?—Yes, it is.

12,870. Is not the paint finely ground enough to make it unnecessary to rub down?—No. A coach-painter has to keep the brush marks out, and that is the only way he can do so, by rubbing between each coat. You must have a smooth surface, or it is a bad job.

12,871. (Mr. Mason.) You have just told us that of the 70 men you have known, six have either died or left the trade, so badly have they been affected?—Yes.

12,872. Is that experience borne out in your capacity as an official of the society, that 10 per cent. of the men are affected to this extent?—Yes, it is. It is more than 10 per cent. according to my experience as an official of the society.

12,873. 10 per cent. are so badly affected that they either die or have to leave the trade?—Yes.

12,874. (Mr. Kinggate.) I take it that the number of cases you have cited are severe ones—the six?—Undoubtedly.

12,875. That does not mean that you do not know of many other cases of white lead poisoning that are of a minor nature?—Oh, dear no.

12,876. You take it that the use of lead generally has a tendency to lower the vitality of the worker, and that practically everyone working in lead is more or less affected?—Yes.

12,877. Some are much more subject to it than others?—Yes.

12,878. The Chairman asked you with regard to compulsory examination of workmen. Is it not a fact that many firms now, especially since the Compensation Act came into force, insist upon a man being examined before they will employ him?—I believe that the Manchester Corporation have done this, and most of the railway companies, I believe, do it now.

12,879. Is it a fact that there were three deaths of our members in the Manchester Corporation's employ?—Yes.

12,880. And since then a very strict examination of the men before they are employed has taken place?—I believe so.

Z 2

1 November 1911.]

Mr. R. J. CORNETT.

[Continued.]

12,881. Would not that be a reason for the objection to medical examination on the part of the men?—Yes, I believe it would.

12,882. They would object because they would not stand a chance, if they were at all affected by lead, of getting employment?—That is so.

12,883. You know, as an old member of the executive, that years ago every medical certificate came before the executive, and we had many cases of statements of deaths of members, which we knew were in some degree attributable to lead, but which were not so stated on the certificate?—That is so; in most cases that occurred, with the painters especially.

12,884. I think you have a certificate of one of our members who dropped down dead in Manchester a little while ago?—Yes, that was a Stockport man. He dropped down dead in the street in Manchester, and this is the coroner's certificate. (*The certificate was handed to the Committee.*)

12,885. I take it that the use of lead in the first instance is really for stopping up the suction of the wood, or the grain of the wood?—That is the idea. The idea is to stop the suction of the timber.

12,886. As long as the suction of the timber can be prevented, that is quite sufficient as far as painting is concerned?—That is quite sufficient.

12,887. It is not so much a question then of its durability when it is varnished?—No; if it came to durability, I should say that the filling, speaking roughly, would be sooner affected than lead as far as that goes.

12,888. If anything can be found for the purpose of priming coats it would have nothing to do with the standing of the coats when it is well covered with varnish?—None whatever, providing a good vehicle, such as linseed oil, is used for priming coats.

12,889. You say that you have used zinc white outside that has powdered. That has not been varnished, I presume?—It has not.

12,890. You think that if it was varnished that would preserve it?—It would; I am satisfied that this "Fordite" would stand without any varnish.

12,891. (*Mr. Robins.*) Has it been your experience that men often complain of feeling ill during working hours in the shop?—Yes, frequently. They have a headache. I have felt myself as though there were something boring into my brain. This has not been when I have been sand-papering; but when I was inhaling the fumes of the paint in the paint-room.

12,892. Do you think that overtime is detrimental to the health of a painter?—I do.

12,893. Do you think that overtime should be abolished by Act of Parliament in paint shops?—Yes. I would go the full length and abolish all overtime.

12,894. (*Mr. Mason.*) Can you give me any idea why lead poisoning should have increased so much during the last few years?—The only reason I can give for that is that the men are massed together more than they formerly were, and the probability is that the cubic air space that the men have now is less than they had in old shops. Then you get such a mass of work going through the process of painting in large shops which you did not formerly, in the earlier days, in the small shops.

12,895. Now Mr. Kinggate asked you about medical examination previous to employment, and you stated that the railway companies now examined men before employing them, but you did not mean to state, did you, that that was consequent on lead poisoning, but that railway companies have, of your own knowledge, examined men for years and years and years before lead poisoning was talked of?—Yes, I believe they have examined men. Nevertheless it would be somewhat hard upon the men, I think, to make it compulsory.

12,896. I only want to correct the impression that railway companies and others have recently instituted medical examination on account of lead poisoning?—I think, latterly, that the medical examination is of a much severer nature than it formerly was. It was just simply passing a chap. I had to undergo medical examination myself as a boy before I could work in a cotton mill. They simply looked at your teeth then. I have lost all my teeth since through my trade.

12,897. The stricter medical examination is possibly only consequential on the Workmen's Compensation Act, and not on lead poisoning alone?—Yes, that may be so.

12,898. (*Mr. Kinggate.*) Would not they be more likely to look for lead poisoning now, seeing that it is one of those things which come under the Compensation Act, and which in other times they would have passed over?—Yes, and a good medical man would probably be able to trace it easily in a man's system.

12,899. (*Mr. Robins.*) Of recent years, seeing that the method of painting has been altered from oil colour to quick colour—presto—would you think that that has had anything to do with the increase of lead poisoning among painters?—I daresay that that has had something to do with it, but where lead has been used anywhere, I could tell whether it is slow or quick. The smell of the room is sufficient for me to trace it. And then with the quick colour there is a tendency on the part of the men to soften the stuff that has dried on their hands with some vehicle. For quick colour some use turps, and that may affect them—I do not know—I would not like to say that it does.

12,900. You have a greater amount of sand-papering with quick colours?—Yes.

12,901. Causing dust?—Yes, causing dust.

The witness withdrew.

## EIGHTEENTH DAY.

Wednesday, 8th November 1911.

### PRESENT:

SIR ERNEST F. G. HATCH, Bart. (*Chairman*).

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary*).

Mr. G. D. PATTERSON (H.M. Office of Works) recalled.

12,902. (*Chairman.*) The Committee are anxious to put to you a few additional questions regarding the specification for paints supplied to the Office of Works. In your table, of which members have copies, you state

the proportion of oil, driers, and varnish, taken altogether. Can you state the proportions of each?—I cannot well disclose the proportions used by individual manufacturers, as they are the firms' secrets. The

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

Office of Works leave the sub-divisions somewhat to the discretion of the firms tendering, but the answer to question 1110 in my previous examination gives the approximate quantities of these. I was asked, "What proportions have you found to answer best?" and I replied: "In the tests carried out for external paints, one part of varnish to three of oil were found to give the best results with zinc oxide, while for iron oxide and other dark paints one of varnish to two of oil were found best for a protective gloss paint"; that is to say, consistently with the cost, because that is the limitation.

12,903. Do I understand that you do not specify definite proportions of oil and varnish and driers separately?—We do not. We wanted carefully to guard ourselves from the position that we were instructing the manufacturers. We wanted to leave manufacturers as far as possible with a free hand. We wanted to gain the benefit of any experience they might have had. Our specification was given as a general one, and not as a definite something to which everybody must toe the line to a fraction.

12,904. But as long as the total is in accordance with the specification, each paint manufacturer who tenders is free to use whatever proportions of varnish and driers he has found to be best?—Yes, if we find it satisfactory on trial.

12,905. Is it usual to have a substantial proportion of varnish in your paints?—Yes.

12,906. And this is of material use in securing durability?—Undoubtedly. The paints stand better when they have a proportion of good varnish. We think their life is increased, as well as their appearance improved, by the addition of good copal varnish.

12,907. Varnish is a somewhat costly ingredient, is it not?—Yes, if good.

12,908. But do not you find that, even with varnish added, zinc paints are more costly than lead paints?—No.

12,909. You have compared the zinc varnish paints with lead paints free from varnish?—Some of the lead paints we have had, have had varnish in them and some have not. I find for the same cost that the zinc paint with varnish is as good in withstanding weather conditions, better in appearance, and more permanent in tint than the lead paints.

12,910. I understand that you have asked for quotations for lead paints to confirm your view as to the relative cost. Will you please read the relative quotations without mentioning names?—Yes. One firm to whom I wrote say: "We are in receipt of your favour of the 18th instant. We beg to advise you that the price of our lead and zinc base paints is the same in their respective brands." That is No. 1 firm. No. 2 write: "In reply to your inquiry as to the relative costs of paints made with zinc oxide and white lead bases respectively, we beg to say that the difference in the cost per gallon would be practically nil, on the assumption that the respective covering powers are approximately alike. Assuming a 21-lbs. per gallon zinc paint an equivalent of a 28-lbs. per gallon lead paint would bring the cost to practically the same value." As a matter of fact we get them, if we want them, for the same price. In the case of another firm, the third, they say: "We have pleasure in quoting for similar paint to our zinc, but made with a white lead base. You will notice that this works out slightly more expensive than zinc." The difference is as between 7s. and 7s. 6d. in this case.

12,911. Now, I understand that you prefer not to disclose the names of these three firms?—I would prefer not. It might be said (not that I have any diffidence other than this) that we were advertising or condemning, as the case might be.

12,912. Can you give the Committee a very positive assurance that these three firms are of the very highest class?—Yes.

12,913. (Mr. Rice.) Are the quotations of recent date?—The date of the first is the 18th May this year; the date of the second is the 23rd May 1911; the date of the third is the 23rd May 1911.

x 7790

12,914. I am not quite clear with regard to the third quotation—7s. and 7s. 6d. Which is the 7s. 6d.—the lead or the zinc?—The white lead comes out at 7s. 6d. as against 7s. 0½d. net for zinc.

12,915. (Chairman.) It has been suggested that your specification is drastic in regard to the use of pure zinc and the like?—It is no more stringent than the specification for pure or "genuine white lead" would be, we think, and if you admit a certain percentage of other ingredients, it is just as easy to allow as large a percentage of baryta, gypsum, silica, or whiting in a zinc as in a lead paint.

12,916. Do you use flattening paints?—Only occasionally. Our specification is for a glossy paint.

12,917. Do you know if zinc paints are practicable for a flat finish?—Yes; zinc paints are supplied in three grades generally—flat, egg-shell, and full gloss paint. If required flat they can very well be got so by grinding in turps and oil, instead of exclusively in oil, and if they have the ordinary paste, that is to say, if a painter wants to mix up a flattening and he only has the ground paste, in zinc he can at least adopt the expedient of breaking it up with turps, and then allowing it to stand overnight and skimming the excess of oil off it, and so in that way getting a flat. But if a manufacturer was making it, he would do as is done to a very large extent indeed; he would simply break it up in part oil and part turps. If it is broken up in all oil, the chances are that he will get about an egg-shell gloss.

12,918. Statements were made by a witness before this Committee as to the want of durability of paint work done without lead at Canterbury Post Office. Have you made inquiries regarding this?—Yes.

12,919. It was stated that the work had to be redone within a year. Is that the case?—No. It was not repainted until it was fully due in accordance with the Board's rules, that new work shall be repainted in two or three years after completion; that is to say, we find new work shrinks, and from a variety of causes which I need not particularise, it needs to be gone over in the second or third year at most—to be thoroughly stopped, and, when shrinkages, &c., have taken place, to be gone over and repainted.

12,920. Does that apply equally to lead paints as to zinc paints?—Yes.

12,921. When was the first painting done at Canterbury?—The contract was done at three periods. The sorting office portion was done in November 1906; that is, the painting of it was done about November 1906. The public office portion was done in March 1908.

12,922. You said three portions. You have given us two. Have you any other?—The third, the intervening portion, must have come between. The building contract had to suit the postal work, and I have given the extremes, the beginning and the finishing.

12,923. When was it repainted?—The order for repainting was given in August 1910, and as a matter of fact it was actually done in January 1911.

12,924. How long then had elapsed from the first painting?—In the case of the sorting office just over four years, and the rest of the building 2½ years.

12,925. Was any report made at the time of repainting as to the condition of the old work?—Yes; it was examined by the architect, who reported that the state of the old paint was quite as good as could be expected after three years' wear, and the repainting was done because of the Board's order that new work should be always repainted in three years at least.

12,926. Now, Mr. Patterson, do you still adhere to the statement made before the Committee when you were last here in March, to the effect that zinc paint can replace lead paint without loss of quality or increase of cost?—So far as our experience goes, and with the same exception as I then mentioned, I do.

12,927. You referred in your last examination to the exception in regard to greens?—Yes.

12,928. What proportion of lead do you think necessary in the case of those colours?—I think I stated 10 per cent. In the present state of our knowledge, I should like to be free to use 10 per cent. of lead in greens, but fresh colour materials are being

Z 3

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

placed on the market at frequent intervals, and the difficulty of getting leadless greens may disappear. In my former evidence I referred only to the wide future before aniline colours. That forecast has been since supported by the introduction of an aniline green which I have not yet had time to consider, but which is said to be eminently suitable for use with any zinc base paints, and so may come in as a substitute for the chromates of lead.

12,929. Have you had experience with paints under trying conditions?—Yes.

12,930. Such as in warm, moist atmospheres?—Yes, in the greenhouses at Kew.

12,931. How does lead compare with zinc?—Both are, I regret to say, equally unsatisfactory.

12,932. Do I understand you to say that you found the zinc no better and no worse than the lead paints?—There does not seem to be anything to choose. That is exactly the position. Both zinc and lead fail completely under certain conditions.

12,933. Have you any third alternative?—I am trying various other paints, but as yet I have not pushed my experiments far enough to be able to speak of results, for I have only been at Kew some three months.

12,934. With regard to the length of your experience with leadless paint, several witnesses have suggested that the four years during which the Office of Works have used such paints is insufficient as a test. What do you say with regard to this?—Well, I would stretch that four years to between five and six specifically. As you will remember, I told you in my previous evidence that some of our experiments have gone on for nine years. I can speak personally to between five and six years' experience with definite watching, and what I should call scientific precision in the matter. A paint that stands well for five to six years I think needs little defence.

12,935. Would you say the result was quite as good as with lead paints?—Yes; not that I have not found failures in both. I wish that to be perfectly understood. I can put my hand on failures of both schools, but when I know the conditions and ingredients, and have had them under my own eye, and can testify that each has had equal chances, I find them, especially under these trying conditions at Kew, practically equal.

12,936. Now it is no doubt easier for the Office of Works to make experiments than for outside firms?—I do not see why, quite. We are not in the position of outside firms, but I suggest to you that we are in a similar position to, say, the Admiralty, the War Office, and the large shipping and railway companies, who paint their ships with a particular paint, and send them out for a three years' round. With regard to their railway carriages, they paint a set of coaches with different paints, and when they come in at the end of one, two, three, or four years, they examine them. They have similar opportunities, therefore, to ours for judging.

12,937. But, however that may be, when such paints are on the market, is it equally easy for any painter in a large or small way of business and doing any class of work to succeed with them?—Yes, I do not see why he should not.

12,938. But may the Committee take it, then, that in respect of substitutes for white lead paint, you are in no better position than the ordinary house-painting firm would be. I would add this rider to my question: would you say that smaller employers would be subject to a keener criticism of results?—No; on the other hand, I was just thinking that they would be exempt from certain things that come to us. For instance, if a man in charge of a Government building has a particular office or offices done with certain paint, he makes his records, and he has to keep under observation (I do it at least annually) the result of that painting. He has particularly to make an examination of it, whether he will or no, at the end of four years, for repainting. He should be able to, and does, observe the state of it, and if there has been any failure, it is brought home to him in a very definite way. But a small house painter who is called in to give an estimate, or to do paint work, however it may be, does the work, and if it looks satisfactory, he gets paid for it,

and the probabilities are that he may never see that building again, and has no further interest in it. I mean he does not go back to make an estimate for repainting possibly, and he does not know how that paint has succeeded or otherwise; so in a sense he is freer than we are.

12,939. Then would you state very positively that the small employer, the ordinary house-painting firm, would be in no sense at a disadvantage in comparison to the Office of Works?—I do not think so. I think he would be able to get his paints, just as we do, ready mixed by ordering.

12,940. I want to ask you one other question with regard to the greens. Suppose the Committee restricted the use of lead to 5 per cent. of soluble lead, with an exemption, we will say, for two years, would it not be possible to comply with such a condition in that time in respect of green colours?—That would entirely depend on the march of events, and the substitutes that might come upon the market in the meantime. It is quite possible that in less time a good substitute might be found for it, but it is quite possible that it might not. Greens and yellows are now being made up with the aniline colour that I mentioned, and we are hoping to achieve success in that direction.

12,941. Five per cent. of soluble lead would allow much more than 5 per cent. of lead chromate, as this is largely insoluble?—If you take the soluble lead only, this 5 per cent. would allow from 7 per cent. to 8 per cent. of lead chromate.

12,942. (Mr. Sutherland.) In speaking for the Office of Works, may we take it that you speak for all the painting operations of the department or for a section only?—Well, I am sent here to represent the Office of Works, and I speak for those who have sent me.

12,943. Then your testimony given in March really is applicable to all the operations carried on by the Office of Works generally?—To the Office of Works painting.

12,944. Since you were here, you have submitted to the Committee a table showing the analysis of your zinc oxide paints, and also one of your lead paints?—I do not remember submitting it. I suggest that that wants qualifying. You speak of an analysis of our lead paints. These are lead paints that were put for trial on the Patent Office roof, not to any formula of ours.

12,945. I am going to ask you about them. They were subjected to tests on the iron plates on the roof of the Patent Office?—Yes.

12,946. Has a disparity in the results in these two sets of experiments, as reported in your exhibit, struck you?—Yes. I have not the particulars of those tests; in fact I did not bring them, or I should have been glad to go more fully into them.

12,947. In the report on zinc oxide paints which consist of five stone colours and four whites, only one is reported good and eight reported fair?—Yes.

12,948. In the report on white lead paints (and for the purposes of comparison we can only take the stone colours, of which there are five) there are four returned as good and one as bad?—Yes.

12,949. How do you account for that?—I cannot account for it. I should say that Sir Henry Tanner had these experiments made with the lead paints that were sent in by a variety of firms, and I came on to the scene only after they had been put on and judged at various periods by giving a series of marks to the various plates, and not knowing whose they were. A committee of three of us went round and assessed these.

12,950. In the zinc oxide tests, you made experiments in four cases with white paints, all of which were reported upon as fair?—Yes.

12,951. But you made no test of white lead by itself?—The stone colours are so near that you would not get more than 2 or 3 per cent. of colouring material, so that you may take the stone colours as equivalent to white.

12,952. I will deal with the percentage afterwards. Why did you submit zinc oxide to four tests and not genuine white lead? I did not make any tests at all, as I have already explained, at the Patent Office.

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

12,953. But these are put in as tests by the Office of Works?—I have already explained that I did not make these tests. I was on a committee which judged of the results afterwards, and I had nothing whatever to do with the choosing. I think practically all-comers' paints were put on, and at so many prices that it is a very large subject. I am sorry that I am not prepared to go further into it. If I had known that questions were going to be asked on this I should have gone into it more fully.

12,954. You recognise from this that you have not made, or at all events you have not made to this Committee, any return of tests made with genuine white lead by itself?—Let me be clear. I do not wish to speak for the Patent Office, but such tests have been made elsewhere.

12,955. But they were Office of Works' tests, carried out in the Patent Office, and we must deal with them as such?—Yes. I was going to say that the tests I am speaking of are the tests I think I spoke of previously when I was here, viz., those carried out in the Savings Bank.

12,956. But we have not particulars of those before us. Excepting the general reports, you have no analyses or particulars or anything of the kind?—The analyses are the same for the zincs as those that have been submitted to you, and the same brand of paint, but with a lead base, was put on one of the blocks of the Savings Bank for comparison at the same time, and of that I can speak definitely.

12,957. Do not you think it would have been better to have established the relative value as a paint of the two compounds—pure zinc oxide and genuine white lead—by submitting them both to a common test?—That is exactly what we did at the Savings Bank. And lest there should be any doubt upon it, whenever we find a case of difficulty, as at Kew, we are actually doing that. We are not cutting the moorings entirely. We have had one side of the same house done with zinc and the other side of the slope done with lead, and we are not confining them to one maker. We have had as many as five makers' paints put on one house, subject to one temperature right through the house.

12,958. In submitting the lead paints to a test, as shown in your exhibit, and restricting ourselves to the five stone colours, are the Committee to understand that the Office of Works mixed these paints themselves?—Only in the case of the samples named as Mowlem's.

12,959. There are none named as Mowlem's here. They are all under numbers?—Then they would be the paints that were sent by the different firms.

12,960. You will see from your own analysis that none of these stone colours can be accepted as a test of good lead paint. You would not accept as a good lead paint mixtures which contain an average of 20 per cent. of other matter apart from vehicles, and one of which has in it no lead whatever—only barytes—whilst the other four represent a percentage of 54 per cent. of lead?—According to our specification, you will see in the zinc paints we allow as much as 10 per cent. of what you call impurity, and it is a very controversial point as to whether some of these things are impurities, and do you notice that the paint with barytes and no lead has stood as well as those which are almost pure lead?

12,961. Yes, I know, but this is an inquiry as to the use of white lead in building operations, not as to the use of impurities?—Yes.

12,962. I am dealing with the respective stability of white lead as against zinc oxide, and in that case I submit that the question concerns pure materials and not mixtures. Here is a paint returned as stone colour in which there is no white lead whatever. It is under the analysis of lead paints—7.19 oxide of iron, 52.06 per cent. of barium sulphate and chalk, and 38 per cent. of vehicle. It cannot possibly be an analysis of lead paint when there is no lead in it?—It has been sent to us as lead paint or it would not be under that head, and you notice it has stood as well as lead. These paints that were put on were from all comers, and they were labelled. They were not supplied to any specification of ours; but every

caller who chose to come and say: "We should be glad to have our paint tried; will you put it on?" had his paint put on, and it was with a view of getting at possibly the relation of the result ultimately that analyses in all cases were made of these particular paints to enable us to arrive at something like a conclusion.

12,963. I take it that these are proprietary paints?—They are proprietary paints generally.

12,964. If the Office of Works wished to test the comparative stability of lead and zinc, why did they not proceed on the usual lines of mixing their own paint from pure materials on definitely recorded formula, using only genuine white lead and pure zinc oxide?—We are doing that now and have been doing it, as in the case of the Savings Bank—not mixing our own because we have no mills, but getting makers to do it for us.

12,965. On this formula?—Yes.

12,966. Have you submitted your formula?—Not of lead.

12,967. Only of zinc?—Only of zinc.

12,968. Would not that have been a more scientific way of arriving at definite conclusions?—It would have been a scientific way of arriving at definite conclusions. We have, however, to deal with lead paints as they are presented on the market, and we take the various makers as they come to us.

12,969. Yes, but do you think that your evidence is sufficient for this Committee to make so great a change upon as would be involved in the prohibition of white lead?—Yes, according to our experience.

12,970. Do you think it gives us any basis whatever to form a conclusion upon?—Apart from these experiments at the Savings Bank I do not care to speak, but of them I have no doubt.

12,971. But you are the representative of the Office of Works?—I am, and my evidence-in-chief, I think, has not touched, so far, the paint records of the Patent Office. They are put in with a view to giving all the information, but the gentleman who started these experiments is dead, and I have had to take them up and try to piece them together for your information, as I have done quite impartially. The very fact that some of them tell one way and some the other shows that they have been taken in quite an indiscriminate way, and had I known that I was to be asked anything very particular about the Patent Office, I am afraid I should have had to say, as I have said already, that I only know in part what was done at the Patent Office.

12,972. Then you do not buy this varnish and paint, and you do not mix the paint yourselves?—We do not buy our own varnish direct or manufacture it. We get it through a contractor. In fact, we buy all our materials through contractors, excepting in the manufactured paints, where we go direct to the firms.

12,973. I understand that, when you were here before, you said you bought about 5,000*l.* worth of paint and spent about 18,000*l.* in wages?—Yes; that is through contractors.

12,974. Do not you employ the men at all?—We do not employ anybody except through contractors. We employ day-work men through contractors and measured-work men through contractors.

12,975. They are really Government employees, are they not?—In the sense that they do work for the Government.

12,976. Strictly under your instructions?—But in the sense that they are employed through a contractor, they are contractor's men.

12,977. They have to comply with your conditions?—Yes. The contractor has to conform to his specification and the conditions of the contract, and the men under him work accordingly.

12,978. Do you realise that the Chairman is putting your results at the Office of Works to all the witnesses, master painters and others, as conclusive of the question that white lead can be dispensed with?—Well, I am simply here to give my evidence of the results of our inquiries, and, so far as we are concerned, we speak as we find.

Z 4

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

12,979. You have not submitted to us a single case of a test of genuine white lead?—I am not here as an advocate of either one or the other.

12,980. No, but you are here to compare the merits of the two?—I am here to compare the merits of what we have been using for many years, that is lead paint, with the substitutes which we have been trying of late years in order to get at an equivalent which shall be non-poisonous.

12,981. You are here advocating the use of non-poisonous paint?—Yes, I am here, at any rate, advocating, or rather not as advocating—I must withdraw that—but as giving you the result of our experiments in that direction.

12,982. I submit that your experiments have not been at all scientific, and they have practically no value to be taken by the Committee and acted upon?—That is a matter of opinion.

(Chairman.) That is a matter for the Committee to determine.

12,983. (Mr. Sutherland.) The Office of Works, according to you, take all and sundry paints that come, and submit them to tests like this. If you refer to the procedure of the Dutch Committee, it was very scientific. They formulated a series of tables of lead and oil and drier and boiled oil and varnish in some cases, and turpentine, and the same with their zincs, and they submitted a series of these to definite tests, and they took the results from them. That is a scientific way of proceeding. But this is analysis of paints picked up on the market indiscriminately?—Yes.

12,984. Anybody who wanted to send paint in to you, could send it in and have it tested?—He could have it put on to the Patent Office roof if he sent it to my predecessor, and it was tested.

12,985. But I am only dealing with the Office of Works?—Exactly.

12,986. You do not appear to have made any experiments, as experiments apart from actual work on wood or plaster. All these tests are on iron plates?—The fact is we have been having tests on wood and plaster for many years, and most of our experiments at the Savings Bank were on iron, wood, and plaster, on a large scale.

12,987. But we have no returns made of them?—You may have no tabular returns, but to say that we have no tests on wood or plaster is not according to fact.

12,987a. So far as this Committee has knowledge, it is not so?

(Chairman.) I understood the witness to say that the results of his experiments applied to all kinds of work.

12,988. (Mr. Rice.) Would it clear the point up if you submitted tables of the more recent tests that you have made on wood, plaster, and iron with white lead and with zinc—relative tests? You do not seem to care to back up these tables?—I am not here as an advocate of tables which I had not the compiling of, and which I cannot speak personally for; I prefer to speak from my own experience.

12,989. (Mr. Sutherland.) The Office of Works is still using lead, is it not?—Yes. I myself, as I have already told you, have had lead put on one side of a house.

12,990. But you are using it in your daily contracts?—I should say we are using lead on occasion, but generally we are using zinc.

12,991. Do you know that something like five tons of lead have gone to the following places this year:—British Museum, the Horse Guards, Victoria and Albert Museum, Church Street, Islington, King Edward VII. Buildings, Tower of London, Regent's Park Savings Bank, Somerset House, Chelsea Hospital, Buckingham Palace, St. James's Palace, Royal Mews, Natural History Museum, Hyde Park Store Yard, G.P.O., Houses of Parliament, Hercules Buildings, Customs House, Greenwich Park and Customs House Post Office, and Kensington Palace?—No. I am not at all surprised that large quantities of lead are supplied and used for a variety of purposes, and I stated when

here last that we were using lead for wood and iron primings.

12,992. The Menai Suspension Bridge is painted by the Office of Works?—It was in charge of the Office of Works years ago. I cannot say whether it is now.

12,993. Are you speaking for the Office of Works, or only a section?—I am speaking for the Office of Works altogether so far as I know, but obviously this is only a small part of one's duty, and I am not acquainted with everything, except in a general way.

12,994. But the Chairman has been putting, very much on your evidence, to all the painters and other witnesses, that you have solved the question of leadless paints. Now here, in the London area, you have five tons of lead, or over, used since April; and on the Menai Bridge, painted since April, you have used another five tons, which represents a very considerable amount of paint. Ten tons makes a big hole in the 5,000l. worth of painting? Yes, but is it fair for you to assume that every atom of white lead that has been sent to these depôts is used in paint? Is that what you mean the Committee to assume? And if even it were all used in paint, does it exceed the estimate I gave you of what we used?

12,995. Yes, white lead paints; paste white lead that has been sent to the order of the Office of Works?—Yes, but white lead paste is not the same thing as white lead paint.

12,996. But it has been sent for painting purposes with the oils and the turps, and the driers and the colours?—You know, probably, without my reminding you, that white lead is used for a variety of purposes.

12,997. As what?—For fillings, stoppings, plumbers and gasfitters use it for joints, and a variety of purposes of that kind. Both white and red lead are used for those purposes, and not always for paint mixing.

12,998. But you could not use five tons for stopping if you stopped all London?—No; but you could use it for the other purposes I have named.

12,999. Here are places which are quoted by the Chairman, on your evidence, I presume. Buckingham Palace is submitted as a place and St. James's Palace, but you are using lead there, and the Menai Bridge was painted in May and you used five tons of white lead paint on that. Does it not weaken your evidence, as advocating leadless paints, when the Committee are in possession of the information that this quantity of lead paint has been used—five tons on one job and five tons spread over the others that I have put to you, and those cannot exhaust the painting done?—You appear to have got it all in. I do not know but that it does exhaust it, but even then you may say, "Have not you lead in your depôt." I say, "Yes, we have."

13,000. But these amounts have been supplied this year?—Yes; and to-day I have told you that we are not banning white lead in the sense that it does not come into the yard and is not used for any purpose. What I have told you is that the bulk of the paints now used by us are zinc. I have already told you that, finding as I have found at Kew, that no paint under certain conditions there on certain houses has stood, I have started using in the same house lead and zinc, and as many as five makes of paint in one house. We have not cut the moorings, if that is what you mean.

13,001. (Chairman.) No. What Mr. Sutherland means is this: If you have established the fact that leadless paints are so efficacious, why do you use lead now in these buildings?—I think largely because of the men's experience, which you cannot cut except by drastic and prohibitive means. You will not get rid of a man's experience or of white lead till you prohibit its use.

13,002. But are you prepared to-day to state that in the future, if the Committee determine that white lead should be prohibited, you will accept that with full confidence that your work would not suffer in consequence?—With the exceptions I have named.

13,003. (Mr. Sutherland.) I will ask you this final question: Why did you use white lead after your own experience, according to your own testimony, on the Menai Bridge where you would have had a suitable

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

opportunity of demonstrating the value of leadless paint: Why use it on such a large contract as that?—I have no knowledge of the contract and circumstances in question, and so I cannot say.

13,004. We may take it that your evidence does not apply, then, to Office of Works' operations?—You may take it that it does.

13,005. No, we cannot?—If you are going to judge that it does not from one particular contract I can show that it does from a considerable number.

(Mr. Sutherland.) No; I am sorry. There are a lot of good paints besides white lead, I agree, as I have submitted to the Committee all through; but no material will take the place of white lead in its adaptability and service, for outside painting at all events. The Office of Works agrees with me evidently, because in an exposed position like the Menai Bridge they have painted it all over from end to end with white lead, although they had the formula of these other paints in their possession.

13,006. (Mr. Rice.) You mentioned, Mr. Patterson, in conversation before you commenced your evidence, that you were asked concerning certain evidence tendered here with regard to the post office at Canterbury?—I was asked to give the facts.

13,007. Do you know what evidence was given?—I have not the letter here, but the statement, I understood, was generally made that zinc paint had been used there with very unsatisfactory results.

13,008. By a witness here?—By a witness here.

13,009. Who asked you with regard to that?—I was asked what were the facts concerning the Canterbury Post Office, and I appear here to give the facts as I have had them from the architect in charge of the building.

13,010. Who asked you to give those facts?—The Secretary of the Committee wrote to me saying there was a contradiction in the evidence, and I was asked the facts, and how this was reconciled with my evidence.

13,011. Mr. Wiltshier or another witness said that the zinc paint at Canterbury Post Office was not satisfactory. You say that, in accordance with the custom of the department, the work was repainted, and not because the paint was defective?—Yes.

13,012. Your evidence is now against that of Mr. Wiltshier?—Yes.

13,013. Now I do not quite understand the addition of 10 per cent. You said this morning that you would add 10 per cent. of white lead to zinc-prepared paints?—No; excuse me.

13,014. Would you tell me in what way the 10 per cent. addition was used, because I do not understand?—I was asked how much lead I would stipulate for in zinc paints, and I said up to 10 per cent.

13,015. Up to 10 per cent. in greens?—Yes.

13,016. That does not in any way vary from your former evidence?—It is in agreement with my former evidence.

13,017. You were asked at Question 1088: "I want to get this quite clearly. Do I understand that you have purely zinc paints now which are perfectly satisfactory in all colours for interior work?" Your reply was: "Yes, with a few exceptions in damp situations and dark colours." The next question was: "Are they equal to the lead paints they have displaced?" Your answer is: "Yes, with the above exceptions, and these we find can be overcome by the addition of a little lead." Next question: "What added quantity of lead do you suggest?" Your reply is: "For stability something like 5 per cent." Do I understand that this remains, or do you wish to alter the 5 per cent. to 10 per cent.?—There is an addition to the 5 per cent. If you look at the specification you have there, you will find lead compounds six and eight. I think you have eight and then two. The 10 per cent. roughly was got at in this way, that you would want something like 7 or 8 per cent. of lead chromates or lead compounds to produce your greens, and I wanted two or three which roughly made up the 10 per cent.

13,018. This table is to be increased by what?—Up to 10 per cent. I stated 10 per cent. in my evidence

with regard to greens, if you will be good enough to look.

13,019. The term "dark" would cover greens, I take it?—Yes, both greens and browns.

13,020. You want 10 per cent. instead of 5?—Five for browns and other dark colours we found good, but I wanted also something like seven or eight for greens made from lead chromates. When you have lead compounds in, you have not so much of white lead. But 10 per cent. as a total would cover the necessity.

13,021. I take it that that is in addition to the 5 per cent. already added?—I think you may take it that 10 per cent. as a total would cover the necessity.

13,022. Five per cent. for ordinary paints and five additional for greens?—Yes. You would want 10, I think, really for greens in the present state of our knowledge.

13,023. It is perfectly clear that it is 5 per cent. for ordinary paint?—For ordinary whites and other paints where lead chromates are not necessary.

13,024. Yes, and an added 5 per cent. at least where they are necessary?—Yes, an added 5 per cent. at least, and 10 per cent. as a total.

13,025. (Lord Henry Bentinck.) Is this large amount of white lead ordered lately to be accounted for by the fact that you do use a certain percentage of white lead in your paint?—I do not think so. I think it is to be accounted for largely because of the men's experience of lead, and they continue to use it for the purposes I have named. They have not yet become accustomed to the newer zinc paints.

13,026. Who orders these large amounts of white lead?—The various clerks of works who are dealing with the work in the various districts for small works done by day work.

13,027. Then, as far as I can make out, your evidence that zinc white was largely used, is rather broken into by this statement of yours. If the clerk of works orders what he likes, what do you know about it?—The clerks of works are instructed to use zinc paints and do it generally.

13,028. But then they may not?—They are not prohibited from ordering lead. There is no prohibition up to the present. I think the factor that counts most is that men's experience in lead is held to. We all hold to our experience doggedly, and I suggest that both with regard to practical painters and others we are not ready to go on to a new material. I find occasionally men ask their foreman for such-and-such materials as they are running out. They are asked "What do you want it for?" They say so-and-so. "But why are not you using zinc paint?" "We have always been used to order lead, that is the reason we are ordering it."

13,029. It is a very incomplete arrangement?—I am afraid it is, but you see how it comes about—that unless there is a definite stand taken it is human to say: "We have always ordered so-and-so and we want the supply replenished."

13,030. I understood you used nothing but zinc paints?—We are dealing now with lead paste rather than lead paints, and we are using lead paste for a good many things besides paint. My previous evidence also made it clear that we were using lead paints on wood and iron for primings.

13,031. For what other things—stopping, for instance?—For stopping, and filling in painting, and for joints in plumbing, gasfitting, and engineering. It has a variety of uses.

13,032. (Chairman.) Would you like to make inquiries about this statement that Mr. Sutherland has made, and report to the Committee?—I accept the gentleman's statement. I suppose he has verified it.

13,033. (Dr. Collis.) I understand that there is no legal requirement that you should use nothing whatever but zinc, and that consequently you have continued to use lead paint to a certain extent as in the past; but can you inform the Committee the extent to which lead paints are used to-day, and non-lead paints; that is to say, what proportion of the paint now used by the Office of Works contains lead and what proportion does not contain lead, as compared with the amount used, say, 10 years ago?—I cannot.

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

13,034. Would it be possible to ascertain that?—I can try.

13,035. (*Lord Henry Bentinck.*) You can tell us how much paint has been used in the last few months, and how much lead you have used in proportion to that paint?—Yes.

13,036. (*Dr. Collis.*) And compare it with the proportion 10 years ago—the Admiralty gave us such a statement not necessarily the total amounts, but the proportion of non-lead paints used to-day and the proportion of non-lead paints used about 10 years ago. Now, with your very large experience of the use of non-lead paints, particularly of zinc oxide, there is one point I would like to ask you. In the use of paint containing zinc, have you ever known any of the men complain in any way at all with regard to anything in connection with their general health?—No.

13,037. It might have occurred without you knowing it, but you have not known of any complaints?—No.

13,038. Have you, on the contrary, known any of the men say that they noticed any difference which was beneficial to their health?—No.

13,039. The question of the painting of the Menai Bridge has been brought up. I believe the Menai Bridge is painted about every three or four years. Are you aware that on every occasion on which that bridge has been painted there has always been an outbreak of lead poisoning there?—I am not aware of that.

13,040. My attention was called to that last week by the inspector in that district. I asked that particularly because it is painting in the open air, you see?—Yes.

13,041. (*Mr. Parsonage.*) With regard to the using of this large quantity of lead, you say that a certain proportion of it is used for other purposes than painting?—Yes.

13,042. You would not use lead filling or lead stopping if you were finishing a work with leadless paint or zinc paint, would you? We have tried in that also, as in other things, to do without white lead, and we have had a variety of ingredients with japanners' gold size—and we find them quite effective. It is not because we cannot do without lead for some things that it is used, but rather it continues to be used because of experience.

13,043. You see it would be useless to do away with the use of white lead if you must have white lead for stopping?—Exactly; and more harm, I take it, comes to men in rubbing down work with the consequent dust, if it is done dry, than in the actual putting on of the paint. That is why I conducted a considerable number of experiments in the matter of fillers with a view to obviating that. At the Savings Bank we dispensed with lead in that connection.

13,044. Lead is dispensed with now to a very great extent for filling purposes by painters who use nothing else but white lead for paint, so that even the painters who use white lead and who do not believe in leadless paint believe in using non-poisonous filling?—Yes, when they are so ordered.

13,045. And they find that it applies equally well?—Yes.

13,046. So that cannot be the reason why all this quantity of lead should be used?—I suggest that as one of the things for which it is used as well as for ordinary paint.

13,047. There is a question of the experience of the workmen. The best work done under the Office of Works is specified to be done with white lead. The most experienced workmen then are the men who cannot use the leadless paint and are more used to working with lead. The interior of Buckingham Palace is done with lead. Lead is specified for that, and the best class of workmen are on that work. We are told that the men have not had experience with the leadless paints?—Those are a series of statements and deductions with which I cannot agree. I think that the statement was made when I was here before, or rather the question was asked: "Why has Buckingham Palace been done in lead paint?" I asked about it, and it was one of those things one could not get a very satisfactory answer to. It was not a question of either lead or

zinc, but of inviting certain firms to give a price for the palace decoration. The question of lead as against zinc had not come into the matter. I have since made formal inquiries into the matter and am informed that zinc paints are generally used at this Palace and not lead.

13,048. But the same thing obtains up to the present time. If a specification is prepared for work to be done with leadless paint, you should not permit the clerk of works to allow the contractor to substitute lead for it?—He ought not to and I am informed does not.

13,049. But you say it is allowed, so the specification is valueless?—I have not said we allow a specification to be ignored. I will make a note of your question.

13,050. I understood you to say that you had not such control over the clerk of works that if the contractor preferred something else he would be allowed to substitute it?—Excuse me; I did not say so. Do you mean that if a clerk of works orders zinc paint and the contractor likes to send in lead, he will not have control over him to make him send it back?

13,051. The clerk of works does not prepare the specification, does he? But when the firm are invited to tender, the specification is sent specifying leadless paint. How can the clerk of works allow them to substitute lead for it?—If that was the specification issued, obviously the clerk of works' duty would be to see that it was carried out.

13,052. Does the Office of Works at the present time specify for work to be done with white lead paint?—That is a question that I will transmit and get the explanation of if possible—as to why lead paints are specified in connection with Buckingham Palace.

13,053. I am not confining it to Buckingham Palace alone, but the impression left on my mind by your answer is that the best work cannot be done with leadless paints. It follows that they get a better finish with lead paints, and that is the reason why leadless paints cannot be used. You speak of the men being able to use the different materials according to their experience?—My own experience is that they can get a better result with zinc than they can with lead as most of the best enamels are in zinc. You are speaking of the internal work of Buckingham Palace.

13,053a. Yes, internal work, and yet for the best work they stipulate white lead. I cannot understand it and am informed it is not true.

13,054. (*Chairman to the witness.*) We will call you again. Perhaps you can tell us what the particular orders are which the Office of Works give in connection with the use of paint. Is there a distinct understanding throughout the system that only zinc paints shall be used?—There has been a circular issued stating that zinc paints only are to be used, and I think in the last contract that concluded a few months ago it was further stipulated that wherever lead had been used in the past zinc was to be substituted.

13,055. (*Lord Henry Bentinck.*) When was this?—The early part of this year.

13,056. Have many places been painted since then?—That was for the London district only.

13,057. (*Chairman.*) Since then you have had five tons of lead in the various public offices, so that the orders have not been carried out?—It would appear so.

13,058. You will make the investigation, because it is very important?—I will raise these points.

13,059. (*Mr. Sutherland.*) Could this Committee have copies of different specifications issued during the last 12 months? You would have printed copies of specifications, would you not, for your painting operations?—Do you refer to the London contracts or to the specifications that are issued for the painting of new buildings.

13,059a. The specifications that you issue to contractors for painting operations in the London area.

13,060. (*Mr. Rice.*) We only want the portion of the specification relating to painting. It would be very useful if we could have that?—The specification appears as part of a large document—what we call a schedule—dominating the extent of the London area, and the painters' specification would come under that. The

1 November 1911.]

Mr. G. D. PATTERSON.

[Continued.]

schedule, of which I have handed in a copy, will, I think, be found to be part of that document.

13,061. There are large buildings as well, besides those under the triennial contracts?—The new buildings come under a different category. Each architect draws up his specification. The architect is the almighty power.

13,062. You will see whether he continues to specify white lead, and why?—I have a schedule of new works, and so far as my knowledge goes, all the architects follow the line of the instruction that has been given.

13,063. (Mr. Sutherland.) We cannot take it that the Office of Works has decided to do away with lead paints, and use only leadless paints?—You may take it that an instruction has been issued to that effect.

13,064. But when was it issued?—I have not a copy of it, and I am sorry I cannot carry these dates in my mind.

13,065. (Chairman.) Will you bring that information next time?—Yes.

13,066. (Lord Henry Bentinck.) Who issues the instructions?—The secretary and principal architect.

13,067. What control has he got? Does he examine all the specifications and the orders and the bills?—He is like the heads of other Government departments. When he issues a general instruction, he expects to have it carried out.

13,068. He does not expect to have it carried out at all, sometimes?—Always.

13,069. (Chairman.) Who authorised the architect to issue this order?—Sir Henry Tanner, I think you will find, issued the instruction on his own initiative, and from the results of experiments that he had had carried out.

13,070. Then he would be extremely annoyed, would he not, to find that his instructions had not been carried out?—Well, I shall be seeing him shortly, and I will put before him what has passed here, and the observations made and the deductions from them.

13,071. (Mr. Mason.) The question of 5 per cent. added lead has been spoken of in the Committee on several occasions. Am I to understand that that 5 per cent. is actually added, as you add sugar to tea, or is it 5 per cent. impurity?—Five per cent. of impurity; 5 per cent. of genuine white lead, do you mean?

13,072. No. What I ask you is this; is the 5 per cent. added by hand or is it 5 per cent. of impurity in the zinc ore?—You will remember from the last evidence, if you will be good enough to look over it, that in some cases 5 per cent. of lead had been added

for a definite purpose, and it was suggested that if that 5 per cent. of lead salts were allowed, it would also allow direct made zinc to come in, and so have the tendency of getting cheaper quotations as well as allowing this element of lead. It would not shut everybody out except those who had a distinct and pure standard of zinc. It was made, I think, with a double purpose.

13,073. So I understood. It would still, then, be necessary in the case of large buyers to add the lead at their own works in their own paint-mixing room?—Not if they had already 5 per cent. in the zinc.

13,074. If they chose to buy zinc from one firm and lead from another?—If they were buying it merely without any guarantee or without any standard, I can quite conceive that looseness would come in, if that is what you mean. Do I follow you?

13,075. You do not suggest that one should buy zinc with the added 5 per cent. of lead?—No. What I suggest is that I want liberty either to buy zinc with 5 per cent. of lead, or if I buy pure zinc, to add 5 per cent. of lead.

13,076. The Committee is faced, then, with rather a difficulty, inasmuch as somebody might by accident or otherwise add more than 5 per cent. of lead?—Obviously. An accident need not stop at 5 per cent. of lead, nor 15.

13,077. With 5 per cent. of impurity already in the zinc, it would not be necessary to add anything other than for the browns and the greens?—I do not want to say that lead would be an impurity in zinc paint. With 5 per cent. of lead salts, lead sulphate or white lead, you would not need, according to our experience, to add other lead except in greens.

13,078. Further lead?—Further lead.

13,079. (Mr. Sutherland.) Except for staining purposes?—Except for colouring purposes—exactly—for example, lead chromates.

13,080. (Mr. Mason.) I take it that all your figures are open to all the other Government departments, such as the War Office, the Admiralty, and so on?—That I could not say. We do pass a great deal of information mutually between each department, and so far as I know there are no secrets between us. It is a matter of courtesy to have intercommunication.

13,081. It seems curious that the other departments have not availed themselves of this valuable information and gone in for zinc instead of lead?—Some people may think it valuable, and some people may not.

The witness withdrew.

Mr. R. W. EDGINTON, M.D. examined.

13,082. (Chairman.) Are you the certifying surgeon for North Birmingham?—Yes.

13,083. Have you seen a considerable number of cases of lead poisoning?—Yes; I have seen, from January 1909 until the present time, 106 cases.

13,084. How many of those were house painters?—Of these there were 11 house painters; seven up to June and four since.

13,085. That is 11 house painters in all since January 1909?—Yes.

13,086. How many of those have been reported to the Home Office?—Three.

13,087. Then the other eight were not reported at all?—No.

13,088. Why was that?—Because they occurred in painting operations and not in factories.

13,089. If you alone have seen eight non-reported cases, would you say that there must be a very large number in the whole city not reported?—Undoubtedly, there must be.

13,090. Will you give us some details regarding the house painters whom you have examined for lead poisoning?—I have a list of them here with the names, date of examination, and the symptoms. Would you wish me to read it?

13,091. No. You might put it in, please. (The list was handed to the Committee.) Were these 11 cases

that you examined all severe cases of lead poisoning?—No; many of them were very mild.

13,092. Do you tabulate a case as lead poisoning when only one symptom, such as colic, is present?—No. I require always to have it confirmed by some secondary symptom.

13,093. You have also examined a number of coach painters suffering from the effects of lead?—Yes, 18 in all since January 1909.

13,094. How many of these cases were reported to the Home Office?—I should say that all of them would be reported.

13,095. What do you consider the most prevalent cause of lead poisoning?—I think that dust impregnated with lead is the commonest cause of lead poisoning.

13,096. Has not the wet process largely taken the place of sand-papering in the coach building trade?—Yes, almost entirely, for body painting, but not for the painting of chassis or wheels of motor cars.

13,097. Have you seen this work done with an exhaust draught to remove the dust?—Yes.

13,098. Is that system quite efficient?—I do not consider that it is quite efficient. I think that the pull of the fan is too low down in the exhaust hood, so that a considerable quantity of dust might float about

1 November 1911.]

Mr. R. W. EDGINTON, M.D.

[Continued.]

on the level of the man's face for a certain time before it sank low enough to come within the pull of the fan.

13,099. Is that in consequence of the nature of the work—the wheels and so on?—No; I should say that it was in consequence of the faulty construction of the hood.

13,100. But do you think that it would be possible to have a hood so constructed as to collect all the dust?—No, I do not.

13,101. Then is there no reliable way of preventing lead poisoning, except by the use of non-poisonous substitutes for lead?—I consider that that is the only safe way.

13,102. (*Lord Henry Bentinck.*) Have you ever thought out a system of regulation for painters?—Do you mean for house painters?

13,103. Yes, and also for coach painters?—No, I cannot say that I have ever thought out a system of regulation, and I should say that it would be difficult to apply.

13,104. Cannot you suggest any regulations?—In the case of house painters it would be almost impossible, because they are working away from their workshops at houses where they could not possibly be regulated or inspected in any way whatever.

13,105. (*Dr. Collis.*) Would you say of the house painters who come to you, that they are more cleanly or less cleanly than their fellow workers, from your experience of that class of workmen?—No, I should not say that they were any different.

13,106. You do not think that the mere insistence on cleanliness in their work preserves them from the possibility of lead poisoning?—No, I do not. I think that house painters working away from their workshops in various houses, many of them empty houses, would have great difficulty in cleaning themselves. They would find it almost impossible to cleanse their hands thoroughly before taking food. There would be no conveniences for that.

13,107. But those that have come to you with symptoms of lead poisoning have appeared to you to be a reasonably respectable class of men, and not men who are careless or drinkers, for instance, or are they?—No, I should not say that they are.

13,108. So that probably, even if you very much increased their conveniences for washing, you would still not entirely remove the possibility of their getting affected?—No, I think not.

13,109. (*Mr. Sutherland.*) You do not discourage habits of cleanliness, doctor, do you?—Oh, dear no.

(*Mr. Sutherland.*) Dr. Collis seemed to attach no importance to it, from his question.

(*Dr. Collis.*) That is not correct.

13,110. (*Mr. Sutherland, to the witness.*) What is your opinion as to the general appearance and health of painters who have come under your notice, apart from specific lead poisoning? Have they been healthy men?—I have only seen those who have been affected with lead poisoning, and, as you know, lead poisoning is a most insidious disease which very often renders a man in ill-health for some considerable time before he breaks down, and those who come to me are not good specimens to express an opinion upon.

13,111. Do not you see painters in other than cases of lead poisoning?—No.

13,112. But you think there is great value in a man being personally clean in his habits?—Certainly.

13,113. And that it would minimise the risk?—It would minimise the risk.

13,114. We had a witness here who said that Birmingham was "honeycombed" with lead poisoning. Do you accept that statement?—It is only honeycombed to the extent that you see in my district, because I think I may say that I do three-fourths of Birmingham.

13,115. But the witness who gave this evidence implied that almost every other man you met was touched with lead poisoning?—That is ridiculous.

(*Mr. Sutherland.*) I thought it was an over-statement, but he was very positive.

(*Mr. Parsonage.*) There are many cases where the insurance company admit the liability without their going to the certifying surgeon.

13,116. (*Dr. Collis.*) It is a fact, is it not, that the cases with which you become acquainted are those men who come to you for certificates, so that they may obtain the benefit under the Workmen's Compensation Act?—Yes.

13,117. They come to you as a certifying surgeon for a large district of Birmingham?—Yes.

13,118. It is possible that there may be other men who may fall sick, but to whom the occupier may pay compensation without their having obtained your certificate?—Yes, that is so.

13,119. So that though the list you put in represents for a large area of Birmingham, those who obtain certificates, there may be others over and beyond those?—Yes, certainly.

13,120. (*Chairman.*) That would account for your answer to my question—that there must be a large number of other cases in the whole city?—Yes.

13,121. (*Mr. Fell.*) You said that you had had 106 cases, out of which some were coach painters and 11 house painters. Who were the other people in your 106? To what classes do they belong?—If you would look at this list of trades in which I have had cases of lead poisoning, then I think that will answer the question.

13,122. Have you had any cases of coach makers, apart from coach painters, before you?—No.

Dr. COLLIS in the Chair.

13,123. (*Mr. Mason.*) It has frequently been mentioned here that men who are suffering from lead poisoning implore the doctor not to put that on his certificate. Have you had much experience of that?—My experience is quite the other way; they implore you to put it on their certificate, so that they may get compensation.

13,124. (*Dr. Collis.*) That is all they come to you for?—That is all they come to me for. Many of them implore me when I cannot comply with the request.

13,125. That is in the nature of your office?—Yes.

13,126. (*Mr. Mason.*) I do not quite know whether you have private practice as well?—No, none at all.

13,127. (*Mr. Kinggate.*) I take it that men who come to you come solely for the purpose of obtaining compensation?—Yes.

13,128. That is their only object. Of course, you would recognise that they are generally severe cases?—No; on the other hand, I consider that very often they are extremely mild cases.

13,129. They might be suffering from something else that you find which is not lead?—That is so occasionally. I have often had to refuse certificates.

13,130. They themselves have attributed it to lead, but it has not been so?—Yes; they are very ready to do that.

13,131. But there would be a number of those who are reported who would be suffering from lead, who would not attempt to obtain compensation?—I have no doubt there are, but I have no knowledge of them at all; there must be such, of course.

13,132. You would admit, I think, that working in lead, especially in lead dust, must be injurious to the general health of the worker?—Undoubtedly.

13,133. We have it brought to our notice sometimes (*Mr. Mason* asked the question) that some men have asked medical men not to state definitely that it was lead poisoning, from the fear of discharge from their employment?—That has certainly never come before me. As I said just now, I am rather struck with the eagerness with which they wish to be considered to be suffering from lead poisoning.

13,134. You have not heard at all of work in Birmingham where the employers have refused to employ men suffering from lead poisoning?—No.

13,135. (*Mr. Robins.*) You were mentioning with regard to carriages, that there was no dust contracted by working on the bodies, as I understood, but it was all done by the wet process?—I said that the wet process was much more general now than it used to be. I am not prepared to say that it is universal, but so far as I know it is.

13,136. Body work is not free from dust?—I said that the wet process of rubbing down is much more

1 November 1911.]

Mr. R. W. EDGINGTON, M.D.

[Continued.]

usual now than it was a few years ago. I am speaking of bodies, but I am not prepared to say that it is universal, although it is so, as far as my knowledge goes. You see what I mean. There may be a small coach builder in some part of Birmingham who now uses the dry process in rubbing down, but all the coach builders that I go to, and know of, use the wet process.

13,137. But the greater part of the rubbing down is exactly the same process that has been in use now for 40 years, and where the dust comes in is between the priming coats and lead colour filling up, but rubbing down wet has always been done the same for a longer number of years than I have lived. The mode of operation has not been altered in any way whatever?—But has it not been altered lately.

13,138. No. I speak as a painter?—Very well.

13,139. Do you think that very excessive working on overtime has been partly the cause of men being afflicted with lead poisoning?—Do you mean that extra work with the dust makes a man more liable to poisoning from lead?

13,140. The excessive overtime that men work in the coach trade these last few years?—The only answer I can give to that is, that the longer a man works in lead, the more likely he is to get lead poisoning, and if his time is made longer, he must in that time be more liable to get lead poisoning.

13,141. Do you believe that it will be beneficial to the painter if overtime is abolished by Act of Parliament?—That is a very big question for me to answer. I do not know that I can answer that. All I can say is, that if a man works for a longer time in a dangerous process, he is certainly more liable to suffer from that dangerous process than if he works for a shorter time.

13,142. Do you think that his vitality would be lowered by these excessive hours?—I do not think it would affect that.

13,143. His vitality would not be lowered by excessive hours in a paint shop?—No, I do not think that would affect him. Lead poisoning is a question of idiosyncrasy to a large extent. Some men may work in lead all their lives, and all the hours of their lives, and not become affected with lead. On the other hand, you may put a susceptible person into a lead process, and in a very few weeks he will become affected by lead.

13,144. With regard to the question of lead poisoning and the vitality of the men, can you explain how it is that a painter, when he has been working a day in a paint shop, as a coach painter, feels so different when he has been out in the air for an hour after he has left the workshop. Does not that show that his vitality has been lowered? If it does not I do not know what it does show?—He is breathing a poisonous air all the time; that is all.

13,145. In the shop, then, his vitality must have been lowered?—Not at all; it does not affect it.

13,146. Is he in the same state of health as he is an hour after he has left the shop?—I am not speaking of state of health at all. The more he is poisoned, the worse for his health. When he enters the room he comes in fresh.

13,147. (Lord Henry Bentinck.) His vitality is lowered, is it not? He gets worse and worse from the poison. "Vitality being lowered" is such an indefinite phrase.

13,148. (Dr. Collis.) Perhaps you have different ideas of what is meant by vitality?—It is an indefinite phrase altogether. It means very little. The man gets worse and worse from the poisoning.

13,149. (Mr. Robins.) It is only different degrees of poisoning?—It is only different degrees of poisoning.

The witness withdrew.

Mr. H. AUSTIN examined.

13,166. (Chairman.) You are one of the witnesses selected to give evidence on behalf of the Society of Motor Manufacturers and Traders?—Yes.

13,150. But there is poisoning all the while?—That is the point.

13,151. (Mr. Gardner.) Your answer to the chairman's question seemed to deal more with the coach painters as to the air being impregnated with lead dust. What is the cause of poisoning in the case of the house painter?—I think there are two causes of poisoning in the case of the house painter: first of all from the fumes which are undoubtedly given off from a freshly painted lead surface, and secondly from the want of cleanliness which may convey a certain amount of lead into the system with the food that he takes from his hands.

13,152. Is lead carried into the air with the volatile spirit in the paint—in the fumes?—I am sure it is.

13,153. With regard to cleanliness, you have already admitted to Dr. Collis that on the whole the painter is as clean as his neighbour?—Yes, but that does not say that he is clean.

13,154. No, certainly not. You said that in many cases he could not get facilities for keeping clean on jobs?—Yes.

13,155. It all points to the necessity for adequate accommodation and for the supply of hot and cold water, and facilities being provided for cleaning before taking meals?—Supposing he is painting away at somebody's house. I cannot see how you are going to regulate somebody's private house. If the facilities could be given, it would be all the better.

13,156. People will not allow a painter into the kitchen or lavatory to get hot water, but if such a regulation was laid down they would have to?—It would be interfering with the rights of private people very much.

(Mr. Gardner.) But whenever you make a regulation you are interfering with the rights of somebody?

13,157. (Chairman.) Turning to coach painting, do you know whether any attempts have been made at the works that you visit to do anything to change from lead paints to other paints?—Yes. I was at the Wolsley Motor Car Works on Friday, inquiring into the matter. I have a letter from them which says, "Dear Sir,—Referring to your visit to the works, I have pleasure in informing you that we do not use any kind of lead paint whatever in the painting of our chassis at these works."

13,158. Do you know if they had any reason for that, such as illness of their workpeople?—They had several cases of lead poisoning amongst the painters of chassis and wheels, and in a conversation I had with the manager, he said he was going to do away with lead paint altogether, so as to get rid of these cases.

13,159. (Mr. Gardner.) You do not know what kind of paint he is using at present?—No.

Sir ERNEST F. G. HATCH, Bart, resumed the Chair.

13,160. (Mr. Mason.) Do you know of any reason why cases of lead poisoning should have increased to such an extent within the last few years?—I think that the Compensation Act has done that.

13,161. You think that?—Yes.

13,162. Has there been a great increase in Birmingham within the last few months, during the hot weather?—I can tell you exactly the number of cases. From what period would you like me to begin?

13,163. I only wanted a general answer as to whether the hot weather showed any increase?—Would the number of cases I had this year do?

13,164. Yes. That would do quite well?—57 cases this year.

13,165. Have those been mostly in the second half of the 10 months (January—October)?—Yes, I should say they have.

13,167. Are you a carriage and motor body maker?—Yes.

1, November 1911.]

Mr. H. AUSTIN.

[Continued.]

13,168. What length of experience have you had in the trade personally?—About 12 years.

13,169. How many men do you employ?—In carriage work it would average probably 150.

13,170. Do they all come in contact with lead?—No, I should not think so. The workshop we have is all under one roof, and the painters are not separated from the carriage builders, so that possibly they might come in contact in extreme cases.

13,171. Therefore all the men employed work in the same shops where the lead painting takes place?—Yes. They are more or less removed.

13,172. Although they are not actually in contact with lead, they breathe the air which has been contaminated?—They might.

13,173. Have you known many cases of lead poisoning?—Very few—practically none—and only minor cases.

13,174. Do you know that in the coach-building industry there have been 767 cases of lead poisoning recorded by the Home Office in the 11 years 1900-1910?—I have heard of that, but I am not personally aware of it, because I have had no experience with ordinary carriage building.

13,175. Of these, 47 have been fatal?—I do not remember the number.

13,176. There has been no apparent reduction in the rate of attack, seeing that the average yearly number of lead poisoning cases from 1900 to 1907 was 66½, while in 1908 there were 70 cases, in 1909 there were 95 cases, and in 1910 there were 70 cases?—That number would correspond probably with the increase in carriage building which has been taking place in England. It is proportionate.

13,177. As there has been no reduction in the average cases reported each year, I am sure you recognise that something must be done to remove the evil?—Yes, I think that something should be done.

13,178. Are you aware that of 376 cases of lead poisoning reported in the five years 1905 to 1909, 46 arose from motor car works?—No, I am not aware of that. I have practically no knowledge of lead poisoning cases.

13,179. Out of 697 cases reported in the 10 years 1900-1909, 297 arose in the ordinary coach and carriage building works of the country?—I was not aware of that, either.

13,180. Have you, as a society, taken any steps to test the merits of the different substitutes on the market?—I am not aware of any. I have not heard of any being taken.

13,181. Or to institute any inquiry as to the precautions necessary to combat the evil which exists in many branches of the industry?—I am not aware of any. I have not been on any committee connected with that kind of work.

13,182. Have you tried substitutes for white lead in your painting work?—No, none.

13,183. Do you think that it would be possible to prohibit or greatly restrict the use of lead without inflicting a hardship on your industry?—Well, as we deal with it, it would cause some difficulty. I mean to say, that it would be a hardship in that we have no difficulty to remove, and white lead is certainly advantageous as we use it.

13,184. Have you any other objections to raise why white lead should not be prohibited?—None. I have had no difficulty with it. I have seen no serious illness from it in work that I have controlled.

13,185. Are you thinking of foreign competition as a serious possible evil?—At the present time the English carriage-building industry is passing through a peculiar stage. Some years ago the motor car portion suffered considerably from foreign competition; people bought foreign makes. To-day I believe the leading carriage builders in England could export carriages into places like France, for instance, pay the duty, and then undersell the best makers there.

13,186. Would the possible restriction or prohibition of the use of lead be detrimental, having regard to foreign competition?—Well, it might in this way. If the use of substitutes detracted from the finish or from the durability of the painting that is

done in England, then I think it would be a serious matter, because to-day English carriages, as shown at various exhibitions, are considered to be better finished than foreign carriages. The painting is considered to be better finished, and the varnish is considered to be better finished, than in foreign carriages. That may not be only from the point of view of the finishing coats, but from the point of view of the ground coats, which are largely formed from white lead. It would be a great pity to destroy the view of foreigners that English carriage painting and English carriage building are really well done.

13,187. Do you think that there would be any increase in cost if lead was prohibited?—I do not think so. I do not think it is of any value in that respect.

13,188. Would you agree that if a substitute could be found for white lead, the use of the latter should be prohibited?—I think so. I think that there is always danger from the use of white lead.

13,189. Do you know that for the past six years the Midland Railway Company have used no lead in their carriage and wagon works?—I was not aware of that. I have heard that the substitute is really not entirely a substitute. I have not gone into the matter at all, because I am not interested in it, but I am told that it is not really a good substitute.

13,190. I do not want you to speak of things that you do not know yourself?—No, it is not really proper evidence.

13,191. We know that the Midland Railway Company's carriage and wagon paint has no lead in it?—Probably some of the other white lead substitutes are not what they might be.

13,192. Are you aware that they are entirely satisfied with the results obtained with a mixture of zinc and baryta?—No, I am not aware of that. Perhaps their work is not subjected to exactly the same conditions as motor carriage work.

13,193. We have also had similar evidence from a representative of the Bradford Corporation Tramways Department. Are you aware that white lead is no longer in use at the Daimler Motor Works in Coventry?—I am told so. I know the head of the carriage building department there.

13,194. And that the Wolsley Motor Company use no lead on the chassis?—I think that that must be a mistake, because if they paint the chassis they must paint it in the same way as they paint the body work.

13,195. I am putting to you the evidence that we have had?—That is speaking possibly of one or two coats that they give a chassis before they send it out.

13,196. The Wolsley Company state in a letter which I saw to-day: "We beg to inform you that we use no lead whatever in painting our chassis"?—That is quite possible. If that were made a regulation it would be very easy to comply with it.

13,197. Do you hold that white lead is the most perfect substance that can be used?—No. But from experience it is the most convenient at the present time.

13,198. What do you mean by the most convenient?—It complies with the conditions as we know them, better than any substitute—better than anything else that I know of.

13,199. But do you hold that white lead is the most perfect ingredient that can be used in paint for your industry?—I can only speak from practice. I would not say that my knowledge of the subject of substitutes would warrant my saying that it is absolutely necessary.

13,200. You are open to conviction that a substitute might be found equally good?—Quite.

13,201. How does your work compare with the Daimler motor bodies?—Exactly the same.

13,202. They are one of the largest firms in the industry, are they not?—I should think they are the largest.

13,203. Do they turn out work of the highest finish?—Yes, I think so.

13,204. The buyers of Daimler cars are of about the same class as the customers of your own or other leading coach body firms, and they would demand the

1 November 1911.]

Mr. H. AUSTIN.

[Continued.]

same finish, would they not?—Yes, just the same, I should think.

13,205. Now, the witness representing the Daimler Company told us that they are entirely satisfied with the substitute they are using for all purposes for which white lead is commonly used in coach building works?—He ought to know. He is an experienced man, and they have been using a substitute for a considerable time. He told me so. Perhaps he may be speaking prematurely in regard to results that may only be apparent in three or four years' time.

13,206. The Daimler Company have used no white lead for two years, and they have had no complaints from customers?—I should not think that two years was long enough.

13,207. They claim that their paint work is thoroughly durable, and that it is, in fact, a little more economical than when they were using white lead. Do those considerations dispose you to modify your views at all?—Well, I have considered the point before, and I think that probably two years is not sufficient time to form a complete judgment.

13,208. You have told us that they are one of the largest firms?—Yes, but I do not know that their carriage building department at the present time is any larger than ours, as far as that goes.

13,209. But they are a firm of very considerable importance?—Yes, they are a firm of very considerable importance—much larger than any other carriage builders in England that I know of.

13,210. Do not you think that it would be extremely risky for them to introduce a substitute which might prove to be detrimental to their work?—Yes, but I have had a good deal of experience of innovations that come home to roost long after two years. They use a great deal of metal panelling.

13,211. If they introduced a substitute which proved detrimental to their work, would that not be likely to very seriously jeopardise the good name of their firm?—Yes, but perhaps they have not arrived at the date when the difficulty is apparent.

13,212. Is it likely that a great firm like that, with probably a very large amount of capital, would embark on a venture of this description without being pretty sure that it would be successful?—I think it is quite possible.

13,213. You think that they would run such a risk?—I do not think that they would knowingly do so, but they might make an innovation like that with every faith in the result, and they might be disappointed. As I say, they use a great deal of metal work in their body work, and white lead is not altogether a good thing to put on aluminium.

13,214. Do they use more metal work than any other motor car body builders do?—Most chassis builders doing their own work put much more metal work than others. A good deal more goes into ours, for instance, than an ordinary coach builder uses. We have a mechanical side, and we naturally tend in that direction.

13,215. I suppose that the Daimler Company use a good deal of wood too—in the Limousines, for instance?—It is partly wood and partly metal. They use wood and metal on the same carriage for panelling.

13,216. Do the Daimler Company use more metal on the bodies than you do?—Not on the individual body—perhaps not so much. I think that we do it more than most other firms do.

13,217. Do you think that the dangers attending lead painting can be practically eliminated by regulating the various processes?—Yes, I think they can—in fact, I am sure they can. We have had no serious case of lead poisoning in a factory that I have controlled.

13,218. Have you had any cases recently?—No, not recently that I am aware of.

13,219. Have you had any in the last two years?—They have not come under my notice.

13,220. Would you be surprised to know that you have had two cases in the last two years?—Not serious cases.

13,221. Yes. They were reported to the Home Office?—They have not been reported to me, and anything serious comes under my notice.

13,222 3. (Dr. Collis.) One was a case of extensor paralysis of the right hand?—Was that on the carriage side? Are you thinking of the case of a man in the automatic section where he was poisoned from the oil?

(Dr. Collis.) He was a mixer. He mixed all the paints for himself and others.

13,224. (Chairman.) I have told you that there have been 46 cases of lead poisoning in the motor industry in the last five years?—Yes.

13,225. Now, supposing that you put the case conversely, and that of the users of motor cars 46 had been poisoned in the last five years, do you not think that there would have been a great outcry for the abolition of lead?—Do you mean poisoned by the mere use of the motor car?

13,226. Supposing that it was stated that amongst the users of motor cars there had been 46 cases of lead poisoning, because they used motor cars, do you not think that there would be a great outcry?—The users themselves?

13,227. Yes?—I do not know. There are a great many of them, and I question whether there would.

13,228. Taking those of us around this table, for instance, do you think that if we knew in buying a motor car that we ran the risk of contracting lead poisoning, we should not be rather chary about buying one?—A risk simply from the ordinary use of the car?

13,229. Yes?—I should think so.

13,230. Do you not think that there should be an outcry with regard to the men who mix or use the paint for the motor car, supposing that there is a risk of lead poisoning?—If you were as careless in the use of a motor car as the man who does the painting, you might not be so concerned about it.

13,231. Then do you put down the cases of lead poisoning to carelessness of the men?—Very very largely. In the shops that I control the painting has been done under rather better conditions than obtain in the ordinary carriage shop, and from what I can learn from discussion with others in the trade, the difficulties that we have are very much less than are experienced elsewhere. I can only say that the conditions under which the men work with us are better than they are in the case of some other people.

13,232. Are you prepared to answer questions regarding the various processes in detail?—No, I have not studied that lately.

13,233. Are you a strong advocate of adequate washing accommodation being provided for the men?—Yes.

13,234. Also a proper proportion of basins to the number of men employed?—Yes; they should be kept clean.

13,235. Should hot water as well as cold water be laid on?—Yes. I do not know that there is any advantage in it for white lead particularly, but I certainly think that adequate accommodation should be provided.

13,236. But do you think that hot water should always be provided?—I think so, because in cold weather the men would be more likely to wash themselves if hot water was provided than they would if they only had cold water.

13,237. Do you think that clean towels should be supplied regularly?—Yes.

13,238. And soap and nail brushes always available?—Yes.

13,239. And that time should be allowed to the men for washing before leaving off work, and before meals?—I do not think that matters a bit.

13,240. But would you agree to it?—If regulations were made I would agree to them, but I do not think it matters.

13,241. Do you provide a mess-room for the men to take their food in?—Yes.

13,242. Is this mess-room kept clean and equipped with suitable seats and tables, and properly warmed in winter?—Yes.

13,243. Is provision made for storage of food brought by the workers so that it need not be taken into the working room?—Yes.

13,244. Do you provide overalls for the men?—Never.

1 November 1911.]

Mr. H. AUSTIN.

[Continued.]

13,245. But do you not see the necessity for the wearing of overalls?—I quite agree that everyone should be compelled to do it. There is no question about it.

13,246. Should the masters provide overalls for the men?—I should object on principle, not because of the expense of doing it, but because of the difficulty attending the provision of such things for workpeople.

13,247. Would you agree to a regulation requiring you to see that the overalls were properly washed once a week?—If the regulation was made, certainly—if it was usual in the trade.

13,248. Would you agree to provide a cupboard for the storage of overalls when not in use?—I provide cupboards for all the painters now.

13,249. For their ordinary day clothes as well as for their overalls?—For whatever the painter uses. Possibly the cupboards that we use would not be suitable from a medical standpoint for the clothes, because all our cupboards are made with wire netting faces to them, to prevent the storage of greasy clothes and things of that kind.

13,250. The whole point is this—that the Home Office have enacted provisions in other industries where lead is used to protect the workmen's clothes from coming into contact with lead dust. Would you agree to the enacting of such a provision?—Yes.

13,251. Have you impervious washable floors in your painting shops?—Blue brick floors.

13,252. Are they cleaned down wet?—Regularly.

13,253. How often are they cleaned?—Every week.

13,254. Would you agree to having them cleaned every day?—Do you mean washed down every day?

13,255. Yes, washed down every day?—I do not know that there would be any great difficulty in connection with that at all, if it was introduced.

13,256. What are the usual hours worked by your painters per week?—51.

13,257. Do they frequently have to work overtime?—Yes.

13,258. I suppose that a great deal of overtime has arisen in the last few years in the case of motor car body builders?—Yes; more so in the paint shop probably than in the other departments. That is the last operation, and it is the last operation generally that involves overtime.

13,259. Would you agree to a strict limitation of the hours of employment, say to 48 hours per week, as has been recommended in potteries?—I should not agree with a very good grace.

13,260. The medical evidence before the Potteries Committee stated very clearly that it was most important that the men should not be allowed to work for too long hours in an industry where lead dust was generated?—It is quite impossible to say whether 48 or 51 should be the hours.

13,261. The fewer the hours are the better?—The difficulty is with the combined factory, one part running shorter hours than another.

13,262. I do not say that there is no difficulty, but the Home Office might wish to level up this industry to that of the Potteries, and would you agree?—It would be extremely awkward. The men would object very very strongly. They would object as much as the masters.

13,263. Would they object to 48 hours if they got the same wages as they do to-day for 51?—I believe that they would.

13,264. Are you quite sure?—If you offered them 48 hours instead of the time that they work now, with the overtime, they would object strongly if the rate was the same. Most painting is done by piecework, and the men could not earn enough in the time. It is not a question of the hours, but of the amount of money a man earns.

13,265. You understand that this Committee is bound to take notice of the recommendations of a former committee on a similar industry?—Yes.

13,266. Both the employers and the employed, and the independent members of that committee recommend unanimously that the hours of labour should be limited to 48 per week?—I think that if the conditions were the same, naturally the working hours should be

the same, but where the conditions are entirely different, then, perhaps, some modifications of those conclusions should be made.

13,267. The conditions that this Committee have to weigh are the same, inasmuch as both sets of men are engaged in industries where there is a great deal of dust generated?—Yes, but in one case it might be possible to reduce the difficulties, and in the other case it might not. I think that the difficulties at present connected with coach building could be very largely reduced.

13,268. The difficulties connected with the pottery industry were met one by one, and as far as human ingenuity could devise, were met satisfactorily. Now we should hope, if lead was continued to be used in your industry, to have conditions similar to those which were recommended by the committee on the pottery industry, including a reduction of working hours?—I hope that you will not do that, at any rate.

13,269. Do you have a periodical medical examination of your workers?—No; they will not agree to it at all.

13,270. Do you know that if lead is allowed to continue to be used, that will be one of the very first conditions that the Home Office will impose?—If they made the regulation, we would agree to it. I have not the slightest objection to it.

13,271. Do you think that the cost of such a system should be borne by the employers?—I do not think it matters a bit.

13,272. Together with compensation for any workers suspended by the doctor on account of doubtful health?—I would not have the slightest objection, as long as it was made general.

13,273. I suppose that it would be fairly costly to carry out these regulations and recommendations?—I do not think so necessarily. The difficulties that we have connected with the use of lead are so small, as a matter of fact, that I believe any reasonable regulation could be complied with without a lot of expense, as far as I am aware of what the intention of the Committee is.

13,274. The Committee have not made up their minds yet. You agree, do you not, that one of the most serious incidents of danger in your trade is the inhaling of lead dust?—Yes.

13,275. I have not taken you through the various processes, because you ask me not to, but can you tell us in what way you could really get rid of the lead dust in your industry?—By some apparatus or some method, you mean?

13,276. Will you tell us whether you think that it is possible in every case where lead dust is generated to have an exhaust fan to carry away the dust?—I think it is quite possible.

13,277. Would it not be a very costly operation?—Not for taking away the main portion.

13,278. Take for instance the wheels. How would you arrange to have a fan to take away the dust?—I should paint the wheels in a case, and have an exhauster from the case. It is not a difficult matter at all. So far as motor cars are concerned, the wheels are to a very large extent changing. If the present practice continues, it is quite possible that they will be mostly metal wheels, not painted at all, but simply enamelled. They are very largely so in our works at the present time.

13,279. Do you state deliberately on behalf of your firm that you prefer a system of regulations such as I have foreshadowed to the prohibition of lead or a restriction to 5 per cent. solubility?—It is rather difficult to answer that, because I have not used substitutes, and I do not know how far I could use them. I might find them very difficult. Apart from the hours of labour, I do not think the restrictions that you have mentioned would be difficult or expensive to comply with. The idea that I have heard suggested of a workman working with an apparatus round his head, and that sort of thing, is impossible, but I do not think that the restrictions which have been outlined or proposed would be difficult or expensive to comply with.

1 November 1911.]

Mr. H. AUSTIN.

[Continued.]

13,280. I should like to tell you that the installation of exhaust apparatus throughout your industry would be very expensive?—I can only speak from my own knowledge. I do not know how far you intend to go. A body builder uses lead, and would it be necessary to have a restriction with regard to him? He has a little pot of lead, and he puts a little lead on the joints.

13,281. Any man using any quantity of lead, however small, would be considered by the Home Office working in a dangerous trade, and so he would come under the regulations with regard to medical examination, the wearing of overalls, &c. In addition, I think that the Committee might recommend, although I do not know their views, that some exhaust apparatus should be devised by which all the dust generated should be carried away from the worker so that there was no possibility of his breathing the dust at all?—If you limit it to the dust generated, that is different. In the cases that I am speaking of they are using lead already mixed with oil. I do not think that where dust is generated in the painting of a motor carriage as we practise it to-day, any exhaust apparatus that is necessary would be such a very expensive matter, unless you have views entirely outside what I think is necessary, and I cannot possibly imagine what they could be.

13,282. The most simple forms, as long as they were effective in their operation, would be those that we should recommend?—With regard to the painting, we might find that a regulation as to the dust might be an advantage. Dust flying about a paint shop gets on to the finished painted bodies all ready for the varnish coat and spoils the finish. We try to eliminate that, not for the sake of the workmen, but for the sake of the work.

13,283. (*Lord Henry Bentinck.*) You do not use exhaust apparatus?—No, it is very awkward to use any kind of draught in a paint shop, because it pulls in the dust or generates a cloud of dust.

13,284. (*Chairman.*) You rather hesitated to answer the question, so I will not press it, as to whether you prefer a code of regulations such as I have foreshadowed, or the prohibition of the use of lead?—I do not know which would be the cheaper or the better at the finish.

13,285. (*Lord Henry Bentinck.*) Your shop is an up-to-date modern one, is it not?—Yes.

13,286. It is not really a fair test when you come to think of all the small shops there are nowadays?—No, and it is rather hard for a shop that is well up to date to be troubled with regulations that are made for the smaller shop that is not up to date, the regulations not being necessary for the larger and better conducted shop.

13,287. Do your men suffer generally in health at all?—No, we are rather careful about that. We do not like to see our men ill, and it is always a trouble if they are away from their work. They might be good and necessary men.

13,288. They do not lose much time?—No, very little.

13,289. (*Dr. Collis.*) How often do you recommend that your motor bodies should be renovated after they have been turned out by you?—It is impossible to say. We try to get customers to touch up and re-varnish once in two years. We really advise it once a year, but we do not find that anybody takes any notice of that.

13,290. Do you find by that time that the pigment that you have placed upon the body is destroyed, or is it the varnish which is used to cover it which is then getting worn away?—Generally the varnish, but in cases of metal bodies, particularly aluminium, it may be the first coat that has not been a good one.

13,291. The question of the pigment used in the original paint is not so important as the question of varnish?—No.

13,292. Even assuming that there is a slight inferiority in the substitutes for lead in that class of work, it does not much matter which you use?—No, possibly not, in that case.

x 7790

13,293. In the case of a metal body, do you use terne plates at all?—Yes, occasionally, but not often. Mostly it is tin-coated steel.

13,294. What do you paint terne plates with?—In the ordinary manner, with the lead coat first.

13,295. Does the paint adhere very well?—Yes. We used to have trouble with terne plates. We do not use so many now; we only use terne occasionally. We had trouble, not because of the painting so much, but more from what we considered was the inefficient washing after the pickling of the plates. If they are not efficiently washed before they are coated with lead or tin, you are liable to get scaling of the paint; we put it down to that. Now we use mostly tin-coated steel.

13,296. You mean pure tin plates instead of zinc?—Yes. We have tin-coated steel for mudguards.

13,297. You use tin and you use lead?—Yes. We use what I have told you, owing to the scaling.

13,298. Scaling of the paint?—Scaling of the tin or zinc.

13,299. The whole thing scaled off?—The whole thing scaled off and left a rusty surface underneath.

13,300. You have not tried painting with non-lead paint?—No, I do not think we have.

13,301. Do I understand you to say that it is difficult to get the paint to adhere well to aluminium?—It is. We put black varnish on the aluminium first, and that we find most efficient.

13,302. The Daimler Company seem to get their covering on all right?—Perhaps they use black varnish as we do as a first coat, but not many people know it. We used a lead coat first, but it set up an oxidising action, particularly where we used brass screws.

13,303. The representative of the Daimler Motor Company said that they use the American method of painting. Now, you mentioned that you had had practically no experience at all of lead poisoning; indeed, I believe that in your answer to the form which was circulated by the Employers' Association, you said that you had had no cases among your men since 1907. I have here a case that was reported from your works in August 1910?—It is strange.

13,304. The case was notified by a practitioner and confirmed by the certifying surgeon. It was stated to be a moderate case, but it must have been rather severe, as the man had extensor paralysis of the right hand?—Was he a painter?

13,305. Yes, he was a painter in your employ, but I gather from the report that he was not employed entirely on motor bodies; he was mainly painting about the factory?—Was that a case of carriage painting?

13,306. He was mixing paints for himself and others?—We have one or two painters who do work about the building, and in making a report we should not consider that they were painters. They are labourers and so on; they are not really painters. They do whitewashing and painting and that sort of thing.

13,307. This man was an old hand as a painter?—But that department is really the building department of the works.

13,308. In August of this year a painter of motor bodies in your employ immediately after having been notified to us as a case of lead poisoning was examined by a certifying surgeon, who again confirmed the case as one of moderate lead poisoning. He was a painter of motor bodies applying the first two coats and the filling?—He would probably be on the most dangerous work.

13,309. Have you no knowledge of him?—No.

13,310. You answered this form, and I should have thought your attention would have been drawn to the fact and that you would have gone into it before you came here?—It has not been brought before my notice. I do not know why, I am sure. I suppose that it was not considered serious enough.

13,311. Do you use any paint known as non-poisonous white lead?—We have tried it, but I do not know the result of the test.

13,311a. I ask you that because of what this man is said to have been employed at. Do you know the composition of that paint?—No.

A a

1 November 1911.]

Mr. H. AUSTIN.

[Continued.]

13,312. Your firm undertook at the request of the factory inspector to ascertain that?—Have they not made any report about it?

13,313. No?—Then I suppose they are still making inquiries about it, or testing it.

13,314. It would be interesting to know whether you were, perhaps without knowing it, using non-lead paint?—I know that it has been tested, but I do not see how they could arrive at a conclusion as to the use of a thing like that under several months.

13,315. I wondered whether you might be using it without knowing it and whether, that being so, you might possibly have experience of leadless paints?—I do not know.

13,316. We had precisely the same description given us, "non-poisonous white lead," by another firm. Analysis in Government laboratory showed that it was non-poisonous, but it was not lead?—Since the Committee was appointed we have made several tests, but with what result I cannot say. It is not possible to give an opinion.

13,317. You are making experiments with non-poisonous paint?—Yes. It is very difficult, because we must keep the particular car that we use it on somewhere near by so that we find out the result. That result may not be satisfactory in much hotter countries; for instance.

13,318. These cases that I have put to you show that perhaps illness may be going on among your workpeople, of which you have no knowledge?—I heard that a man was off, but I did not know that it was a serious case of lead poisoning. Now I come to think of it, I know that he was off. In the other case, as I say, the man was only a painter's labourer, and we should not consider him a painter. The regulations attaching to the workshops in which he is employed are entirely different from those with regard to a regular painter. He might do all his own mixing.

13,319. We are considering the whole question of the use of lead paints. Your present evidence is on motor bodies?—His case may be outside painting, and I have no experience of house painting or outside painting.

13,320. (Chairman.) With regard to the question that I put to you as to whether you preferred a system of regulations, or prohibition or restriction to 5 per cent. soluble lead, would it assist you at all in giving an answer if the Committee suggested that a period of two years should elapse before the prohibition of lead came into force?—I think that it would very largely assist me to arrive at a decision, because I should immediately make suitable tests.

13,321. Supposing that the Home Office issued an order that after the expiration of two years no lead was to be used, would you then prefer the prohibition or restriction of the use of lead to the regulations?—I could not say. It is difficult to answer. I would rather like to answer the question at the end of two years, after I had made tests of the substitutes which may be used at present or which may be brought out in the meantime.

13,322. You would not have an option; the regulations would come into force at once and the exemption would last for two years?—From what I know other people are doing, I prefer to have the prohibition of lead under the circumstances, as I know what prohibition might mean, but I do not know what the regulations concerning special painting shops and that kind of thing might mean. With prohibition we should be on all fours with everybody else.

13,323. (Dr. Collis.) You had this form circulated to various members of your trade?—Yes.

13,324. Some stated, like yourself, that they had no experience of lead poisoning, but on examination we found cases of which the employers had no knowledge. There were a very considerable number, although the firms said, in absolutely good faith, that they had no knowledge of ill-health from lead poisoning?—I do not know whether they would look at it in the same light as I do. It might be a serious case, or a case not sufficiently grave to take note of.

13,325. One case was definitely stated to be a moderate case, not a slight case. We have three

groups—slight, moderate, and severe?—The Government method of grouping them might make a case moderate that we should consider only slight.

13,326. They are grouped together by the certifying surgeon, who has knowledge which, at least, must be in advance of any knowledge which a non-medical occupier has as regards the general condition of the men examined?—He may not notify the firm that the case is serious.

13,327. He is not expected to. His report to us is confidential, but the fact is that you have every one of these cases entered in the general register of your factories. You are bound by law to have them there?—Whether it is a serious case or not?

13,328. Yes, whether it is a serious case or not. Now, these replies have been made to us, notwithstanding the condition of your register, and that places an extraordinary amount of doubt, we consider, on the *bona fides* of these answers, and I think you must grant that we are in a position to cast that doubt?—Certainly it would give that impression.

13,329. Occupiers have only to turn to the general register of their factories to see any case entered therein?—In discussion with other members of the Carriage Builders' Institute, we have discussed that matter very considerably at our meetings. It has been seriously considered, and the general opinion among the members is that they do not take any notice of what might be considered a moderate case of lead poisoning as a case of lead poisoning. They only take the severe cases. The general opinion is that any amount of lead poisoning takes place, and that the cases never come before the authorities at all. A man does not even knock off work. He takes certain precautions, and gets over his difficulty. He keeps on working. In plenty of cases a man is not able to knock off, and those cases would never come before the employer at all.

13,330. No, I am speaking of definitely notified cases which have been inquired into by the certifying surgeon and the inspector. I will give you a case of a man whose case was considered slight, and was so reported to us by our certifying surgeon. That man left the works, and the works had no further information with regard to him. I attended the inquest on him in September. He was engaged in the motor car industry?—What was the report on the register? Was it "slight"?

13,331. The report from the certifying surgeon at the commencement of the illness was "slight," but it ended fatally. My point is that you have no right whatever to form these opinions as to the seriousness or riot of a case; and I hold that it is your duty, as employers, when you are asked for these returns when inquiry has been made, to give the reports from your general registers; but you have deliberately not done so?—Some have not, undoubtedly.

(Dr. Collis.) It is a breach of *bona fides*.

13,332. (Mr. Fell.) You said that you saw no difficulty in applying exhaust apparatus. I suppose that you alluded to the dust arising from the work of a man who was rubbing down?—To the dry operations connected with painting.

13,333. There are two causes of dust; one the rubbing down and the other the splashing of paint on the floor, which dries and in time forms dust?—Yes, it is kicked up in walking.

13,334. You have to provide against that as well?—But that would not be provided for by exhausters, except in certain cases. It would be provided for by washing down.

13,335. If only a week even elapsed between the washing down, you would get a considerable amount of dust which was not washed down?—Certainly.

13,336. So that you really have to have some sort of general arrangement of exhaust?—Yes, or more washings down. There is a little difficulty in connection with the painting of motor carriage bodies, as at present practised at any rate. Some of the painting takes place while the body is being mounted on the chassis. It is not possible, unless you have very strong regulations and lose a considerable amount of time, to do all the painting when the body is separate from the

1 November 1911.]

Mr. H. AUSTIN,

[Continued.]

chassis. It is much more convenient to do a certain proportion of it when it is only partially built. It may be during the time that it is being mounted, or during the time that the iron work is put on it. You see how difficult making any regulations about using exhausters in connection with the painting might be in the various shops.

13,336a. When the chairman was putting to you how difficult it would be to apply exhaust apparatus, I think you said that there was no practical difficulty in it?—I do not say that there is no difficulty in it, but possibly if it was a question with us of sacrificing considerable value in the painting by using a white lead substitute, as against having regulations which necessitated expense or delay or alteration of the system of painting, we might go in for the expensive apparatus, and keep up the quality of our work. It depends entirely, I think, on the class of work we should be catering for. It is impossible for anybody to answer upon this question until the regulations are made and the work is gone carefully through to see what is necessary for carrying them out. It might be very much more difficult than I am thinking at present it is likely to be. As I said before, I know to a certain extent what the regulations with regard to prohibition may mean, but I do not know what the other regulations may be. I have not seen a list of them. If I had a list before me I might form an opinion.

13,337. (Mr. Mason.) Seeing that the whole of your work goes on under one roof, and that you have had several cases of lead poisoning, it would be interesting to know whether any of those cases have affected men other than painters?—I have not heard of it. Very often a man will suffer from a complaint and not say anything about it. It is quite possible that cases may have arisen that have not been brought to the attention even of the foreman.

13,338. In answer to the chairman you stated that you have known of one or two definite cases?—I know of the case of this man who did the outside painting; that is to say, I have heard of it; and I remember one or two cases that happened in connection with the Wolsley works many years ago, when I was manager of the works.

13,339. But not in your own works?—No. Many of the men may suffer from it all the same. I do not say they do not. They are extremely dirty. I have seen them eat their food with dirty hands, with paint all over them, and never wash themselves, never brush themselves, and never wear overalls.

13,340. You said that the trade was now in a position to export bodies to France. I have been led by others to believe that there is a certain amount of importation of bodies from Belgium to England and from such places?—Yes, they have built a type of carriage body which has appealed to a certain class in England, and which has been largely advertised. It is not a serious matter—perhaps 600 or 700 carriage bodies in the year.

13,341. Then the fact that they are allowed to use lead, and that the English carriage builder is prohibited from using lead, would make little or no difference?—It might make a considerable difference. I do not know of anyone to-day who can really seriously assert that white lead can be dispensed with without detracting from the quality of the painting of a carriage body.

13,342. Do you suppose that if foreign firms were allowed to use lead, and English firms were not, it would seriously injure the English trade?—It might. It certainly would if it was going to injure the quality of the paint.

13,343. If it were possible to prevent bodies with lead paint on coming in from abroad, what would you say then to prohibition?—We would not object at all to prohibition then.

13,344. I believe that a strong effort is being made to capture the Argentine and other foreign countries; would the prohibition of lead in such a case have any detrimental effect?—It would if you were not able to obtain with the substitute a result practically equal to the result from white lead in regard to durability, because we should be in competition then

with Continental firms who were able to use white lead, while we were prohibited from doing it.

13,345. (Mr. Kinggate.) You have admitted that you have no knowledge of the use of substitutes for white lead?—Not sufficiently to give any opinion.

13,346. With regard to the Daimler Company, you think that two years is not sufficiently long to be able to know whether it can stand or not?—I do not think it is.

13,347. Have you had large experience of coach painting?—I have not done the actual coach painting myself, but we have a very large coach building department, and it is a part of the business that I pay a considerable amount of attention to.

13,348. If the base of the painting is not good, does it not show itself very quickly. For instance, if a body was painted in a very great hurry, as it frequently has to be, and is done in what we call "Presto," one coat put on the other quickly—that very soon shows itself?—Yes.

13,349. Any fault in the base will show itself in less than two years—even in 12 months?—Yes, but I am thinking particularly of carriages that are exported. The result might be very bad, but the manufacturers would not hear of it, perhaps, until after two years.

13,350. I am only asking with regard to your experience in these matters. When the base of the painting is not good, it shows itself quicker than that. You use the lead for priming coats, and mixed with your filling?—Yes.

13,351. If the base is wrong, and the colour is quick colour, "Presto," small cracks will show in less than 12 months in the ordinary way?—Yes.

13,352. Are you aware that the man who introduced the American method of painting into the Daimler Company's works is a thoroughly practical man of 25 years' experience, who has made a great study of the material that he uses?—I was not aware of that, but even then I think it is possible for him to make a mistake.

13,353. Of course, it is possible for anyone to make a mistake. What is the object of the first coat of lead, speaking specially in regard to wood?—To protect the wood.

13,354. For something more than that, is it not?—No. Beyond getting sufficient body work to hold up the colour, I do not think any painting is done except to protect the wood.

13,355. You might put anything on to protect the wood, and it would do it for any length of time, but you would see all the grain showing through?—That is merely a matter of getting sufficient surface or body so that you shall not see that. I do not think the object is anything except to protect the wood.

13,356. The object is to stop the grain of the wood, and get a good surface?—That is a matter of quality.

13,357. Is not that the main object?—I understood that the object of painting was to preserve the wood.

13,358. You might put tar on it to preserve the wood, if that was the case?—You might, and it might be a good deal better, probably.

13,359. From your knowledge of the trade you know that a very fine surface is desirable?—That is a question of quality.

13,360. That is what I am speaking of. The object of lead first of all, and the filling coats is to stop the suction and to stop the grain of the wood showing?—Yes, to form a surface.

13,361. If you can get an elastic material to hide the grain of the wood, that is an advantage, is it not?—I think so.

13,362. The object of the Daimler Motor Company is to get something that hides the grain of the wood, that is elastic in character and that is not liable to crack?—My experience is that it does not crack; it peels. Enamels all peel.

13,363. The great difficulty is that it has to have all these qualities?—I have always found enamels fill up much quicker than a paint does, but they peel. They crack at the corners.

13,364. If the base was wrong in the painting of a body, would not you think, as a practical man, that the defect must show in less than two years?—I do not know about that. You ask me as a carriage manu-

A a 2

1 November 1911.]

Mr. H. AUSTIN.

[Continued.]

facturer, and I give you evidence on which you might say it was perfectly safe to insist on the abolition of white lead, but I do not think two years is sufficient. It is not the practical man who comes into the question, but it is the man who sells the carriage and who gets into touch with his customers and hears their complaints. The practical man can say whether they are right or wrong, or what is the cause, but his opinion is never asked.

13,365. Take a man who in the ordinary way manages a concern as a foreman. The employer would come to him naturally to know the reason of the failure?—But if he has not the failures brought to his notice, how is he going to ask the foreman about them? If you send a car abroad, or if you use it in England, and you have no complaints about it, you assume that it is all right; but suppose that at the end of the third year it is not all right. What is the position then?

13,366. You have had many years' experience. Would it not be found out before that?—I am not altogether sure of that. It is not only a question of the use of white lead that makes the painting of a body successful or unsuccessful.

13,367. I admit that. The point is that you contend that two years is not sufficient time to know whether the method adopted by the Daimler Motor Company will stand?—Not sufficient, I think, for a Government department to make strict regulations which might seriously inconvenience the industry. That is how I look at it. I do not want to give any evidence that might be considered as definite, when I do not really think that two years is sufficient.

13,368. (Chairman.) What would you consider a proper test?—It is extremely difficult to say. In my experience I have found that in many cases it takes much longer than one would think to arrive at a definite conclusion.

13,369. But would not an ordinary owner of a motor car have it painted in three years?—I have seen cases where a motor car has been very carefully used, and even used quite considerably, where at the end of four years the paint has been in an exceedingly good condition.

13,370. But would not most motor car owners have their cars painted at the end of three years from the time they were purchased?—No, I do not think most of them would.

13,371. (Mr. Rice.) Does it not rather depend on whether they have bought at an exhibition or not?—They might have it touched up or varnished. My experience of motor car owners is that they are extremely careless about their cars, and take very little interest in them compared with what they would take in an ordinary carriage with a horse. A man likes a horse and carriage to look nice; he does not care to have his horse looking bad. He likes to have it looking spick-and-span, and the harness and the carriage as well. He would be ashamed if it were otherwise, and I do not know why he is not ashamed of the look of his motor car.

13,372. (Mr. Kinggate.) A motor car is subject to more rough work than a carriage?—Yes.

13,373. It would want varnishing every two years?—There is no question about that.

13,374. Any defect in the base would be seen?—Yes, with regard to a painter looking at it. I am thinking of metal bodies where the peeling takes place some considerable time after.

13,375. That is the action of the metal?—Partly that, and the first coats, and the fact that it is not varnished.

13,376. Is very much "Presto" used by you?—We do not use it.

13,377. You have used white lead for jointing?—Yes. We have tried glue and found it quite unsatisfactory.

13,378. Have you tried jointing paste?—No.

13,379. Do you know that some of the largest firms in England have used it, and found it satisfactory?—I was not aware of it.

13,380. With regard to the Wolseley Company, we had it stated that they are not using any lead at all in

the painting of the chassis. When that point was put to you by the chairman, you could not understand why they should paint that differently from the body?—The wheel is part of it, and surely they would paint it the same as they would the wood on the body. In the carriage-building trade it is generally considered to be the part where there is more dust made than with regard to any other part.

13,381. That is my point. The Wolseley Company have had several cases of lead poisoning. It is quite possible in the painting of the body to do all the rubbing down wet, and have no dry rubbing down of any kind, is it not. The rubbing can be done with pumice-stone instead of sand-paper?—Yes.

13,382. That is impossible with the wheels, and the Wolseley Company have adopted this plan of using no lead at all in the painting of the chassis to avoid the dust arising?—I do not see why they could not rub down a wheel under the wet process, the same as they can any part of the body work.

13,383. You must know that that is practically impossible, and it is exceedingly costly. I should think that if you were to talk about rubbing down wheels with a stone to any practical man, he would smile, to say the least?—I do not think he would. The wheel is not a very important part in this connection—I mean there is no difficulty in connection with the painting of a wheel.

(Mr. Kinggate.) But look at the trouble it would be to rub down a wheel by the wet process.

13,384. (Chairman.) You do not profess to be an expert on the processes?—No.

13,385. (Mr. Kinggate.) But you know the difficulty of rubbing down curved surfaces with stone?—Yes, but that is merely a matter of a little more expense. The wheel is probably the most important part of the carriage.

13,386. No, the panel is the most important part?—No, the wheel is the most important part—the wooden wheel—and you have to make a good job of this part of the painting of the carriage. I know enough about it to be able to say definitely and firmly that the wheel is more important than any part of the carriage, and it is one of the most neglected parts with regard to painting, and more peeling takes place there than at any other part. If you could dispense with white lead there, you could dispense with it on any other part. There is no question about it, that more difficulty occurs in connection with the painting of the wheel than in connection with any part of a carriage body. Look at any carriage or motor car particularly, and you will find, if peeling is taking place on any part, it is on the curve of the spokes, where the end grain is, and where water from the washing of the spokes has got on the inside and caused the paint to peel off.

13,387. I have been for 45 years in carriage-making shops, and I cannot agree with you?—You speak of carriage building perhaps, not motor car building.

13,388. Both?—I am certain that I am right. I have had very considerable experience of these points.

13,389. The greatest danger arises from sand-paporing?—There is no question about that.

13,390. It struck me forcibly that the Wolseley Company were doing away with lead on the chassis and wheels for the obvious reason that dust was created by the sand-paporing, and that was one of the methods of getting rid of lead poisoning in their works?—If regulations were made it would be very easy to have a special arrangement made about the sand-paporing of the wheel, but it would be extremely difficult to make arrangements with regard to the sand-paporing of the body. It is easy to paint or rub down or sand-paper a wheel in a chamber, but it would be extremely difficult to put a carriage body in a chamber, because a man could not reach it from outside. I cannot understand any firm painting the wheels of a motor car without white lead, if they say that it is necessary to have white lead on the body of the work.

13,391. (Dr. Collis.) I do not think they have said that?—The Wolseley Company say so, I understand.

(Dr. Collis.) They only say that they are doing without white lead on the chassis.

1 November 1911.]

Mr. H. AUSTIN,

[Continued.]

13,392. (*Mr. Mason.*) You think perhaps that they paint the chassis with one colour and the body with another?—No. I am speaking of painting the chassis in a different manner from the body.

13,393. (*Mr. Kinggate.*) Are you aware that the Sunbeam Motor Company and the Star Engineering Company do not use any lead at all now?—I have heard so, but I am not conversant with their practice.

13,394-5. (*Mr. Robins.*) With regard to the Wolsley Company, only about two months ago orders were sent down to the paint shop that, on account of lead poisoning, leadless paints were to be used on chassis, and two months were given for experiment, so that it is only a recent occurrence?—As you know, with regard to the painting of parts like that, defects do not show perhaps for a year or more.

(*Mr. Robins.*) It is not said that the bodies can be painted with leadless paint, the same as the chassis can?

13,396. (*Chairman.*) You told us that if you had two years of grace you would prefer prohibition or restriction to 5 per cent. of soluble lead to a code of regulations such as I foreshadowed. Now, when you gave that answer, did you take into consideration first the importation of foreign-made bodies, and, secondly, the exportation of motor cars to foreign countries?—No.

13,397. Would you still adhere to your declaration with regard to prohibition in view of these two matters?—I think I would. I do not know the conditions that may be imposed.

The witness withdrew.

Mr. C. I. SMYTH examined.

13,398. (*Chairman.*) Do you attend to-day as the representative of the firm of Mander Brothers, of Wolverhampton?—Yes.

13,399. What manufactures are your firm engaged in?—They are very varied. We make a number of different articles, mostly paints, varnishes, enamels, and printing inks.

13,400. Have you for some years manufactured a leadless grey priming paint?—Yes, for the use of coach-painters.

13,401. How many years have you supplied that paint?—As far as I recollect, about five years.

13,402. How does it compare in cost with white lead paint?—It is slightly more expensive than paint made with white lead, but if it were made in quantities comparable with white lead it would be cheaper. I might say that this depends to some extent on the respective market prices of lead and zinc.

13,403. Naturally. Have you found that the demand for it among users of paint has increased since the time you introduced it?—Very little. We have had a few inquiries for it lately.

13,404. Have you had any complaints regarding the paint on the score of durability, or otherwise?—None whatever.

13,405. Have you sold a considerable quantity of this paint?—No; a small quantity.

13,406. Are you able to state quite positively that it has been a success?—I am in a position to state that we have supplied it to one very important firm of motor car builders ever since we first made it. In fact we made it for this firm originally, and they have used it ever since.

13,407. How long have they used it?—About five years. I could not give the exact time.

13,408. Is it a motor car firm of some reputation?—The Sunbeam Motor Car Company.

13,409. Have you introduced other leadless paint?—We have introduced a leadless filling, or paste which is used by coach-painters, but only recently. We have also, from time to time, made other paints, but mainly when we have been asked to do so.

13,410. What other leadless paints have you introduced?—Paints of all sorts for coach-painting, in small quantities, when we have been asked to do so by customers. We have never pushed them to any extent.

13,411. Do you think that you have succeeded in replacing white lead in paints?—As far as white paint is concerned, I consider that we have done so with great success, but with regard to other paints, some of them so far have not been successfully replaced.

13,412. What grounds have you for saying that you have been eminently successful with non-lead white paints?—I can show you two boards which have been done with zinc paint. One will show you the finish of the paint and the body, and the other will show you the durability.

13,413. But have you had any practical experience in the use of these white non-lead paints?—We do not use them ourselves.

13,414. Have you had experience with regard to selling them to users of paint?—We have had no actual

opinion from users. It is more or less experimental work, which we have been going into for several years.

13,415. Do I understand you to say that the only instances you have of its success are the boards that you produce for us to see to-day?—They are the only evidence that I can give you.

13,416. What is the composition of your leadless paints?—They are made up on a basis of zinc.

13,417. Do you find that such a paint has sufficient body and covering power?—Yes.

13,418. How did you ascertain that?—By testing them.

13,419. Simply on the boards that you present to us?—Yes.

13,420. Have you found that this non-lead paint is durable?—I have. I have a board here which will show you the durability of it. It has been exposed now for rather over two years. I might say with regard to durability that I do not consider it depends so much on the pigment, that is, as to whether it is lead or zinc, as on the medium with which the colour is combined.

13,421. Where have you exposed these boards for testing purposes?—On a wall with a south aspect in our works at Wolverhampton.

13,422. For how long were they exposed?—This board was exposed on October 19th, 1909 (*handing a board to the Committee*). The whole board was first painted with two coats of white lead. This portion *here* (*pointing*) received two additional coats of white lead.

13,423. When was it painted?—In October 1909. The top portion was painted with two coats of zinc-oxide paint. In both *this* case and *that* the paint was thinned with the same medium, that is, a mixture of linseed oil and turpentine in the proportions of two parts of linseed oil to one of turpentine. The middle partition was painted with a specially prepared zinc-oxide. The zinc-oxide itself was the same, but the medium was a different one. The white lead has become grey; the zinc-oxide has retained its colour. But in both of these cases the surface is covered with very fine cracks, which will eventually get worse and worse until the whole of the paint has disintegrated. The middle one has a perfect surface. There are no cracks whatever visible.

13,424. (*Mr. Sutherland.*) Although *this* looks dirty it has the body of lead on it?—Yes.

13,425. As a preservative it has the body of lead on it?—Yes, but it will go worse and worse.

13,426. Dirtier?—Both of the two outside ones will crack more. When cracking has once started in a paint it will gradually get worse and worse until the paint has perished completely. The durability of a paint depends entirely on its elasticity, that is its power of standing expansion and contraction which are caused by differences in temperature.

13,427. (*Chairman.*) Have you any other specimen to show us?—This is a specimen on which I have had painted two coats of best white lead and two coats of zinc-oxide paint.

13,428. When was that painted?—This was finished the day before yesterday.

1 November 1911.]

Mr. C. I. SMYTH.

[Continued.]

13,429. What does that show?—That shows the body and the superiority of the finish of the zinc-oxide, or rather of this particular zinc-oxide paint. It also shows superiority in colour—in whiteness.

13,430. (Dr. Collis.) Are there the same amounts on each?—Exactly the same.

13,431. Weight for weight?—Not weight for weight.

13,432. The lead would add to the weight?—Yes.

13,432a. (Mr. Sutherland.) Was the same vehicle used in each case?—No.

13,433. You have varnish in the zinc?—There is no varnish at all.

13,434. Why did you not put the same in both?—I want to prove that the permanency and durability of a paint depends to some extent on the medium. This shows that when made up with this particular medium you can get as good a body of colour as you can with ordinary white lead.

13,435. This is merely to supplement the middle piece?—Yes. We have two coats of white lead over the whole of them, so you could not form an opinion as to the body of that.

13,436. Is this two coats on bare wood?—No, on pink priming. All wood is so primed.

13,437. But what is the basis of the priming?—It is generally made with white lead.

13,438. Is that necessary?—I do not think that it is necessary, but it is usual.

13,439. (Chairman.) Is it a necessity in the first instance to coat with white lead before you apply the zinc-oxide?—Not in the least. The pink priming could be made just as easily with zinc as with white lead.

13,440. Why did you not have it so painted in this illustration?—Because there was not time to do it.

13,441. It is not what we want. If there is any lead connected with such exhibit it lessens its value?—I only decided to do this on Monday, and it could not have been done in time.

13,442. Is your experience of zinc paints which have proved as durable as lead paints only illustrated by the boards which you have shown to us?—Yes.

13,443. What is the relative cost of such paint for outside use?—Zinc paints if made with zinc-oxide are dearer, weight for weight.

13,444. As zinc-oxide is so much lighter than white lead specifically, there would be much less weight of zinc-oxide than of lead in a gallon of paint mixed ready for use, would there not?—Yes.

13,445. How then would the price of zinc-oxide and white-lead paints compare, gallon for gallon, when the paint is ready for use?—The ordinary qualities of zinc-oxide, when prepared for use, would come out almost identical in cost with white lead. If a more expensive zinc-oxide, which is lighter in gravity, were to be taken, it would actually come out a few pence per gallon less. I am assuming that pure linseed oil and pure turpentine are used for thinning in each case.

13,446. Do I understand that the original board that you painted two years ago had a coating of white lead?—Two coats of white lead.

13,447. The foundation was white lead?—Yes, the foundation was white lead.

13,448. What does that prove then?—It only proves that the white lead on the top has cracked, but the zinc white on the top has not cracked.

13,449. Does it not also show that, on the face of it, a first coat of white lead is necessary?—I have not the slightest doubt that if two years ago I had known I was going to give evidence here, and I had had the foundations done with zinc instead of lead, it would have lasted equally well.

13,450. But we are here to investigate this question, and we want evidence if possible to show whether non-lead paints are as good as the others?—Yes.

13,451. If you bring an illustration the first layer of which is lead it does not carry us much further?—The only thing is that the conditions are the same for the finishing coats.

13,452. Yes; but what we want to find if possible is a leadless paint. If you are going to have the first coat made of lead it opens up all sorts of difficulties, and I understand that the exhibits you have produced to us have this first layer of white lead?—Yes.

13,453. (Mr. Rice.) Have you or your firm a board prepared two or three years ago all painted with zinc white?—No, we have not that. I should have brought it if we had.

13,454. Have you had any difficulties with certain colours?—In replacing them with colours not containing lead?

13,455. Yes?—Those colours which contain orange and red lead, and which contain chrome yellows.

13,456. Are you acquainted with the test of solubility in dilute hydrochloric acid?—Yes.

13,457. Have you examined the solubility of lead chromate?—I have. Pure lead chromate will only dissolve in a proportion of 1 per cent. The various chrome yellows, so called, are not all pure chromate of lead. Some of them contain sulphate of lead; some of them contain white lead; and a few of them are pure chromate of lead. The tests which I have made show that pure chromate of lead has only a solubility of 1 per cent. Chrome yellow which contains lead sulphate is soluble to the extent of 15 per cent., and chrome yellow which contains white lead, 35 per cent. Orange lead is completely soluble and red lead is completely soluble.

13,458. A restriction to 5 per cent. of soluble lead would allow you to use considerably more than 5 per cent. of these lead chromates?—Certainly.

13,459. Would you be able to produce an equal range of colours if the use of lead compounds were restricted to not more than 5 per cent. of lead soluble in dilute hydrochloric acid?—I am satisfied that there would be no difficulty whatever in making a green paint to come within that standard. With regard to reds, of which the basis has hitherto been orange lead, I should want to experiment further, but I think that success in that direction is quite possible.

13,460. What grounds have you for giving this evidence with regard to these different colours?—What particular evidence do you refer to?

13,461. The statements you have made as to the colours you have described to us?—Evidence that greens, for instance, can be made without lead?

13,462. You have given us some exhibits of white. Have you any similar exhibits to give us with regard to colours?—No.

13,463. On what do you base your opinions then?—On actual work which we have done, and colours which we now make, which are free from lead.

13,464. Are they in constant use?—No. They have been made more or less during the last two or three years, and they have been exposed at our works, and have stood exceedingly well; and, moreover, with regard to greens, I see no reason why those should not be made as they are now, considering the fact that pure chromate of lead is only soluble to the extent of 1 per cent.

13,465. (Dr. Collis.) You state that you have no evidence on the durability of non-lead paints, but you tell us that you have been making and issuing a priming coat without lead to the Sunbeam Motor Company for years. Have they not said that it is suitable?—They gave us a testimonial a considerable time ago saying that it was perfectly satisfactory; but when you talk of durability you must remember that this lead priming paint is a priming paint, and there is no question of its wearing. It is simply used to stop the pores of the wood previous to putting on what is known as filling up.

13,466. I quite follow that, but the question of a non-lead priming coat is a very important one. It has already been introduced with regard to the question of the board which you have shown. The fact that the priming coat proved satisfactory to the Sunbeam Company is important?—It is important as regards coachbuilders' work, but I would distinguish entirely between coachbuilders' work and decorators' work.

13,467. How do you think it would answer if it was used for decorators' work in houses?—Perfectly well, I think.

13,468. On that point you have no actual experience?—No actual experience.

13,469. Have you sent out your non-lead paints to any other users?—Not to any extent.

1 November 1911.]

Mr. O. I. SMYTH.

[Continued.]

13,470. You have not had repeat orders. You have had nothing more than experimental trials?—We send small quantities to coachbuilders all over the country. I could not say how much.

13,471. Do they send repeat orders?—Yes, they repeat orders.

13,472. Do they continue with non-lead paints or do they revert to lead?—I should say not, but I could not answer that question.

13,473. Perhaps you will be able when you return to submit to us the names of other firms besides the Sunbeam Company?—With pleasure.

13,474. Especially with any note of recommendation which they have made with regard to the paints used. In the early part of your evidence in chief you spoke of not succeeding in producing certain leadless paints. Did that refer to the coloured paints?—Yes.

13,475. With regard to solubility you said you think you could succeed with greens but not with reds. Reds are your difficulty?—Yes, reds are our difficulty.

13,476. Have you any idea why the Sunbeam Company use particularly a non-lead priming coat?—Yes. They had a case of lead poisoning at their works. I went down to investigate it myself at their request, and found that it was due to the dry rubbing down of the particular priming paint they were then using. It was made from white lead. I suggested that they should have one made without lead. They agreed to the suggestion, and they have used it ever since.

13,477. Do you know what they finish their bodies with?—With all sorts of different colours, and of course with varnish.

13,478. Yes, but what do they cover the grey priming coat with?—On the top of that they would use a filler.

13,479. And then a final coat?—They would then put a coat of colour on.

13,480. Would they use a leadless colour?—They would finish their cars according to the desire of their customer. They have no fixed colours for their cars.

13,481. They are usually green, are they not?—They use a number of different colours. We ourselves supply them with a dozen different colours.

13,482. They may have a lead base?—Some of them contain lead; some do not.

13,483. Some have a zinc base, tinted?—Yes.

13,484. The greens may be tinted with chrome?—Yes.

13,485. You can get the finished product with all the colours on the top of the priming coats, with paints which do not contain more than 5 per cent. of soluble lead?—Yes.

13,486. (Chairman.) When did you go to the Sunbeam Company to investigate?—About five years ago.

13,487. Have they been using leadless paints ever since?—Yes.

13,488. (Mr. Sutherland.) Would the primer do for decorators?—We could supply it in a form suitable for decorators. It is lead colour for the coachbuilder, but we could supply it in white.

13,489. Would that do?—It would do as an undercoating for decorators, but I would not at present recommend it as a finishing coat.

13,490. Would it serve exactly the same purpose as ordinary lead priming?—Exactly the same.

13,491. If that could be established it would cut away a great deal of the difficulty, because the difficulty comes in the rubbing down of the first coat with sandpaper. Do you suggest that zinc-oxide mixed with pure linseed oil and pure turpentine would give you as good a paint for outside work as lead and oil and turpentine?—I do not consider that it would be equal in body, but I consider that it would be equal in durability.

13,492. Without any varnish?—Without any varnish. Supposing that the two were thinned up in exactly the same way, with the same materials and in the same proportion, I consider that one would be just as durable as the other.

13,493. You have no demonstration of that except that board?—That is the only demonstration. It is not considered satisfactory, but to my mind it is perfectly satisfactory.

13,494. Tests have been made in connection with the National Association of Master House-Painters. You know that?—Yes.

13,495. Five panels were painted with non-poisonous paint and one with lead?—Yes.

13,496. And the lead is the only one in point of durability that has answered the test. They are all mixed in the same way as to the medium—the oil and turps?—I may tell you also that I am so convinced as to the possibility of having durable paint made of zinc that I have had my own house done with it. It has been done for two years—the whole of the outside—and it is standing splendidly.

13,497. What did you mix the paint with?—I am not prepared to say exactly what I mixed it with, but it is mixed according to the method which we think is the right one.

13,498. But could you give the Committee the information?—I am afraid not.

13,499. (Chairman.) Is it a trade secret?—Yes.

13,500. (Mr. Sutherland.) Had that had a previous painting with white lead?—Yes.

13,501. All the testimony that we have had from experts, not master painters only, but experts like yourself, has been qualified by desiring a primer of white lead?—I do not desire it in the least.

13,502. In the case of your own house the ingredients are more than oil and turpentine, are they not?—Any house now-a-days would have a grounding of white lead. I was not going to have the whole of the outside paint taken off on purpose to put zinc on as a priming.

13,503. But your paint that you put on the outside of your house has something in it more than oil and turpentine?—Yes.

13,504. It is common knowledge to the Committee that zinc paint strengthened with a varnish is a good paint. Now, would not that add to the cost of the paint?—Yes, it would.

13,505. Can you give us any idea of the cost without giving anything away that you do not wish. Would it be 10s. a hundredweight?—No; I should think 5s. a hundredweight.

13,506. You say that the durability of paint depends on its elasticity?—Yes.

13,507. Oxide of zinc mixed with oil and turpentine is not elastic?—No.

13,508. It hardens and peels and chips, or tears off?—Yes.

13,509. It needs the addition of some medium to give it the elasticity that you laid down as a sound basis?—Yes.

13,510. (Mr. Gardner.) With regard to the medium with which the middle portion of the panel is painted, if it is not varnish it is a question whether or not it is an oil which an ordinary house-painter can get. The ordinary house-painter is not going to depart from his practice of purchasing his zinc or his material in paste form. Ready-made paint, you will admit, is no use to the ordinary painter. The ready-made paint which suits one part of the article is no good for another part, and the ready-made paint that will suit one job will not suit another job?—Yes, I see your point. I think that that could be partly got over by the paint being supplied in a partly thinned form, not completely ready for use.

13,511. That would bind the painter to one firm for his material?—Not necessarily.

13,512. I want to get something which the painter could buy in the open market?—Whether we should be prepared to supply such a medium I cannot at present say.

13,513. But unless the painter can get that medium it is no use saying, "Here is a paint which is equal to white lead paint for outside work"?—I can only give you the facts as they are.

13,514. But then you see the ordinary painter is still in the same place. He says in effect that he cannot get anything effective without white lead mixed with oil and turpentine. You say that you have found something that will obviate his difficulty?—We can supply it in this form either thinned or ready for use, or partly thinned, so that it will require nothing but the addition of a little oil and turpentine.

A a 4

1 November 1911.]

Mr. C. I. SMYTH.

[Continued.]

13,515. That does not get us over the difficulty?—If other people cannot supply it that is not my fault.

13,516. (*Mr. Gardner.*) But then you say this is a trade secret. Other people could not supply it?

13,517. (*Mr. Fell.*) I understand that you are going to supply a list of the places where it has been supplied?—Yes.

13,518. (*Mr. Mason.*) Would you consider that a zinc paint containing 36 per cent. of boiled oil and varnish, the proportions of varnish and oil being one of varnish to three of oil, would cost more than white lead?—That is a matter which I should have to calculate out. I could not tell you off-hand. Another point is that it depends entirely on what kind of varnish is used; what the price of the varnish is, and what the constituents of the varnish are. Varnish may be made of rosin, which is perfectly useless for outside work.

13,519. We are told that a paint composed of those materials will stand equally well as lead, and will not cost any more?—I say that that depends entirely on the nature and the cost of the particular varnish.

13,520. (*Mr. Sutherland.*) It hangs on that, does it not?—It hangs entirely on that.

13,521. (*Mr. Mason.*) I understood you to say that the difficulty in priming that board which you showed us with a zinc primer, was that it would take longer than lead, or rather that you said that you had not had time to prime it with zinc?—It was only on Monday that

the suggestion was made that such a board should be done. We had boards ready prepared with lead priming but not with zinc.

13,522. Did I understand you to say that you supplied the Sunbeam Company with some dozen different kinds of paints, some of which contained lead?—Yes.

13,523. Do those paints contain more than the 5 per cent. solubility?—Some of them contain very much more.

13,524. (*Mr. Sutherland.*) One of the witnesses before the Coach-painting Committee said in reply to a question, "The priming is composed of what we should otherwise pass on one side practically as useless or waste. It is the refuse Japan and varnish mixed together with a little lamp black, or white, or green, or yellow, whichever is necessary to put into it, and then thinned down with turpentine." Do you think that that would make a good priming?—I think it might.

13,525. It appeals to me as the basis of a good primer?—I think it might, but one would have to be very careful with such a mixture as that. It is not a thing which I should like to recommend. Although I would not deny that it is possible to make one in that way, there would be a want of uniformity, I am afraid.

13,526. Uniformity in results?—Yes.

The witness withdrew.

## NINETEENTH DAY.

Thursday, 9th November 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman.*)

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.

Mr. A. GARDNER.  
Mr. J. PARSONAGE.  
E. A. R. WERNER (*Acting Secretary.*)

Mr. J. O. VAUGHAN examined.

13,527. (*Chairman.*) Do you attend as a representative of the National Association of the Master House Painters and Decorators?—I do.

13,528. What is the nature of your business?—A plumber and decorator.

13,529. Where is it carried on?—At Hereford.

13,530. How long have you been concerned with house-painting work?—Over 30 years.

13,531. What is the average yearly number of painters employed by your firm?—An average of 30 to 35.

13,532. Do they all come in contact with lead?—Yes.

13,533. Have you known any cases of lead poisoning or painter's colic?—I have never to my knowledge met it with the exception of a case that came to my knowledge a fortnight ago, when one of my workmen was away from work a week. I inquired the cause of his absence, and he told me that his doctor told him he had had a touch of painter's colic.

13,534. I am very glad to hear such a good record, but I am not surprised, because, as you are doubtless aware, in the pottery industry there are a large number of works which have been immune from lead poisoning cases for many years. The trouble is that some of the best works are not immune, and, moreover, works that have been free from lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly. Now, do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—I do—only within the last two or three years.

13,535. Have the rates been raised at all?—In the last few years I believe they have.

13,536. Do you know the reason?—My own experience is that the Commercial Union Assurance Company have raised their rates generally, not for any specific cause, but a variety of causes, of which lead may, or may not, be one.

13,537. Have you known men who have broken down temporarily on account of lead absorption?—Only within the last fortnight. I worked as a journeyman painter myself for seven years, and never had illness.

13,538. Have your men had occasional days of sickness due to lead?—No, not to my knowledge.

13,539. Do you have a periodical medical examination of your men?—No.

13,540. Then is it not possible that some of them may be suffering from the slower and more insidious forms of lead poisoning without your knowledge?—It may be so, but I should not think there is one employer in a thousand who has been medically examined for that purpose. I am speaking now of master painters.

13,541. Do you take a prominent part in the work of the National Association of Master House Painters?—Yes. I am past President of the National Association of Master House Painters.

13,542. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—I cannot say that it has; I do not remember.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,543. Do you know why?—We have never feared it very much.

13,544. But you must have heard of the prevalence of lead poisoning among the men who handle lead paints?—Yes, in other trades.

13,545. Have you never seen the Board of Trade returns?—Casually; not to take an interest in them. Honestly speaking, we have never felt alarmed at this question.

13,546. But have not the Board of Trade returns shown a rather lamentable amount of sickness and illness due to lead poisoning?—Not among house painters. I have never come across it very much.

13,547. So far as you are aware, your association has never realised the danger of lead poisoning to which house painters are exposed?—Not to my knowledge. I have often discussed it with members, but it has never been, to my knowledge, actually discussed, unless it is within the last 12 or 18 months.

13,548. But do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—I should not think that a large percentage, considering the number of men engaged in the house-painting trade in Great Britain.

13,549. Look at it the other way. Supposing there had been 284 people who died from living in houses that had been painted, do not you think there would have been a great outcry in the country?—Yes, I think probably there would.

13,550. Would you not see it in leading articles in the newspapers, with heavy lines?—Yes.

13,551. Would not there be a great outcry in the country?—Well, it does not take much to make an outcry.

13,552. Do not you think that people, almost with one accord, would say, "We must not have our houses painted with lead paint. We may be among the next to die in connection with it"?—Probably they might.

13,553. Do not you think the same protection and consideration and sympathy should be given to these poor men who die from contact with lead dust, as would be extended to the general public? 284 people have died within the last 10 years because of their connection with the trade?—Yes, I will admit that what you say would probably be true, but I would qualify my answer by saying (knowing a good deal of the industry) that those men have contributed to their deaths by their dirty habits.

13,554. Then do you know that the death rates from Bright's disease and nervous diseases due to work in lead are also very high?—Is Bright's disease brought about entirely by persons using lead?

13,555. No, but Bright's disease is much more prevalent amongst house painters than among any other subjects?—I would not admit that the death rates are very high.

13,556. Then how can you account for the fact that Bright's disease is much more prevalent amongst house painters than it is amongst the general public?—The doctors say that, I suppose—or do you say that?

13,557. The Registrar General says that?—All I can say is that I am surprised to hear it; but of course that is a matter of medical science. I can only express my surprise to hear it.

13,558. I want to show you the evils that result from connection with lead?—Take the average man that we see painting railway stations. You can see almost every colour of the rainbow on his coat as he works. It is not the man that will come into your house, and paint your drawing room that will get it. It is the man who daubs himself all over with paint as he uses it.

13,559. Are you sure of this statement you are making?—I am only telling you what comes under my own notice.

13,560. But how do you know that those men who get paint on their aprons and overalls suffer from lead poisoning?—Those are the type of men one would assume. They get it on their hands.

13,561. Is it only an assumption of yours?—Yes.

13,562. Then why do you state what you do not know? You must not make such statements here?—

I qualify it by saying that the only case of lead poisoning I have seen occurred a fortnight ago with the dirtiest man in our employment, a man whom we have cautioned about getting paint on his coat and hands.

13,563. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the last 10 years?—No.

13,564. Do you realise that these cases, reported voluntarily, are only a fraction of the whole; inasmuch as the Home Office has no legal right to pay for such reports, and is therefore bound to discourage reporting to some extent?—Are those reports sent by the trade societies?

13,565. No, by the medical practitioners of the country. You had not realised the state of things that I have put to you?—No.

13,566. Have you seen a copy of the "Board of Trade Labour Gazette," which was published in the middle of last month?—I never see that paper.

13,567. The table on page 187 of that issue shows a definite increase in the deaths from lead poisoning amongst painters as follows:—38 deaths in the first nine months of this year, as against 30 deaths in the first nine months of last year. So that it is an increase?—Does it always increase like that? It may be a peculiarity of one year.

13,568. I am only giving you a comparison between this year and last year?—But it may not be every year the same—a continual increase. It may be only a peculiarity of one year, as I say.

13,569. (*Dr. Collis.*) It is above the average for 10 years. It has not been steadily on the increase for 10 years, but there has been no diminution, and a diminution has been occurring in other industries with regard to lead poisoning?—I see.

13,570. (*Chairman.*) If the proportion of deaths to the attacks is the same in the painting industry as in other industries where lead is used, the total number of attacks in the house-painting must be between 9,000 and 10,000 in the 10 years?—Well, when you take those figures you want to give on the other side the number of people that are employed in the industry. It does seem alarming, but, on the other hand, many thousands of men are engaged.

13,571. It is alarming, but you think it might be minimised by the number of people occupied?—Yes; there must be hundreds of thousands of house painters in the kingdom.

(*Mr. Sutherland.*) We calculate that there are about 250,000 painters in Great Britain.

13,572. (*Chairman.*) Would you be surprised to hear that the total number of deaths amongst house painters has been for several years greater than among all other lead industries taken together?—I am very much surprised to hear it.

13,573. And that the men's society's figures are quite as bad as the Registrar General's records; yet the society takes no painters' labourers, railway men, or the like as members—only *bona fide* painters. I am sure you would agree with me that all this sickness and death is very deplorable?—I do.

13,574. Do not you know that this deplorable evil has attracted the most careful attention in many foreign countries?—In France it has.

13,575. Do not you think that it is regrettable that this country should be behind other nations in this respect?—Yes.

13,576. Are you here to answer questions in connection with the details of painting work and the processes?—I will answer any question that you put to me if I can.

13,577. I suppose you attach much importance to personal cleanliness on the part of the men?—I do. I think it is the crux of the question.

13,578. Do you consider lavatory accommodation essential?—I do.

13,579. Is it generally practicable for the men to have lavatory accommodation?—No, only of a rough and ready type. In every painter's workshop washing accommodation is provided of a type, but I should not call it all that may be desired.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,580. For instance, is it always possible for the men to get hot water?—No, it is not, without going to some trouble.

13,581. Do you mean that they can get it at some place near where they are working? Although an employer may place every facility for them to boil the water, it is a hundred to one that they will not trouble to do it. I do not know that I have ever seen a man in a painter's workshop boil water to wash his hands.

13,582. I am not speaking of the painter's workshop, but of what happens when men are on a job?—They may go and beg a can of hot water where they may be working, but there are no other facilities generally.

13,583. You say that it would be difficult for the men to get hot water?—I do not think it would if it was compulsory.

13,584. You said just now they may go and beg for hot water. Supposing it was refused, how would they get it then?—They would not trouble to wash themselves until they got home.

13,585. So it is not always practicable to get hot water?—No, it is not.

13,586. (Mr. Rice.) I understood you to say that there is a disinclination on the part of the men to get hot water as well as difficulty?—Yes. I have seen men sitting down and eating their midday meal without washing their hands, hundreds of times—and plumbers more than painters.

13,587. (Chairman.) Then with regard to clean towels and so on, and nail brushes, are they always provided?—No—very rarely.

13,588. Supposing that we made a rule that the men were to have hot water provided, and a proper number of towels, nail brushes, soap, and so on, could they be provided?—Yes.

13,589. How would you enforce it?—I would make it compulsory for every employer or employee to provide them.

13,590. I am not speaking about the employee, but about the employer?—I would make it compulsory.

13,591. But how would you enforce it?—Most employers, if it was known, would do it.

13,592. Would tell somebody to do it?—I would make it an offence if it was not done.

13,593. How are we going to enforce such provision?—I do not see any difficulty.

13,594. But how would you suggest we should do it?—If it was an Act of Parliament, I would make it an indictable offence, and take a man before a magistrate.

13,595. But how is the Home Office to know that every painter working in country places and single rooms, in large places and so on all over the country, is going to have hot water, clean towels, soap and nail brushes provided?—The only way that appears to me possible now is to arm local policemen with authority to go to see. I would put it in the hands of the police.

13,596. (Mr. Sutherland.) You had better not suggest that?—I do suggest it—unless you pay a staff of inspectors to go about the country and make surprise visits, the same as you do under the Factory and Workshops Act.

13,597. (Chairman.) It would be impossible to provide sufficiently trained men to do the work?—Then the only person, on the spur of the moment that appeals to me as the likely man, is the sanitary inspector or the Inland Revenue officer who is knocking about in the country. He could make surprise visits. Take a man, for instance, who goes about looking after breweries.

13,598. You say there are hundreds of thousands of house painters working all over the country. Accepting that as the case, is it practicable to have those men inspected to ascertain whether they are having hot water provided for them, and that they have a proper number of towels and soap and nail brushes?—I say, if there was an Act of Parliament that it should be done, and it was known, employers themselves would see it done. I would go further than that, and make it an indictable offence if it was not.

13,599. But how are the employers to see that it is carried out?—Easily enough.

13,600. If it is so easy, tell us how?—If it was my duty to send a certain number of towels to a particular place where I had men at work, it would be the duty of the yard man every Monday morning to see that they were sent, and it would be the duty of the foreman to see that he had soap and towels and nail brushes on the premises. It may seem a peculiar regulation to make, but if it was the law of the land it would have to be carried out.

13,601. But how are the Home Office to know that it is carried out?—By finding out.

13,602. Yes, but how?—Although it would be an annoying thing, arm the police with authority. I do not see any other way out of it. I quite appreciate your difficulty.

13,603. I want you to appreciate that?—I can quite see that it would not be impossible to do it in large towns. It would be necessary to have a highly paid man under the Act of Parliament. In a place like Manchester or Liverpool you might have three or four men whose duty it would be to take a certain part and make surprise visits wherever they saw a painter's ladder or painter's steps.

13,604. Do you know how many factories and workshops there are in the country to-day that are inspected?—I do not.

13,605. There are a quarter of a million factories and workshops to be inspected every year, and only 200 factory inspectors to do it. You are going to multiply this quarter of a million indefinitely?—To take your argument, after all is said and done, it would not cost much, supposing you increased the staff of the factory inspector by an additional sub-inspector for so many districts.

13,606. This point is very important. You come up and tell us that this can be done, but the Committee will have to deliberate one of these days to see how it is to be done. I have told you the number of factories and workshops that the 200 factory inspectors have to inspect to-day. How would you suggest that the Home Office are to know for a certainty that hot water, towels, and soap, and so on, were provided for the workmen?—The only answer I can give to your question is by a system of surprise visits by someone.

13,607. But how many painters are there at work over the country approximately?—I cannot tell you. Mr. Sutherland said 250,000.

13,608. But you said just now hundreds of thousands. You did not mean that?—There are approximately between 200,000 and 300,000; so there are hundreds of thousands. There are two or three hundred thousand. I only guess it; I do not know. You said there were between 9,000 and 10,000 cases of lead poisoning, but when you compare that with the hundreds of thousands of painters there may be in the kingdom, the percentage is not so great.

13,609. Then you say hundreds of thousands? How many men do you think would be required to inspect these hundreds of thousands of painters all over the country?—Not so many. I would like to qualify what I say, so that my reply shall not appear ridiculous. I understand that England is divided for the purposes of the Factory Act into districts. The district in which I live, which embraces Herefordshire and Worcestershire, is worked by an inspector of factories and a sub-inspector of factories. That is two counties by two men. I can quite imagine that other sub-inspectors, 150l. a year men, say, could be spread out through England. If the sub-inspector was under the control of the Inspectors of Factories for the different counties, it would not be such an alarming cost after all.

13,610. How many of these hundreds of thousands of painters do you think these few sub-inspectors could inspect?—It is not the number of inspections. It is dropping on people unexpectedly. If a man came once in six months, and we never knew when he was likely to come, that would answer the purpose.

13,611. You do not seriously think it is possible, with that handful of sub-inspectors, to be certain that

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

this very important rule would be carried out?—Yes, if you make it a vital point.

13,612. (*Dr. Collis.*) In what way is an inspector to know where he is to go to? In regard to factories and workshops, they know the absolute place. Factories and workshops do not walk about. But how is the inspector to go into this room and that room, now in the attic, now on the ground floor, and now in the conservatory? How is a factory inspector to know when he passes the outside of a house that the gentleman is having his conservatory painted? The gentleman will certainly resent a visit to find out whether his stables or conservatory are being painted?—I admit all those difficulties.

13,613. Every single place undertaken by a painter becomes a new factory and a new workshop for the time being. Sometimes you put 10 men on a piece of work, and three days later there is only one man left to keep the place warm. Nine men are taken to start another piece of work. Every householder knows that. How is the inspector to have any means of seeing that the regulations are carried out?—My answer to that is this: I cannot assume that the master painters are going to say, "We will not comply with the order." I imagine that if you issue an order making it compulsory for every master painter to provide these facilities for the workmen, the master painters, knowing that that is the law, will comply with it.

13,614. If you see the number of prosecutions that take place every year, you will get some idea of the amount of breach of the law?—That may be through ignorance.

13,615. The Factory Act and the regulations show exactly what a man has to do. He cannot plead ignorance?—I am with you entirely.

13,616. But how can the regulations be enforced?—You are dealing with an article which to my mind, up to now, for certain purposes you have not found an alternative for. In connection with that, if I take up the point that I cannot find anything else but lead to use on the outside of a building, you want some scheme which you can enforce upon the persons using that article which cannot very well be done without. I am putting it in that way. Therefore a painter is bound to use lead from my point of view on the outside of the building.

13,617. We are not disputing that point, but how can the regulation be carried out? That is what we are asking?—I want to make a point which I do not think I have made, but perhaps I can make it later.

13,618. How can what you suggest be carried out?—I have not thought the matter out, but I have told you to the best of my ability how what I suggest can be carried out.

13,619. You see some of the difficulties?—I quite admit the difficulties that the Chairman has put. I have seen those all the way through.

13,620. (*Mr. Sutherland.*) I will mention a system that obtains in Manchester, which points to a solution something like what you suggest. The Operatives' Society have what they call a walking delegate—he has been before this Committee—Mr. Frank Lowe—and his duty is to walk about from job to job, painters jobs, to see that there is no infraction of the working rules between the employer and the man. Now, if that can be effected in a large area with one man without any Government official, I think the oversight of these jobs could be met by a Government inspector, and the force of public opinion, if prosecution occurs, would soon do what you suggest?—Yes.

13,621. (*Chairman.*) I am not satisfied. As far as I can see, it is impossible to be quite sure that the Home Office Order would be observed?—Speaking on behalf of the body that I happen to be a member of, I say that they would faithfully carry out any system.

13,622. (*Mr. Sutherland.*) You are speaking of the National Association?—Yes; they would do anything they could.

13,623. (*Chairman.*) No doubt you are saying what you believe, but the experience of the Home Office is that, with a system of inspection, people are continually found breaking the rules. To leave the industry to the haphazard inspection of a few sub-

inspectors would be impossible. Now, do your painters wear overalls?—Yes, generally.

13,624. Do you supply them?—No.

13,625. Would you object to a rule that overalls are to be provided and maintained by the employer, as is prescribed in other lead industries?—If we had to do it I do not think I should object, although I should think that it was not my duty.

13,626. Do you know how often the overalls that are in use now are washed?—Weekly. If a man came with dirty overalls I should object.

13,627. Would you be prepared to arrange for the overalls to be washed at your expense, as is done in other industries where lead is used?—Yes, certainly.

13,628. It is insisted in other industries that lead workers should not take overalls home to be washed, owing to the danger that that involves. Do you understand that?—I follow your question.

13,629. Where can the overalls be kept from day to day when men are working continuously on one job?—That would have to be arranged. Each job would be dealt with on its merits. If you drew up a regulation that they were not to be kept on the job, they would have to be kept off it somewhere or other.

13,630. Can you always provide a place for the workman to hang up his coat when there will be no risk of dust falling on it?—Yes.

13,631. Where would you do it?—In my own particular case, when we are working on a house where there are no facilities for a workshop and a mess room, we provide them. We have portable workshops and portable mess rooms.

13,632. Is that the custom of the trade?—No, it is not the custom of the trade.

13,633. I am not speaking of your plan, but of places where it is not the custom?—Putting myself in the position of a foreman painter, I can hardly imagine his going on to a job and not finding some place or other.

13,634. Other witnesses have told us that very often the men have to hang their coats in the rooms where they work?—They generally hang them in the paint shop. To be perfectly accurate, I often see my workmen's coats hanging in the place where they mix their paints. That is more from carelessness than anything else.

13,635. I know, but you would want half a dozen inspectors for your own firm to point out to the men their carelessness?—The same thing applies all over the trade.

13,636. But that is the danger?—The danger is not appreciated by the workmen.

13,637. But can you always provide a place for the workmen to hang their coats up, so as to be free from any connection with the dust?—In my own case I find no difficulty.

13,638. I accept your case, but in other cases would it always be possible?—Not always. Take the West End of London. I worked for six years there, and I know that there is no difficulty existing there, but if you asked me the same question with regard to the East End of London, I should say there would be difficulty.

13,639. But would it not be practically impossible to be sure that such a regulation was carried out?—I think it would practically.

13,640. Do you advocate also a rule regarding meal rooms, so that no man shall eat his food in the place where paint is being handled?—I do not advocate it, but no doubt it would be a very good thing to advocate. I have never done such a thing.

13,641. Do you not think it essential that the men should not be allowed to eat their food in any room where paint is being used?—I agree with you.

13,642. Can you always provide a place quite free from risk of contamination where the painter may leave his food during his working hours?—No.

13,643. All these precautions and others as well are insisted on for the mitigation of lead poisoning risks in potteries. You have told us that in some instances it would be extremely difficult faithfully to carry out special rules?—Yes, but if it was an enactment that it should be done we should do it.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,644. You say that, but I come back to my old original question, How are we going to be quite sure?—I can only answer the same as I answered before with regard to enforcing it.

13,645. Now there are certain other risks which the painter has to face in connection with his work; first, as regards the dry rubbing down with sandpaper. I understand that this process is indispensable?—Not so much in our trade as in other trades.

13,646. Is it generally indispensable in the trade?—I will give you my own experience.

13,647. But cannot you tell me whether dry rubbing down is indispensable or not?—It is not indispensable.

13,648. Then I understand it could be dispensed with?—I am speaking of house painters, not of coach painters. I say that pumice stone and water, if used instead of sandpaper, would turn out better work, and would not be so dangerous to the painters employed.

13,649. (Mr. Parsonsage.) But painters do not like putting their hands in water?—That is the painter's fault.

13,650. (Chairman.) Would you agree that in no instances dry rubbing down should be permitted?—It could be done without if you enforced it.

13,651. What would you say with regard to new paint after the first coat?—I would rub it down with pumice stone instead of glass-paper.

13,652. Is that possible?—Yes.

13,653. You are the first witness who has told us that?—I am assuming now that you prohibit our using glass-paper.

13,654. How long would it take for the first coat to dry?—You can make paint to dry as quickly as you like. You could use rotten stone; you could use lots of things. For the purpose of my argument I am assuming that you prohibit the use of glass-paper.

13,655. Would you get up at a meeting of your Association and tell your brother members that you would agree to the prohibition of dry rubbing down in every instance?—Yes, if you say so.

13,656. It is not a question of my opinion, but would you say it was possible to do it?—What I wish you to understand is this: that you are not absolutely compelled to use glass-paper to rub down paint at any period.

13,657. Not after the first coat?—Not after the first coat, or second, or third coat. You can use rotten stone or felt if you are compelled to do so. I am assuming that you take away glass-paper. I am not saying what you use.

13,658. I must leave this then to the other members of the Committee to ask you about. I ask you if it is possible to dispense with dry rubbing down?—I say yes.

13,659. Now I want to ask you some questions with regard to the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the back-ground of the ornamental work, has it not?—Yes.

13,660. This gives rise to splashes, which must frequently fall even on the face of the worker?—Yes, that is so.

13,661. How can you deal with the splashes which arise in this operation?—I cannot deal with it. I do not know of anything on the spur of the moment that you could do except covering a man's face up.

13,662. Do not precisely the same considerations apply to the process of stippling?—No, not to stippling.

13,663. Why?—Because the paint is already on when you stipple.

13,664. But the motion of stippling causes splashes?—There is not much splashing; there may be a little.

13,665. You could not get rid of that?—No, you could not do anything there.

13,666. Would not the stippler be likely to be splashed by the painter who was painting alongside him?—You see it is usual to paint a patch and then stipple.

13,667. I have seen them painting and stippling at the same time?—I do not think there is anything very serious in it.

13,668. But the great evil of this lead poisoning is the multiplicity of small dangers, and the small amount of lead painters may get from stippling, the small amount from something else, and the small amount they may get from eating their food with dirty hands, and all the rest of it, make up a big evil; so we have to take every operation singly?—There is not half the seriousness in the stippling that there is in putting the paint on; but it is a point.

13,669. Whatever evil there is in it, you cannot suggest a remedy?—No.

13,670. Do you have the old paint burnt off with a spirit or charcoal burner?—With spirit always—petrol.

13,671. Are there certain fumes arises from that operation?—Yes.

13,671a. How can you prevent the worker from inhaling the fumes which arise from this process?—You could prevent it, but we do not. No doubt it could be done by respirators or something of the sort, but it is not done.

13,672. Is that seriously the only suggestion you can make?—I do not make it seriously.

13,673. Other witnesses have said that it is impossible?—I do not say that.

13,674. What do you suggest?—The same precaution as they use in lead works when a man is taking lead out from the stack.

13,675. A respirator?—Yes.

13,676. It appears from your evidence, then, that there are certain indispensable processes in carrying out which, a painter must necessarily inhale some dust, spray or fumes containing lead. How are these dangers to be met?—I cannot tell you on the spur of the moment.

13,677. Is it possible to remove those dangers entirely, in any other way than by using a substitute for lead?—You may mitigate them, but you will not prevent them entirely.

13,678. Have you tried any non-poisonous substitutes for lead?—Pretty nearly everything that has been produced.

13,679. What results did you obtain?—I have never been able to find any paint yet that has not had lead for its basis that will stand outside wear, or wear on such places inside as a sash or a window.

13,679a. A representative of His Majesty's Office of Works has been before the Committee and has told us that they have been making experiments for the last 10 years, and that for the last five or six years they have been using a substitute for lead which they assert is entirely satisfactory. Does that weigh with you at all?—I should be very glad to know what it is. I do not do painting for the Office of Works.

13,680. Would you consider that if the Office of Works gave up the use of lead entirely that would have great weight with your Association?—I should think so. It would have with me personally. I would not buy lead if I could get something else as good.

13,681. If the Office of Works can abandon the use of lead?—Then other people ought to be able to do the same.

13,682. What are the usual hours worked by your painters?—Ten in the summer.

13,683. How many a week?—56½.

13,684. Would you agree to a limitation of the hours of employment say from 48 hours per week;—Yes, I would do so with pleasure.

13,685. Would your Association agree to that?—I do not know.

13,686. Paying the same wages for 48 hours as for 56½?—That alters it. Would you give me the question again?

13,687. The question is this: Would you agree to a strict limitation of the hours of employment, say to 48 hours per week, as was recommended by the Departmental Committee that sat on the pottery industry?—I cannot see that it would make very much difference to me if everyone else had to do the same, and therefore I would agree. If every other employer had to do the same, I should not object.

13,688. You have told us that you do not have a periodical examination of your workers?—Yes.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,689. Do you know that in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—Yes, I know that that does exist.

13,690. Would you agree to a rule of that kind?—Certainly I would.

13,691. And to pay for the cost of it?—Yes, if it was compulsory, and everyone had to do the same.

13,692. Would you agree to pay compensation to a workman who was suspended because the certifying surgeon thought that he might contract lead poisoning if he continued in his work—paying the workman half wages during the time of his suspension?—That opens up the question of further insurance. You see we cover ourselves from everything of that sort.

13,693. No, not against that?—No, but if that was enforced we should have to cover ourselves. We should have to insure. We could not individually do it; it would be such a drain on the finances of the ordinary man in business, and the risk would be so great. I would like to answer that question by asking another.

13,694. Yes?—Do the potteries insure.

13,695. Other work is found by the employer, or he compensates the workman during the time of his suspension?—I follow.

13,696. Now you understand that if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures in the same way as in other industries where the workers handle lead?—Yes.

13,697. And they will have to be quite sure that these rules are carried out?—Yes.

13,698. Taking all these points into consideration, would you say that you prefer that the industry should be regulated by these special rules, or that the use of lead should be prohibited or very closely restricted?—Well, if science would provide us with some other medium in place of lead, master painters would not use lead on account of the irritating conditions suggested by the Home Office.

13,699. Not suggested by the Home Office; suggested by this Committee. I must ask you to give me another answer than that. Science, I understand, according to you, has not provided a substitute?—I have not been able to find one.

13,700. Supposing that in your view a substitute has not been found, which would you prefer, regulation, or prohibition, or very close restriction?—I should say that if a substitute for lead has not been found, then for the benefit of my customers I must use lead.

13,701. But which would you prefer. I have given you an idea of what these special precautionary measures would be, and I ask you which would you prefer, that the industry should be regulated by these special rules, or that lead should be prohibited or very closely restricted?—I should prefer that lead should be regulated. I should like to give my answer. It will not take a minute. From exhaustive experiments I have made on my own property, and inside my own house, I have found a substitute for lead for all interior work that will last, with the exception of windows. I have not yet found a substitute for white lead that will stand the climate as an exterior paint on woodwork.

13,702. But that is not my point. The point is this: if the Committee agree to the prohibition of lead, all house painters will be in precisely the same position?—Yes, absolutely.

13,703. I must tell you that the majority of the house painters who have been before us in answer to the question I have put to you have said that they prefer prohibition to special rules; they have seen the question in such a comprehensive way that they have realized that it would be impossible to enforce these special rules?—I do not want you to think that what I have said has been said in a spirit of hostility. I am with you heart and soul if you can provide something else. Painters do not want to use white lead.

13,704. But it is not for us to provide that. The position of the Home Office is this: that other industries where lead is allowed to be used have come under their cognizance. Now the house-painting industry has been left alone until the present time; now, however, it is clearly imperative that they should

consider how to level this industry up with the rest?—I understand.

13,705. So it comes to this; either that special rules will have to be provided to protect the workers, or lead will have to be prohibited. You have told us, and so have most of the master painters, that there are certain dangers which workmen undergo which you cannot meet under any circumstances. You have not told us how precautionary measures can be enforced, and so when we review the evidence of the master house painters, this Committee may come to the conclusion that as you suggest no remedies for some of the evils, and as you can suggest no proper inspection for others, there may be no alternative but to recommend that lead should be prohibited?—We have never been asked to suggest anything.

(Chairman.) But you have said that regulations could not be enforced, and so also have your brother members.

13,706. (Dr. Collis.) The point after all works out to a matter of pound, shillings, and pence to the person who has his house painted?—It does.

13,707. I want to get a comparison of the cost?—If you are going to work shorter hours, and give the same pay, you will have to charge more for doing the work?—Yes.

13,708. If you have to have your men medically examined and pay the doctor, you will have to charge more for doing the work?—Yes.

13,709. If dry rubbing down is to be abolished, and the work is to stand longer to dry, it will cost more, and you will have to charge more?—That depends on circumstances.

13,710. In the majority of cases?—No. If you had only one room to paint, it might cost more. If you had 100, it would make no difference, or if you had half a dozen it would make no difference.

13,711. Does not wet rubbing down make a difference in cost?—I should not consider that a serious point at all. It is more costly, but it produces better work.

13,712. In other words, you would have to charge the person more?—Yes.

13,713. If you had to pay increased compensation again, you would have to allow for that in your charges for the work?—I am sorry to say that we do not, but we ought.

13,714. But you would have to, under the suggestion of increase of compensation that the Chairman puts before you?—The Insurance Companies' rates have been increased so much the last two or three years that we have had to pay a lot more, but I am afraid the spirit of competition has prevented us from charging our customers any more.

13,715. There comes a point when you do not work for nothing?—We try not to, but sometimes we have to.

13,716. It finally comes back on the customer's head?—I cannot say that it does not, although I do not say that it does.

13,717. Now, with regard to non-lead paint, you have not succeeded with it in every case, especially with regard to outside painting. Now let us consider the position of the man who has his house painted. I presume that the substitutes which have failed have not failed at the end of the first day, but have failed to protect the woodwork in the way that it would have been protected if painted with lead. That means repainting sooner?—In the West of England a man usually expects to paint his house once in three or four years outside; generally, let us say, once in three years. With any other paint except white lead you would have to do it once in two years, I should think.

13,718. That is for the outside woodwork?—Yes.

13,719. Now, having set up all the machinery which has been suggested, if the free use of lead is allowed to continue, would it not possibly be exactly as costly to the man who possesses the house that is painted, as painting the house once in two years instead of in three?—Yes.

13,720. When you have set up the machinery, a vital point to consider with regard to the protection of the worker is, how will you insure that the regulations are carried out? Perfect inspection is necessary to

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

insure that all the regulations are accurately carried out, and what is that going to cost? So that it may be that the house owner is going to pay exactly as much, and his shoulders will have to bear as big a burden if lead continues and the regulations are put in force as if it was prohibited, and the outside of the house has to be painted oftener. In one case the worker has safety, and in the other case he has not. After all, it comes to the pounds, shillings, and pence point of view. Have you looked at it from that point of view?—There is not much in it.

13,721. Then we come back to the question of the protection of the worker pure and simple, which is insured in one case and remains a risk in the other?—I am with you. I think you are very nearly right.

13,722. Everyone would be on the same basis?—The only weak spot is the spirit of competition.

13,723. But that is keen to-day, and it will be no keener if you do not use lead?—We have in our trade what does not exist in many trades; that is the small employer. I hope that all employers would carry out anything issued from this office, but it is the small employer who cuts down the prices by competition, and the large employer naturally does not like to lose his customers, and he cuts as well, and the result is that the customer, although he ought to pay, does not.

13,724. But there would be no difference in competition in the future?—No.

13,725. You are not faced with fresh competition from abroad, for instance?—No.

13,726. There is the possibility that in the increased use of paints not containing lead human ingenuity may find a very perfect substitute. I do not say it will. Do you not think it is probable that this ingenuity is more likely to come into play when it is called upon to provide such a substitute?—I should think it would.

13,727. So that it may be that the house owner may have to paint his house more frequently to obtain the same protection for ten years, but at the end of that time human ingenuity may have brought about fresh improvements through the extra expense of finding the substitute; while if no substitute is found and the regulations are enforced he will have to bear for all time the same expense?—Up to now human ingenuity has not provided a substitute.

13,728. Human ingenuity does not produce a substitute when there is nothing to call for it and it is not necessary. Unless the thing is going to be materially cheaper it will not have a chance in the market. You will go on with what you are accustomed to, unless the new article is considerably cheaper and produces the same effects?—Yes.

13,729. (Mr. Parsonage.) You say that in the West End of London there would be no difficulty in a man having a room in which to keep his clothes?—When I worked in London that was my experience. I do not know how it is now.

13,730. Supposing you have a drawing room to do, and have to go up a ladder to it, and are not allowed to get into the house?—Could you not go into the basement?

13,731. Supposing you are not allowed?—That is probably an isolated case.

13,732. It is done regularly?—I worked for Trollope's between six and seven years, and never met a case like that.

13,733. I have met hundreds. I suppose you adhere to your answers in regard to dry rubbing down?—Do you differ with the views I expressed?

13,734. Yes, so far as concerns sufficient time being allowed for work to dry between each coat?—How about the old days of hand polishing, which painters do not do now? They used to have to do it then.

13,735. (Mr. Gardner.) How long did it stand?—It stood for years.

13,736. But before it was rubbed down, I mean?—Days, probably. I am assuming that regulation prohibits the use of glass paper, and I stick to what I say, that if that was prohibited I would use pumice stone, or rotten stone, or something which would answer the purpose.

13,737. Allowing sufficient time between each coat for the work to dry?—Yes, of course, allowing for sufficient time.

13,738. (Chairman.) Would it be practicable to allow sufficient time?—Not if you were only doing a single room.

13,739. I ask you again, then, would you recommend the prohibition of dry rubbing down?—Yes, because I would tell the customer who would not give me time that under the existing circumstances he must not complain if the work were not as smooth as it ought to be.

13,740. (Mr. Parsonage.) Dry rubbing down would be stopped, but nothing else would be substituted for it, and the work would be finished in a worse condition. That is what it means?—Yes.

13,741. (Chairman.) That would be preferable to using zinc white?—I did not say that.

13,742. That is the deduction?—I am dealing with lead, not with zinc.

13,743. (Mr. Gardner.) I understand that you have been astonished to be told to-day that there is so much lead poisoning among painters?—I have.

13,744. And that you attribute it almost wholly to the dirty habits of the workmen?—I did not say that.

13,745. I beg your pardon; I thought you did?—I said in a measure, and I illustrate it by referring to the railway painter as against the house painter.

13,746. But all these men who have suffered from lead poisoning have not been unskilled painters. I take that part of your evidence to mean that you think that untrained and unskilled workmen should not be allowed to play with paint. You probably consider the railway painter an unskilled man?—I had not that in my mind, but now you put it into my mind I will say, and I think you will agree probably, that the ranks of painters, such as railway painters, are filled up from people who have been in casual employment, soldiers, for instance. They drift into the painting trade, not through any proper apprenticeship system. They are first rough painters, engaged in painting rough structures, such as railway stations. But when I made that answer that did not influence me.

13,747. In Scotland railway painters are apprenticed?—The system of apprenticeship, as you have it in Scotland, unfortunately does not exist in England.

13,748. In Scotland the incidence of lead poisoning has not been quite so great as it has been in the southern part of the country. In Scotland lead poisoning is not so bad as in England. Of the males engaged in all industrial occupations in Scotland, the deaths from lead poisoning are one per annum in every 397,000, but painters' deaths from lead poisoning are one in less than 9,000. Is not that somewhat serious?—Yes, it is.

13,749. Then again, if the apprenticeship system is in vogue so much in our part of the country, and lead poisoning is largely due to the dirty habits of the workmen, what have the employers done to train their apprentices in habits of cleanliness, and what have they done in order to provide facilities for the men keeping themselves clean while at work. That applies to the whole country?—I know it does, but I cannot associate Scotland and England together in the painting trade.

13,750. I will take England alone. How have the master painters in England trained the apprentices in habits of cleanliness, and what facilities have they given them to keep themselves clean while at work?—As a rule we do not take apprentices in England.

13,751. (Mr. Parsonage.) That is wrong altogether. You are speaking for Hereford?—I am speaking for the West of England.

13,752. I can give you scores of towns where it exists?—I say the apprenticeship system does not exist in England to the same extent as it does in Scotland by any means.

13,753. (Mr. Gardner.) Then how is the trade recruited?—The boy is at the trade, but he is not apprenticed.

13,754. He is an apprentice, although he is not indentured?—You may call him one.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,755. They are not indentured in Scotland; although they are apprentices. Then again, during a number of years, there have been quite a large number of non-lead paints or distempers put upon the market which are very largely used?—Very largely: I use tons of them.

13,756. Then how can you account for the increase in the number of cases of lead poisoning if lead has been much less used?—I do not think these distempers that you are referring to or articles with a basis of zinc in them have been used in proportion to the amount of lead that is used. The proportion is not great. If you were to put the number of tons of lead consumed in this country, and the number of tons of these compounds together the proportion would not be large.

13,757. Is a zinc compound advocated largely for the painting of walls and in many cases of wood?—My own experience has taught me that it is better.

13,758. It is displacing lead?—It is. I used to buy ten tons of white lead a year, and I do not buy more than five now.

13,759. You said that white lead could not be done without?—I said I had not found that it could.

13,760. A master painter here told us that in his opinion white lead could not be done without; he went away; he made enquiry and he came back, and he sent in word that he retracted. He recanted and said that white lead could be done without. Do you not think it is a question of the master painters not having experimented and tried what could be done with the leadless paints?—I would say that not only master painters but the War Office have not. I have done a great deal of work for the War Office, and they paint their barracks with lead paint.

13,761. (*Dr. Collis*.) But that is not applicable. We are a Government Department that is considering the point now for the War Office and every other Government Department?—But this gentleman is blaming the master painters for not having found out a substitute for white lead, and I say we are not wholly to blame. Not only has the master painter not found it out, but the War Office is a sinner.

13,762. (*Chairman*.) They themselves do not paint?—No, but they specify lead. I want to point out that we are not the only sinners.

13,763. (*Mr. Gardner*.) You expect your customer to experiment for you?—No.

(*Chairman*.) That is the point.

13,764. (*Mr. Gardner*.) The War Office give you a job. Is it not the duty of master painters as an organised body to say, if they specify a certain thing which is dangerous to the workmen "You are quite wrong. This other material is very much better for the purpose, besides which it is not dangerous to the workmen"?—I do not know that other material.

13,765. You have not found it out?—I have not found it out. I am not a chemist.

13,766. Should not the employers as an organised body try to set their house in order and find out what is necessary for the purpose?—I have tried to do that, and I have discovered a material that will answer my purpose and my customers' purpose, to a certain extent, but I have not discovered anything that I can recommend for outside woodwork.

13,767. Then you are astonished at what I told you the master painter came back and said?—I do not know. The Office of Works have only experimented for four years I understand.

13,768. (*Chairman*.) Nine or ten years. They have had the substitute in use for the last five or six years?—That is what I mean. It is not a very long time. Still, if they have used it for five or six years, and are satisfied with the result, then that ought to be good enough for anybody else.

13,769. (*Mr. Gardner*.) My point is, that once the master painters began to make serious enquiry into the subject, they could find out if lead paint could be done without?—I do not see that master painters as a body should try to push a dangerous article, unless it is for the benefit of their employers. If any customer will let me use zinc on the outside of his house, I will not grumble at him, because it will want doing again in

two years. I do not mind because I shall have a job oftener.

13,770. But that is not the point. A master painter told us that white lead could not be done without, and he went away and enquired, and sent us word: "I am now convinced that lead can be done without." Does not that show that sufficient enquiry has not been made by master painters?—Probably. I will not admit it, but I will not dispute it.

13,771. With regard to polishing down work, have you ever tried sandpaper saturated with oil or with turpentine?—I have never tried it, but I have heard of it.

13,772. You have never tried it as a matter of practical experience?—No.

13,773. (*Mr. Sutherland*.) You would not attach much importance to the judgment of a man who comes in at five o'clock, and says there is no substitute for white lead, and at half-past five sends in a note to say that he has discovered one?—No.

13,774. It is sudden conversion, is it not?—Yes.

13,775. No real value can be attached to it?—No.

(*Chairman*.) He spent a week end in investigating it, and after having made enquiries, he was convinced that he had found a substitute.

13,776. (*Mr. Sutherland*.) Now you do not think that the National Association has been negligent of its duty in reference to this question?—I do not think that the house painting trade of England has appreciated the seriousness of the figures that have been produced to-day. I have not appreciated it.

13,777. The Board of Trade Returns are more interesting to statisticians than to anybody else?—The man in the street scarcely ever looks at them.

13,778. You have had the opportunity in a trade journal in the last six months of seeing the figures. I will not name the journal. How is it you have not read them?—I said in my evidence that within the last year or so I have seen the figures, but I do not consider them alarming.

13,779. Would you think the mortality statistics of mining and railways sufficient cause to abolish railway travelling or mining operations?—I do not think that that has anything to do with it. I do not think that that point applies.

13,780. The point of the question is that in the opinion of a large number of people, you have not a substitute for white lead that will give the protection that white lead gives to property?—If this committee instructed someone in their employ to carry out tests, I will undertake to say, that if you painted five pieces of wood and exposed them to the atmosphere, one painted with white lead and the others with various other materials, at the expiration of twelve months the piece of wood painted with white lead that had been exposed to the atmosphere would, if judged by practical men, be found to have stood the test far better than anything else.

13,781. You made a distinction between railway painters and painters engaged on big public works which are of a dirty nature, particularly railway stations, and the ordinary house painter?—I said that for this reason: that taking the number of deaths or the number of cases of lead poisoning, if they were divided between the ordinary house painter and the railway painter or the ship painter, it would be more accurate, before condemning the house painter, to prove that it is the house painter who gets poisoned and not the railway station painter. As a rule, you see the railway station painter as I said, with his blouse and apron smothered with paint, and I should think, although I do not know (it is only what I should imagine) that if those returns were analysed, probably there would be a very much greater percentage of poisoning cases amongst that class of painter.

(*Dr. Collis*.) They have been analysed, and it proves the contrary. We have the figures for the whole of the men's societies, and they come out worse than the Registrar-General's figures.

13,782. (*Mr. Parsonage*.) My society stipulates that they shall have served five years to the trade before they are 21 years of age. We have no railway painters, as you term them, in my society?—What society is that?

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,783. (*Mr. Parsonage.*) The National Amalgamated Society of Painters, which probably some of your men belong to. We do not take these men in our society. They are entirely outside. I have given returns to this Committee proving the large number of deaths in my society.

13,784. (*Chairman.*) They show a heavier percentage than those supplied from outside sources?—I am very sorry to hear it.

(*Mr. Gardner.*) Out of 18 deaths only one is specified as an engine painter.

13,785. (*Mr. Sutherland.*) The dirty atmosphere of the station itself is inimical to the health of the painter, and very different from the conditions under which an ordinary house painter works. The railway painter has to work on the roof of a railway station and in dusty places?—Yes. Speaking as a practical painter, I do not dispute the figures, but they are extraordinary.

13,786. You have heard this morning that the ratio of deaths in Scotland is very much less than in England?—Yes.

13,787. And you know personally that the class of work done in Scotland will compare with the very best work done in this country?—Better.

13,788. And that the conditions of the house painter there are a good criterion of house painting of the best class?—It is a very much higher standard than in England.

13,789. But they use lead very largely there?—I do not know what they use.

13,790. They have been here, and have told us what they use. My point is this: that lead is an evil, and they use it in Scotland very largely and proportionately more than the average painter in England, and it does not produce the effect that it is said to produce in England to anything like the same extent. What is the explanation?—May I give you my opinion? In my opinion the Scotch painter is more highly trained than the English painter.

(*Mr. Parsonage.*) But the best Scotch painter does not stop in Scotland; he comes to London and gets lead poisoning. There are more Scotch painters in London than in Edinburgh or in Glasgow.

13,791. (*Mr. Sutherland.*) In the matter of ceilings and stippling, and that kind of thing, the modern water paint has very largely superseded lead paint, which is very rarely used for those purposes?—Very rarely.

13,792. You use water paints which are non-poisonous?—Yes.

13,793. Do you know the tests of the Office of Works?—No, I do not know anything about the tests of the Office of Works.

13,794. The Office of Works have never established a test of their own. They have advertised for paints to be sent in, and they have painted them on various surfaces?—I would say this: the trial that has been given is not sufficiently long for the Office of Works to come to any conclusion. Four or five years is not sufficient.

13,795. (*Dr. Collis.*) Do you wish us to make experiments?—Yes.

13,796. Are we to go on for another 10 years?—I do not say that.

13,797. (*Mr. Sutherland.*) Are you surprised to know that this year in the very area covered by the witness from the Office of Works, in London, five tons of lead were used on Office of Works work?—I should answer that by saying that I am not surprised, because I could have given evidence if I had known that this question was likely to have been asked of what the Office of Works are asking their country contractors to do to-day with regard to painting the outside of their buildings.

13,798. Would you think that the three proprietary paints which were named here yesterday by the Office of Works (good paints) would be sufficient to justify the putting aside of the use of lead in the building industry?—I should say that if the Office of Works were satisfied, every other body ought to be satisfied.

13,799. But what would you apply as the substitute?—If I, as a practical painter, knew that the Office of Works would accept a certain paint, I should

immediately procure that paint myself, I should have it analysed to see what was in it, and, if I thought that it was a paint that I could safely recommend my customers to have used, I should abandon white lead.

13,800. But these are proprietary paints put up in tins ready mixed. They are not paste paints like white lead paints?—I may say, generally, that nine master painters out of ten would agree not to use white lead if you could produce an article equal to white lead. Unless something has been produced within the last six months that I have not heard of, I will say this: that all advertised brands of paint supposed to supersede white lead have been experimented with by me and my assistants. I will tell you my test. It will not take a second. We paint a piece of wood three or four times, and we put it into a soft-water butt, which is the most severe test you can apply to any compound, and at the end of 48 hours, we take it out and test the appearance of the various articles. We have painted slips of wood a foot long, three or four inches wide all over top, bottom, sides, and everything with various makes of proprietary articles, and we have tested them by immersing them in soft water, as I have stated. Lead has always come out far and away the best. Nothing else has come out as well.

13,801. (*Lord Henry Bentinck.*) How did you mix those paints? I suppose you are aware that zinc-oxide paints ought not to be mixed in the same way as white lead paints?—What I made the tests with I bought from the manufacturer ready for use. A London firm, knowing I was making these tests, offered to send me some paint down, and I used it exactly as it was sent to me, and did not put anything into it.

13,802. You have been asked some questions about the Office of Works. A witness appeared before us and told us that he was interested in zinc-white paints, and that he had sold large quantities in the last four years for the painting of Buckingham Palace, the Home Office, the Stock Exchange, the British Museum, St. Thomas's Hospital, and other places?—You have only his evidence that it was used. It has not been proved, has it?

13,803. It was bought, and I suppose that it was not thrown into the river?—It is to the advantage of the zinc people to push their wares. They have said to me, "We have some stuff equal to lead." I have said, "Let me have some to try, and if it is I will use it." My experience is that it is not equal to lead.

13,804. Are you aware that there are some manufacturers of zinc-oxide paint who are doing a larger business every year in zinc paint?—A movement has been made in the last two or three years to induce the painter not to buy white lead, but to buy the ready-mixed paint.

13,805. What paint?—Ordinary paint. I had a man yesterday trying to convince me that it was cheaper to buy a ton of paint ready mixed than to buy a ton of white lead and mix it myself.

13,806. But that does not answer the question. I say, how do you account for the fact that the manufacturers of zinc-white paints are doing a better business every year, and that their paints are growing in popularity?—Zinc-white is being used more largely now than ever it has been used on interior work. Whatever I say about white lead as being an absolute necessity applies to exteriors only. I want the Committee to understand that.

13,807. The outside of the London Stock Exchange has been painted for some years now with a zinc-oxide paint?—I have no doubt of it. What they will find from experience is that they will have to paint their places very frequently. That will be the end of it all.

13,808. A witness, talking of the Stock Exchange, says that it has been used on the woodwork for outside over 20 years?—Inside, I daresay.

13,809. But outside?—Does he tell you how often it has been repainted?

13,810. The same paint. It has not been changed at all. Supposing that the Office of Works finally decided to abandon the use of white lead altogether, do not you think that the painting trade throughout the country ought to adopt similar measures?—I do, and I would do so myself.

9 November 1911.]

Mr. J. C. VAUGHAN.

[Continued.]

13,811. (*Mr. Sutherland.*) I traverse entirely the authority of the Office of Works on this question. Why should the painting trade be influenced by or follow the Office of Works when it has not conducted a single experiment on a scientific basis?—I assumed that they had done that.

13,812. (*Chairman.*) They have made experiments, of course?—The line that I should take up is this: I am as desirous of abandoning white lead as anyone is if it is as bad as you say it is, but on the other hand, if a customer complained to me and I had the excuse, "Well, it is used in all the Government Departments," I could say, "If they are satisfied with it, you ought to be." If it is good enough for the Office of Works after they have conducted tests it ought to be good enough for me.

13,813. (*Mr. Rice.*) You say that you have worked for seven years in London?—Yes.

13,814. As journeyman or foreman?—As journeyman.

13,815. Did you ever, in the course of your London experience, find that you had to climb up a ladder to get into a room to paint it?—Yes.

13,816. And were not allowed up the staircase or in the basement in the ordinary way?—The firm I worked with did a very good class of work, and I cannot call to mind a single case in my experience where we have not had our paint shop or our workshop or our mess room down in the basement. I am speaking now of 20 years ago.

The witness withdrew.

Mr. G. H. MORTON examined.

13,824. (*Chairman.*) Do you attend to-day as the representative of the National Federation of Building Trades?—Yes, I do.

13,825. What is the nature of your business, and where is it carried on?—Decorators and painters at Liverpool.

13,826. How long have you been concerned with house-painting work?—Over 40 years.

13,827. What is the average yearly number of painters employed by your firm?—The average number would be about 60 or 80, but a larger number of men have passed through our hands in that time. Men change.

13,828. Have you known any cases of lead poisoning or painter's colic?—Only once; that was about 20 years ago.

13,829. I am pleased to hear that your record is so good, but I am not surprised, because, as you may be aware, in the potteries there are a large number of works which are quite immune from lead poisoning cases for many years?—Yes, I am aware of that.

13,830. The trouble is that even some of the best works are not immune; and moreover, a works that has been free of lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly?—Yes.

13,831. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act of 1906?—The ordinary insurance.

13,832. Has the rate risen lately?—It has slightly increased lately.

13,833. Have you known men who have broken down temporarily on account of lead absorption?—No.

13,834. Have your men had occasional days of sickness due to lead?—None have been reported to me.

13,835. Do you have a periodical medical examination of your men?—No.

13,836. Then I suppose men may have been ill without your knowing it?—Of course there is that possibility, certainly.

13,837. Do you take a prominent part in the work of the National Federation of Building Trades?—Yes; I have been president of the National Association of Master Painters of England and Wales.

13,838. Has the question of the serious prevalence of lead poisoning amongst house-painters been dis-

13,817. You have admitted, I think, very frankly, the difficulty of enforcing regulations for painting?—Yes.

13,818. You have made three suggestions?—On the spur of the moment, not carefully thought out.

13,819. You suggested that the sanitary inspector might supervise the work, or the police, or that the Home Office should appoint inspectors?—Yes.

13,820. Does it occur to you that it might be possible to overcome the difficulty of inspection by each employer giving notice to some central authority of the work that he has to do, so that the inspector, the policeman, the sanitary inspector, or the Home Office officer, or whoever he might be, would have the right to go to that house to see that the regulation was being carried out?—I cannot imagine that there would be any difficulty at all. People being desirous of working together for the public good would fall into line and adopt anything that any recognised authority suggested. I cannot see any difficulty.

13,821. Do you see any difficulty in the employer giving notice to a central authority that he was going to work on a given day in a certain place?—There is no difficulty.

13,822. (*Chairman.*) Supposing that he did not send the notice to the central authority?—Then I should punish him. That is the man I should punish.

13,823. Have you calculated how many inspectors you would require, when the employer has sent notice to the central authority?—No.

13,839. (*Mr. Sutherland.*) And at Derby?—Yes, during this year and last year, but not previously that I know of.

13,840. (*Chairman.*) Was the prevalence of lead poisoning among the men who handle lead paints not known before then?—The knowledge of lead poisoning I have had for a long long time.

13,841. Then why did not the masters collectively take notice of it and take action in connection with it?—I do not know. For myself it was because I thought there was very little risk in the matter, not having had many cases—only one.

13,842. Did your Association ever consider the advisability of having a medical examination made of persons employed?—No, I do not think so; not to my knowledge.

13,843. Has your Association ever taken any collective measures to discover a substitute for white lead in paints?—Not specially.

13,844. Then it does not appear to me that you have realised, as an association, the extent of the danger of lead poisoning to which the house-painter is exposed?—No, I have certainly not appreciated it. It has never come to me officially in any way. I quite appreciate the risk of lead poisoning, and I should be very glad to substitute anything for it, because a non-poisonous paint must be better than a poisonous pigment.

13,845. If you have realised the magnitude of this lead poisoning evil, why have not you brought it before your Association?—It has never been thought of.

13,846. You say that you have realised the magnitude of the evil. Why have you not brought it forward?—I do not take a very active interest in the Association. I am more interested in the artistic side, and should leave it more to the manufacturers.

13,847. It has never occurred to any other member of your Association to bring it forward?—No. I do not know what caused it to be brought forward. I think it was because of a paper being read by somebody, and the discussion following.

13,848. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—I have read the reports at various times.

9 November 1911.]

Mr. G. H. MORTON.

[Continued.]

13,849. And that the death-rates from Bright's diseases and nervous diseases, due to work in lead, are very high?—I did not know that.

13,850. Do you know that about 2,000 cases of lead poisoning in the painting trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—I know that cases have been reported. I was not aware of the number.

13,851. Do you realise that these cases, reported voluntarily, are only a fraction of the whole, inasmuch as the Home Office has no legal right to pay for such reports, and is therefore bound to discourage reporting to some extent?—I have not heard much about it.

13,852. Do you know that the number of deaths in the trade have increased this year as compared with last year?—No, I was not aware of that. I do not see why they should, but that is not the question I know.

13,853. There were 38 deaths in the first nine months of this year and 30 in the first nine months of last year?—I should accept that statement with considerable questioning, because we can only judge this thing from our own experience.

13,854. But why should you question it?—It is extraordinary, is it not, when I have not heard of a case amongst our own men or amongst any other men in Liverpool.

13,855. These are actual figures taken from death certificates supplied by the Registrar-General?—It shows that there is more of it than I was personally aware of.

13,856. You would not venture to question the accuracy of the figures?—No, not at all.

13,857. If the proportion of deaths to attacks is the same as in other industries where we have all cases reported, the total of attacks must be between 9,000 and 10,000 in the 10 years?—Yes.

13,858. Is not that a very alarming state of affairs?—It is a very alarming state of affairs indeed. It is very serious.

13,859. I am sure you will agree with me that all this sickness and death is very deplorable?—It is very bad indeed.

13,860. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes.

13,861. Do you not think it regrettable that this country should be behind other nations in this respect?—Certainly.

13,862. Now a great many small dangers attend the use of lead; for instance, the contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—Yes, I think they ought to be very clean.

13,863. Do you consider that washing accommodation should be provided?—Yes.

13,864. And that hot water and soap and nail brushes and all the rest of it should be provided for the men?—Yes. The better the arrangements that are made for washing and cleanliness the better it will be.

13,865. Do you think that it is always practicable for the men to have hot water to wash in?—It is very difficult in some cases. In an empty house or outside work it would be extremely difficult.

13,866. But you see the importance of a supply of hot water to them?—Yes.

13,867. Now, supposing the Home Office issues a regulation that all painters are to be supplied with hot water, nail brushes, and towels and soap, how are the Home Office to be quite sure that that regulation will be enforced?—They would have to trust to the masters for one thing. They would have to mainly rely on the men themselves insisting upon it. A man need not work unless he has all that.

13,868. But there would be no possibility of the Home Office being quite sure that the regulations were carried out, would there?—No, I suppose not. It would be a matter of inspection, or something of the kind. The worst of a business like that of the painter is that they are scattered over such a large area. It is not like men in a factory.

13,869. Would it not require a great many inspectors to inspect the house-painters all over the country?—Some master painters want looking after no doubt. We have a fairly respectable class of trade, and naturally have not much difficulty.

13,870. Would it not be almost impracticable to provide a sufficient number of inspectors?—Yes, very nearly impracticable, I should say.

13,871. Do your painters wear overalls?—Yes.

13,872. Do you supply them?—No, they supply themselves.

13,873. Would you object to a rule that overalls are to be provided and maintained by the employer, as is prescribed in other lead industries?—Yes, I would object to anything that made more trouble for the employer. I think that he has far too much on him already in many firms. I think that the men ought to look after themselves in that respect.

13,874. Would you be prepared to arrange for the overalls to be washed at your expense, as is done in other industries where lead is used. It is insisted that lead workers in other trades shall not take overalls home to be washed owing to the danger that that involves?—I would rather give them an increase of wages, and let them find their own. Personally I think that nothing should be taken from the men's responsibility, because whatever anybody may do, inspectors, masters and anybody, is as nothing compared with what a man can do for himself. Surely his own life is of more importance to him than to anybody else.

13,875. But the men are working in a trade where a dangerous element is allowed to be used, and is it not the duty of the employer to safeguard the men in every possible way?—In the past all our men have found their own overalls.

13,876. But should not the employers be bound to safeguard their men if they are allowed to use dangerous elements?—No, I think the employer should not be bound to provide men with clothing. The men should do it themselves.

13,877. That is not what I asked. I asked: Should not the employers be bound to safeguard their men, if they are allowed to use dangerous elements, from all risks entailed in their work?—No, I do not think so.

13,878. You would not agree, then, to wash the overalls for the men?—No, I think that is the men's affair.

13,879. Where can the men keep their overalls from day to day when they are working continuously on one job?—They can leave them on the job.

13,880. Can you always provide a place for a painter to keep his coat away from the work that he is doing?—In most cases we can.

13,881. But could it be done generally throughout the country?—In many places it would be difficult, especially with regard to big outside work.

13,882. Can you always provide a place for the painter to hang up his coat where there will be no risk of dust falling upon it?—It is generally provided in the house where they are at work.

13,883. Supposing that it is only one room or a small job, can you be quite sure that the workmen will have a place for their ordinary day clothes, away from any contamination of dust created in the work?—I do not know. It ought to be done.

13,884. I am not asking about what ought to be done, but from your knowledge of the trade is it always possible?—No, it is not always possible.

13,885. Would you advocate a rule that it should be made imperative?—Yes.

13,886. Do you think that it could be carried out?—If there was a rule about it it would have to be carried out.

13,887. You said that it would be very difficult?—Yes.

13,888. How would you get over that difficulty?—You would have to have a sort of room like the builders have for outside contracts.

13,889. Something portable?—Yes.

13,890. Would it be practicable to take a portable room about with them to all jobs?—I do not think so.

9 November 1911.]

Mr. G. H. MORTON.

[Continued.]

13,891. Then why do you suggest it?—It would be very troublesome.

13,892. I want to know whether you think it is possible for us to be quite sure that the workman would have a place to keep his clothes, so that the clothes would not come into contact with the lead dust which is generated in his work?—It would be extremely difficult, but it could be done.

13,893. How would you do it?—It would depend on the cases. If it were an empty house the butler's pantry or something like that could be used. I have seen it done. In a tenanted house the public treat the men very badly sometimes, and will not give them a place.

13,894. What would you do in those cases?—I would make it a rule that the client should be compelled to give them a place.

13,895. Do you think that that would be popular with your customers?—I do not care whether it would be popular with them. Some customers are most cruel to the men, and do not even let them have a place for their meals. They would have to do it.

13,896. You have nothing practicable to suggest?—I have not.

13,897. You mentioned difficulties just now?—Yes; I think they would be very great indeed. It is not like a factory.

13,898. I quite appreciate the difficulties myself. Now with regard to the men's meals. Do you advocate a rule that a room should be provided for the men to have their meals free from any contact with dust?—A room in the house could generally be put on one side for that, and that is generally done.

13,899. Could you be quite sure that in the majority of cases the men would have a room in which to eat their meals apart from the work?—I do not think you could. It is sure to get mixed up with it more or less.

13,900. Now with regard to some of the actual processes, I want to ask you a few questions; first as regards dry rubbing down with sandpaper. Is this process indispensable?—No, it is not indispensable; it makes a better job. I suppose that is the idea but it is not indispensable.

13,901. Would you say as a practical master painter that it could be prohibited?—Yes; very little of it is done. The prices do not pay for it.

13,902. And after the first coat has been put on, can sufficient time be allowed in all cases, for the first coat to dry, so that it can be rubbed down with pumice stone and water?—I do not understand the question.

13,903. You have told us very plainly what your views are, and I am giving an illustration. After the first coat is put on can you say that in every case time should be given for the first coat to dry before it is rubbed down with pumice stone and water?—Time should be given, but it is not always done.

13,904. But would you say that in the future that should be the law?—I do not know how you could influence that. Circumstances are different.

13,905. But you said just now that you would agree to the prohibition of dry rubbing down, and I have given you an illustration?—There should be no dry rubbing down after the first coat. The dry rubbing down refers to old work. You say time after the first coat is put on. In that case you have an oily paint.

13,906. Would you agree to the prohibition of dry rubbing down of all work?—Yes, of new work, but you have to rub down between the coats, I think.

13,907. Is not this the most serious part of the evil?—New paint is not so hard as all that.

13,908. It must create a certain amount of dust because it is only done when it is quite hard, is it not?—No, it is not absolutely hard as a rule. It is better if it is hard, probably.

13,909. Is not there a good deal of dust generated in the dry rubbing down between coats?—There is some, but not a good deal.

13,910. Now, how do you propose to protect the workman from that dust that is generated in the operation?—Water and size might be used, but size would rather tend to make the paint crack afterwards.

13,911. I have got to the point now when the dust is actually being generated by the dry rubbing down. I want you to follow me. I want to know how that dust, whether it is large or small, is to be got away from the workman?—I suppose, if it is sandpaper, most of it will fall on the floor.

13,912. That does not answer the question?—I do not see how it could be kept away from the workmen unless they had respirators or something of the kind.

13,913. The next process is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

13,914. This gives rise to certain splashes?—Yes, but if it is done properly there ought to be very little indeed.

13,915. Yes, but I want you to realise that it is the multiplicity of small dangers which builds up the big evil, and so we are bound to deal with these small evils one by one, and although you may not think that this is a very large matter, a special rule would be necessary to deal with it. I want to know how you would deal with the splashes which arise in this operation?—I do not know. You are bound to have them. I have no suggestion to offer.

13,916. And precisely the same considerations apply to the process of stippling, I take it?—Yes.

13,917. The splashes are not very large?—They are small. It depends very much on the man. Some will do a ceiling without a single splash of any kind.

13,918. But have you anything to suggest to protect the workman?—No, except using something non-poisonous.

13,919. Do you have old paint burnt off with a spirit or charcoal burner?—We use both processes.

13,920. How can you prevent the worker from inhaling the fumes which arise from this process?—You cannot possibly. It is a very disagreeable odour, but mostly oil. I should think nothing would fly about in it.

13,921. They cannot get away from it?—No, they are bound to be near it.

13,922. If it is injurious and they inhale it, it must do them harm?—Yes, I should think so.

13,923. Can you suggest anything to protect them?—No.

13,924. It appears from your evidence that there are certain indispensable processes, in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. How are these dangers to be met?—If you use a dangerous material you have to suffer the consequences, I suppose, or substitute something other than white lead. It points to that.

13,925. Then from your point of view you mean to say that you have nothing to suggest to remove these evils?—No.

13,926. Now, various witnesses have told us about non-poisonous substitutes for lead. Have you had any practical experience with such substitutes?—Yes.

13,927. What results have you obtained?—They have been unsatisfactory in two ways at least. They have been far more costly as a whole, and they have not been permanent.

13,928. Now the Office of Works have told us, through their representative, that they have been making experiments for the last nine years with a view to finding a substitute for white lead, and that during the last five or six years, in some instances, they have used a non-poisonous paint, which they say has given them entire satisfaction, and so much is this the case that an order has been issued by the head of the Department, although it has not been carried out, prohibiting the use of lead in any of their operations. Now, if the Office of Works eventually abandoned the use of white lead altogether would that fact weigh with you at all?—Yes, it would, no doubt; but we ourselves are trying something. I am trying something myself at the present moment. I have painted part of our place with white lead, and part with non-poisonous paint, to see whether it will last. So far it looks as if it will be all right.

B b 2

9 November 1911.]

Mr. G. H. MORTON.

[Continued.]

13,929. What are the usual hours worked by your painters per week?—8½ hours a day—47½ hours a week.

13,930. Do you have a periodical medical examination of your workers?—No.

13,931. Do you know that in other industries where lead is used the Home Office insists on monthly or even weekly examinations by the certifying surgeon?—No, I was not aware of that, but I can quite understand it in a factory. It is a very different thing in the confined air of a factory, but our men are in the open air, and that prevents lead poisoning, no doubt.

13,932. Do you know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—No, but I dare say it is so.

13,933. To bring this industry into line with other industries, in which lead is used, each man would have to be medically examined and carry a health register. He would have to see the appointed surgeon at least once a month, and the employer would have to pay the fee for the medical examination?—Yes.

13,934. Have you any objection to paying for that?—Yes. As I said at the first, I have objection to taking responsibility of the men. Let the men take their own responsibilities. I would rather pay more wages and be done with it.

13,935. The Home Office have enacted in other industries, where lead is permitted to be used, that this medical examination should take place?—It is different where you have the same number of men employed always. We have at the present moment only an eighth of the number of men we shall have in the summer, and it is extremely difficult.

13,936. I quite agree, but I am only pointing out to you the kind of regulation which will be insisted on by the Home Office if lead is continued to be used, and there is no other way of meeting the case of medical examination than that it should be done by a certifying surgeon, and I suggest that the men should carry a health register. I do not suppose you agree. Now, supposing that a man is found to be affected with lead poisoning, and is suspended by the certifying surgeon for a fortnight or a month or longer, up to three months, would you agree to the employer finding him other work or paying him half wages during the time of suspension?—No. It would be too irksome altogether. I have a respect for the medical profession, but the first thing a doctor asks is: "What is the matter with you," and the man says "lead poisoning," but many cases, no doubt, are not due to lead poisoning.

13,937. A committee that sat here for two years dealing with the pottery industry recommended unanimously the very point I am putting to you?—I should object to it most emphatically.

13,938. In the Potteries they accepted it?—It is so different. You can do it in a factory, but you cannot do it with house-painters. You would want nearly as many doctors as men.

13,939. You understand do you not, that if the free use of lead is allowed to continue in the industry, the Home Office would have to insist on the rigid observance of all the precautionary measures, in the same way as in other industries where the workers handle lead?—Yes.

13,940. This would involve an extremely complicated and elaborate code of regulations?—Yes.

13,941. Are you fully prepared to set up the necessary machinery to secure the complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation, avoidance of dust, limitation of hours and all after such matters?—No. I should most emphatically object to it.

13,942. Now taking all these points into consideration would you say that you prefer that the industry should be regulated or that the use of lead should be prohibited, or very closely restricted?—The use of lead prohibited, most decidedly. It is a matter for the public. The public will get work that will only last half the time. It will have to be paid for. That is all.

13,943. (Mr. Sutherland.) The occupations of the ordinary painter are very varied are they not? Yes, very varied.

13,944. And the time spent in actual painting is not the greatest proportion of his occupation at all?—No; actual painting I should think is a third probably.

13,945. And the time spent in rubbing down paint would be an infinitesimal portion of that?—Very little.

13,946. So that in the course of a week's work a painter, speaking generally, unless he was doing some specific work, would spend very little time in rubbing down paint?—Very little.

13,947. Have you formed any estimate of it?—No, but I should think an hour or two a week, compared with the other work that he does.

13,948. I was going to put to you an hour a week, but I thought I would let you give your own answer. If a medical examiner came to you and said, "This man is showing evidence that he is likely to suffer," you could put him to washing off, such as distempering, stripping preparation, and that kind of thing without inconvenience?—Yes.

13,949. So that if a regulation was imposed by the Home Office, that would not involve a very great hardship on the master?—No.

13,950. Generally speaking, the man has facilities for getting hot water, and the buckets of water that he requires for use on the job, and a fire is always on the job?—Yes, he could get hot water. There would be fires about.

13,951. (Mr. Parsonage.) Would you expect a man to prepare, strip, wash off ceilings, and get a room ready for painting, and then leave it for another man to come in and do the painting?—It would be a little bit of an upset, but the man in charge of the job would manage it if he were told that the man was not to touch lead for a time. He would naturally put him to something else.

13,952. If he was told to keep him away from lead?—Yes.

13,953. With regard to a statement this morning with reference to men who preferred to be said to be suffering from lead poisoning, I know cases, particularly in Liverpool, where men have been prevented from getting employment because they have been suffering from lead poisoning, and instances where they have asked not to be certified as suffering from lead poisoning, because the insurance companies discriminate with regard to them?—What is the question?

13,954. The point is that instead of wishing to be put down as suffering from lead poisoning they would prefer not to be?—As regards a case of lead poisoning, I have never had a man applying to me who was affected. I have not heard of it from himself or any other source; so I have no experience personally.

13,955. We could give the name of a man and the firm that discharged him?—Probably if a man had lead poisoning he would have a recurrence? (Mr. Parsonage.) The principal insurance companies are discriminating against these men. I have had proof of that several times.

13,956. (Mr. Gardner.) If a painter is only engaged for a very small proportion of his time in rubbing down paint and coming into contact with lead, and yet the dangers of lead poisoning are so great, does not that prove that these processes must be exceedingly dangerous?—I do not know that it proves that they are. It proves that the lead itself is dangerous.

13,957. (Dr. Collis.) You have, I believe, stated that you think it would perhaps be better to regulate the amount of lead rather than to have regulation of the way in which the men are employed in using it?—I would rather have a prohibition of white lead altogether than irksome regulations.

13,958. Can you give any estimate at all of how the respective costs to the public would work out. You see there would be apparently more cost in the rubbing down process in leaving the coat to dry before you rubbed down, and there would be medical examination. You already employ your men on short hours, so that point would not come into consideration perhaps. Then there is the question of the possible increase in the compensation. They would be extra

9 November 1911.]

Mr. G. H. MORTON.

[Continued.]

expenses on the head of the employer, which, I presume, would reflect on the price he would charge for his work to the person for whom he was doing it. With regard to paints not containing lead, how much oftener would external woodwork require painting, if painted with paints not containing white lead, than it would if painted with paints containing white lead?—Twice as often, speaking broadly, I should say.

13,959. Taking into consideration that that is only part of the painting of a house as a whole, and that, for other purposes apparently, paints not containing lead are available, do you think that the cost of the regulations which would raise the price of the work which you would have to charge your customer would have any relation to that double painting of this woodwork?—I do not know what the cost of the regulations would be. It would be very considerable, I should think.

13,960. It is impossible for any of us to say?—You would want an army of inspectors to start with.

13,961. So there would be some comparison—it is not a drop in the ocean—as regards the total amount you would have to charge your customer?—You mean the cost of these regulations.

13,962. Yes?—It would hardly cost double, I suppose.

13,963. It is only part of the structure which you have to consider, because for internal work and certain other work the use of paints which do not contain lead seems to be quite advantageous?—They perish so soon from what I have observed. We are trying substitutes. We have some paint now which seems to be quite as satisfactory as white lead. They call it "Dixon's White." I have painted part of our works with it, and we are watching the progress of it. It seemed to cover equally well or rather better. In that case it would cost no more. My other answer may have been an over-estimate. On the spur of the moment you may exaggerate a thing a bit.

13,964. Quite so. I am asking a very intricate point?—We have had it three or four months, and it appears to be bearing up better than white lead.

The witness withdrew.

Mr. FRANK GRIFFITHS examined.

13,972. (*Chairman.*) Do you attend to-day as the representative of the National Federation of Building Trades?—Yes.

13,973. Have you any idea of the regulations which obtain in other industries where lead is permitted to be used?—Only as to personal washing in the potteries being made compulsory.

13,974. And such things as compulsory medical examination?—Yes. That is another one.

13,975. The provision of overalls by the employer?—Yes; I am reminded of that now.

13,976. The washing of the overalls by the employers?—Yes, that is right.

13,977. The provision of exhaust draught to carry away any dust that is generated during the operation which the workmen perform?—Yes, I remember that now.

13,978. The provision of separate rooms in every instance for the men to take their meals?—I do not know that it is in existence, but it has been suggested so often that it is quite familiar.

13,979. I may tell you that, as a matter of fact, it is the law to-day in the principal industries in which lead is used. I have only foreshadowed these regulations to see whether I can shorten your examination. Then there is the medical examination of all employes?—Yes, and intending employes.

13,980. At the expense of the employer?—Yes.

13,981. And, further, if the certifying surgeon, suspends a worker because he is in delicate health, then during the suspension he should be given other work of a non-dangerous kind, or he must receive half wages during the period of his suspension, say up to three months?—Yes, I see.

13,982. I wonder whether you can answer this question (if so I shall not ask you any other question), whether you in your industry, in your particular

13,965. For external work?—For external work. I am watching to see whether it disintegrates or gives way. It is whiter than the white lead, and it covers better.

13,966. (*Mr. Sutherland.*) It is easily applied?—Yes, it is easily applied. I watched the man, and he painted half of a window with one and half with the other. I was very careful about the brush he used.

13,967. (*Dr. Collis.*) We have received certain evidence in England, and we know what is done in Austria, which seems to show that there is perfect justification for the prohibition of the use of lead paints for interiors, quite apart from anything else. Now, if similar prohibition were enforced for external painting; you would quote to your customer the extra cost of the double painting, which is claimed to be necessary, of the whole of the external woodwork. The regulations would have to be carried out for the whole of the industry?—Yes.

13,968. But you have only to consider the extra cost of the external woodwork?—There would be extra cost. It must be fairly great with regard to external work. Inside it might be very different.

13,969. Inside, very probably, we may leave the lead paints out. Consequently, as far as the general public is concerned, the difference in cost with the regulations or with a strong modification of the amount of lead for external work as well as internal, would possibly be very small?—Yes.

13,970. In one case the worker is fully protected and in the other case we cannot ensure that he would be, because of the difficulty of carrying out the regulations?—Of course it does not follow that all outside work is white lead. There are the darker colours.

(*Dr. Collis.*) If you are not using white lead you are outside the regulations, of course.

13,971. (*Mr. Sutherland.*) There are the darker colours, the greens and the blues?—Yes.

business, would prefer a system of regulations such as I have foreshadowed or the prohibition of lead, or at any rate the restriction of the use of lead to a 5 per cent. solubility limit?—That is practically total abolition of white lead.

13,983. Yes, it is practically total abolition of white lead?—I should prefer total abolition if the restrictions are at all arduous.

13,984. The restrictions are what I have suggested?—I do not know that there is anything very severe in what you suggested which makes them so that they cannot be carried out.

13,985. Let me give you a few of the difficulties which occur to me. In the first place the Home Office would have to be assured that the provisions with regard to supplying the workpeople with soap and nail brushes and hot water to wash themselves would be carried out?—Yes.

13,986. Could you be quite sure that those provisions could be carried out?—As it happens, that question is rather applicable to me, my firm doing as much plumbing in a large way as we do painting, and I do not see why the plumbing should not be hurried on in a new building. The painting is the last trade in the building. I do not see any hardship in hurrying the plumbing on and getting the hot water to work. In fact, it is a benefit to the building, and I cannot see why the sanitary accommodation for the permanent staff cannot be used for the decorators.

13,987. I must take not only your particular business, but the whole industry. Do you think it possible to provide hot water in every case, and soap and towels?—I do not think that it is impossible at all.

13,988. How would the Home Office be certain that the regulation was carried out?—Only by inspection such as we have now in other cases.

B b 3

x 7790

9 November 1911.]

Mr. FRANK GRIFFITHS.

[Continued.]

13,989. But there is such a vast number of painters employed all over the country that it would be practically impossible for the Home Office to provide a sufficient number of inspectors to inspect?—Do you wish a suggestion as to a means of seeing that this is carried out by the employers?

13,990. We cannot recommend, as a Committee, anything which we are not perfectly certain is practicable?—Why cannot the workmen's association take it up. In Liverpool the Union arranges with regard to all operatives in the building trade that the employers shall provide boiling water at meal times, and a proper place to have the meals in.

13,991. You could not place the carrying out of this in the hands of the operative?—In Liverpool some of the operatives have stated that the water has not been provided, or that the place for meals is not efficient, and the Master Builders' Association have taken it up.

13,992. That would not be sufficient for the Home Office. They would issue certain rules, and the employers would have to see that they were carried out. How could you be certain that they were carried out?—Only by prosecuting the employer if they were not carried out.

13,993. Who is to find out whether the employer should be prosecuted?—That opens a very wide field.

13,994. Do you think it is practicable that such a set of regulations in connection with the workpeople with regard to washing, for instance, could be carried out?—To have proper inspection the machinery would be too elaborate. In inspecting the factory you have the factory there, but out of a painter's shop every morning the men are sent to various places for weeks or even six months.

13,995. Would it not be practically impossible to ensure that the regulations would be carried out?—Yes, it is almost impossible.

13,996. Now let us take the different processes. First of all the dust generated in dry rubbing down?—Dry rubbing down should be prohibited.

13,997. Could that be done in every case?—Yes.

13,998. After the first coat has been applied, would not waiting for the first coat to dry entail a great cost. If you waited before you rubbed down with pumice stone and water would it not be a very costly operation in a considerable number of cases?—Yes.

13,999. Would it therefore be practicable to dispense with dry rubbing down in every case?—Hardly, but if it was prohibited it would be minimised to a small degree, and that would be a benefit.

14,000. You cannot prohibit unless you prohibit entirely?—That is the difficulty.

14,001. Then there are other instances where dust is generated, and there is the splashing in stippling and so on. How can you prevent splashing on the men?—You cannot prevent that. It is a personal matter for the men.

14,002. Then with regard to medical examination, would it not be extremely difficult to get the men examined?—Very. In our firm we might take 50 painters on at once and discharge 30 at the end of the week; and every week is different. You could not examine 50 men every week.

14,003. If the use of lead is permitted to continue in your industry you may be quite sure that the Home Office will insist on your industry being levelled up to the others where lead is used, and so you would have to give some assurance that the regulations would be carried into effect, that the dust would be removed, and so on. Now I ask you again, having given you an insight into what the regulations would mean, would you say now that you prefer the adoption of regulations or the prohibition of lead?—The prohibition of lead.

14,004. (Mr. Sutherland.) With regard to the difficulty of examination, a man would only be examined at stated intervals, and he would carry a certificate about with him?—That would obviate that difficulty at once.

14,005. You would not have him examined every time he was taken on?—I see; that removes the difficulty.

14,006. (Chairman.) He would have to be examined every month at least?—That gets over the difficulty.

14,007. (Mr. Sutherland.) You ask him for the certificate and he shows it?—That gets over it right away.

14,008. (Chairman.) I ask you again which do you prefer, the rules or the prohibition?—To put it quite plainly, unless the regulations were of a mild nature, I prefer prohibition. I quite admit that we can do a great deal and still use white lead. To prohibit white lead is a very serious thing. My own opinion is that a lot of lead poisoning can be done away with, although we have only come across one or two cases ourselves in 40 years. The washing and so on can all be provided for in my opinion.

14,009. I do not want you to give an answer that you are not quite sure about. You have told us that with regard to the washing arrangements, and so on, you cannot devise any means by which you can be quite sure that the rules are carried out?—Yes; if they became law they can be carried out in exactly the same way, as we provide boiling water at the present time.

14,010. How would you provide it where they are doing one room?—We have furnaces.

14,011. How would the large number of small master painters make provisions to be quite sure that these rules are carried out?—On every job there is a boy, and the boy is always told off about 11 o'clock to get the cans and the water hot.

14,012. How would the Home Office be quite sure?—Inspection would have to be left very much in the hands of those who are carrying out the work, because it is too wide a question altogether. The men would have to make the complaint; they are on the job. You could not expect anybody else to make the complaint.

14,013. (Mr. Sutherland.) There would be a foreman on the job?—Yes.

14,014. And the men themselves would complain that facilities were not given to them?—Yes.

14,015. In other lead industries where regulations have been enforced, the mortality and sickness statistics have come down very sensibly?—Yes.

14,016. Do you not think it is worth while, before lead is abolished, to see what the result would be of strict regulations?—Yes.

14,017. And then fall back on prohibition, if necessary?—Yes.

14,018. (Chairman.) The corollary of that is that you would be put to the expense of all kinds of arrangements, and if the rules are not found to be effectual, then you are to have prohibition?—I do not look upon the expense as serious. Our workshops are scheduled under the Factory Acts. We have wash-bowls for the men, and towels, and hot water is provided, and soap. There is no difficulty about it.

14,019. But how in country places, or on small jobs, are you going to be sure about hot water, nail brushes, and soap, and all the rest of it?—The foreman on the job can be allowed a sum to provide for that.

14,020. (Mr. Rice.) Do you understand that the medical examination has to be done at the expense of the employer?—I did not understand that.

14,021. If you took on a man to-day and discharged him in a month's or a fortnight's time, you would have to have the expense of having him medically examined before he went to other work?—That is a serious matter with 300 men.

14,022. I thought you did not understand that?—I may be expressing an opinion that is not wanted, but, in my opinion the working man is becoming more clean than he was years ago.

14,023. (Chairman.) And yet lead poisoning is increasing?—It is very rarely that you find a man going to his meals without washing himself. That is the case latterly.

14,024. If that is so, and the men are more careful, but lead poisoning is on the increase, does not that show that the danger must be very severe?—I should say, "Yes"; but, taking my own personal opinion, the more men we get, the fewer cases of lead poisoning we get. We have not had one for years.

9 November 1911.]

Mr. FRANK GRIFFITHS.

[Continued.]

(Chairman.) In the potteries many have not had a case at all, so I am not surprised to hear that.

14,025. (Dr. Collis.) It may mean that the men are more regular workers and less casual?—Yes.

14,026. Medically I put considerable stress on that. We find that casual work is associated with an increase of cases of lead poisoning; that is to say, that when a man comes into it first he is more liable to get it than he is after he has been employed in the trade for 12 months?—You think he becomes acclimatised to it.

14,027. I have no doubt of it. I think it may account for what you are speaking of now—that you are employing more regular labour and less casual?—The painting trade is difficult in that way. No other trade is like it as regards casual labour.

14,028. There is a good deal?—A very great deal of casual labour.

14,029. (Mr. Parsonage.) You take on the men in exactly the same way as you always did?—Yes.

14,030. When you do not want a man he is discharged?—Yes.

14,031. (Chairman.) You have to remove all the dangers which the men come into contact with to-day, and I must enumerate them again. First of all you must have these washing arrangements, and you must convince us that they can be carried out. You must devise some means by which you can be quite sure that all dust is removed; you must have medical examination at your expense, you must have overalls provided for the men, and washed at your expense, and you must be quite certain that under no circumstances are the men allowed to have their food in the rooms where the work is being performed. Then there must be provision made for the men to put their coats away so that they do not come into contact with lead dust. Now, taking a survey of the whole trade, do you think that such regulations could be put into force effectually, and if so do you prefer those regulations or do you prefer the prohibition of lead?—It may not be answering your question directly, but I think that regulations could be put into force without any great hardship on either masters or men.

14,032. I shall have to go through the whole thing again. I do not want to press you into giving an unconsidered answer?—I do not want to come here and give a hasty answer. I can briefly state one or two of the difficulties with regard to all that you have mentioned, quite easily. Supposing that there was a law about overalls and you had a hundred suits of overalls; you have one man 5 feet and another man 6 feet, and how are you going to sort them out.

14,033. (Mr. Parsonage.) It would take a long time to do that on a Monday morning?—Yes. If the provision of overalls was left to the men it would be all right. It is very rarely that I find a decent painter coming on Monday morning with dirty overalls. Splashing is a personal matter. Some men are as clean on Saturday as others are dirty.

14,034. (Dr. Collis.) With regard to washing the overalls, if a man takes them home to be washed, and carries them into the house at all, lead poisoning may arise from that. Should not the overalls all be washed away from the home at the expense of the employer?—But what are you to do. Our business is all over the country. You would have to send them to a laundry, where the danger would still exist.

14,035. Each factory would have its own personal washing arrangements?—That would be a difficulty in our trade.

14,036. (Mr. Parsonage.) If you had a small country job you would have to send them to be washed by some poor woman in the village who had half a dozen children, and they would be liable to danger?—Yes. You might as well prohibit building because workmen have accidents. They can be prevented to a certain

extent by seeing that things are in order. They are better than they used to be. So in this white lead matter we can, by sensible regulations, minimise the evil very much indeed.

14,037. (Chairman.) I must get a definite answer, so I must go through all these points with you. Now, the first point is with regard to overalls; where could they be kept overnight when the men were working continuously on one job. You understand that you would probably have to provide the overalls, and see that they were washed?—A room would have to be allotted.

14,038. But can you always get such a room?—No. You could on a large job. It might be a private house. Very often it could not be provided.

14,039. Then what would be the good of such a regulation. Supposing that the rule was in existence, what would you do?—I should go in for prohibition, because the other would be impossible to carry out.

14,040. I have told you what the rules would deal with. Now, you would have to arrange, in such a case as you spoke of just now, for the men to be quite certain that they could have their overalls in a place unconnected with their work?—It would have to be left to the foreman.

14,041. But what sort of rule are we to frame to make it quite certain that they would not have to take their meals in such a place?—It could not be done without having an inspector.

14,042. We cannot afford an army of inspectors. That is another difficulty?—That is a very great difficulty.

14,043. Then, again, with regard to the men's clothes, it has been enacted in other industries, where lead is permitted to be used, that under no circumstances are men's clothes to be placed in any room where they can come in contact with lead dust. How would you get over that?—It would be very easy in some places, but not in others. In a large new building you could not do it. Building is all rush. A man is taken into a room to plaster it, and out go the coats. It is not a question of whom they belong to, they are shifted.

14,044. You understand that medical examination would be done at the expense of the employer?—Yes.

14,045. How would you ensure that the men you employed had been examined?—Only by producing the health certificate, as Mr. Sutherland put to me.

14,046. Supposing that they had not got certificates?—Then do not employ them.

14,047. But supposing you wanted the men, what would you do then?—We should have to do without them.

14,048. But could you do without them?—We should have to. Sometimes now we cannot get the men.

14,049. Would not that be a very great inconvenience to the trade?—Yes, it would—and to the men.

14,050. I am speaking of your inconvenience at present?—It would be at times.

14,051. I can give a lot more illustrations. For instance, how are you going to safeguard the men from breathing the dust that is generated in all kinds of ways and the danger arising from splashes on the floor—splashes on their faces in stippling, and so on, which I have seen?—You could not do that in a practical way. They will not wear masks, or that kind of thing.

14,052. That is another difficulty. Now I will ask you again—unless you would like me to go on with these difficulties that I have been putting to you?—I will give you a definite answer this time.

14,053. Which would you prefer—regulation by a set of rules such as I have foreshadowed or prohibition?—Prohibition.

The witness withdrew.

B b 4

9 November 1911.]

Mr. W. J. STYLES.

[Continued.]

Mr. W. J. STYLES examined.

14,054. (*Chairman.*) Do you attend to-day as the representative of the London Master Builders' Association?—Yes.

14,055. What is the nature of your business and where is it carried on?—Building and decorating, principally decorating, at 2, Market Street, Jermyn Street.

14,056. How long have you been concerned with house painting?—All my life. I entered the business in 1874.

14,057. What is the average yearly number of painters employed by your firm?—We employ about 100 per week. The most I have ever employed at one time is 250.

14,058. Are you aware of the magnitude of this lead-poisoning evil?—No, I am glad to say I am not. My experience has been very fortunate.

14,059. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—No.

14,060. Or that the death-rate from Bright's disease and nervous diseases due to work in lead is very high?—Directly traced to lead poisoning, do you mean?

14,061. That the death-rate amongst painters from Bright's disease is very much higher than in any other part of the population?—Has it been absolutely traced to lead poisoning?

14,062. The only inference to be drawn is that it is through lead poisoning?—I did not know it.

14,063. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—I did not know it.

14,064. Do you realise that these cases, reported voluntarily, are only a fraction of the whole, inasmuch as the Home Office has no legal right to pay for such reports, and is therefore bound to discourage reporting to some extent?—I did not know that.

14,065. If the proportion of deaths to attack is the same in your industry as in other lead industries, where we have all cases reported, the total number of cases of attack must be between 9,000 and 10,000 in the 10 years?—When you say in the house-painting industry, do you mean house-painters or the manufacturers of white lead?

14,066. House painters?—You surprise me.

14,067. Now I am sure you will agree with me that all this sickness and death is very deplorable?—I quite agree with that.

14,068. Do you not think it regrettable that this country should be behind other nations in protecting the men in this respect?—I do; but at the same time I can only speak from my own experience, and my experience is that we have had no lead poisoning at all.

14,069. I am not surprised to hear that you have had no cases, because in the pottery industry there are 500 potteries in Staffordshire, and only some 100 of them have had cases of lead poisoning at all; so that there are some firms that are quite immune, while others in practically the same situation might have a great number of cases of lead poisoning?—You are sure you are not speaking of manufacturers?

14,070. I am speaking entirely of painters?—Then I am surprised.

14,071. There are two ways of dealing with this evil; one is by a set of rules, and the other is by the prohibition of the use of lead, or, at any rate, by restricting the use of lead to a very small quantity. Now I will tell you very briefly what the regulations would involve, and I will go into them more deeply if you like. In the first place, you would have to provide proper washing arrangements for the men, and supply towels, soap and nail brushes, and also a proper supply of hot water. Do you think it would be possible in every case to meet those requirements?—I am sure it would not, but we allow five minutes for the men to wash themselves, and we always supply them with soap, and so on. I can only speak for my particular business. I do a very large small business, if you understand.

14,072. I do perfectly?—We get so many 5l. jobs or 10l. jobs. Some people would not give us the

facilities for boiling water, and our business does not demand it. It would be impossible to provide hot water.

14,073. The next thing is the supply of overalls for the men?—They supply them themselves.

14,074. But in other industries they are supplied by the employers. The point is this: if the State allows a trade to use a very dangerous element, they say that you must protect the men from all the dangers that ensue. Amongst other things they say, "You must provide the overalls, and you must see that they are properly washed." Would you object to that?—I do not know why I should; do you, Mr. Rice?

14,075. (*Mr. Rice.*) You must not ask me. The point you ought to be clear on is that the overalls would have to be supplied at the expense of the employer and maintained by him and washed by him weekly at his expense?—That is a serious item for me. Our rule is that the men supply their own, and they are clean every Monday morning.

14,076. (*Chairman.*) You will bear in mind the regulations that I have indicated and I will tell you some others, and then you will be able to say exactly how you feel about it. You would have to provide in all cases a proper place for the men to keep their overalls when they had finished work for the day?—That would be impossible.

14,077. And further, you would have to provide a suitable place for the men to keep their ordinary daily clothing while they were at work, so that they did not come into contact with lead dust?—In my particular business that would be impossible.

14,077a. Then with regard to food, you would have to be quite sure that in no instance were the men allowed to have their food in the places where they were working?—So far as I am concerned I should be very glad to arrange it, but you ask me rather a funny question. As I said just now, I have what you would call a large small business.

14,078. I know. You are the very witness that I want to get hold of?—If I am sent for to-day for one room, the people may say, "You must not come up the staircase." You have to have a ladder up to the balcony. Then with regard to getting water, I have had cases where we have had to go and take water from the cab rank.

14,079. (*Mr. Parsonage.*) That kind of thing does happen?—Very often.

14,080. (*Chairman.*) So that it would be extremely difficult to provide a separate room for the men to take their meals, would it not?—Yes. As I told you, I often have to do up a room where we must not go into the house. We have to put a ladder up to the balcony. The men might stop in the room and have their dinner, or go to the nearest coffee house.

14,081. If the men stay in the room it is a very dangerous thing for them. The dust is in the air, and they have had no opportunity of washing, probably. Then in any other industry where lead is permitted to be used it is enacted that medical examination must take place with regard to each of the workmen, and that the workman who has been examined shall carry a sort of certificate in his pocket. That examination is at the cost of the employer. Would you object to such a rule as that?—If it becomes law I cannot object to it. It simply means that the customer would have to pay for it. I cannot afford to pay for it; the profits are too low now.

14,082. Then with regard to the dust generated in different operations; can you dispense, for instance, with dry rubbing down?—No.

14,083. We are told that there is a considerable amount of dust generated in that process and other processes?—No doubt.

14,084. This Committee would insist, I think, at any rate the Home Office would, on some means being devised for carrying away the dust so generated. Can you think of any practical way of doing it?—No; I should be very glad to hear of one. You will have no first-class work if you do away with it.

14,085. Now I will put the last question. Having heard from me some of the restrictions that would be attached to your industry if lead is continued to be

9 November 1911.]

Mr. W. J. STYLES.

[Continued.]

used, would you prefer such a set of regulations or would you prefer the prohibition of lead?—Well, that is a funny question to put to me. If lead is prohibited something else would have to be used, so it would not interfere with my business at all.

14,086. I asked you which you prefer. We are here to settle this question?—I understand.

14,087. Which do you prefer, regulation or prohibition?—Personally it does not matter to me at all, but I should say that for the trade generally prohibition would be better. I fail to see how you are going to do away with white lead. If you can give us a substitute to use I will say prohibition.

14,088. That is not my question. I asked you which you prefer—regulation or prohibition?—You put a straightforward question to me, and as I say, if white lead is done away with, and I must not buy white lead because of the law, I must buy something else. It would not interfere with my business at all.

14,089. I have given you an idea of some of the rules which would attach to the trade if white lead is continued to be used in it. Now, would you prefer such a system of rules or would you prefer the prohibition of lead? You would be on the same footing as everyone else?—Of course I would. It is a funny question to put to me. If lead is prohibited something else must be used; therefore it would not interfere with me at all. If you ask my advice as to whether it should be prohibited or not I will give it.

14,090. I do not ask that. I ask you which, as an employer, you would prefer—rules or prohibition?—It does not matter to me which, as I say.

14,091. Yes, it does matter, because the putting into force of rules such as I have described would be a very costly operation?—Yes, but then my customers have to pay for it, so it does not appeal to me at all.

14,092. But still I would like an answer if you can give an answer. I will not press it if you would rather not give an answer?—I must qualify my answer somehow. You put a rather difficult question to me. Let me answer your question in this way: If you put this prohibition on it means extra cost of the work; therefore my customers have to pay for it, so it does not matter to me which way you put it.

14,093. I will leave it at that, then?—But I should say prohibition would be better, because I do not see how you are going to do away with white lead.

14,094. You say prohibition. I do not follow you?—I mean regulation. If we have to provide hot and cold lavatory arrangements, and all this, that, and the other, I do not see how it is to be done.

14,095. You have admitted the impossibility of carrying out these regulations?—To an extent I have. If I have a house to do up it is no trouble at all. It is where we have these small jobs that we have the trouble.

14,096. Now, which do you prefer, these regulations or prohibition?—You see the position I am in, do you not?

14,097. I think your answer is quite good enough. If you say you do not care which, I am content to take that?—I do not think I do mind which it is.

14,098. I do not want to press you to give me a definite answer?—You see, if lead is prohibited I have to use something else. If these regulations are in force I have to abide by them. I have one man in my employ at the present moment who has been with me over 30 years. He has had every one of his meals in the colour shop. He is with me now. He is just about my own age, and he is as well and hearty as, thank God! I am at the present moment.

14,099. Some men are quite immune from lead poisoning?—Many of the men in my employ are.

14,100. It is not rare?—I quite see the point.

14,101. (*Dr. Collis.*) Have you had any experience yourself of the use of paints which do not contain lead?—Very slight.

14,102. What was the result of that slight experience?—My men did not like it nearly so much as they do the white lead and oil.

14,103. But how did the work turn out?—It was very good.

14,104. Was it external or internal?—Both.

14,105. Could you give an estimate from that experience, though small, of how much extra it would cost your customers to have their work done equally well with a paint not containing lead instead of a paint containing lead?—I could not.

14,106. It would cost them more according to your experience, would it not?—I do not know of a substitute to take the place of lead for external work.

14,107. I grant that you do not know its equal, but even then if it was painted sufficiently often you could get the same protection with a paint not containing lead, could you not?—Our firm say not, and my men say not.

14,108. Not if you painted it twice a year? Could you not get the same protection?—Of course you could. If you only put whitewash on twice a year it would last, and that is only a water-colour.

14,109. There are some paints which do not contain lead which are more useful than whitewash. For instance, would a surface require painting once in three years with lead and once in two years with non-lead paint? I want whatever your experience leads you to think?—They are bringing forward so many of these enamels and leadless paints now that one has not had time to try experiments, has one?

14,110. I do not know what your opportunities have been?—If you painted the front of an ordinary house with whitewash or distemper or washable colour, or whatever you like, it would not last half the time.

14,111. Whitewash is different?—I meant some of these various oil paints which are on the market now which do not contain lead. I have not tried them, except enamels.

14,112. (*Mr. Parsonage.*) You do not use those outside?—For shop fronts.

14,113. (*Dr. Collis.*) You may take it that enamels do not contain lead?—I do not know what the ingredients of them are. If you say they do not contain lead, very well. They will last as long as white lead, I should think.

14,114. You have no experience of comparing flat paint with lead and flat paint without lead. Enamel is more or less a bright paint, is it not? I am referring to the comparison of an oil paint containing lead and an oil paint which does not contain lead. Enamelling is a more expensive method, and you would not use it for the front of a house, would you?—You would use a lot of it for the woodwork, but not for the main front.

14,115. Can you give me an estimate of the extra expense that would be thrown on the customer by painting with non-lead paint? If you used lead paints under regulations would it not put up the price that you have to charge to your customers practically to the same level?—I could not give an estimate.

14,116. (*Mr. Sutherland.*) Do you know that in Germany the Government, who own the railways, in deference to a demand something of this kind, made very extensive experiments with non-lead paints, and came to the conclusion that they could not dispense with lead paint, and they would not dispense with it. That in itself is a strong argument against the abolition of lead, is it not?—Yes.

14,117. In Germany the regulations were framed very much on the lines that the Chairman has foreshadowed to you. Now, do you not think that what the foreign painting trade can stand we ought to stand in this country?—I should think so.

14,118. Rather than part with a known basic material like white lead, whose qualities are established?—And unequalled.

14,119. Therefore, before you abolish white lead, would you not be disposed, as an experiment at all events, to submit to regulations to see whether they mitigated the evil effects?—Certainly I would; but you are putting it in a different way from what the Chairman put it to me.

14,120. (*Chairman.*) Shall I put it to you in my way again?—I have no prejudice one way or another.

14,121. The point is this—that the Office of Works have been making experiments for the last 10 years, and during the last six years in some instances they

9 November 1911.]

Mr. W. J. STYLES.

[Continued.]

have abandoned lead altogether, and they say the result is highly satisfactory. They have told us that they are going to abandon lead altogether, though they have not done so yet?—They are using lead in rather large quantities. Why do they use it on their own property?

14,122. They have been making experiments?—Only last year they painted a lot of their own property with white lead.

14,123. In some cases, where they have done without lead, the results have been very highly satisfactory. A witness who came here yesterday told us that the Office of Works had issued orders to prohibit white lead altogether, but it has not been done yet. That is as far as we have got. Now would not that influence you a good deal with regard to a substitute?—No.

14,124. Would not the Office of Works' experience be sufficient?—No, I should say still that white lead is the best stuff for external painting. I have no bias at all.

14,125. That answer is very conclusive. I do not want you to answer it if you would rather not do so; but I will still put my question to you as to which you prefer, to see whether you would like to change your mind at all. I ask you whether you would prefer the regulations, or whether you would prefer the prohibition of lead?—I should say the regulations.

14,126. Then I must put a few more regulations to you to see if you really mean that?—The few you have already told me are impossible in my business; that is the awkward part of it.

14,127. That is the point—how could you carry out the regulations?—I could not do it.

14,128. Then I will put it in this way: what do you think the Committee ought to do under the circumstances?—That is very awkward.

14,129. We have to protect the men's health?—I agree with you.

14,130. I put it to you as a practical man that certain regulations are necessary to protect the men's health. You tell me that those regulations are impossible to carry out. Now, under those circumstances, do you not think that it is imperative for the Committee to recommend the abolition of lead?—No, I do not.

14,131. You understand the corollary of that. It means that you are going to let these men suffer?—May I tell you something before you put down my answer. When I was advised to attend this Committee I took the trouble—or not trouble, but interest—to enquire of several of my men. I went round to the men who have been with me a number of years. I went to a man in the colour shop. First of all I went to my foreman, who has been with me about 14 years. I have several men who have been with me anything from 10 or 20 to 25 years. I asked them if they could suggest anything at all, and they all said to me, "It is simply a question of cleanliness amongst ourselves."

14,132. It is not a question of your own firm. I must take you back to the question. Do you know why this Committee has been formed? It is because of this grave suffering which exists among the workmen in your industry. The Home Office have asked us to advise them as to the best means for getting rid of the evil. You are a practical man, and I have told you of some of the regulations which, if enforced, would remove some of the dangers that the men suffer from to-day. You say that those are impossible to carry out?—I am afraid so.

14,133. Then I say, is not prohibition the only way of preventing the men suffering?—You see you are asking a very reasonable question, but it is difficult for me to answer. Only on Saturday we started at twelve o'clock to paint the ceiling of a jeweller's shop. We left off at twelve on Saturday night and started again at twelve o'clock on Sunday night and left off at six o'clock Monday morning. Now how could we possibly have all these regulations?

14,134. I admit that you have put to us very clearly that it is impossible in your class of trade to carry out the regulations which I have put before you. Now as regulations or prohibition are the only two things to remove the evil which the men suffer from to-day, if

you cannot carry out the regulations is it not a certainty that we must recommend prohibition?—I think you would have to recommend regulations.

14,135. Which you cannot carry out?—Now for instance on the Friday night I should have to say to the customer in the case of this particular Saturday night's job, "You must provide a lavatory for my men." If the customer objected, I should have to say, "You must do it." It would be the same for me as for everyone else. If nobody else had to ask him to do it, I should lose the customer, but not if everyone else had to.

14,136. It is very unsatisfactory?—I am trying to answer properly.

14,137. You have admitted to us that you cannot carry out these regulations. You have said this is impossible and that is impossible, and then, when I suggest that that means embracing prohibition as an alternative, you say, "Regulations"?—Now you put it to me in the light that you have put it to me now, I should say "Regulations" because then I should speak to my customer about what facilities he must give me.

14,138. Would you be prepared to bear the cost of medical examination, overalls, and so on?—I think I ought to have had notice of these questions and then I could have gone into the cost.

14,139. I do not want to press you. Would you like to take your evidence home and read it, and see how it looks, and then come again? I do not want to press you to any decision that you have not thought over. Would you like time to consider the whole matter?—No. I think, in answer to the question, I would say "Regulations," and the customers would have to pay for it.

14,140. What about the expense of medical examination, overalls, and all that sort of thing?—The same thing applies.

14,141. How are you going to arrange about the washing of overalls, not allowing the men to have their food in the room where painting is being done and so on?—They would have to go to a coffee house or a public house.

14,142. Do you think that these regulations which I have foreshadowed are practicable?—It will have to be done if it is the law.

14,143. You do not seem to have a single mind on the question?—I have. You, as Chairman, may think I have not, but, as I tried to explain just now, if I am not allowed to use white lead I shall have to use other stuff, and so will everybody else, and, therefore, I am protected with regard to my customers. If I am allowed to use white lead with restrictions then it will cost my customer more. It will be the same in the case of everybody.

14,144. (*Dr. Collis.*) Surely if it makes no difference to you it is much simpler to you not to be pursued by some inspector making you carry out a whole host of regulations and possibly dragging you before the court because one has been omitted, notwithstanding your best endeavours to carry them out. If you are going to be on all fours with your competitors if lead is prohibited, although you are going to be on all fours with them with lead and with regulations, surely life is going to be easier for you under prohibition. That is the view the Chairman presented to you?—I know of no substitute for white lead at the present moment. If I did I would say prohibit at once.

14,145. (*Chairman.*) I will put it in this way: if the majority of the witnesses before us have been in favour of prohibition instead of regulations, would you fall into line with them?—I practically answered that just now. If it was prohibited I should have to fall into line with other people.

14,146. But I ask you if the majority of your competitors have agreed to prohibition rather than regulations, would you fall into line with them?—Yes, I think I would. It is a funny question to ask, because I tell you I have no interest in white lead. You see what I mean.

(*Chairman.*) It does not matter. I will not ask you any more questions.

9 November 1911.]

Mr. W. J. STYLES.

[Continued.]

14,147. (*Mr. Sutherland.*) Would not the difficulty be removed if the use of white lead was prohibited for inside work and retained for outside work?—Yes, it would all have to be mixed inside. It would have to be ground down inside. That could not be done outside.

14,148. It is not in the mixing where the danger comes in, but in the rubbing down, and the dust arising from it?—But you would have to rub down in the case of other colours; with any colours you would have to rub down dry.

14,149. Not necessarily dry. There has been a big body of evidence that the question of white lead might be met by retaining it for outside work. The French are to abolish it two years hence, but they abolished it for inside work long before they decided to abolish it for outside work. Have you tendered to the Office of Works?—Yes.

14,150. Have you seen their specification?—Yes.

14,151. They use lead largely, do they not?—Yes.

14,152. (*Chairman.*) You have told us with regard to dry rubbing down that it is indispensable?—Yes.

14,153. There is a considerable amount of dust generated in that work?—Yes.

14,154. Do I understand that you know of no possibility of getting rid of that dust from the workmen?—I know of no possibility.

14,155. Then what do you suggest we should do in that connection to protect the workmen?—I cannot suggest anything.

14,156. Then supposing we were to devise—I do not say it is possible—an exhaust apparatus to remove the dust, would you pay the cost of that too?—Yes.

14,157. Would you pay the cost of overalls, and of medical examination and would you take care that all those other regulations were carried out to the letter?—Yes, provided it becomes law.

14,158. (*Dr. Collins.*) Under those circumstances, which do you think is going to be the most economical, the lead or the non-lead paints?—I cannot tell you.

14,159. (*Mr. Rice.*) You represent the London Master Builders' Association?—Yes.

14,160. The views which you have expressed are your own individual views?—Yes.

14,161. You have not been in conference with any other members of the London Master Builders' Association?—Not one.

14,162. Do you still think that the regulations foreshadowed by the Chairman, including the expense of medical examination which has to be borne by the employer—I do not know whether you were clear about that—and the purchase and weekly cleansing of the overalls, are regulations that you would be prepared to carry out?—I qualified that. I said provided it becomes law. The customer will have to pay for it.

14,163. You see no difficulty in doing it?—I see a lot of difficulty. I think it is an impossibility.

14,164. Then the conclusion is that, if they became law, you could not carry them out?—We should have to.

14,165. But the difficulties of carrying them out would be very great?—Very great indeed, almost impossible, more particularly in my class of business.

14,166. (*Chairman.*) How can you reconcile that with your previous answers to my questions?—I know of no substitute for white lead.

14,167. But how can you tell us that laws are impossible when you say that you will observe them?—They are not impossible if the customers will pay the money.

14,168. But you said just now that they are impossible to carry out?—I think they are impossible, because I do not think the customers would ever pay for them.

14,169. But you said that the rules would be impossible to carry out?—I will say so again. I have a single room to do and they will not let me up the staircase; I have to have a ladder up to the balcony. Now, who is going to watch what I do?

14,170. I ask you again. How are you going to carry out the rules I have put to you?—I do not know how to do it.

14,171. If they became law, you could be prosecuted for not doing it?—We should have to refuse the work.

14,172. You see the point?—I see the point. I know what I have said, and I fully realise the peculiar position in which I have put myself.

14,173. (*Mr. Rice.*) You hold no brief for the use of white lead?—Absolutely none. I have no shares or anything.

14,174. Do you think that the fact of white lead being prohibited would interfere with painters and cause loss of work?—I do not think so. We should have to find a substitute.

14,175. Do you think it possible that your customers would refuse to have work done, assuming that you could not get such a good finish with zinc white as you can with white lead?—No, I do not think they would, but if they ask me which I think is the better of the two I should have to say white lead.

14,176. (*Chairman.*) But supposing that white lead was prohibited and all the master painters were in the same position, what would be your objection to falling into line?—I should fall into line. I should have to find out some leadless paint. That is what I have been trying to explain to you all the way through.

14,177. Then if the Home Office prohibited the use of white lead you would not object to it?—No, I certainly should not. I could not if it became law. That is what I have wanted to tell you all the way through. I am not biassed in any way whatever. I thought that I was coming here to give you my opinion as to white lead. If it is forbidden I must find something else. It will be forbidden for everybody if it is forbidden for me, so it would not affect my business.

14,178. If all the master painters are on the same footing then would you not prefer the prohibition to the rules, taking it that none of them is allowed to use lead. Would not you rather be in that position than have these vexatious rules?—I suppose I ought to say yes. It would appeal to me more than to the high-class decorators who get the large work. I get so much small work and the difficulty would be far greater for me than for them.

14,179. (*Mr. Rice.*) I think the witness is rather confused. He is quite willing to abide by any law that is made, but he does not quite realise, I think, that the object of this Inquiry is to make that law, and that it is desirable that the law should be made to suit the best conditions possible. (*To the witness.*) We quite understand that you, as a law-abiding citizen, would abide by any law. The object of the Committee is to find the best law that can be made, and the object of your examination is to help the Committee to form an opinion. Does that help you to give a definite answer?—When I came into the room I was prepared to stick to white lead, but when the Chairman reads to me these terrible figures I do not know why I should stick to white lead, although there is my history perfectly clean, and perfectly true.

14,180. (*Chairman.*) You would not suffer if all the employers were in the same position?—No, I should not suffer; at least I hope not.

14,181. Would it not be an advantage to have prohibition instead of the rules if all the employers were in the same position?—If you make all these restrictions I think it would be better, but we should not get any work to do in white lead.

14,182. If all master painters were in the same position would you not prefer prohibition rather than rules? All would be in the same boat. I will not press you?—I am trying to think it through. You see, when I came here, I did not think we should have gone so deeply into the matter as that. I understood that I was coming to give my experience of the use of white lead amongst my employées. I have done that, and I have given it fairly and honestly, and I am prepared to stand by it. I can prove it. Men are still living who have been with us for many years.

14,183. (*Mr. Sutherland.*) You have a life's knowledge of the value of white lead, and you do not like to part with it?—If I cannot make my living out of white lead, but I can out of zinc white, why should I not?

9 November 1911.]

Mr. W. J. STYLES.

[Continued.]

14,184. (*Chairman.*) If all the employers are treated in the same way would it not be very much better for you to be exempt from all these troublesome rules and regulations?—Now what do you want me to answer?

What is the question? What have I not answered? Do you ask whether I would rather agree to the regulations or to prohibition. Is that the point?  
14,185. Yes?—I should say prohibition.

The witness withdrew.

## TWENTIETH DAY.

Wednesday, 22nd November 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman.*)

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary.*)

Dr. IGNAZ KAUF.

*Evidence to 14,228 handed in and taken as read; witness then called and examined (through an interpreter).*

14,186. I am a Doctor of Medicine and have for a number of years devoted great attention to the subject of lead poisoning in general and among house painters in particular. I was for some years a Government Medical Officer (Bezirksarzt) for a district of Vienna. I was attached to the Labour Statistical Department of the Handelsministerium (Ministry of Commerce), and was specially commissioned by the Austrian Government to assist in the work of the Austrian Commission on Lead Poisoning. I was also Professor (Privatdozent) for Industrial Hygiene in the Technical High School of Vienna.

14,187. Since 1907 I have been a departmental chief of the Zentralstelle für Volkswohlfahrt (Central Organization for Social Hygiene) in Berlin; Professor for Industrial Hygiene in the Technical High School of Charlottenburg; and Editor of the *Archiv für Soziale Hygiene* (Archives of Social Hygiene), and in these positions have had an opportunity of studying the question of lead poisoning from an international standpoint. I am also in a position to study the operation of the Regulations for the use of White Lead in house painting both in Austria and in Germany, and have collected statistics which indicate the effect they have had upon the health of the workers.

### AUSTRIA.

14,188. In the course of my duties as Bezirksarzt in Vienna, I had occasion to note the great amount of lead poisoning that took place there, and in 1902 I wrote for the Austrian Society for the Protection of Labour a brochure on the subject—"Blei und Phosphorvergiftungen in gewerblichen Betrieben Oesterreichs" (Lead and Phosphorus Poisoning in the Industrial Undertakings of Austria).

14,189. In April 1904 the Austrian Government appointed a Commission to inquire into the whole question of lead poisoning. The result of the labours of this Commission is contained in six volumes published from 1905 to 1907. I was appointed a member of the Commission by the Austrian Handelsministerium, and I gave special attention to the matter of lead poisoning among painters, and was chiefly responsible for the report upon that subject contained in the 5th volume.

14,190. For the purpose of investigation of the subject of lead poisoning among house painters, the Austrian Government Commission drew up a set of 43 questions covering the whole area of the inquiry, *inter alia*—

(a) Production of white lead pigment.

(b) The process of painting, including the question of dry rubbing down, and the use of particular pigments and the question of substitutes for white lead.

(c) Provision of clothes and washing utensils for painters.

(d) Rules for the workmen.

(e) Medical inspection and instruction of painters.

14,191. The Commission called to their assistance 36 experts, being master painters and painters, Government officials, chemists and doctors, manufacturers of white lead and paint makers, and the questions were put to these experts and discussed with them all in conference. The Commission also made special inquiries in particular branches of house painting and among house painters, and made visits to various places of work.

14,192. The Commission found that it was only for Vienna that reliable statistics of lead poisoning could be obtained. There are three classes of what are called in England collectively "house painters," *i.e.*, Anstreicher, Maler, and Lackierer. For my present purpose I will refer to these by the general name of painters (Anstreicher). All the painters of Vienna are grouped together, and are members of the compulsory Sickness Insurance Fund (Krankenkasse), and it is from the annual returns of this fund that the Commission's figures are chiefly taken. These figures showed for the years preceding the Commission a somewhat large and steadily increasing rate of lead poisoning, as will be seen from the following table:—

*Lead Poisoning among Members of Sickness Insurance Fund of Painters of Vienna.*

| Year. | Number of Members. | Cases of Lead Poisoning. | Days of Illness. | Percentage of Illness Cases. |
|-------|--------------------|--------------------------|------------------|------------------------------|
| 1901  | 2,853              | 130                      | 3,053            | 4.5                          |
| 1902  | 2,988              | 125                      | 2,278            | 4.1                          |
| 1903  | 3,744              | 163                      | 3,387            | 4.9                          |
| 1904  | 3,539              | 197                      | 4,258            | 5.5                          |
| 1905  | 3,712              | 198                      | 3,763            | 5.3                          |
| 1906  | 3,661              | 253                      | 5,702            | 6.9                          |

14,193. The causes of lead poisoning may be divided into the objective causes, such as the processes creating poisonous dust, and the subjective causes due

22 November 1911.]

DR. IGNAZ KAUP.

[Continued.]

to carelessness on the part of the workmen. It was found that the workmen emphasised the objective causes, such as the processes of dry rubbing down and pumice-stoning; while the master painters emphasised the subjective causes such as the uncleanness of the workmen.

14,194. The Report lays very great stress upon the danger of dry rubbing down. In the first place, the Commission obtained information as to the processes of painting followed in a large number of businesses, particulars of which are set out on pages 15 to 20 of the Report. It was found that for inside painting it was the practice to rub down dry or to pumice-stone dry several of the various coats of paint, and that for considerable periods of time. Specimens of the air suffused with the dust caused by the rubbing down were taken and were analysed. These were found to contain white lead varying, in accordance with the amount of white lead in the surface rubbed and the intensity of the rubbing down, from 1 milligramme to 25 milligrammes of white lead in 1,000 litres of air.

14,195. The Commission found that the opinion of the workmen as to the danger of this process corresponded with the probabilities of danger shown by this analysis. They caused 50 painters, who had had repeated attacks of lead sickness, to be medically examined and questioned. "Of these 50 cases of lead poisoning, 23 men, *i.e.*, 46 per cent., were positive that the cause of their first attack of lead sickness was the dry scraping and rubbing down with pumice-stone or emery powder of priming filling or coats of paint containing white lead. These all stated that they had always kept themselves clean, and, in particular, had never eaten with unwashed hands." "When the technical-hygienic evidence as to the lead contained in the air and in the paint is remembered, and also the amount and duration of the dry process, and when it is also borne in mind that in the course of 5 hours' work a painter breathes about 5.5 cubic metres of air, then it is clear that the theoretical danger of the dry rubbing down is in complete agreement with the testimony of those concerned."

14,196. In the next place it was shown that—Far more lead pigment is used in Austria for outside painting than for inside:—

14,197. "For inside painting.—There has been used in Austria in the year 1904, almost exclusively on wood in building and alterations, including furniture and the interior painting of ships—

White lead - (about) 2,750 quintal = 270 tons.

14,198. "For outside painting similarly:—

White lead - - - 5,500 quintal = 540 tons.

Red lead - - - 4,000 quintal = 393 tons.

Of which last about 4,000 q. of white lead and the whole quantity of red lead was used for the painting of iron on bridges, machines, ships and rolling stock; the rest of the white lead being used for painting the fronts of houses and for wood on carriages and railway coaches. The fact that lead pigments are predominantly used for outside painting is clearly shown here. This use of them is more than three times the use for inside painting."

14,199. It was also shown that:—"Among master painters in Vienna there are for inside painting about 163 cases of poisoning per annum with a use of white lead of about 1,600 quintal = 157 tons; although for outside painting with white lead and red lead for the whole of Austria (9,500 quintal = 933 tons) there were not 80 cases, of which about 50 are in Vienna."

14,200. From these calculations the report drew this conclusion:—

"It would seem therefore that in inside painting there was a quite special process causing poisoning which does not occur in outside painting. In the ordinary work of inside painting, and especially for painting wood, the circumstances are primarily more favourable because non-poisonous pigments, such as zinc white, lithopone and earth pigments, &c., are always used with white lead, and therefore the pigment is almost always notably less poisonous than in the painting of iron on outside work which is commonly done with wholly lead pigments. The particular cause consists in the dry pumice-stoning and rubbing of

primings, puttyings, and other coats of white lead. The important fact in this is the causing of dust and the atmosphere of white lead dust which is formed thereby in which the painters of the room which is being scraped or rubbed down must remain for the whole of their work."

14,201. "Dry rubbing down is characteristic of inside painting only, as the fronts of houses are not in general rubbed down. Iron also is not commonly rubbed down, and carriages and railway coaches are only rubbed down wet, like the finer painting of furniture, and there is therefore no danger in them."

14,202. It was further calculated that of the 163 cases of lead poisoning in Vienna not more than 48 were due to simple painting, and that the rest were therefore due to dry rubbing down.

14,203. It will be seen that in view of the circumstances of Austrian painting the Report distinguishes between inside and outside painting. The general observations of the Report on this point may be usefully quoted.

14,204. "A sharp distinction is to be made between inside painting and outside painting. In both inside painting and outside painting the materials of the object to be painted differ. For inside painting there is chiefly wood, more rarely walls, and still more rarely iron or some other metal. For outside painting iron is the most important, and walls and wood are of less importance. It is well known that for each kind of painting there are different requirements. For inside painting resistance to the atmosphere of interiors, especially to the effect of certain gases. For outside painting resistance to the outside atmosphere, to severe changes of temperature, and to rain, &c. Employers agree that the change of colour and the yellowing of inside painting is due to the use of white lead for the last coat, whereas a coat of zinc white obviates this. On the other hand, for outside painting white lead has, as is well known, special advantages over other colours, such as zinc white and lithopone. There are also distinctions as regards inside and outside painting in respect of the kind of lead pigment used. In painting wood and wall surfaces in inside work white lead only is used, and red lead is only used in the rare case of painting iron. On the other hand, for outside painting white lead is predominant only for moving objects, and for the large area of painting of iron red lead has equal importance with it. The other lead pigments, such as chrome yellow and chrome green, are of about equal importance one with the other, and have only a subordinate place."

14,205. The facts found by the Commission in regard to the use of white lead for outside painting were in marked contrast with those in respect of inside painting. For outside painting there was found to be a very large and a growing use of white lead and at the same time a relatively small amount of poisoning. The great cause of poisoning, namely, the dry rubbing off, did not exist in the case of outside painting. Moreover, there was very strong evidence that, owing to the peculiar chemical combination of the white lead with linseed oil and the notable qualities of great resistance to water and great covering power due thereto, there was in the present state of knowledge no satisfactory substitute for white lead for outside use. This was especially the case in respect of minium (red lead), as several witnesses emphasised the fact that for the painting of iron surfaces there was no possible substitute. The final conclusions of the Report on this point are as follows:—

14,206. "The facts in regard to outside painting are notably otherwise [than in regard to inside painting]; there is a large use of white lead and red lead and a relatively small amount of lead poisoning. Having regard to the undoubted advantages of white lead for outside painting and of red lead especially for iron painting which are declared by all in the business, there is not likely to be any decrease in these figures, the more so in that the question of substitutes for outside painting is still in the stage of experiment and inquiry."

14,207. In its inquiry into the causes of lead poisoning distinguished by it as subjective the Commission was in the nature of things obliged to rely

22 November 1911.]

Dr. IGNAZ KAUF.

[Continued.]

less upon statistics than upon the evidence of masters and workmen and visits to work places. The state of things found left very much to be desired. In far too many cases there was a great absence of elementary cleanliness, hands were not washed before meals, food was kept in the workroom or even in working clothes, and was eaten during work; cigarettes were also smoked during work; no special clothes were provided for work, and ordinary clothes were hung up in the workroom. In the opinion of the Commission this uncleanness could not be wholly ascribed to the carelessness of the workmen, although it was largely due to their ignorance of the dangerous properties of white lead and the absence of instruction upon the point. In a very large degree it was due to the absence of the provision of proper appliances for the observance of cleanliness. Insufficient time was given for meals, and too often no place was set apart for them. Upon this point the Report concludes with the following observations:—

14,208. "The recommendations on an earlier page for regulations for painting businesses and factories show sufficiently that there is still much to do for the protection of the health of workers in outside painting with white lead and red lead. In accordance with all experience the returns of the numbers of poisonings in these occupations could be reduced to a minimum by thorough sanitary precautions."

14,209. The sanitary and other regulations which were pressed by the medical experts included the following:—

- (a) The provision of proper means of washing and a place for clothes and food.
- (b) The prohibition of smoking and drinking of spirits during work.
- (c) Medical inspection of workmen before being allowed to engage in employment with lead colours, and subsequent periodic inspection.
- (d) Leaflets of instruction as to the dangers of lead colours.

14,210. One other point to which great importance was attached by the experts was the necessity of a declaration in respect of all colours containing lead that lead was therein. It was pointed out that the painter and even the employer did not know that a large number of paints sold under fancy names contained a high percentage of lead.

14,211. As a result of the Report of the Commission a set of Regulations was issued by the Minister of Commerce in April 1908.\* The chief provisions are:—

- (1) Prohibition of dry rubbing down and pumice-stoning (section 7).
- (2) Prohibition of white lead for inside use (section 4).
- (3) Notification of lead contents on paint cans, &c. (section 3).
- (4) Provision of washing appliances by employer and in certain cases work clothes and respirators (section 8).
- (5) Provision by employer of special rooms for washing and for keeping clothes where more than 20 employed (section 2).
- (6) Periodical medical inspection where more than 20 employed, and medical certificate before re-employment of a workman once lead-sick (section 6).
- (7) Provision of instructions as to the danger and nature of lead poisoning and the means of avoiding it (section 11).

14,212. In pursuance of the policy of requiring lead colours to be so declared, an Order was published on 26th April 1909 by the Ministers of the Interior, of Finance and of Commerce, prohibiting the transport of such colours unless the fact that they contained lead was clearly indicated.

14,213. It is now some 2½ years since the Regulations of 1908 came into force, and it is already possible to trace a marked diminution in the number of the

cases. I append a table in which the figures of lead poisoning for the years preceding the Commission, which have already been given, are for convenience repeated:—

*Lead Poisoning among Members of Sickness Insurance Fund of Painters of Vienna.*

| Year. | Number of Members. | Cases of Lead Poisoning. | Days of Illness. | Percentage of Illness Cases. |
|-------|--------------------|--------------------------|------------------|------------------------------|
| 1901. | 2,853              | 130                      | 3,053            | 4·5                          |
| 1902  | 2,988              | 125                      | 278              | 4·1                          |
| 1903. | 3,744              | 163                      | 3,387            | 4·9                          |
| 1904  | 3,539              | 197                      | 4,258            | 5·5                          |
| 1905  | 3,712              | 198                      | 3,763            | 5·3                          |
| 1906  | 3,661              | 253                      | 5,702            | 6·9                          |
| 1907  | 3,765              | 108                      | 4,939            | 5·5                          |
| 1908  | 3,546              | 167                      | 3,852            | 4·7                          |
| 1909  | 3,589              | 143                      | 2,973            | 3·9                          |
| 1910  | 3,917              | 138                      | 3,155            | 3·5                          |

14,214. It will be seen that the decrease commences in the year 1907, in which the Commission was sitting. No doubt the attention called by it to the dangers of lead poisoning, and subsequently the publication of the Regulations, had an effect even before the Regulations came into force.

#### GERMANY.

14,215. In the year 1903 elaborate regulations for the white lead factories were passed by the Bundesrath, and in the year 1905 extensive inquiries were instituted by the Department of Commerce and Industry with a view of making regulations for the painting industry. No Commission was formally appointed, and there is no public account of the investigations. As a result of the inquiry a set of Regulations were issued on the 27th June 1905\* :—

- (1) Prohibition of dry rubbing down and dry pumice-stoning (section 3).
- (2) Provision by employer of washing appliances (section 5).
- (3) Provision of special rooms for washing and for clothes (section 8).
- (4) Rules by employer (a) to require special work-clothes, and prohibiting (b) spirit drinking and smoking during work, and (c) eating or drinking before washing (sections 4 and 9).
- (5) Half-yearly medical inspection, and prohibition of work before recovery from lead poisoning (section 10).
- (6) A medical register (section 11).
- (7) Provision of instructions as to the danger and prevention of lead poisoning (section 6).

14,216. It will be seen that the German Regulations are in many respects similar to the Austrian Regulations, which, indeed, were to a large extent based upon them. There is in the German Regulations no prohibition of the use of white lead for inside painting corresponding with the prohibition in Austria, the circumstances of which have already been explained, but there is a similar prohibition of the dry rubbing down and pumice-stoning to which the Austrian Report attached such great importance. There is no provision in the German Regulations for the declaration of white lead contained in paint. The provision for medical inspection is somewhat different, and it is required to take place every six months instead of every three months. It is generally felt that the instructions as to the danger and the means of preventing lead poisoning prescribed by the German Regulations are unduly long and complicated and defeat their object.

14,217. I have given much attention to the collection and analysis of statistics showing the effect of the German Regulations upon lead poisoning; and I published some of the results of this investigation in the issue of the 5th September 1910 of the *Archiv für*

\* See Appendix IX.

\* See Appendix VI.

22 November 1911.]

DR. IGNAZ KAUP.

[Continued.]

*Soziale Hygiene* (of which I am an editor) in an article entitled "The Position of Lead Poisoning in the Industrial Undertakings in Prussia." The great statistical difficulty in Germany is the absence of any obligation to notify cases of lead poisoning. The only available figures for a large area such as Prussia are the records of the hospitals, and these, although reliable for an estimate of the increase or decrease of lead poisoning, do not give an accurate picture of the full extent of it, inasmuch as workmen only go to the hospital as a last resource. The returns for the Sickness Insurance Funds (*Krankenkassen*) give a more exact account for particular towns such as Berlin, but they cannot be obtained for many other places. A comparison of the Berlin Hospital and Sickness Insurance Fund's figures shows that the hospital figures must be multiplied by four or five.

14,218. The total hospital figures of lead poisoning in general for the whole of Prussia and for Berlin in particular from 1904 to 1908 were:—

Number of Cases.

| —           | 1904. | 1905. | 1906. | 1907. | 1908. |
|-------------|-------|-------|-------|-------|-------|
| Berlin - -  | 178   | 167   | 151   | 146   | 130   |
| Prussia - - | 1,050 | 1,103 | 898   | 920   | 900   |

Days in Sickness.

| —           | 1904.  | 1905.  | 1906.  | 1907.  | 1908.  |
|-------------|--------|--------|--------|--------|--------|
| Berlin - -  | 3,873  | 3,339  | 3,287  | 4,255  | 2,944  |
| Prussia - - | 27,943 | 26,965 | 22,855 | 23,586 | 21,150 |

14,219. It will be seen that, with the exception of the year 1905 (Prussia), these figures show a general decrease since the time of the 1903 regulations for white lead factories coming into force.

14,220. From the same hospital figures for painters in particular, of which I annex a table, it will be seen that there is an even more marked decrease since the 1905 regulations for painters came into force.\*

14,221. It will be seen that for and since 1906, when the regulations came into force, there is a decrease not only in the number of cases, but one even more marked for the number of days of illness, and this diminution is common to all the districts, although in differing degrees. It is also to be noted that not only is there a decrease in the number of cases of lead poisoning among painters, but that the proportion of the cases among painters to that of the cases of lead poisoning in general also shows a considerable decrease, the figures being as follows:—

| 1904.             | 1905.             | 1906.             | 1907.             | 1908.             |
|-------------------|-------------------|-------------------|-------------------|-------------------|
| Per cent.<br>35·5 | Per cent.<br>35·4 | Per cent.<br>31·8 | Per cent.<br>31·4 | Per cent.<br>28·8 |

14,222. The foregoing figures for the period ending 1908 relate to Prussia in general. I have been able to get statistics for Berlin for the period since 1908, namely, for the Sickness Insurance Fund of the Painters of Berlin. These are as follows:—

Lead Poisoning among Members of Sickness Insurance Fund of Painters of Berlin.

| Year. | Cases of Lead Sickness. | Percentage of Lead Sickness. | Days of Lead Sickness. | Percentage of Days of Lead Sickness. |
|-------|-------------------------|------------------------------|------------------------|--------------------------------------|
| 1907  | 379                     | 7·3                          | 19,451                 | 260                                  |
| 1908  | 298                     | 6·0                          | 19,223                 | 265                                  |
| 1909  | 235                     | 6·0                          | 11,769                 | 246·1                                |
| 1910  | 268                     | 5·4                          | 11,135                 | 224·5                                |

\* See Appendix XV.

14,223. These figures also show a steady decrease, not only of the number and percentage of cases of lead poisoning among painters, but also of the number and percentage of days of sickness.

14,224. There can be no doubt that the decrease of lead poisoning among painters both in Germany and Austria is due to the effect of the regulations. I have a strong opinion that the technical hygienic provisions of the regulations must, both in Austria and Germany, be supplemented by thorough and well organised measures for the medical instruction and the medical supervision of the workmen. This can only be done by a close co-operation of the doctors with the officials. Circumstances both in Austria and in Germany are not so favourable for this purpose as in England. There are too few officials to do the work of inspection as thoroughly as it should be done, and there are far fewer doctors than in England. So far as I am acquainted with English circumstances it would seem that in the widespread and numerous local sanitary inspectors and local medical officers of health, there is an organisation ready to hand and well adapted to carry out regulations in the way which I think most desirable. I would also point out that in England the circumstances are also more favourable, in that there is no wide gulf between the workers and the doctors or officials. I regard this as of great importance, as in my opinion the danger of lead poisoning, as of other industrial diseases, will be reduced to a minimum when the circumstances are such that workmen are ready to listen to doctors and so to become aware of the dangers and the way to meet them, and are ready to co-operate with doctors and officials in securing the observance of the regulations.

14,225. I have also a very strong view as to the importance of compulsory notification of all cases of lead poisoning. No industrial disease can be properly studied and checked unless there be sufficient material in the way of statistics.

14,226. I also attach great importance to duty of declaring lead (*Declarationspflicht*), i.e., that every pigment containing lead should be labelled "Containing lead and poisonous." The Austrian regulations require a notification of lead, but does not go on to require it to be notified as poisonous. Unless this declaration is made, master painters and workmen alike, and even paint dealers, handle poisonous lead pigments, often under fancy names, without any idea of their danger.

14,227. There can be no doubt that the greatest source of danger is the dry rubbing down. This is clearly shown by the facts stated in the Austrian Report. It was to meet this danger that the use of white lead for inside painting was forbidden, because it only occurs in inside painting and because in Austria very little white lead was used for inside painting.

14,228. The evidence before the Austrian Commission showed that the use of white lead for outside purposes, and especially for the painting of iron, was large and growing, and that it was regarded as indispensable for this purpose. With proper regulations I do not regard the prohibition of the use of white lead for outside painting as necessary, and certainly in the present state of knowledge, when there is no effective substitute for it, such a prohibition would be unjust both to the consumer and to an important trade.

14,229. (*Chairman.*) In the evidence that you have submitted to us you have laid stress on the danger of dry rubbing down?—I consider dry rubbing down and dry pumicing as extremely dangerous.

14,230. Did you ask the witnesses before the Austrian Commission whether they could dispense with dry rubbing down?—For the painting of outside work, particularly rolling stock the rubbing down is exclusively wet; but for inside work there is still a certain amount of dry rubbing down, but it has been very much restricted. On furniture, rubbing down is exclusively wet. I think it quite possible to dispense with dry rubbing down entirely, as wet rubbing down yields a very much better painting surface for high quality painting, because it gives a fine surface; but the drawback to wet rubbing down is that it involves, according to some painters, a slight increase in cost

22 November 1911.]

DR. IGNAZ KAUP.

[Continued.]

Some painters maintain that the increase in cost may be as much as 10 to 15 per cent., but the result is very much better with wet rubbing down.

14,231. Did you ascertain how they would smooth the first coat of paint before applying the second coat?—In indoor painting, chiefly on doors and walls, the first thing done is that a coat of size is applied; something which permeates into the wood or into the wall. Then over this they put a coating of some paste to fill in all the crevices and little holes. In Austria they use something termed "spotting out."

14,232. Is that lead?—It is not necessarily lead, but sometimes lead is added. I have in my report a number of compositions of such pastes as are used for this purpose. When it has been smoothly applied it is necessary to rub it down to polish it. For indoor work, particularly for doors, in Austria, they still persist in rubbing down dry, generally with pumice stone. The danger is very great, as in 200 working days, 80 days are occupied with rubbing down dry. I wish to add that of 50 cases of lead poisoning 23 men, that is 46 per cent., stated that they believed the lead poisoning to be due to dry rubbing down of paints used for obtaining a smooth surface by rubbing down with pumice stone or emery.

14,233. Do I understand that you cannot dispense with dry rubbing down in Austria?—I think it quite possible to dispense with dry rubbing altogether, because certain master painters found that dry rubbing led to a number of cases of lead poisoning, and the only disadvantage of wet rubbing down was the increased cost, and those master painters on their own account decided, before the regulation came into force, to abandon dry rubbing and substitute wet rubbing, which gives a superior surface to that given by dry rubbing. The German regulations and the new Austrian regulations have prohibited dry rubbing down altogether.

14,234. Both for inside and outside?—I think that the prohibition of dry rubbing down can apply only to inside painting, because outside paint in Austria is never rubbed down at all; rough surfaces are quite good enough for outside paint. For very delicate outside work, such as ornamental work, very superficial rubbing down is done with emery, but not the thorough grinding down which is done on inside surfaces. I think it very necessary to prohibit dry rubbing down altogether, although some of the outside paint, such as that upon carriage work, is rubbed down. In Austria this is exclusively done in the wet way, and as rubbing down might be done by people in a dry way, I think the prohibition should cover outside work as well.

14,235. Would it be practicable to invent any exhaust apparatus to remove the dust in dry rubbing down?—I think the construction of such an exhaust apparatus quite impossible, because the work is chiefly applied to such things as doors, and the working place consequently changes all the time. The door is probably placed on a couple of stools. The man uses a piece of pumice, and stoops down over his work. It may last anything from eight to ten hours a day, and the dust which is created from the rubbing down would rise straight up. No man will wear a respirator during eight or ten hours. An exhaust cannot be used, because the place of work changes all the time. The man may work on one door at one end of the room at one time, and later at another end of the room, and the door may be turned over. The exhaust is only practicable where the working place is fixed and the man is not inside that working place.

14,236. Now with regard to leadless paints. What witnesses did you examine with regard to the use of leadless paints for exteriors?—I wish to know whether you would like my general information on the point of replacing lead paints by other paints for inside and outside work.

14,237. Tell us first of all what witnesses you examined in the Austrian Commission?—The Austrian Commission consulted master painters, working painters (that is working men), factory owners, and the technical staff of factories. There was an endeavour to obtain as complete an evidence as possible.

14,238. Did the Austrian Commission, in examining the master painters, ascertain whether they had made any experiments, and for how long, with leadless paints?—A number of painters before the Austrian Commission have had experimental evidence on the point of other paints. In particular, a Mr. Meissl, who will be before your Commission to-morrow, has made exhaustive experiments with zinc white, as he himself is an owner or shareholder in a zinc white factory. Mr. Meissl's views are endorsed by all the master painters in Austria, and he is considered to be the leading authority amongst painters, as he is, apart from being a painter, also chemically educated, and he has made exhaustive experiments with substituted paints.

14,239. I want to know whether the master painters took their opinion as to the merits or demerits of zinc paints from Mr. Meissl, or whether their opinion was formed from personal experiments which they made?—A number of other master painters who gave evidence have made experiments on the durability of leadless paints, because the Austrian Government in inviting tenders specify either a pure lead or pure zinc paint, or they state that the paint must last a given number of years, generally five years. If five years is specified, it means practically a pure lead or chiefly lead paint.

14,240. (Mr. Sutherland.) That is the Government specification?—Yes, in inviting tenders.

14,241. (Chairman.) Do I understand that the Government contracts stipulate that the paint should have a duration of five years?—None of these master painters made scientific experiments, but practical experiments, and they invariably found that if they wanted to guarantee the paint to last three to five years, they had to use exclusively white lead; otherwise they could not guarantee that durability.

14,242. I am still rather in the dark as to what experiments they made?—Obviously they made experiments by making outside paints with other materials, and found that these other paints did not last.

14,243. That is the obvious interpretation; but was that kind of evidence given to the Austrian Commission?—The master painters of Vienna stated that for outside paint white lead was absolutely necessary. On the other hand, the master painters of Galicia, one of the northern provinces, stated that quite satisfactory results might be obtained with zinc white. The contracts for Galicia do not require paints of such high quality, as altogether Galicia is very backward.

14,244. You have not told us what kind of experiments the master painters made, and for what duration of time, and to what extent they were under inspection before they were condemned?—Mr. Meissl and other painters found, by practical testing, that zinc white was seen not to last after three years. After three years a zinc coat perished, whilst they found that the lead paint was still good after eight years. It began to perish after eight years.

14,245. Do I understand that the practical evidence was based on Mr. Meissl's examination?—No; Mr. Meissl and other painters.

14,246. But I want to know what experience the other painters had had. I do not want a mere statement that other master painters have said that zinc paints are impracticable. I want to know on what they based their decision?—No scientific experiments were made, but all the experiments and all the evidence are based on the result of fulfilling Government contracts or other painting contracts. It was frequently observed that zinc white was easily wiped off by very slight friction after three or four years, while this was not observed with lead. Lead might be relied on for a very much longer period. All the evidence is based on the results of these contracts with practical painting, but not on scientific experiments.

14,247. If the Committee desire it, could you furnish us with the evidence of the witnesses in respect of what you have just told us?—I can give you, in detail or in extract, the full evidence before the Austrian Commission or before the Berlin Board of Trade, dealing with the question of paints.

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

14,248. But dealing with the question of the durability of the trials of leadless paints?—I find that an inspector of the Austrian State railways has made experiments with leadless paints, and found that surfaces coated with leadless paint showed after a very short time (the time is not stated definitely) fissures and ruptures, and the coat was pervious to moisture, and the rain came through the roofs of the wagons which had been painted with leadless paints, whilst this was not the case with lead paints. I have here a very long report on experiments by Mr. Meissl on the respective durability of white lead and zinc white, but I think it is not necessary to give you this, because I think that Mr. Meissl will be here to-morrow to give you it himself.

14,249. Quite so?—The report says that other experts from Vienna, who had been called before the Commission, and master painters stated that they had nothing to add to the statement of Mr. Meissl.

14,250. Were the master house painters heard verbally and cross-examined on their experience with lead-free paints?—To these experts who were called a series of 43 questions was put. Every one of the experts present remained in the room and was entitled to cross-question the witnesses. Also the members of the Commission cross-questioned the witnesses. Mr. Meissl appeared for the painters of Vienna and gave a full statement. All the other painters said they had nothing to add to this, with the exception of a Mr. —, who made an added statement.

14,251. Do I understand that Mr. Meissl was the only witness who was really examined or cross-examined?—With the exception of Mr. —, Mr. Meissl was the only one who gave any lengthy evidence.

14,252. I did not specify lengthy evidence. I want to know if he was the only one who gave evidence, and if there was other evidence, what that evidence was?—The other evidence was from Mr. —, that he had two houses in Lemberg, one of them coated with white lead, and after five to six years the coating of paint was quite capable of being washed, and it withstood the washing quite well, whilst a house in the same neighbourhood had been painted with lithopone, but the lithopone had not worn as well as the other, so that the owner of the houses noticed the difference after a very short time.

14,253. "Short time" is too vague. What was the time?—The words used are "after some time."

14,254. That is not much use to us?—There is a further piece of evidence. In a similar case, a painter in Lemberg had painted his kitchen with lithopone; after nine months the coat of paint could be wiped off with the dry hand.

14,255. Are we to understand that the only evidence adduced before the Austrian Commission was that of a Mr. Meissl, who, I suppose, was the representative of the house painters?—And these two illustrations, one of the man who painted the outside of his house somewhere in the country or in the provinces, and the other of a man who painted his kitchen both with lithopone. All the other evidence is confined to a statement that they fully agree with Mr. Meissl, they give opinions without scientific experimental foundation.

14,256. (Mr. Sutherland.) Were the other witnesses present when Mr. Meissl was examined?—Yes, all the members of the Commission and all the witnesses were in the room, and they were all entitled to cross-question.

14,257. He spoke on their behalf?—He spoke on their behalf, and said they had nothing to add. I wish to add that there were a number of other experts present, such as Mr. Andes, the owner of a paint factory, and a Mr. Stehly, the owner of a zinc white factory. They made statements that lithopone or zinc white might yield very satisfactory results, but they gave no definite evidence. I wish to emphasise that these other gentlemen do not produce definite evidence; they only say that it answers.

14,258. So that, balancing one with the other, there is nothing left. Is that it?—I wish to emphasise that I attach particular importance to the evidence given by the master painters, but very little importance to the evidence given by factory owners.

x 7700

14,259. But have you not told us that you had no evidence from master painters?—Evidence from Mr. Meissl.

14,260. (Chairman.) Has any Austrian Government Department given leadless paint a trial on a large scale, as the British Office of Works have done?—The Austrian State Railways made practical experiments, regarding which I have already quoted the report of an inspector.

14,261. The following experiments have been made on a large scale in England with leadless paints which have proved eminently satisfactory. The Savings Bank in London was painted in 1906 inside and outside with zinc paints, and was reported to be in excellent condition in 1910. A large number of post offices and sorting offices in the London district were also painted with zinc paints, and were eminently satisfactory. The top structures of the Orient Steamship Company's liners, the Royal Yacht Victoria and Albert, and the Medina, on which their Majesties are at present travelling to the East, were all painted with zinc paints. Railway bridges and station roofs, for example those at Charing Cross and Cannon Street, are painted with coal tar, silica, graphite, and other such paints. Various gasometers and other iron structures have been painted with zinc and iron oxide paints. The exterior of the London Stock Exchange was painted with leadless paint; the results are reported by the official architect as being very satisfactory. Do you think that experiments made on such a large scale should weigh with this Committee in regard to the efficacy of leadless paints? I might also add that the Midland Railway Company's carriages and wagons have been painted with leadless paints since 1904, and the Daimler Motor Car Company paint with leadless paints, and the Bradford Corporation Trams are painted with leadless paint. I emphasise the New Savings Bank, because that was the experiment upon which the Office of Works decided to abandon the use of lead. The point is this: if the Office of Works in England, on the strength of experiments, consider it good enough to agree in the future to abandon the use of lead, do you not think that a very strong argument for this Committee to consider?—Before I answer that question, I wish to state that I think that for outside purposes, the only thing which is necessary is that the final coat is lead paint. The other coats can be zinc paint or some other paint. The only thing necessary is a final coat of lead paint, which will resist moisture and other influences. The primary coats can be some other material than lead. I wish to know whether, in all these cases which you state, the final coat was free from lead, and also whether the paints which were used and might have been sold as leadless paints had been analysed for freedom from lead.

14,262. (Chairman.) All the paints were analysed, and proved to contain no lead whatever, and all the coats, including the final coat, were non-lead?—I wish to state that while these experiments seem extremely important, and coincide with the results obtained by the Dutch Commission and the French Commission, they are in flat contradiction to the results found by the German and Austrian Commissions, and I think that all the chemical evidence is strongly against the possibility of such results as these experiments show; and Dr. Ragg, an English scientist, thinks the results of the Dutch and French Commissions, which coincide with these results, are somewhat to be doubted, and not to be taken as final. The experiments are not done on a sufficiently large scale to be conclusive. Dr. Ragg, of Woodford Green, Essex, maintains that the results of the Dutch Commission and the French Commission are not to be taken as valid. The evidence is inconclusive.

14,263. But do you know anything about Dr. Ragg?—Nothing whatever.

14,264. But you have not come here to quote Dr. Ragg as an authority, have you? We do not want to know your opinion of our English doctors, but we want evidence of what has happened in Austria?—I wish to state that, as I am a medical man, I have to obtain all my chemical information, so to speak, second-hand from other people, and as Dr. Ragg's

C e

22 November 1911.]

DR. IGNAZ KAUF.

[Continued.]

results, which are chemically obtained, coincide with the practical results obtained by master painters, I have to take these results as conclusive.

14,265. Master painters in Austria?—Yes.

14,266. We could produce a hundred, or many more, English doctors who would give precisely an opposite opinion to that given by Dr. Ragg; do you not think that these practical experiments, concluding with the determination of the Office of Works to abandon the use of lead altogether, should weigh very much with this Committee? I will read out this certificate from the Office of Works: "In 1902 Sir Henry Tanner" (who is the head of the Office of Works) "began experiments on Patent Office roof." Mr. Paterson, who signs this, says, "I commenced to use it in 1904; thought it bad; was told to pursue experiments; did so; and these warranted us using it for a comparative test on a large scale at the Savings Bank in 1906—see schedule. In 1908 we were so satisfied with the results—he does not put that in, but that is what he means—"that a general order was given to specify zinc paints. In 1911 the London Schedule gave zinc as base of all paints." That is the determination of the Office of Works in England after the experiments which they made. In England we have passed the experimental stage?—I wish to state that similar experiments were carried out in Germany and in Austria, and I have here the Decree of the Railway Office in Berlin of the 23rd September, 1907. It is a notice to other places where they build wagons: "After thorough experiments lasting several years we have definitely found out that paint free of lead, in particular lithopone and mineral white, will not do to replace white lead, in particular for painting wood and other parts of railway carriages. Therefore lead-free paints are not to be used in future, and only any stock of lithopone or mineral white which may be in hand is to be used. In future white lead is to be used." I wish to state that in 1909 the Public Health Office sent out a circular to the various States requesting them to enforce laws to restrict the use of lead paint as much as possible. Experiments were made, and in 1911 they published, that, for outside purposes, their experiments were not conclusive. Again in 1911, in Bavaria and in Würtemberg, they prohibited the use of lead for inside paints, and for public buildings the use of lead paints inside is prohibited in all the States of Germany now. For outside purposes the use of lead is continued.

14,267. What are the exact words you used about the trials of leadless paints?—The use of lead paints to be restricted as much as possible.

14,268. What do you mean by the results of experiments with leadless paints in 1911 being inconclusive?—The words used are, "they have not so far given a conclusive result."

14,269. What does that mean?—I cannot add to what I have said that the experiments were conclusive as regards inside painting; but with regard to outside painting the evidence does not lead to any conclusion.

14,270. Then that does not come to any conclusion either way—either good, bad, or indifferent?—Not either way—good, bad, or indifferent.

14,271. Thank you. That is what I wanted to know?—I wish to state that the request of the Government to restrict the use of lead paints coincided in time with an international movement for the protection of the working men, particularly to fight lead poisoning and other industrial poisonings, and they concluded their communication with the request to prohibit the use of lead paints entirely for inside purposes, and that all lead paints used should be labelled as containing lead and poisonous.

14,272. (Dr. Collis.) Is that a request by the International Association to the Austrian Government, and did they practically adopt that, and is that the reason why they did not go outside?—This communication was sent to all the Governments, and on this communication the German Government issued a note saying that the use of lead paint was to be restricted as far as possible.

14,273. And their regulations are based on that request?—Yes. I wish to state that I sat on the

Committee which published this report, and they arrived at the same conclusion as the Austrian Commission, and found that for inside purposes lead-free paints were quite as satisfactory as lead paints, and should be used exclusively, whilst for outside paints this Committee did not arrive at definite conclusions, as they considered the evidence was not yet quite clear.

14,274. (Chairman.) They came to no definite conclusion?—Yes, for inside paints.

14,275. But with regard to outside paints, the conclusion they came to was that it was not yet quite clear whether or not zinc paint could be used?—Yes.

14,276. In other words, that their experiments have not been sufficiently progressive?—Exactly.

14,277. Could you tell us the composition of these leadless paints that were used, and what you mean by zinc white?—Zinc white is zinc oxide.

14,278. (Mr. Sutherland.) Have you used zinc sulphide outside?—I have no experience of zinc sulphide having been used at all outside. My only experience is either with lithopone or pure zinc oxide.

14,279. (Chairman.) Is not the only conclusion to be drawn that the Austrian State Railways and others have not had as good zinc paints as the Midland Railway and the Daimler Motor Car Company and His Majesty's Office of Works?—I have on this point only second-hand evidence. My general experience is that the paints used in Austria are very much purer, as they work from a very pure zinc ore, and that the English zinc paints used frequently contain quite considerable percentages of lead. The Austrian ones are quite free from lead. But this is second-hand evidence.

14,280. Can you tell us whether a suitable medium has been used?—The mixing of zinc paints is generally identical with the mixing of lead paints. The zinc oxide is always mixed either with pure linseed oil or linseed varnish—that is, linseed oil with an added drier, such as a lead soap.

14,281. In England the advocates of leadless paints consider that a different medium is absolutely essential?—I want to know then what medium is used if you do not use linseed oil, as they use for white lead.

14,282. Generally speaking, a refined boiled linseed oil, liquid driers and varnish?—That is identical with the Austrian procedure, but they use also boiled linseed oil for white lead.

14,283. And liquid driers?—The English way of mixing paint is very much the same as the Austrian, as they use for white lead always boiled linseed oil, to which you have added 1 to 2 per cent. of lead to form lead linoleate, and you also frequently add to the paint manganese borate, or manganese linoleate.

14,284. I note that you have put, in paragraphs 14,197-9, particulars of the amount of lead used in the whole of Austria. Your statistics regarding lead poisoning cases, however, refer to Vienna only, do they not?—I give the amount of lead used in Austria, and also the amount of lead used in Vienna. The statistics of lead poisoning cover Vienna only. They correspond with the amount of lead used in Vienna only.

14,285. Can you tell us if the sickness insurance scheme covers the whole of Austria?—The insurance holds good all over Austria, but the figures given cover only Vienna.

14,286. Then I shall confine my questions strictly to the city of Vienna?—Exactly.

14,287. In paragraph No. 14,211 of your evidence you summarise the Regulations of 1909, which have been in force in Austria for the last 2½ years. How is the observance of those regulations enforced in Vienna? Can the Government, for example, satisfy themselves that the prohibition of dry rubbing down is observed?—There are a great number of factory inspectors, a greater number than in England, who control all these painting places. Secondly, every workman can denounce his employer if there is any dry rubbing, either through his trade union, or else through the insurance society, or else through the member of Parliament for his district, because in every working place there is a copy of the regulations, and a man is compelled to give information against his employer.

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

14,288. Is there any liability attaching to the employee if he does not denounce his employer?—I am not certain whether the employee can be fined, but the employer is invariably fined if dry rubbing down is done.

14,289. Can you tell us whether there are any statistics to show whether the employees have so denounced their employers in any instances?—There are no definite statistics, but I know a good many cases of employers having been denounced by their men either to the trade union, or to the inspector, or to the insurance society.

14,290. Can you tell us whether there have been any prosecutions in consequence of the intimation given by employees that the employers were breaking this rule?—Invariably prosecution takes place according to the regulations in every case where a man gives notice with regard to his employer.

14,291. You told us just now that there were more factory inspectors in Austria than there are in England. Can you tell us the number of factory inspectors in Vienna?—I am not able to give the exact figure.

14,292. Can you tell us how many factories and workshops and other places there are to be inspected by these factory inspectors?—I am not able to give the precise figure, but I have it from the Report of the Basle Convention for the Protection of Working Men that Germany has the biggest number of factory inspectors per factory, and Austria the second biggest number.

14,293. In Europe?—In Europe.

14,294. Then England only comes in third. We have in England, as you may be aware, 200 factory inspectors to inspect a quarter of a million factories and workshops. How does that compare with Austria?—I can only state that in Germany there are 600 factory inspectors, and whatever the number of factories is the industrial state of the two countries must show that the number of inspectors per factory in Germany is very much greater than in England.

14,295. Could you furnish us—not now, but at some other time—with the exact figures as to the number of inspectors in Germany and Austria, and the number of factories and workshops they have to inspect?—I shall be very pleased to send you accurate figures from Berlin.\*

14,296. Thank you, they will be very valuable. Can you tell us how often the inspector visits a place where painting is being done?—I cannot say how often the places are visited, but I think that the control is quite insufficient, and I think it highly necessary that for places where lead paints are made or where painting is done, you should employ auxiliary inspectors who only deal with this kind of inspection.

14,297. Could you tell us how often these auxiliary inspectors should pay a visit to the places where painting is in progress?—I think it is impossible to fix how often they should call. I think that inspection is much more necessary in places where lead paints exclusively are used, but I think it highly necessary that the inspection should be quite irregular, so that the people inspected cannot prepare for the coming of the inspector. Particularly, I think it necessary to inspect far more frequently in the summer, as very little painting work is carried on during the winter.

14,298. How does the inspector know when and where house painting operations are in progress?—The master painter is compelled to give information to the inspector regularly when there are any new buildings to be painted, of how many men he sends there, and at what time his men are there. The inspector must always have full information where the men of any master painter are working. If this information does not come regularly to the inspector the master painter is liable to a fine.

14,299. Do I understand that in respect of every job, however small, or however large, the master painter has to send a notification to the factory inspector, giving him the places and the number of men, &c., who are sent to undertake the work?—I think that I cannot quite settle this question because

small jobs are hardly inspected at all. I think that inspection of such small things is unnecessary. Information is only given on big buildings. I would not definitely say that there is no control.

14,300. But there is a possibility of very grave results if the small jobs are uninspected. They may be continuous, though small?—I think it extremely improbable that any working men would be without inspection for any length of time because a man would have a small job one day, but the next time he would probably be at work on one of the big buildings.

14,301. But supposing, as is the case in England, that men are kept continuously at work on small jobs, how would such men be inspected?—These inspectors also visit the small paint shops and odd places where painting is carried on, but the inspection is not nearly so frequent as in places where lead painting is done on a large scale and continuously.

14,302. Has the inspector the right of entry into private houses?—I do not know whether there is a definite right for the inspector, but the question has never been raised, because when any inspector comes to any house in Austria, saying that he comes from the Government, he is always admitted without question. Of course, it is very different from here.

14,303. I do not know whether to say "Happy Austria" or not?—I have done a good deal of inspecting myself, and I have never yet been refused admission.

14,304. I am sure that could not prevail in England. Have you ever heard the saying that an Englishman's home is his castle, and he is very jealous about protecting that?—I think that the Austrian esteems his own house quite as highly as the Englishman, but he is always willing to subordinate private interests to public interests.

14,305. Next, with regard to the prohibition of the use of lead for interior painting. Is this distinction observed in your opinion in Vienna?—It is carried out quite strictly, partly by the inspectors mentioned before, who will visit places, and sometimes even carry testing water, that is sulphuretted hydrogen water, with them, to test the paints. Also the control is greatly facilitated by the declaration that every vessel containing paint must be labelled as lead paint and poisonous, provided there is lead in it.

14,306. Are you aware that Dr. Ramhousek, speaking of the Kingdom of Bohemia in his evidence, states that there is no doubt that large amounts of lead are used surreptitiously for interior purposes?—I am quite willing to believe Dr. Ramhousek's statement that lead is used, and it simply endorses my statement that the control is not nearly sufficient.

14,307. But is it possible that the same surreptitious entry of lead might be introduced into Vienna?—I think that in Vienna extremely little or no white lead is used for internal purposes, because the regulation prohibiting the use of white lead for internal purposes was made at the suggestion of the master painters of Vienna.

14,308. But was not that suggestion of the master painters of Vienna made with a view of mitigating any of the rules that were applied to them?—I think that the attitude of the master painters in suggesting the prohibition of lead for internal uses was quite honest, and not done on tactical grounds, because in every case they did their level best to keep down the number of cases of lead poisoning, and altogether a case of lead poisoning is very costly for the master.

14,309. But do you think that the master painters of Vienna are more public-spirited than the master painters of Bohemia?—I think that the sole difference is due to the better information of the Vienna master painter. In Vienna extensive experiments were carried out, and extensive inquiries, while such inquiries were not carried out in Bohemia on any large scale; and the better conditions in Vienna are simply due to the better information.

14,310. (Lord Henry Bentinck.) Not to the new regulations?—Not to the new regulations.

14,311. To the awakening of public interest in the matter?—It is not a question of public interest, but of better knowledge.

\* See Appendix XVI.

22 November 1911.]

DR. IGNAZ KAUP.

[Continued.]

14,312. (*Chairman.*) But do I understand that that would account for the surreptitious use of white lead in the interiors of buildings in Bohemia?—I think it is simply due to the lack of knowledge amongst Bohemian master painters and lack of control.

14,313. But are not the Bohemian master painters under the same regulations as the Viennese master painters?—The same regulation holds good for the entire Austrian Empire.

14,314. Is the inspection in Bohemia as good as that in Vienna?—The control is the same, but it is insufficient in both cases.

14,315. Then your conclusions are that the use of white lead for interior painting in Vienna is not general?—Not general—very rare.

14,316. How is the provision of washing accommodation secured in every case for fixed workshops and for scattered jobs—particularly for very scattered jobs?—In the case of fixed workshops there is a very efficient control, and there is always provision of proper washing places, but in the case of temporary workshops, as in new buildings, the law only prescribes the provision of portable washing vessels, and it frequently occurs that the provision of these portable washing vessels is insufficient, and any kind of unclean vessel which may contain paint is used. The practice is only carried out efficiently in fixed workshops.

14,317. Is hot water prescribed in the regulations?—I think that only water is demanded.

14,318. In what manner is the rule for the periodical medical examination of the workers carried into effect?—In Austria every workman is inspected by a medical man once every three months, in Germany once every six months. In both cases there is a complete register of all men employed in paint shops.

14,319. Who keeps the register?—The owner of the workshop, but the register is controlled by the factory inspector.

14,320. Who pays for the inspection?—The employer has to pay for the medical inspection. The employer is responsible for the medical control entirely. I wish to point out that there is a similar regulation in Belgium, where every workman has to be inspected. The State pays partly for it, and the rest is paid for by the employers.

14,321. You have told us that there is a register kept of the workpeople who are medically examined. Can you tell us whether the workpeople are at liberty to see what is registered against their names?—I think that the working man has no right to inspect the book.

14,322. Where are these workpeople examined? Take the case of certain men on a job; I understand that they can be examined if they are located in the city of Vienna, but where are they examined when they are working on the outskirts or in country districts?—The contract between the employer and the man is always made in the town, even if the man does work out in the outskirts of the town.

14,323. You say they are examined in Austria every three months?—Yes.

14,324. Have the Government particular doctors who make these examinations?—The choice of medical officer is entirely at the discretion of the employer. The factory owner or the master painter has the right to pick any medical man he likes. I wish to state that I greatly admire the English way of having a sort of industrial medical men who control the statements of the private medical men.

14,325. Is it obligatory on the part of the men to be examined, or is it obligatory on the part of the employer to see that the men are examined?—The employer is compelled by law to provide the medical officer for inspection every three months, and the working man, if he does not submit himself to inspection, is liable to instant dismissal on account of breach of contract, as the three-monthly inspection is part of the regulations, and submission to the regulations is the basis of all contracts.

14,326. Supposing that the working man is put to any expense in getting to the doctor, does he have to pay that expense himself, or not?—The employer is liable for all expenses connected with it.

14,327. Are the workmen furnished with a certificate which lasts for a three months period?—The only certificate is the entry in the register.

14,328. Then how is a man who goes from one firm to another to assure the second employer that he has been properly examined?—The employer can always obtain the information from the Professional Insurance Society. The Insurance Society is run by the Government, and every painter or lead worker will belong to one particular professional society, and the employer can always obtain information from the medical officer of that society.

14,329. Does it ever happen, or can it happen, that any workman has any difficulty in getting employment because he cannot show at once that he has been medically examined by a doctor, probably in some distant town?—I have never heard of such a case.

14,330. If leadless paints only are being used in any particular case in Austria, do you grant an exemption from the regulations?—The workshop where leadless paints only are used would come simply under the regulation which enforces the provision of washing places in any painting or any working place—just under the ordinary factory regulations.

14,331. But such things as medical examination and the prohibition of dry rubbing down, &c., would not be enforced?—The question is not touched on in either the Austrian or German regulations, but in my opinion medical inspection and the prohibition of dry rubbing should still hold good, because there is always the danger of the so-called leadless paints containing a considerable percentage of lead, and also of lead being imported by the presence of linseed oil containing driers.

14,332. Do I understand that there is no inducement held out to encourage painting and decorating firms to dispense with lead altogether?—I think there is no particular inducement, but in Germany they apply certain regulations with the statement, "To apply only if certain processes are carried out." The Austrian regulations do not contain any such provision. According to the wording of the first rule, all these regulations hold good for work in places where lead or lead compounds are used, or paints containing lead—in any case whatsoever.

14,333. It would appear then as though there were exemptions for any master painter who did not use lead compounds?—Yes.

14,334. Would you like to modify your reply in view of that? I take it that it would be the case that if any master painter did not use lead compounds in the way specified there, he would not come under those regulations?—As the regulations stand at present, there is no particular inducement for any firm not to use lead paints, but I think it very important that one should make such a regulation and hold out this inducement to the firms.

14,335. In the pottery industry in England the users of leadless glaze are entirely exempt from all the regulations which appertain to those places where lead is used?—I greatly admire that regulation, and it is very frequently carried out in German regulations and in other Austrian trade regulations, but not in this particular case.

14,336. I note that the provision of working clothes and respirators by the employer, the provision of special rooms for washing and for keeping clothes, and the provision for periodical medical examination only apply in certain cases. What are those cases?—It holds good only in cases where there are 20 or more men employed.

14,337. What does this condition mean? Does it mean where there are more than 20 men employed on one job, or more than 20 men employed by one firm altogether?—As long as the firm employs 20 working men, then these regulations apply.

14,338. Then why has a distinction been made between places where more or less than 20 people are employed?—The regulation has been made chiefly because the employer who employs 20 men is more likely to be able to defray the cost of medical inspection and working clothes and so on. This is in particular a concession to the small employer.

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

14,339. Then it practically means that a vast number of working men who are employed by small firms get no protection whatever in this respect?—I think that men employed by the small workshops are quite well protected, because firstly, the small workshops use extremely little white lead, and secondly, there is a great variety of work that a man is probably employed on, and he will consequently work with white lead only at rare intervals.

14,340. But surely one man can contract lead poisoning working by himself just as easily as if he is working in company with 20 others?—But the point is that it is very unlikely that he will be on white lead work for any length of time.

14,341. Are there in Vienna a large number of small master house painters who employ just a few men?—A very considerable number.

14,342. Then I understand that that considerable number of small master house painters are relieved of the responsibilities attaching to these particular rules?—In small workshops the employer is responsible that the men wear overalls at work and head coverings, but the men have to supply their own. With regard to medical provision, in cases of less than 20 employees the employer is responsible that the man is given all information on entering on the work, and at the first sign of lead poisoning he is handed over to the medical man of the insurance society.

14,343. But surely that is a permissive arrangement; at any rate, so far as the small employers are concerned, they are not obliged, unless they employ 20 men, to conform to the regulations that I have just enumerated?—The small man has to provide a washing arrangement.

14,344. You state, in paragraph 14,211, that the provision of working clothes and respirators by the employer, the provision of special rooms for washing and for keeping clothes, and the provision for periodical medical examination only apply in certain cases. Are these not exemptions from the regulations?—To some extent. The washing need not take place in a separate place in the case of less than 20 employees, and the men have to find their own overalls in a case of less than 20. The only real exemption is that the employer need not supply the medical inspector.

14,345. (Chairman.) In paragraph 14,213 you gave detailed statistics of lead poisoning among painters in Vienna. What proportion of these are house painters, and could you tell us what proportion are coach painters?—The division is strictly not house painters and coach painters, but coarse painters. Coarse painters would cover house painters and varnishers, and the varnishers would cover coach painters and painters of small tipped goods.

14,346. (Mr. Sutherland.) Lacquered goods?—Yes, lacquered goods. Three-fifths of the total cases of lead poisoning are amongst the coarse painters (that is the house painters) and almost two-fifths amongst decorative painters—that is, painters who do finer work—whilst only a very small fraction is confined to the varnishers. The varnishers would be the coach painters.

14,347. What proportion of the number of cases which you have given us are house painters?—Some 12 to 13 per cent. are painters—that is decorative painters—and the remaining 87 per cent. are coarse painters (literally layers on of paint in house painting).

14,348. May we take it that 87 per cent. of the figures are represented by house painters, and the remaining 13 per cent. by coach painting and other artistic work?—No; the coach painting itself represents quite a small fraction, something very much less than 13 per cent. The 13 per cent. includes the painters of fine ornamental work in houses.

14,349. Could you tell us what percentage of the men are engaged in house painting, whether it is ordinary house painting or decorative house painting?—Apparently there are three-fifths house painters and two-fifths decorative painters; and varnishers are quite a negligible fraction.

14,350. (Mr. Parsonage.) It is all house-painting work; that is the point?—Yes.

14,351. And coach painting is 1 per cent., perhaps?—It is quite a negligible fraction.

14,352. You are drawing a distinction between the ordinary house painter and the decorator, both working in house-work?—Yes.

14,353. (Chairman.) Are any of the two-fifths engaged in factory work?—No, they are not engaged in factory work. I only mention the members of the friendly societies of the particular guild of house painters.

14,354. Are we to understand that, generally speaking, the whole of the figures that you give us are men who are engaged in house painting?—They might be also painters of bridges. These figures do not cover men in factories, but only members of the painting trade.

14,355. (Mr. Sutherland.) Would railway stations come under this? I do not mean waggons, but the structures?—Yes, with the exception of a very small number who are engaged in varnishing.

14,356. (Chairman.) Can you complete the second column of that table (paragraph 14,213) by stating the number of members in 1906, 1907, 1908, 1909, and 1910?—I have not the figures with me, but I can send them to you from Berlin.\*

14,357. How do you estimate the number of fully employed house painters?—Those men are marked down as such in the insurance society.

14,358. Will you explain to us how these figures in column 1 of the cases of lead poisoning were compiled?—I do not count the number of working days, but the number of men who have worked 300 days, and the number of men is reduced to full workers; that is, workers who have worked 300 days a year. Say, for instance, two men had worked 150 days a year only, these two would be counted as one man.

14,359. (Mr. Sutherland.) It may represent a continually large number of men?—Exactly.

(Mr. Mason.) It is men—days divided by 300, really.

14,360. (Chairman.) This table, paragraph 14,213, shows a decrease in the number of cases. Do you not agree that the rate of improvement is very slow?—I think that the reduction from 5·5 per cent. down to 3·5 per cent. represents a very considerable quantity—a 40 per cent. reduction. The cases of lead poisoning included there include even the very lightest forms of poisoning—cases which might not be called lead poisoning at all in England.

14,361. What do you mean by "might not"? What are the symptoms of a case which "might not be called lead poisoning"?—In my definition of a slight case of lead poisoning, the loss of appetite of a workman is counted as a slight case of lead poisoning.

14,362. So it is in England?—Whilst colic of the intestines, which is a very common thing in England, would be counted as a severe case of lead poisoning.

14,363. (Dr. Collis.) If it keeps a man away from work, we call it a case of lead poisoning if it is due to lead?—I maintain that in England colic of the intestines is 80 per cent. of all the cases of lead poisoning, whilst in Austria it is only up to 10 per cent.

14,364. No; gastric symptoms include loss of appetite as well as colic?—Symptoms showing lead poisoning in the head, such as loss of nervous command, are very much more frequent in England than in Austria, and so I claim that my figures show a very considerable improvement as the result of these measures.

14,365. (Chairman.) It is very difficult now to know how to proceed, because if you are going to belittle these cases that you have given to us, it may affect their importance?—The chief point seems that within four years these measures have brought a reduction of 40 per cent. of all the cases.

14,366. As there is extreme difficulty, I will put it to you in this way: If, for example, we take the first

\* Complete figures have been duly inserted in 14,213.

22 November 1911.]

Dr. IGNAZ KAUF.

[Continued.]

three years, 1901 to 1903, the average number of cases per annum is 139, and the percentage is 4.5. If we take the next three years, 1904 to 1906, the average number of cases per annum is 216, and the percentage something over 5. Then I notice that you do not quote the exact percentage for 1906. Leaving out the year 1907, which you suggest in paragraph 14,214 may have been an exceptional year by reason of the fact that the Commission was sitting, we come to the last three years, 1908-10. The average number of cases per annum in 1908-10 was 149 and the percentage 4, which is a fall from 4.5 to 4 per cent. I ask you whether that is not an extremely slow reduction?—I acknowledge that the drop of the first figure, 4.5 to 4 per cent. is only 11 per cent., which may not be very considerable. I wish to add that the Regulations came into force only on the 1st April 1909, although they were passed in 1907.

14,367. Even taking the lowest percentage of lead-poisoning cases, namely, 3.5 per cent. in 1910, this is still very high?—I think that, although the figure is not extraordinary, it is very much higher than a fair industrial risk.

14,368. (Dr. Collis.) You consider it is still so?—Yes, it is still so.

14,369. (Chairman.) I should like to compare your percentage of cases, if possible, with those occurring among painters in England and Wales. The Registrar-General gives the number of painters, plumbers, and glaziers as 221,000 at the last census. What proportion of this number would you deduct as plumbers and glaziers?—Dr. Woodliff furnished some figures to the Congress for the Protection of Working Men against Lead Poisoning, and he stated that among the 170,000 lead workers in England 47,000 were plumbers and the remaining 123,000 were either painters or glaziers. According to this calculation, assuming that you still have the same percentage, of the 221,000 about 163,000 would be painters and glaziers.

14,370. If your lowest percentage of illness cases, namely, 3.5, were applied to this estimated number of English painters—160,000 English painters—it would mean 5,600 cases of lead poisoning per annum?—I think that your comparison is grossly unfair, because the figures which I have given you apply only to the big city of Vienna, and you are assuming the figures taken for a big city for the whole of a country. But I am willing to let you assume the figures which you take for the whole of Austria, not for Vienna, and apply those to the whole of the English painters. The figures for the whole of Austria are between half and one per cent., and if you calculate the number of cases of lead poisoning on that basis, then I am willing to make the comparison. I will compare Vienna with London, but not Vienna with the whole of Great Britain.

14,371. You have not given us the figures for the whole of Austria, I understand, because you cannot do so?—I can do so.

14,372. Then why have you not done it?—I will endeavour to work out accurately what the percentage of lead poisoning for the whole of the Austrian Empire is. There is a statistical work by Dr. Teleky, and according to this the percentage of lead poisoning for the whole of the Austrian Empire is between half and one per cent.—nearer to half than one—and the percentage of lead poisoning is in Vienna exceptionally high, because Vienna is a big city, and a big city naturally has more unhealthy conditions than the country. I have calculated the figures for the whole of Prussia.

14,373. I do not want the whole of Prussia now; I will come to that presently. You say Dr. Teleky has compiled a statistical paper?—Yes, two years ago.

14,374. Would it not be better for us to ask Dr. Teleky to come over to England to be examined?—I am prepared to obtain for you all the figures from Dr. Teleky's book and from the registers of the insurance company.

14,375. But I think that the Committee would much rather have the particulars from Dr. Teleky personally, because if he has compiled the statistical paper we can cross-examine him on that, which is very

important?—I wish to say that Dr. Teleky's paper is more than two years old, and dates back a considerable time. It does not contain any figures for the time after the coming into force of the new regulations.

14,375A. But how are you to collect your figures to submit to us?—From the total number of cases of lead poisoning given in the book and from the number of lead workers on the books of the insurance society.

14,376. Exactly. So that you would get your figures from the tables prepared by Dr. Teleky?—Yes.

14,377. So that it would be better for us to have Dr. Teleky over here. It is rather unfortunate that you did not give us the figures for the whole of Austria in your original proof of evidence. Can you tell us whether the figures for the whole of Austria are collected on the same basis as those for the city of Vienna?—They are all counted on the basis of the insurance society.\*

14,378. Now in paragraph 14,199 you state the quantity of white lead used for inside painting in Vienna and for outside painting in the whole of Austria. Can you tell us the year or years to which that statement relates?—These figures relate to 1904 and 1905.

14,379. Then I suppose that the recent cases in Vienna, namely, 143 in 1909 and 138 in 1910, must, of course, have arisen from outside painting, seeing that the use of lead for inside painting has been prohibited?—I am not prepared to make a definite statement on that point. I happen to have the figures from Mr. Meissl's painting works. He says that in 1909 40 cases of lead poisoning occurred there, which all were the result of outside painting. I have no further figures. I think it probable that there are very few cases from inside painting, but I cannot say that there are none from inside painting on account of insufficient control.

14,380. How do you account for the number being 138 in 1910 when the rules had been in operation, certainly, for a year; in fact for nearly two years?—I maintain that the drop down to 138 from the maximum of 253 in 1906 shows a very considerable success, but although the regulations only came into force in 1909, the cases of lead poisoning started to decrease in 1906. On account of the inquiry the master painters and paint producers were visited a great deal by people who sat on that Committee, and these continual inquiries made the men very careful, and so the regulations did their work practically before they were in force.

14,381. But does not this show that the use of lead for outside painting is still a very grave source of danger?—I do not consider the use of lead for outside painting a very great danger. I think that firstly what cases of lead poisoning there are may be partly due to the use of lead for inside paint where it is not stopped by control. On the other hand the provision of washing arrangements and other sanitary arrangements is not kept up with such thoroughness in the case of outside paint as with inside paint, because generally the danger with outside paint is considered very much less than with inside paint.

14,382. You have told us that the opportunities for smuggling in lead for inside painting are practically nil in Vienna?—I maintain that although some white lead may be used for internal painting in Vienna, my chief point is that it is used internally very much less than it is in Bohemia, and the chief danger with outside paint is that the washing arrangements are not so perfect as they are for inside work.

14,383. Then are we to understand that the regulations in force are not consistently carried out?—You are quite safe in assuming that they are not strictly carried out in every case.

14,384. But it shows at any rate that lead poisoning cannot be stamped out merely by abolishing the use of lead for interior work?—I think that with a good controlling staff it would be possible still by the prohibition of using white lead for inside paint to reduce the number of cases of lead poisoning amongst painters to a number which would constitute just a fair trade risk.

\* Statistics obtained direct from Dr. Teleky are given in Appendix XXXIII.

22 November 1911.]

DR. IGNAZ KAUF.

[Continued.]

14,385. Now you have told us that the factory inspectors in Austria are largely in excess of those in England, and yet, notwithstanding that, you do not consider that there is sufficient controlling influence to insist on the regulations being enforced?—I think that, although the number of inspectors is in excess of the number in England, the number is still very insufficient, and I think it necessary to have inspectors dealing only with this particular branch of industry.

14,386. Now, with regard to German regulations which came into force, I understand, in 1906, how is the observance of those regulations enforced in Germany?—Through factory inspectors.

14,387. Who, I understand, are even larger in number than is the case in Austria?—Yes, slightly.

14,388. Who does the inspection necessary to secure the observance of the regulations in Germany?—The factory inspector.

14,389. Can you tell us how many places, factories, and workshops, and the rest, there are which have to be inspected by these inspectors?—I have not these figures.

14,390. Do you know how often an inspector visits a place where painting is being done?—Every working place must be inspected at least once a year.

14,391. I suppose that answer refers to factories?—This refers to factories and workshops coming under the factory byelaws.

14,392. How does the inspector know when and where house-painting operations are in progress?—The German reports of these factory inspectors show that there is great difficulty in seeing where temporary work is done, as the inspectors only have on their books fixed working places, and they visit such fixed working places and find that the men are working somewhere else. A great deal of delay is caused in this way. The arrangements for visiting temporary working places are not as drastic as in Austria.

14,393. Has the inspector the right of entry into private houses?—This is the same as in Austria. The request of the Government inspector would always be granted at once.

14,394. Are we to understand that the factory inspectors pay visits to the painting which is being done in a private house?—Yes, it may occur that the inspector enters a private house for the purpose of watching work done and the conditions.

14,395. Does the same system prevail in Germany as you have told us prevails in Austria—that the master painters are obliged to send in the names and addresses in connection with painting operations which are being done all over the country in private houses?—The master painter is simply compelled to give the inspector any information he may ask for.

14,396. So that the inspectors, to be cognisant of the different places all over the country where painters are employed in private houses, would have to go to the master painters and find out themselves?—Yes.

14,397. Now in paragraph 14,218, you present statistics of lead poisoning for Berlin and Prussia, based on hospital records. Have you observed that the rate of improvement is very low—only 5·5 per cent. per annum for Berlin and still less, 3·8 per cent. per annum, for the whole of Prussia?—I maintain that the difference between the years with the minimum and the maximum is a difference of 25 per cent., and that on an average it is a reduction of 5 per cent. per year.

14,398. 5·5 per cent. per annum for Berlin and 3·8 per cent. per annum for the whole of Prussia?—It leaves very much to be desired; the slow rate of improvement is due to lack of control, and it does not satisfy me.

14,399. Now these tables, being based on hospital figures, must necessarily be very incomplete?—The collection of figures is complete only for Berlin, but all these hospital cases represent more severe cases, and consequently they give a very definite indication of the total rate of decrease.

14,400. But if they only record the severe cases, there must be a vast number of others which are less severe, and which are not recorded?—To obtain the total number of cases of lead poisoning, it is necessary to multiply the hospital figures by four.

14,401. You cannot tell us among how many painters these recorded hospital cases of lead poisoning have arisen, can you?—This is on about 100,000 painters in the whole of Prussia and about 5,000 in Berlin, roughly.

14,402. But how are these statistics compiled?—The figure of 5,000 is given from the insurance register and the figure of 100,000 is taken from the professional census. In the census every man has to state his profession.

14,403. As with us?—Yes.

14,404. You also give us, in paragraph 14,222, a table based on records of the Sickness Insurance Fund. This shows a similarly slow improvement, does it not?—I think that the improvement is very slow—very much slower than it should be.

14,405. In paragraph 14,224, you lay stress on the favourable position for inspection in England. Are you aware that there are only 200 factory inspectors to enforce the Factory and Truck Acts in a quarter of a million work places?—I think that the conditions are so very favourable for factory inspection, because the factory inspectors are so very much supported in their work by sanitary inspectors.

14,406. You refer to sanitary inspectors as being suitable for enforcing regulations. Perhaps you are not aware that these are officials of the local authorities, and therefore your suggestion would involve the inspection by sanitary inspectors of work carried out by employers who are often prominent members of the local governing authority which appoints the sanitary inspectors. Would not this be open to very grave objections?—I do not see that this is any new difficulty at all, because the sanitary inspectors are also inspectors of houses, and frequently their duty might bring them into conflict with a house owner or with an employer who is a member of their county council in the same way; I do not call it a difficulty, because you have the same difficulty in all ordinary work.

14,407. If a large number of the employers of labour themselves prefer prohibition to a cumbersome and irksome code of regulations, what should you say to that?—I think that whatever you do, even if you prohibit lead for inside only, you will still have a fairly complicated set of regulations, because you must control outside paint, and for inside paints you must secure the paints being really free of lead, and I think it extremely difficult to see what this Committee can do.

14,408. But that is not quite an answer to my point. Supposing that a large majority of the witnesses before us, employers, prefer the prohibition of the use of lead to a set of irksome and cumbersome rules, what would you say to that?—I think that the question resolves itself into this—whether you prefer the interest of possibly public health and the health of the workers to the interests of the lead industry on the one hand, and whether there are possibly other interests involved in the lead industry. And even if you do prohibit white lead altogether, you will be compelled still to have control to test that the paints are actually free of lead.

14,409. (Dr. Collie.) I will just take the pages about which I am going to speak and give you the sections—first, paragraph 14,199. You note that it is there stated that the number of lead poisoning cases among painters in Vienna for inside painting is about 163 cases, and I notice that 163 cases in the table on the previous page is the total number for the year 1903. In the same paragraph, 14,199, at the end, it is further stated that these cases are for inside painting, and that there were 50 additional cases in Vienna for outside painting. Should the number for Vienna not be 163 in the previous table, but 213?—It is an average figure. It is not for 1903. I will give you the years for which it is an average figure if you want them.

14,410. I will leave that point, as it is only a small one. In paragraph 14,202 on the same page it is calculated that, of 163 cases of lead poisoning in Vienna, not more than 48 were due to simple painting. Does this mean that even if all dry rubbing down was entirely abolished still those 48 cases could not be got

C c 4

22 November 1911.]

DR. IGNAZ KAUP.

[Continued.]

rid of?—I obtained all these figures simply by inquiring from the various master painters in Vienna and from the men themselves.

14,411. In other words, you cannot answer the question?—If the dry rubbing down had been abolished, I am not prepared to state that there would not have been 48 without experimental evidence.

14,412. Do you think the number of cases of lead poisoning increases when fresh men are exposed to the attacks of lead?—I think that the bringing of new men to lead labour is increasing the chance of lead poisoning by subjective causes—that is, inexperience or lack of cleanliness in working and thereby an increase in lead poisoning is possible by bringing new men.

14,413. Have you noticed in your table (paragraph 14,213) that there is a great increase of the number employed in the year 1903 as compared with 1902?—Some increase is due to a new way of counting. In 1901 the figure has been taken as the number of men in the union on a particular day. From 1902 onwards it is the number of men working days divided by 300, counting only full working men, that is, men who have worked 300 days in the year, as I think I stated before.

14,414. If we calculate the number employed in the following years up to 1909, calculating from the percentage of cases as against the number of cases given (working backwards) it would appear that the amount of work done has been stationary, or even going back during those years. That is to say, that the men employed have been a constant factor among whom you would expect a steadily decreasing number of lead-poisoning cases as this permanent staff became, as we know they do, more immune from the influence of lead?—I do not know of any immunity against lead, even with long use to it. Secondly, amongst these men there would still be a natural change, old workers dying and new men being employed, and you would still have the same number of men unused to the work, and men who increased the subjective danger of lead poisoning. There being no immunity, the number of new hands coming in, thereby keeping up the subjective danger of lead poisoning, it is not fair to assume that the danger would automatically grow less with a stationary number of workers.

14,415. With regard to white lead factories, the regulations stopped women being employed. Men took their place, men being known to be less prone to lead poisoning than women, and the number of cases reported annually increased by leaps and bounds, till we had four times as many each year notified as we had previous to the regulation stopping women from working in white lead. With regard to the years which we are discussing in this table, the number of working days apparently in 1909 is more than 100 less than in 1907, which shows a fair reduction and slack work. You can calculate that?—The amount of painting work done is strictly proportionate to building work done.

14,416. The same point holds good. There is a decrease in the amount of employment, and you would expect an automatic decrease in the number of cases out of proportion to the absolute numbers. Increase of employment and quicker work send up the cases of lead poisoning quite out of proportion to the number of men employed. Similarly, decrease of employment and slack work cause a more rapid decrease of lead poisoning than the absolute number of men employed would show?—The reduction of the numbers of men working in 1909 is not simply a reduction of the number of hours worked, but is only a reduction of men working. The men who did work in 1909 worked their full hours as before, and the other men were simply made unemployed.

14,417. When speaking of the cases in Germany in paragraph 14,223, you draw attention to the decrease in the percentage of days of sickness. Turning to paragraph 14,213, and taking the comparative years which you have given us, starting with 1903, I notice that the days of illness per case have risen since 1903 from 20 to 22 in 1910, passing through the following figures—for 1904, 21·6; 1905, 19; 1906, 22; 1907,

23; 1908, 23; 1909, 20·8; and the full year of regulations 22·2. How does that bear out the statement that the regulations have been beneficial?—I maintain that paragraph 14,223 only refers to the total number of days of illness, not the number of days of illness in any individual case.

14,418. But then on my point of the total number of days for each individual case, it seems to show that the individual cases are more severe?—I maintain that the difference of 21·6 to 23 is quite immaterial. The chief thing is that whilst you have in 1905 a total of 3,763 days of illness, in 1910 you have it down to 3,155. That is a decrease of 600. From 21·6 up to 23 is so small a difference as to be immaterial.

14,419. It at any rate shows that the severity of the cases has not diminished. Do you think that it has diminished, because I understand the paragraph to mean that?—I am quite willing to acknowledge that these figures do not show a decrease in the severity of the illness, but the chief thing is the total number of sick days have decreased, and that is the chief economical result of these new regulations.

14,420. You do not think that, generally speaking, the severity of the cases has diminished?—Not from these figures. The figures do not show it.

14,421. With regard to paragraph 14,222, what does the last column "Percentage of days of lead sickness" mean. I cannot gather its meaning—percentage of what?—It is badly stated in the heading. It should be "number of days of lead sickness per 100 workers."

14,422. That is very different. I absolutely misunderstood it. So that what is claimed to be the effect of the regulations in Austria and Germany is a reduction of the total number of cases, but no alteration of the severity of the cases. I want to get that quite clear?—Yes.

14,423. Then in Appendix XV., in the table on lead poisoning among painters in Prussia, the regulations came into force on the 1st January 1906. There appears to be a marked decrease in the first year, but after that the decrease becomes very gradual, and seems to show that the full power of the regulations can now be estimated. Will you tell us whether that is so or not?—I do not think that this quite exhausts the possibilities of regulation, because firstly, in Germany you have not got the prohibition of the use of white lead for inside paints. It will come into force now.

14,424. When?—It is intended to prohibit the use of white lead on inside paints in Germany, and when this comes into force I expect a further decrease in lead poisoning. Further, from 1905 to 1906 you have a very great drop in cases of lead poisoning, because the regulations are now. You have similar results in all factory regulation. A regulation has its greatest benefit when it is newly put into force. Later people get lax in observation and control of the regulation.

14,425. Were more inspectors appointed when the regulations came into force in Germany, and later in Austria, to see to the carrying out of the regulations?—No, no new inspectors were appointed.

14,426. Did the Austrian Commission take into consideration how many cases of lead poisoning occur in factories in the process of making white lead and mixing lead paints ready for use?—Yes, all these figures of lead poisoning in lead factories were taken into consideration—that is in the making of white lead and oil paint ready for use.

14,427. What is the proportion of cases of lead poisoning in Austria due to the use and the preparation of lead paints and the manufacture of white lead for the preparation of lead paints to the total number of lead poisoning cases in Austria?—I have no accurate information on that point. I only know that there are not more than roughly 300 men employed in white lead factories to some 30,000 painters.

14,428. This chart shows the lead poisoning in the whole of Great Britain, for all industries (showing a diagram to the witness.) The second column is for all industries except the use and making of paints. You have seen Dr. Legge's calculations from the total deaths?—Yes.

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

14,429. That is founded on those?—The inference is that the total lead poisoning has decreased very rapidly.

14,430. That is so in factories, and due to regulations, as shown by columns for industries with regulations; the column for painters shows no fall at all?—A calculation based on deaths does not give a very accurate result.

14,431. Do you not consider that this is an additional reason for considering seriously as great an abolition of the use of lead in paints as can reasonably be adopted?—I, as a medical man, can only appreciate the question from the public health point of view, and not at all from the economical point of view, and, consequently, I do not think myself entitled to answer the question whether the abolition would be justified on these grounds. On the other hand, I wish to say that I am extremely glad that I have been able to see these diagrams on white lead, and I am very grateful to you for having called my attention to these diagrams.

14,432. When men are busy at their work in the summer, is there any tendency for them, even though suffering, to continue at their work, so as to earn all the money they can during the busy season, and not declare the nature of their illness?—Your experience tallies exactly with what I think is stated in the Austrian report with regard to the concealment by men of symptoms of lead poisoning, so as not to lose the opportunity of work. But whilst they are at work in the summer, they are probably well fed, and do not show the poisoning. You have, tabulated, the number of cases of lead poisoning per month, and when the slack season begins and the men begin to be unemployed, they are underpaid, and consequently underfed, and then symptoms of lead poisoning show. So the withholding of information about lead poisoning is not always intentional.

14,433. In which part of the year is the greatest incidence of lead poisoning in Austria, in your experience?—The figures do not refer to lead only—to the general industrial diseases in January, February, and December.

14,434. We find somewhat the same in factories in England, and there is no seasonal occupation in factories, so that that does not support your suggestion. Then it may happen that men working in summer feeling some illness may continue at their work, and not declare the condition of their health?—Yes.

14,435. Did the Austrian Government establish their Commission because of the International Association requesting them to abolish the use of lead for internal purposes?—The request of the International Association came in 1910, whilst the Austrian Committee sat in 1906.

14,436. Then the Austrian Commission considered that the German regulations of 1905 were not sufficiently strict in that they went one better, and abolished for internal painting?—The difference between German and Austrian regulations is simply this—that in the German inquiry it did not come out that the use of white lead for interior painting was much more dangerous than for outside painting. The Austrian Commission was called on different lines, and consequently gave different results. The master painters who were called before that Commission stated that the chief danger of lead poisoning was due to dry rubbing down of inside painting, and consequently the Austrian regulations have that additional prohibition.

14,437. (Chairman.) When you say master painters, you mean Mr. Meissl?—Yes.

14,438. (Dr. Collis.) Would it then be wonderful, or in the ordinary march of events, for Germany to have regulations in 1905 which were shown on further investigation in Austria to require strengthening by the abolition of lead paint for interior work in 1906. If England three years later, in 1911, found it possible to do away with lead in the same way as France has, we should have definite progress of which Germany and Austria had given us two steps, and we only take the third?—I think it is quite a natural sequel,

provided that you can overcome the resistance of the white lead industry of this country, and provided that you can put a sufficiently high value on the public danger against the damage to that industry.

14,439. (Mr. Sutherland.) You use the term "simple painting." What do you mean by that? It is in paragraph 14,202?—These are cases of outside painting where you simply put on a coat of paint and do not polish.

14,440. How do you think the poisoning arises in those cases?—It all depends on the cleanliness of the workmen. They soil their hands and eat and smoke without washing the hands.

14,441. Do you think that there is any danger to the workman from the vapours given off by wet paint newly applied?—I think that the real danger is that all paint containing linseed oil will give out the volatile turpentine contained in the linseed, and that has nothing to do with lead.

14,442. What is the physical action on the air of a room of linseed oil and turpentine spread over a large surface?—The turpentine will exercise an irritation on the breathing organs.

14,443. Do you think that certain effects of nausea and trouble that painters experience come from the absorption of the oxygen in the room by the linseed oil and paint?—I think that it is quite impossible, because when you have fresh paint in a room, you invariably have the windows open, and the consumption of oxygen by the linseed oil would be so slow as to make it impossible to affect the oxygen property of the atmosphere.

14,444. But if you go into a room that has been shut up, for instance, where it is newly painted and newly varnished, you experience the same effects of nausea that are ascribed to lead?—I think it is quite possible that such a thing may cause nausea, but of a totally different type from the nausea due to lead, because nausea the result of lead would show itself only after a considerable time, whilst the nausea due to linseed oil or turpentine would show itself at once in irritation of the breathing organs.

14,445. Some of the complaints that are ascribed to lead may be due to the effect of the oil and the turps on the atmosphere of the room?—I think it not possible that you might ascribe the results of turpentine poisoning to lead, because the symptoms of lead poisoning are totally different from the symptoms of turpentine or linseed oil poisoning.

14,446. In paragraph 14,201 you say that iron is not commonly rubbed down. It is not rubbed down in the sense that we rub woodwork down, but it is chipped, and that creates dust?—I acknowledge that it is possible to raise quite a lot of dust in chipping iron, but this is never done in Austria. Old paint on iron is invariably removed with caustic soda, or if it has to be removed by rubbing, it is done wet.

14,447. In the case of blistered paint on iron, what do you do?—I do not consider that a possibility. I think that if the iron has been properly prepared, there is no possibility of blisters.

14,448. I understand from you that if the regulations in Austria were more strictly enforced there would be a great diminution of the cases of lead poisoning?—I certainly think it very possible to obtain a very great reduction of lead poisoning by better control enforcing the regulations, particularly cleanliness, and giving the apprentices, the men now to lead work, better information and better teaching of how to work with lead and keep clean.

14,449. That points not to the uselessness of regulations, but to the necessity of their enforcement?—Exactly. All that is required is better control and better information for the new men.

14,450. Then as to the question of cost. If prohibition was to be enforced we should still have to keep up a staff of inspectors to see that it was carried out?—I think that it would certainly still require a very considerable number of inspectors, though possibly not the same number that you would require otherwise.

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

14,451. That being the case, would it not be much more reasonable and fair to the established usages of the trade and in the interest of the manufacturers of white lead to first of all try regulations?—Speaking purely as a medical man, I am in favour of total prohibition; but speaking as a medical man and as a national economist, I am in favour of allowing white lead to continue providing a new set of regulations and very strict control to enforce these regulations. Should these regulations and the strict control fail to produce good results, then there is still time for total prohibition.

14,452. Assuming regulations, would it not help to bring about a change in the incidence of lead poisoning in a more natural way by granting exemption to a painter who made a signed declaration that he was not using lead paint?—I think that the exemption of lead paint in workshops where only lead-free paints are used is practicable, provided that you can rely entirely on the good faith of the employers, and that in case of breach of good faith you can proceed against the employers with great severity. And you would all the same be able from time to time to obtain samples of the paint and the oil and analyse them for freedom from lead.

14,453. The Prussian State Railways have no interest in maintaining lead paint?—The Prussian State are in no way interested in the white lead industry.

14,454. Then the fact that after making extensive experiments with zinc and finding that it would not answer their requirements they abandoned it, is a very great testimony to the value of white lead as a paint preservative?—The decision that white lead was superior to zinc was made in 1907. In 1909 there came a further order from the Government to try to dispense as far as possible with white lead. Experiments were carried on, and in 1911 the conclusion was arrived at that for interior purposes on the State railways white lead should be abolished. For outside purposes it is still being used, but experiments are at present being carried out to test whether it would not be possible to use other paints.

14,455. It is abolished for inside the carriages?—It is abolished for inside the carriages.

14,456. For outside the carriages white lead is still being used?—Yes.

14,457. For the purpose of comparison, what would you take as the constituents of a lead paint and a zinc paint?—Do you mean the constituents of the white lead itself?

14,458. Take pure white lead and pure zinc?—I do not feel competent to answer the question, as it is purely a practical question. I can only give you second-hand information.

14,459. Have you any figures showing the number of individuals as against cases?—In 1905, in Vienna, there were 198 cases, 152 individuals, and in 1904, 197 cases, and 159 individuals. I have come across cases where one individual had up to four and five attacks of lead poisoning in one year.

14,460. (Dr. Collis.) In the English statistics we never consider that a man can have more than one attack in one year. If a man is notified to us in July of this year, he could not have another attack, according to us, before August of next year?—I follow.

14,461. (Mr. Sutherland.) You make returns of recurring cases?—Yes. The first figure gives the number of cases, and the second figure the number of persons.

14,462. (Mr. Parsonage.) Have you ever instituted any test to ascertain if the volatile vapour from fresh paint gives off lead compounds?—I have never made any experiments myself on that point, but I have heard of some experiments. I have never yet come across any experiments which I would accept as quite conclusive. Personally, I think it extremely improbable.

14,463. Do you think it possible to so improve on the Austrian regulations as to bring lead poisoning down to the average of an ordinary trade risk?—On

account of the poisonous nature of lead, there always will be a certain number of cases in addition to the ordinary factory accidents which may occur in factories connected with any industries, but I think it quite possible to reduce by proper care the number of cases to a figure exceeding only very slightly the figures obtained from ordinary trade risks.

14,464. My question does not apply to factories, but to ordinary house painting. Can you suggest any improvement on the present Austrian regulations?—I think this is possible, provided you prohibit the use of lead for inside paint, and have very good control to enforce the regulations and give the new men entering on the work very full information. Then I think it is possible to reduce the lead poisoning to nothing more than a fair trade risk.

14,465. But the use of white lead is now prohibited for inside work and while it is still used for outside, how can you prevent it being used inside?—With full control.

14,466. That is control that they have not got at the present time in Austria?—I have stated several times to-day that I am not satisfied with the present methods of control.

14,467. You cannot make any suggestions which will improve them still further to make them effective?—I think it possible to reduce the risk of lead poisoning amongst painters to a fair trade risk by the following methods for temporary work such as outside work on buildings, a good provision of portable washing arrangements; the provision of a separate cloak room so that the men change their working clothes and their other clothes in a place free from lead; the foreman superintending the work at this temporary place to be responsible for the use of the washing arrangements, and for changing of the clothes, and generally for the keeping of all these regulations; monthly medical inspection instead of a three-monthly inspection, and thorough information to new men on the dangers of lead. If possible, this information should be given to all apprentices whilst they are apprentices. And all men to be examined medically before they enter on the profession.

14,468. Would you suggest that all men working at the trade should go as apprentices and learn the trade, and be brought up to the risks of it, instead of men being introduced into it after they have grown up?—I think that a proper apprentice system would greatly reduce the danger of lead poisoning. I think that the persons most easily subject to lead poisoning are new men who enter on painting without any previous knowledge, and who simply get the position, as it is called, by submission. This is a way in which labour is put out for public competition on the Continent, and labour may consequently fall into quite unskilled hands, and those unskilled hands are most liable to poisoning.

14,469. (Mr. Gardner.) Following on that answer, are we to understand that in Vienna quite a number of painters have gone to the trade after they have become adults, without previous training?—The assumption is quite justified. Quite a number of men amongst the painters have not been through a proper apprenticeship.

14,470. Is there an apprenticeship system in Vienna?—Yes, there is a proper apprenticeship system and there are proper trade schools teaching painting.

14,471. Can you tell us if there is much more outside painting work in Vienna than inside painting work?—I cannot give any definite information on that point.

14,472. I understand that the Commission which sat were of the opinion that the lead poisoning which was taking place was due principally to inside work, and that there was very little risk run on outside work, and for that reason they prohibited the use of white lead inside?—Yes. There is very little danger connected with outside work.

14,473. Of the cases which are quoted, it is said that three-fourths, taking them roundly, were due to the dry rubbing down of paint. Dry rubbing down

22 November 1911.]

Dr. IGNAZ KAUF.

[Continued.]

has now been abolished, but I find that in 1910, as compared with 1904 and 1905, there has only been a reduction of about a third in the number of cases of lead poisoning. In 1904 it is 197, and in 1905, 198. So that if three-fourths of the cases were due before that to the dry rubbing down of paint, and dry rubbing down has been abolished, how is it that there is such a poor saving?—I think that on the whole for all painting work the number of cases of lead poisoning has decreased some 50 per cent., and not as you say, 30 per cent.

14,474. I did not say per cent., I said a third. You see in 1905 there were 198 cases, and in 1910, 188 cases. That is only a decrease of 60, and you have no inside work done at all. We were told in your evidence in chief that three-fourths of the cases reported were due to dry rubbing down, and now we find only a saving of 60 cases. Now, in reply to the chairman, you said that a case of lead poisoning in Vienna was very costly for the master. Will you tell us in what way it is very costly to the employer?—All the money for compensation is found by the employers and by the workers, and if the number of cases of lead poisoning goes up, then the amount of money to be found will go up, and that comes out of the masters' pocket partly.

14,475. Partly?—Two-thirds out of the worker's pocket, and one-third out of the employer's pocket.

14,476. But that would not make a case exceedingly costly for the employer, if two-thirds came from the worker, and only one-third from the master. You not being a practical man would know very little about outside work. You said there was no rubbing down of outside work. Can you give us any information as to how outside doors are prepared and brought up in Vienna?—Doors are polished before being painted with the priming coat. They are invariably rubbed down wet, and as they are, so to speak, a finer article than the wall, they do not really come fairly under the heaping of outside painting. Outside painting, as I use the term, applies chiefly to walls.

14,477. But between the different coats of paint they cannot be rubbed down wet. What process is applied to smooth the doors down between the different coats of paint?—They are invariably rubbed down wet.

14,478. You referred to a circular which was issued to the Railway Department, asking them not to use lithopone in future, but to use white lead. I would take it from that that what they had been using on wagons and vehicles was not good zinc white paint, but lithopone. Here we look upon lithopone as one of the very cheapest classes of material which can be used. Was the lithopone which was used equal to good zinc white paint?—I have no information on the quality of the paint used; nor the method in which it was used.

14,479. (Mr. Fell.) I want you to give us some reason, if you can, why the percentage of lead poisoning in the case of carriage painters is so small?—Because for varnish work in Austria wet rubbing down is done exclusively; no dry rubbing at all.

14,480. But carriage painting is done under cover in the same way that you do the interior of a building?—In spite of that work being carried on in closed buildings, there is no reason why there should not be wet rubbing down. In 1905, whilst there were 8 per cent. of house painters having lead poisoning, there were only 2·7 amongst coach varnishers.

14,481. Do you mean that the number of painters employed in the coach-building trades is almost infinitesimal?—I said that there is a small number of men only employed in carriage varnishing, but the proportion of lead poisoning amongst those employed is still very much lower than the proportion of lead poisoning in any other kind of painting.

14,482. Do they do no dry rubbing down at all on the wheels or under parts of the carriages?—No, none at all—exclusively wet rubbing.

14,483. Exclusively wet rubbing?—I maintain that all rubbing down of carriages or coaches is done wet, and gives much better results than dry rubbing.

14,484. The evidence we have received from the practical men so far is wrong, then, because they have all stated that it is impossible to rub down curved surfaces and the under parts by the wet process?—I still maintain that in Vienna, according to my information (I am not, of course, a practical man), it is always done in the wet way, with very good results, but at an increased cost.

14,485. What I cannot understand is this: why should you prohibit the use of lead in a room which is only painted possibly once in five years, and yet not prohibit it in a paint-shop where paint is used daily, and you must have an enormous accumulation of lead dust?—I think it does not matter in the least how much a workshop is used. The only thing which does matter is the amount of lead dust in the air, and the amount of lead dust in the air may be very much more in the case of a room which has been painted only once in five years, than in the case of a properly cleaned workshop, which is used continuously. The lead dust may accumulate, but the lead dust accumulating would fall to the bottom, and would be continually removed by proper cleansing, and the amount of lead dust in the air, under proper arrangements would be less than in the case of inside painting where dry rubbing takes place.

14,486. Do you know that in Vienna and in Berlin, where they have very large tramway systems; they have tried substitutes in connection with the tramways?—I only know that in Vienna they have used a considerable quantity of lead paint in their tramways, such as chrome-yellow and chrome-red, but whether they have tried any substitutes, I do not know. I have no information whatever about the paints of the Berlin tramways.

14,487. (Chairman.) Did the Austrian Commission include in their terms of reference an inquiry into coach painting?—The Austrian Commission has enquired into the low percentage of lead poisoning amongst varnishers (that is coach workers) and has found that the low percentage was chiefly due to the wet rubbing which was exclusively resorted to.

14,488. Then it was included in their terms of reference?—Yes.

14,489. (Mr. Fell.) Do you think that if dry rubbing down was prohibited in a coach building shop, there is no necessity for the prohibition of lead?—I think that lead paint in coach varnishing shops would be quite harmless if you resorted to wet rubbing down, and insisted on scrupulous carefulness on the part of the workers.

14,490. (Mr. Mason.) Are we to understand from the expression "carriage varnishers" that the majority of carriages in Austria are varnished on the natural wood?—The term "coach varnishing" is simply a trade name. Coaches over there are generally given first a coat of size, then a coat of dense paint, over that a coat of ordinary paint, and a final coat of varnish. On account of the final coat of varnish, the whole profession is called "varnishers."

14,491. Can you suggest any reason for the increased percentage of lead cases which is almost universal in recent years, though the conditions are practically the same?—I can give no reason for the increase, because there is no increase. The number of cases of lead poisoning has steadily decreased.

14,492. Since the regulations only?—Yes, since the regulations only.

14,493. In the last sentence of Regulation 4 in the Austrian Regulations special exemptions are mentioned. Can you give us an indication of what those exemptions were?—I have no information whether these exemptions have been used in any way or to any extent.

14,494. (Mr. Kinggate.) Might I ask you the constitution of the Commission that enquired into the question of lead poisoning, and whether any coach maker representative was on the Commission?—The Commission was constituted of master painters, working painters (that is workmen), chemists, factory owners, University professors, medical men; and amongst the

22 November 1911.]

Dr. IGNAZ KAUP.

[Continued.]

master painters was included a representative of a carriage factory, a furniture varnisher, and one worker in a coach varnishing shop.

14,495. Evidence was submitted to the Commission that the whole of the work in a coach making shop was rubbed down wet?—Yes; they had first-hand evidence that the rubbing down was done wet.

14,496. All rubbing down?—All rubbing down.

14,497. We quite understand what is meant by rubbing down in England. With regard to the question of sand-paparing of the bare wood when lead colour is first put on, it could not be rubbed down wet because it would raise the grain at once?—The first coat on the wood is not rubbed with sand-paper at all. On the first coat a second coat of paint is put, which is polished wet.

14,498. And on wheels, taking an ordinary carriage wheel?—I assume that this holds good for wheels as well, because wheels are not specially mentioned, and representatives of the coach varnishing firms were present on the Commission and acknowledged that all rubbing down was done wet.

14,499. It costs a lot of money to do it, and it seems very strange?—I have stated that the wet rubbing means an increased cost.

14,500. A greatly increased cost. With regard to experiments on railways, Mr. Sutherland suggested that very extensive experiments have been carried out. Those are not yet concluded, I understand from your statement?—I stated that in 1911 experiments in favour of using lead-free paints for outside purposes were not concluded.

14,501. If it has been proved by the Midland Railway Company that it is possible to do without lead at all in the outside painting of the coach, is it not quite possible that that could be carried out in Austria?—I think it quite possible, but on the other hand, the Austrian State Railways have carried out such experiments, and they did not come to the conclusion that lead-free paints answered as well as lead paints.

14,502. They are still carrying on the experiments?—Yes, experiments are still being carried on.

14,503. You appear here to-day in a dual capacity as medical man and economist. It is suggested that some injustice would be done to manufacturers by the abolition of the use of white lead, and I would like to put it to you from an economical standpoint: having regard to the amount of illness, and the number of deaths caused by lead poisoning, and seeing the great difficulty there is attending the carrying out of the regulations, would it not be in the interest of the country from an economical standpoint to abolish the use of lead, as the health of the worker is more important than the manufacture of white lead?—I have gone for a considerable time into the cost of providing by the community for those who are ill and for those left by death. It is very difficult to say which is the greater value of the two. Any industry, which endangers life has not the same right to consideration as any other industry. I as a medical man, and as an economist, feel myself not capable of deciding which of these two values is the greater, and before stating that the value of public health is greater than the value of the industry, I would like to test whether it would not be possible to make the industry a fairly healthy one.

I wish to add that although at present the balance in favour of public health against the value of the industry may be doubtful, if by improved regulations you decrease the number of cases of lead poisoning considerably, then you certainly increase the value of one side of the balance, namely, the danger of the poisoning, but there is no chance of the value of the lead industry being decreased.

14,504. You will admit, I presume, from your practice, that there are some men very much more susceptible to poisoning from lead than others?—I certainly believe that some people are strongly predisposed to lead poisoning.

14,505. Then whatever regulations you might make, there is still a danger attending the use of lead?—Yes.

14,506. (Mr. Robins.) Do you think that it would be beneficial to have the hours restricted in a paint shop, and only allow so many hours' work by a painter?—I certainly think that the time at work has a great deal to do with the danger of lead poisoning, as in all cases of employment, and particularly in dry rubbing. The amount of lead possibly absorbed would be directly proportional to the time the man spends at his work. If a man who does dry rubbing for five hours a day would get lead poisoning after a month, a man who did it for ten hours a day would probably get it within a fortnight; therefore I think it advisable that for all kinds of lead painting a maximum should be fixed.

14,507. I take it then you agree that overtime should be abolished? Overtime is worked in England extensively?—I am strongly against working overtime in any industry, and particularly so in lead painting. There is a strict regulation against overtime in lead works, particularly in the chamber process, or in dangerous work, and I certainly think that the prohibition of overtime should extend to lead painting.

14,508. What are the hours in Austria?—The average time is nine hours a day.

14,509. What do you think the hours should be reduced to?—If dry rubbing still exists, then you would have to have a fairly low maximum. If dry rubbing is entirely abolished, there is no more reason to have a maximum than in any other trade. If you have ten to twelve hours a day in iron work, you should certainly not restrict the painter to anything below the present nine hours. If you have only the wet-rubbing, there is no reason why he should not work as long hours as other workers.

14,510. (Chairman.) You have told us that there must still be a certain amount of lead poisoning, a considerable amount, in fact, notwithstanding that dry rubbing has been abolished. You also said that you consider that men working in the lead industry should have restricted hours. How do you reconcile those two statements with the last one?—The question of maximum hours has not been considered generally in Austria and Germany. The figure which I gave before of nine hours a day is only an average, and not a regulation.

14,511. Do you not think that it would be beneficial to the men if the hours were reduced, say from nine to seven?—I certainly think that seven hours a day would be much better than nine.

14,512. But I mean in respect to the health of the men?—That is what I mean.

The witness withdrew.

## TWENTY-FIRST DAY.

Thursday, 23rd November 1911.

Present:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary*).

Dr. JOSEF RAMBOUSEK.

Evidence to 14,530 handed in and taken as read; witness then called and examined (through an interpreter):

14,513. I am an official of the Statthaltereı (Government) of the kingdom of Bohemia, one of the most industrial in character of all Austrian provinces. The Statthaltereı is the highest administrative authority (Verwaltungsbehörde) of this kingdom, and as such is the central sanitary authority (Sanitätsbehörde) of the whole province, including Prague. My own duties comprise the direction of all sanitary industrial questions for the whole of Bohemia. I formerly occupied the same position at Klagenfurt, the capital of the province of Carinthia (Kärnten), and as that country is the centre of the Austrian lead-industry, I had the opportunity there of making a thorough study of this subject. In the beginning of 1907 I was called to the Statthaltereı of Prague in consequence of my many years' experience in industrial hygiene, and was at the same time appointed professor of industrial hygiene (Privatdozent für Gewerbehygiene) of the German Technical High School (Deutsche technische Hochschule) at Prague. I am the author of a number of books and articles relating to the subject of industrial hygiene and its various branches, industrial poisoning in general and lead poisoning in particular. Principally: "Verhütung der Bleigefahr" (Hartleben Vienna, 1907), "Gewerbliche Vergiftungen" (Veit & Co., Leipzig, 1911, which will be published in English by Arnold, London, at the end of 1912), "Gewerbehygiene für österreichische Amtsärzte, Verwaltungsbeamte," &c. (Deuticke Vienna, 1909). In this latter book I have discussed all the questions relating to the Austrian legislation upon lead poisoning. I was recently commissioned by the Austrian Government to prepare the Austrian department of the International Hygiene Exhibition held this year (1911) at Dresden.

14,514. In my official position I have the opportunity to become acquainted with the sanitary circumstances of the whole kingdom of Bohemia, as the Statthaltereı of Bohemia has the supervision of all sanitary industrial matters including industrial inspection (Gewerbeinspektorat), being an industrial authority the second tribunal of appeal. The Statthaltereı as such has the right to impose directions and regulations, which are suggested by the referees, as, for instance, by me, in matters of industrial hygiene and industrial poisoning. The organisation of the official supervision and inspection is as follows:—The industrial authority (Gewerbebehörde) of first instance is the district Bezirkshauptmannschaft, under the direction of which the Bezirksarzt (official doctor) inspects the industries for the purpose of enforcing sanitary regulations. There are 106 such doctors in Bohemia, and in Austria about 400. The several districts (Bezirkshauptmannschaften) are grouped into industrial districts of inspection (Gewerbeinspektionsbezirk), each of which is supervised by an industrial inspector (whose duties are technical and not medical) and who has assistants under him. Of these industrial districts of inspection there are only 11 in Bohemia and 38 in Austria. The way in which this machinery operates is as follows:—When any breach of the regulations or other sanitary trouble is brought to the attention of an industrial inspector or official doctor, either by his own inspection or by some

other means, such as a report from the Krankenkasse (Sickness Insurance Fund) he requires it to be remedied. In case of disobedience he informs the Bezirkshauptmannschaft, which in the first instance gives a warning, and for a repeated offence inflicts a punishment. In all cases of appeal the Statthaltereı decides (as a tribunal of second instance), but has also the right to interpose directly by means of the Bezirkshauptmannschaft. The highest authority (*i.e.*, of third instance) for sanitary matters is the Ministerium des Innern (Ministry of the Interior) and for industrial matters the Handelsministerium (Ministry of Commerce), which, in certain cases, act jointly. Official doctors (Bezirksärzte) are all responsible in the last instance to the Ministry of Interior, the industrial inspectors to the Ministry of Commerce, but both are also responsible to the governor of the province.

14,515. It is in this manner that, as an official of the Government, I have been able to collect a mass of information, and from time to time to give suggestions concerning industrial poisonings, especially lead poisoning. I have collected exact statistics of the number of cases of lead poisoning in Bohemia, especially in the lead-colour factories and among house painters, and, in particular, the results of the regulations of 30th April 1908 (which came into force in 1909), which were a consequence of the Austrian Commission which reported in 1907.

14,516. The Sickness Insurance Fund (Krankenkassen) are obliged to give annual reports to the Statthaltereı as to the state of sickness, with a declaration of the cause of sickness by the Bezirksarzt. From these reports I collect all cases which are indicative of lead poisoning and order inquiries to be made and remedial measures to be taken. The regulations of 1908 have been of great use for this purpose, as I am able to put them into force myself and to control their operation through the official doctors and the industrial inspectors. In this manner I have ascertained the following figures of lead poisoning for the kingdom of Bohemia:—

|       |   |
|-------|---|
| 1905: | 106, of which there were about 20 house painters. |
| 1906: | 91, of which there were about 17 house painters.  |
| 1907: | 147, of which there were about 18 house painters. |
| 1908: | 132, of which there were about 24 house painters. |
| 1909: | 89, of which there were about 13 house painters.  |
| 1910: | 70, of which there were about 9 house painters.   |

Of course, these figures are not complete, as a great many cases escape notice on account of insufficient reports. It is also to be remembered that in the last year inquiries were made with much greater exactness than the previous years (1905-1906); nevertheless, these figures (like those of Kamp for Vienna) show distinctly the beneficial results of the efforts made to check lead poisoning, and especially the regulations of 1908.

23 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

14,517. The effect of suitable regulations, combined with the instruction of the workers, is best to be seen in a lead-colour factory near Prague, which showed 25 lead poisonings when I came here. As a result of my visits there with the official doctor, and the remedial measures effected by me, and the instruction given by me to the workers every year, the figures for lead poisoning show the following decrease :—

| 1906. | 1907. | 1908. | 1909. | 1910.                                      |
|-------|-------|-------|-------|--|
| 25    | 16    | 7     | 2     | 2 (slight poisoning not well ascertained). |

This good result was obtained, although the factory is technically not well arranged and produces red lead (minium, mennige) and white lead every year with unchanged production and management. Similar good results were obtained to my knowledge in a factory in Carinthia, where in the year 1909 there were 30 cases of lead sickness, and in 1910, after the regulations, only 12 cases. I cite these examples, although they refer to factories and not to house painters, because they give exact figures and show well the effect which can be obtained by regulations without prohibition. For the rest, some official doctors expressly mention in their reports, which I have before me, the excellent effects of the regulations, in spite of their not being perfectly obeyed in all respects. This imperfection of observance in Austria is due to the insufficient supervision, owing to the inadequate number of industrial inspectors and official doctors, who have many other duties in addition to these in connection with these regulations. In England circumstances are, I understand, far more favourable.

14,518. Although there can be no doubt of the beneficial results of the regulations, yet the various provisions of the regulations have not been all equally effective. From my observation and information, I have very little doubt that the prohibition of the use of white lead for inside painting is not generally observed. Apart from the difficulty of distinguishing between inside and outside painting, white lead is preferred to zinc white and other pigments for its qualities of durability and covering power, and it is very difficult to discover when it is being used, say, for priming, which is subsequently covered up by zinc white paint. At any rate, there is little doubt that a large amount of white lead is thus surreptitiously used for inside purposes. In my view, this provision of the Austrian regulations, which was due to the special circumstances of Austrian house painting, was unnecessary. The chief danger upon which the Austrian report lays stress is the dry rubbing down. I am of opinion that it was sufficient to have prevented this, as was done in Germany. I notice that the figures for lead poisoning among painters in Germany show a rate of diminution at least equal to that of the figures for Austria, although in Germany there is no prohibition of the inside use. Moreover, experience shows that in the present state of knowledge there is no universally effective substitute for white lead either for outside or for inside use, so that to avoid the expense which repainting would put upon either the consumer or the trade, recourse is had, and is likely to be had, to the surreptitious use of white lead.

14,519. As one whose life study has been hygiene, and whose career has made him familiar not only with the scientific and official standpoint, but also with the actual circumstances of industrial life, I hold a strong opinion that any hasty interference with the natural development of industry for reasons of hygiene is in the highest degree undesirable. All the parts of the industrial structure are so closely inter-related that it is not easy to measure the effect which an interference with one part will have upon other parts. There is always the danger that an ill-considered interference with industry for reasons of hygiene will defeat its own object, and that by the destruction of one industry

those very workers whom it is sought to protect, or perhaps an equally important and numerous body of workers, will be deprived of their livelihood.

14,520. The prohibition of the use of a dangerous article is a mode of dealing with the danger which is, to my view, somewhat childish in its simplicity, and would lead to an intolerable interference with the machinery of civilisation if it were applied to all the substances which are of greater danger than white lead. Danger in varying degrees is an incident of very many industrial occupations, and there are many occupations more dangerous than that of the painter.

14,521. Hygiene must not be merely negative in its action. Its method must be to study all the factors of the industrial situation, and to make a dangerous industry non-dangerous. Science will work by the elimination of dangerous processes, and, in co-operation with both capital and labour, by the regulation of the conditions in which the dangerous article is used. Above all, the danger must be brought to the attention of all who have to handle the dangerous substance.

14,522. Moreover, my study of the matter has shown me that prohibition is always difficult, if not impossible, to effect in the absence of satisfactory substitutes for the dangerous substance. Unless there be adequate substitutes, the use of the dangerous substance will be continued, but it will be used surreptitiously, and this surreptitious use will increase the danger, as those handling it will be the more likely to be ignorant of their danger.

14,523. The question of substitutes for white lead is one which has engaged my attention for some time, and I have closely followed the fortunes of the various pigments which have from time to time been introduced to take the place of white lead. I have noticed that the proclamation of these pigments as complete substitutes has proved to be premature in a double sense, and that the proposed substitute has been found either to be itself poisonous or to be less effective than white lead. Zinc white was said to be a complete substitute, and a great agitation in France ended in the prohibition of white lead, and, to my knowledge, some factories in Germany and Austria gave up the manufacture of white lead. But experience showed that in covering power and durability zinc white is inferior to white lead. Then lead sulphate was introduced from England and proclaimed to be the long-desired substitute; but that was speedily found to be worse than zinc white. Next lead sulphate prepared dry was advocated by the Belgian Chemists' Association as being non-poisonous, but that again has been shown to be deficient in covering power and durability. Then, both by experiments on animals and by unfortunate losses of life, the preparations of lead sulphate were shown to be poisonous. Latest has come lithopone, of which the experience has been equally bad. It is clear that, as was found by the report of the Austrian Commission, we have not yet passed out of the stage of experiment and research; this is perhaps sufficiently proved by the fact that such experiments and researches continue to be made, as indeed is most desirable.

14,524. While dealing with the question of substitutes for lead pigments, I should like to mention that in my visits of inspection in Bohemia I have repeatedly found cases of lead poisoning in zinc white factories, and I am satisfied that the majority of substitutes for lead pigments themselves contain lead. Zinc when unrefined contains much lead, and is thus the more dangerous, as the workmen handle something which they take to be free from danger.

14,525. I may observe that the views which I have just mentioned were expressed by me more fully in an article written by me in 1906, "Verhältnis der Hygiene zu Gewerbe und Handel" (the Relation of Hygiene to Industry and Commerce), and also in other publications by me concerning industrial dangers and the way to combat them. In spite of the many prophecies to the contrary nothing has occurred in the subsequent development of the question which would cause me to modify these views.

14,526. In my view prohibition is only a last resource when the danger cannot be adequately dealt

23 November 1911.]

Dr. JOSEF RAMROUSEK.

[Continued.]

with by regulation. In the present state of knowledge, when there is no satisfactory substitute for white lead, the proper way to combat lead poisoning is by effective and thorough enforcement of regulations, especially the elimination of the dangerous process of rubbing down, and, above all, by the instruction of the workers. Owing to the comparative fewness of the inspectors in Austria and Bohemia, and to the difficulty of supervision, the regulations requiring the provision of washing materials and separate rooms for washing, and for clothes are not enforced as well as might be desired. So far as I know them, the British circumstances, where there is a widespread organisation of local sanitary inspectors, and where there are very many more doctors than in Austria and Bohemia, are far more favourable for this purpose.

14,527. I would like to emphasise the importance of cleanliness (the so-called personal prophylaxis), concerning which I am prepared to make detailed suggestions.

14,528. I also desire to lay great stress upon the instructions of the workmen: Provided that you have prohibited unnecessary dangerous processes, such as dry rubbing down, and have afforded the workmen the means of cleanliness, the most important point is that the workers should know the danger of lead poisoning and the means of meeting it; they will then be in the position of other workers in dangerous trades. From one point of view the great importance of all regulations is perhaps the advertisement which it gives of the dangers of lead poisoning.

14,529. In this connection I attach great importance to the *Declarationspflicht*, i.e., the duty of declaring when a pigment contains lead. Such a declaration calls constant attention to the danger of the pigment, and it is especially necessary when fancy names of colours prevent workmen and master painters from knowing that they are handling lead.

14,530. In any scheme of regulations there should also be provision for periodic medical inspection. Wherever there are workshops this is easily effected, but for the painters' trade in general there should be no real difficulty when there is a system of national health insurance, such as I understand is about to be introduced into Great Britain. Here, again, the far greater number of doctors make the circumstances in Great Britain more favourable than in Austria or Germany. Medical inspection is in particular the only way of preventing the repetition of the poisoning which is a feature of this disease. It enables the elimination of those who have a peculiar susceptibility to this disease. In this connection it has occurred to me that it might be possible to require some sort of a medical certificate or licence before a workman is allowed to take up the occupation of painter.

14,531. (*Chairman.*) You have had unique opportunities of watching the way in which the regulations are observed in the kingdom of Bohemia?—Yes.

14,532. How is the observance of regulations enforced?—The observance of regulations is enforced by medical officers and by technical inspectors.

14,533. Do the medical officers do any inspection themselves?—Yes.

14,534. In what way?—The medical surgeons—the officers—can make inspection in every industry. The official medical men have the right to inspect every industry, and particularly the right of inspecting dangerous industries, which they may inspect more frequently if they see fit.

14,535. Are you speaking exclusively for the kingdom of Bohemia?—Yes, exclusively. I was officer in Carinthia seven years ago. Twice I was in Carinthia. Regulations were not in force then.

14,536. Now, in regard to these doctors and inspection. What is the official name for these doctors?—District surgeons.\* I am also a district medical officer, but in the service of the Bohemian Government and not of the municipality, so I am neither confined to a municipality nor to a single district.

14,537. How many of these medical officers are there?—105.

14,538. How many inspectors are there that inspect factories and the private houses where painting is done?—Approximately 20 factory inspectors (in 12 factory inspection districts) besides 12 further subordinate officers of factory inspection (commissaries). These factory inspectors also inspect private places.

14,539. Can you give us the number of factories?—There are about 600-700 big manufacturing establishments, 6,000 "factory" establishments, and about 38,000 "workshop" establishments in all Bohemia; of these about 9,000-10,000 are visited yearly by factory inspectors, and to this must be added the visits of the district surgeons (*Bezirksärzte*).

14,540. How often does the inspector visit a place where painting is being done?—Inspection takes place sometimes rather rarely; as a rule, only for some special reason if the inspector happens to hear that irregularities occur in the workplace.

14,541. Then he does not pay surprise visits?—All the inspections are made, so to speak, by surprise, but there is no definite number of inspections per year fixed. The medical officer has a right to visit these places also unexpectedly, independently of the factory inspector.

14,542. How does the inspector know when and where house-painting operations are in progress?—The inspector can learn this only by inquiry from the employer. The employer is compelled to answer this inquiry.

14,543. Is it a fact that all the inspectors have to go round to the master painters to inquire periodically where painting operations are being carried out?—Yes. They have to make these inquiries themselves.

14,544. Now, in paragraph 14,518 of your proof, you mention the difficulty of distinguishing between inside and outside painting?—Frequently outside painting and inside painting are carried out at the same time, and consequently it is very difficult to decide which paints have been used outside only and which inside, and they may be frequently exchanged.

14,545. You have stated that a large amount of white lead is surreptitiously used for interior work, notwithstanding that it is forbidden?—I am quite convinced of this; I think the existence of this prohibition of inside painting with white lead more dangerous than its non-existence, as it leads to all sorts of underhand dealing.

14,546. I suppose that it is almost impossible for the factory inspectors to be able to find out whether white lead is used for interior purposes?—It is extremely difficult for them.

14,547. Now, if this regulation is persistently broken, how can you be sure that other regulations are being observed?—I think that it is very much easier to enforce the remainder of the regulations, because the remaining regulations all deal with the personal protection of the workers.

14,548. For example, how can the Government satisfy themselves that the prohibition of dry rubbing down is observed?—This can be enforced by surprise visits of the inspector, which would be particularly frequent after cases of lead poisoning in a particular workshop.

14,549. Yes, but then prevention is better than cure. Would it not be better for the factory inspectors to inspect the places before the outbreak of lead poisoning had incurred?—I wish to state that I think I was rather misunderstood. Inspections are made in such places even without lead poisoning occurring there, only if any lead poisoning cases occur inspections become more frequent in such places.

14,550. You have told us that there are 20 factory inspectors, not counting the 12 subordinate officers, and that they have to inquire from the master painter where the different painting operations are being done, and you further stated that these 20 inspectors pay surprise visits. Now, would you consider it a surprise visit if the inspector had been informed beforehand where these operations were being conducted?—In most cases the inspector would obtain a very large number of lists of places where painting is carried out, and he would visit only a very small number of the places on his list.

\* "*Bezirksärzte*" not to be confused with "*Distriktsärzte*."

29 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

14,551. In regard to the number of factories and workshops in the kingdom of Bohemia, it appears from the reports of the Austrian Factory Department that there are no less than 9,013 in Prague alone? That is all the industries, even the small ones.

14,552. But I understand that all these 9,013 are subject to inspection?—The inspector has the right to visit all industrial places, however small, with the exception of home industries.

14,553. Is not the inspector instructed to visit all industrial places?—It is an instruction to inspectors to visit even the smallest places regularly.

14,554. Could we infer this—that if the factory inspector has not asked for information from any master painter, that master painter knows that he is perfectly safe from inspection?—That inference is not justified, because the inspector may make his inquiry at the very last moment, or whilst the painting is in progress, and may go, after having inquired, straight away to the place of painting. The inspector is also able to obtain the information as to where painting is carried out from the police. There are 12 districts with district inspectors, but several of the districts have two inspectors, or even two inspectors and assistants. There are 20 inspectors (above mentioned) in 12 districts, and the number of inspectors increases continually.

14,555. I understand that the number of factories and workshops in the kingdom of Bohemia is about 36,600. In addition to the inspection of these factories and workshops there must be a vast number of private houses where painting operations are being carried on: so that if you distribute the 20 inspectors over the whole area it must be extremely rarely that a surprise visit is paid?—The number of visits is very small, but the precise figure is given in this report. (See my answer to Q. 14,539.)

14,556. Let me give you an illustration: In Carlsbad, according to the 1909 Report, there were 3,943 factories and workshops, and the inspectors visited 288 of these, leaving 3,655 factories and workshops that were not inspected that year. In 1910 there were in the Carlsbad district 4,042 factories (647 of them large scale undertakings), and of these 754 were visited in the course of the year?—The number of visits paid varies a great deal, as the inspectors have also other work to carry out.

14,557. What time would the factory inspectors of the Carlsbad district have for inspecting painting operations in private houses?—The number of visits paid to private houses depends strictly on the way in which the inspector divides up his own work, and he would visit private places particularly, only if he received information from the medical officer that the state of health was bad in some district, or on some intimation from the Government, or some other private information.

14,558. So that however good the regulations may be the difficulty of enforcing them is very great?—Although it is extremely difficult to enforce these regulations, it is my experience that all regulations dealing with the personal protection of the worker are strictly followed.

14,559. Then I think that we must take it that in the kingdom of Bohemia you trust not so much to the inspection by the inspectors as to the good faith of the employers and the employed to keep the regulations?—They do not rely exclusively or chiefly on the goodwill of the employers to keep the regulations, but experience teaches that all employers, or the majority of them, do their best to enforce the regulations.

14,560. But is not that the same thing?—There is no implicit reliance placed on the good faith of the employers, but I think it fair to assume that a test of, say, a number of 10 cases, will show what the state of other factories will be. To test a small percentage will give you a fair indication of the conditions in other places.

14,561. But there is no certainty that the regulations are being carried out from the fact that the inspectors have called to see?—There is no absolute certainty that the visit which shows the state in a few places will show the state in all places; and the time

since the regulations have been in force is not long enough to say with certainty that the regulations are carried out everywhere. But as far as has been ascertained the regulations are carried out well, and with very good results.

14,562. But you will admit that the facts that have been ascertained with regard to the carrying out of these regulations are very scanty?—Bohemia is divided into 12 factory inspection districts, and further into more than 100 administrative districts (Bezirkshauptmannschaften), so that several administrative districts have one factory inspector. The administrative districts are hereafter called sub-districts. An inquiry into every one of these 100 sub-districts showed that the regulations were well enforced in all these 100 sub-districts, or in most.

14,563. I must ask you how you acquired that information?—The Government addresses a circular to the officials of every one of these 100 sub-districts, and they have to report all their experiences. In what way the sub-districts collect their experiences is not always exactly known and not always the same, because in the relatively small sub-districts it is not difficult for the administrative authority to collect experiences. The officers, especially the older ones, are well acquainted with the local conditions.

14,564. That is important: You have stated on the one hand that there are only 20 inspectors to do a vast amount of inspection required by something like between 30,000 and 40,000 factories and workshops, and then when I ask you on what you base your statement that inspection is carried on, you refer to these sub-districts. I want to know in what way the sub-districts proceed with inspection?—In the case of such an inquiry to the sub-districts, the medical officer or the inspector would visit at least 10 industrial places in every one of these sub-districts, and this inquiry would then give detailed reports of 10 industrial places in each of these 100 districts: so you would have detailed information concerning 1,000 places, which would be one-ninth of the total industrial places there. So the Government can get very precise information and exact answers to inquiries concerning particular industries, as in our case about the painter's trade.

14,565. I do not quite understand what procedure is adopted. Does the medical officer or inspector go round to a factory and ask the occupier whether the regulations have been broken?—The medical officer of the sub-district will make personal inquiries into the place, and visit the place to inspect personally.

14,566. But is the medical officer qualified to inspect all the intricacies of the various operations which have to be safeguarded?—Yes; he is competent to inspect any kind of factory. It is even his duty to watch over all unhealthy trades or factories (Reichs-sanitätsgesetz of the year 1870, § 8).

14,567. Are these sub-districts governed by local authorities?—No, this is a misunderstanding; the Bezirkshauptmannschaft (sub-district) has a Bezirkshauptmann as chief, who is subordinated to the Government, so that all these sub-districts are under the government of the kingdom.

14,568. I am extremely sorry to be so wearying and persistent with regard to this, but you have come here to advocate regulations in substitution for the prohibition of lead; and I am very anxious to ascertain from you in what way these regulations are enforced?—I shall be extremely pleased to answer all questions on any one point, or on all. I am very grateful if I can learn the English view and compare it. It is very interesting to me. If it is impossible to enforce the regulation in England it will still be less possible to enforce the prohibition of white lead, especially as long as no substitute is invented for it.

14,569. Now, can you tell us how the provision of washing accommodation is secured in every case in house painting?—There is always a provisional washing place affixed to the canteen at the place where the building process is being carried out.

14,570. But supposing that it is a small job?—In case of only a few men being employed it would be quite sufficient to provide just the few washing basins without any special place to put them, or in case of its

23 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

being a short job, the man might return to his home for the purpose of washing and having his meals.

14,571. Supposing that there are a small number of painters engaged in painting an occupied house?—In that case the employer is compelled to provide washing accommodation, either in the kitchen or in some other place in the occupied house.

14,572. Is the periodical medical examination of the workers carried into effect in the same way as it is in Vienna?—The regulations for medical inspection are the same for the whole of Austria, with the only exception that every big city is divided into a great number of medical sub-districts, and every city will have, for its small area, a very much greater number of medical officers than the country.

14,573. In paragraph 14,516 you point to an improvement as shown by statistics of the insurance funds. You wish us to understand that these figures are very incomplete, do you not?—The figures are very incomplete, because insurance does not specialise on cases of lead poisoning, but puts a number of lead poisoning cases down as other illnesses. I have the original papers concerning this compilation.

14,574. Can you give us any idea as to how many cases are omitted from the tables?—I think that the number might be, perhaps, two or three times the number given, but I do not wish to say so with any certainty.

14,575. I ask the question because the number of lead poisoning cases shown by your table is so much smaller than that given by Dr. Kaup for Vienna?—In Vienna the majority of the lead poisoning cases are treated in the hospitals, and, consequently, every lead poisoning case is put down as such. Further, the insurance is in the hands of a very few big central insurance places, whilst in a country like Bohemia it is not possible to classify the cases so accurately. Also the insurance is spread over a large number of offices. Dr. Kaup's figures will probably be very complete compared with those of Bohemia. Also, all the insurance societies of Vienna have special medical men dealing with industrial poisoning.

14,576. Is it possible, therefore, that the small numbers recorded in Bohemia do not give a fair indication of the whole amount of suffering from lead poisoning?—The figures given by me are only a relative indication of the amount of lead poisoning going on, but the drop of my relative figures will show that there is an improvement brought about by these new regulations.

14,577. If the reporting is so very incomplete, the records may show half the cases one year and only a quarter of them another year. Is not that so?—I think that the figures are a very fair indication of the improvement brought about, because always, not only with regard to lead poisoning but other illnesses with which I have to do, only a definite percentage will be recorded, and I would not have given any figures if I had thought that there would be any danger with regard to the percentage recorded. The only variation is that towards the later years, when the regulations have been enforced, and the declaration of lead poisoning has become obligatory, the number of cases recorded is far more complete than before, and so the figures appear more unfavourable to the result of the regulations than they really are.

14,578. I suppose that it is fair to infer that the number of cases of lead poisoning in the kingdom of Bohemia is not less in proportion than those that occur in Vienna?—It would be fair to state this, comparing the cases of lead poisoning in Prague with those in Vienna, but not for the whole country, because the conditions in the country are very different from the conditions in a big city.

14,579. In paragraph 14,517 you point to a very fine result of applying regulations in a lead colour factory. This is quite similar to the experience in such factories in England?—I think that the results were very favourable. I wish to state that I inspected one white lead works personally for some time, and the cases from 1906 to 1910 were as stated in paragraph 14,517. They dropped from 25 to 16 in 1907, next year 7, next year 2, the year after that 2, and in 1910 the two cases were only very slight.

14,580. I suppose you will admit that the inspection of a factory is a very different thing from the inspection of a large number of indiscriminate houses?—I still maintain that this shows that in every case if regulations are well enforced the regulations will show beneficial results. The chief point conducive to the carrying out of regulations is not control but good information to the workers.

14,581. Now I will ask you this: If a large number of the employers of labour themselves prefer the prohibition of the use of lead to a cumbersome and irksome code of regulations, do not you think that the Committee should support them?—I think it is not necessary to take any notice of such preference on the part of the employers, because if the new regulations are to be cumbersome and make the industry too difficult to carry out, they will automatically give up that industry, and replace white lead throughout by lead-free paints, provided that these other paints will give as good results as the lead paints.

14,582. I do not think that you quite see the point. This Committee is sitting here to deal with the evils of lead poisoning, and what I ask you is this: If the employers prefer the prohibition of the use of lead to a system of cumbersome and irksome regulations, do not you think that the Committee ought to support the employers?—I think that if the employers really prefer abolition to regulations, then there is no further question, provided that the white lead can really be replaced by some other paint.

14,583. I do not want you to go outside my question. I think your answer was that if the employers prefer prohibition there is nothing more to be said?—Yes. The resistance of the master painters is caused only by the uselessness of the substitutes for white lead, which is proved. The greatest resistance does not come from the employers—that is from the master painters but the greatest resistance comes from the makers of white lead in Austria. I wish to add that Austria, and particularly Carinthia, has a very big lead industry, and this is the chief industry of an otherwise industrially poor country, and the prohibition would not only hit the employers but also a very great number of the workers.

14,584. You speak of the absence of satisfactory substitutes for lead. Have you any personal practical experience which guides you in this?—In Bohemia the Government quite recently made inquiries in all the sub-districts whether white lead could be replaced by lead-free paints.

14,585. To whom did the Government apply?—A number of experiments were carried out in Government works and on Government contracts. Other experiments were carried out by big private contractors, and from all districts the reply came that lead-free paints were not satisfactory substitutes for white lead.

14,586. Who supervised these experiments?—These experiments were partly carried out by private contractors and partly by Government works. One of the experiments was the painting of a Government railway station in Prague.

14,587. On what grounds was the opinion formed that leadless paints were not satisfactory?—Chiefly insufficient covering power and insufficient durability.

14,588. Can you tell us anything about the formulas that were used?—Yes, lithopone and zinc paints were used. It is always the same.

14,589. Do you mean that the formula is always the same?—They are very nearly the same, as lithopone contains a considerable quantity of zinc white; but zinc white by itself also was used. The colours sold in our country as lithopone are not pure and contain zinc oxide as well as zinc sulphate and barium sulphate.

14,590. When were these experiments made?—These experiments were carried out during the last two or three years.

14,591. For how long were these trials made before the decision was arrived at?—The paints were tried for two to three years. In a number of cases it was shown, before the expiration of two years, that the substitutes were unsatisfactory. I have the experience

23 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

in Bohemia that frequently colours which are denoted as lead-free contain lead.

14,592. If the Committee have evidence of practical successes with leadless paints, that must weigh with them very considerably?—If you have actual satisfactory results with lead-free paints, then there is no question that you should go over to these lead-free paints, provided that these results are satisfactory and have been conclusively proved to be satisfactory.

14,593. The Office of Works is a great Government department, and they have issued an Order this year prohibiting the use of lead in any of their painting work in future?—Has this Order been carried out?

14,594. It has only just been issued as a general Order, but the decision was arrived at from experiments made by the Office of Works some five years ago, in painting the outside and inside of the New Savings Bank in Kensington, and they came to the conclusion that the substitute was so satisfactory that they could abolish the use of lead in the future. I must say that they have been using lead up to the present time, but we had a notification from the Office of Works yesterday to the effect that the Order had now been issued to prohibit the use of lead throughout their work?—I would like to know the nature of the paint which was used on the Savings Bank.

14,595. I cannot tell you that. I do not think that that is the point. The point is that the Office of Works have satisfied themselves that leadless paint is a good substitute, and on those grounds, and those grounds alone, they have decided to abandon the use of lead in the future?—I have not the slightest wish to uphold the use of lead, but my experience throughout Bohemia and elsewhere is that lead-free paints do not form a satisfactory substitute for white lead, and I am also of opinion that if you have prohibition you will still have great difficulties in enforcing the prohibition so that only lead-free paints are in use.

14,596. I quite agree. I could give you other instances of large public buildings, for instance, the London Stock Exchange, which is painted exclusively with leadless paints, and which is reported by the official architect to be very satisfactory?—I, of course, have to accept the opinion of the public architect, but my experience is quite contrary to it.

14,597. The workmen, if certified by the medical officer as suffering from lead poisoning, are entitled to compensation. If a man is suspended because the doctor is not quite sure whether he is suffering from lead poisoning, or because the doctor feels that if the man is allowed to remain in the employment he may get lead poisoning, can a workman in Bohemia receive compensation?—The working man is only entitled to compensation if he actually is ill, but he never will be stopped from work by the medical man unless he actually is ill. Would you permit me to make a general remark? I would like you to see the difference between English and Bohemian conditions and Austrian conditions.

14,598. In what way?—In Austria they were trying to decide between the question of prohibition or cumbersome regulations, and they had to decide in favour of regulations, because they had to place a very high value on the white lead industry. Austria is otherwise an industrially poor country, and the prohibition would cause a very great industrial loss and general economic disturbance.

14,599. May we assume that if it had not been for the existence of this important white lead industry in Austria the authorities might have decided to prohibit the use of white lead in painting?—I certainly think that the importance of these industries was not the sole factor which led the Austrian committee to the conclusion not to adopt prohibition. The importance of the white lead industry may have been a big factor, but an equally big factor was the impossibility of replacing white lead by any substitute.

14,600. (Dr. Collis.) How many are there employed in the white lead industry in Bohemia?—There is only one white lead works in Bohemia, and that employs some 30 men, but there is a very big industry in the rest of Austria (especially in Carinthia).

14,601. How many men are employed in all the country to whom the regulations apply?—There are some 300 or 400 men employed in some three big white lead works in Austria, but these white lead works are the property of one big white lead company, who also own the lead mines. The whole of these lead works are the property of the Bleiburger Bergwerks Union. That is one big trust company.

14,602. Do I understand that in the whole of the empire of Austria there are, amongst the men working in factories, fewer than 1,000 men employed in the processes that lead to the manufacture of white lead?—There are several thousand men employed in lead mines and white lead works, as there is one mine by itself employing over a thousand men.

14,603. But all the lead ore which comes from that lead mine is not used for making white lead?—No.

14,604. It is used for the recovery of silver and gold; for making lead sheets; and probably you may be able to say correctly that of the amount of lead ore which is raised only one-third goes to make white lead?—I think that rather less than a third is so used.

14,605. I quite agree; I did not want to underestimate it?—I cannot say with certainty, because Austria exports a large quantity of lead.

14,606. What I wanted to ascertain, if possible, was the real importance in Austria, as regards the number of men employed, of the manufacture of white lead, which had, at any rate, an important bearing on the decision of the Austrian Commission not to entirely abolish its use?—It is impossible to say how many working men might be affected by any decree of prohibition, as not only the white lead makers themselves would be affected but also a large number of men in the mines, and also if the mine would lose the outlet for a certain part of its lead it might become altogether impossible to work the mine at a profit. It is impossible to say how far the effects of this decree would go. For example, the whole Lead Mining Union might be ruined in consequence of this. It is not possible to express such things in numbers. It is very clearly put in the ministerial decree given in this report which I produce.\*

14,607. The argument is clearly put?—Yes, the argument.

14,608. Not the numbers?—The principle is set out.

14,609. But it does not state the numbers, because they are difficult to estimate?—This decree contains no figures whatsoever. It only sets out the principle of the way in which this decree might affect other industries.

14,610. Is zinc white made to any extent in Austria?—There is some zinc white made, but only very little, and the interesting part is that several cases of lead poisoning have occurred in the making of zinc.

14,611. I will come to that. Are there supplies of zinc ore in the mines in Austria?—Not a very large number; only some. The zinc occurs together with lead.

14,612. Is it not possible that the manufacture of zinc white might employ a large number of people who would lose their work if white lead was prohibited?—I think that this is impossible, because the methods of manufacture are totally different.

14,613. I did not mean the very same men, but that the total occupation of the kingdom would not be diminished by one manufacturer taking the place of another?—Austria has not enough zinc to cover the demand. They would have to go to Silesia for their zinc, and the zinc industry would go out of the country in that case. There are only quite small zinc works in Austria.

14,614. So that the manufacture of white lead does bulk very largely in Austria as a form of employment?—Not only is it a very important industry, but it is practically the sole large-scale industry of Carinthia, one of the Austrian provinces.

\* See Appendix XVII.

23 November 1911.]

DR. JOSEF RAMBOUSEK.

[Continued.]

14,615. The conditions in Great Britain are very different. Here the white lead industry, compared with all the industries of Great Britain, is not so large. It does not bulk to the same extent, and we have no special place which depends entirely as Carinthia does on the manufacture of white lead?—I should be glad to know if the English conditions are different from those in Austria, which I doubt.

14,616. If the conditions are totally different in this respect, you will understand that that reason which weighed with the Austrian Commission does not weigh very largely with us?—I quite see that this big factor does not exist for an English committee, but I wish to emphasise that this was not the sole factor moving the Austrian committee. It was only one factor.

14,617. Yes, I understand that, but it is one?—Yes.

14,618. In the manufacture of zinc white in Austria, by which method is it manufactured—by the direct or the indirect method?—As far as I know it is generally made by the direct process.

14,618a. We in England, where zinc smelting is done, not for the purpose of making white zinc but for the purpose of making zinc spelter, also get cases of lead poisoning, and we are not at all astonished to hear that in the manufacture of zinc white by the direct method, lead poisoning cases occur?—It depends whether you work your zinc into zinc white from coarse zinc or from refined zinc.

14,619. Does it not depend on whether the zinc ore contains lead?—It is exactly the same whether you have zinc ores containing lead or metallic zinc containing metallic lead.

14,620. In manufacture?—Yes.

14,621. That is what I mean, but the number of lead poisoning cases which occur in the zinc factories surely do not compare with the number that occur in the white lead factories in the manufacture of white lead?—You cannot compare the number in any way. I made the statement merely for the sake of pointing out a rather curious fact.

14,622. Could you tell us anything in regard to employment during the years 1905 to 1910, of which you give the table in paragraph 14,516. Was trade busier or slacker at any of the periods of those years there given?—There has been a steady increase of employment in Bohemia from 750,000 workmen employed in 1905 up to 850,000 in 1909 and 923,000 in 1910.

14,623. All house-painters?—No; all workers.

14,624. But have you any figures concerning house painters only?—I cannot give any figures relating to house painters only. It is a very fluctuating number.

14,625. Trade was bad all over Europe in 1909, and probably there were fewer employed?—The general depression of trade in 1909 does not affect the figures for Bohemia, because the steady increase of men employed was kept up during 1909.

14,626. But you do not know for painters?—No. It only applies to the workers employed generally.

14,627. I ask the question, because in England in 1909 and 1910 (both of which years were bad for lead industries generally) we had, owing to the slackness of trade, a considerable fall in lead poisoning cases in our factories. We did not ascribe it all to the effect of regulations, as I understand you are claiming for Austria. We recognised the industrial conditions of the moment, and were not surprised when we found in 1911 that we were reaching the level that we stood at previously. I think that to claim 1909 and 1910 as years to show a reduction is not fair?—I have watched the conditions in Bohemia steadily for these last few years, and I have not observed any depression in the painting trade during 1909 or 1910, and I have not known of anyone making a statement to that effect either.

14,628. We would like figures, if possible, because I think it is a matter of common knowledge that there was depression in business circles over the whole of Europe and in America—in fact, in the whole world—during the two years that I have quoted, and I have

not heard that Bohemia was an exception to the rest of the industrial world?—I know of no depression in the painting trade in Bohemia during the years you refer to.

14,629. I would suggest that your own figures of lead poisoning for the kingdom appear to establish the same point, because, if you take the number of lead poisoning cases among workers other than house painters for the kingdom of Bohemia for the period, you get a fall between 1908 and 1909 from 108 to 76, and between 1909 and 1910 a further fall from 76 to 61, and these are for the whole kingdom. They are not affected by the regulations at all, and seem to justify my conclusion that slack trade produced the fall and not the regulations?—I maintain that my figures actually show an improvement as the result of the regulations. The figures for lead poisoning have apparently gone up, because the statistics have been far more complete since the time the commission sat. After 1907 and 1908 the records are more complete. Before 1907 the records are very incomplete.

14,630. You do not answer my point. General cases, apart from house painters in Bohemia, have fallen steadily from 1908 to 1910 as far as the figures go?—Other cases have also fallen, because regulations were made concerning all lead industries, not only house painting.

14,631. When did they come into force?—Regulations are made in single cases wherever lead poisoning occurs by the Government directly. I am personally the district officer dealing with lead poisoning in such cases, and I ordered the inspection of places where lead poisoning has occurred, and I have myself made regulations. As soon as the insurance sends notification of a lead poisoning case, inspection of the place takes place at once, and then regulations are made for that place. Regulations may be made specially for one place, if in one place lead poisoning occurs more than in other places. The case quoted in paragraph 14,517 is a case in point of regulations being made for one particular place and of special regulations showing good results. There is no general regulations for lead works in general. There are special regulations for painters using lead paint, and other sets of special regulations for any special industry, but there are no general regulations for the lead trade in general.

14,632. We recognise the value of regulations, but we also recognise that we must, in considering their value, pay attention to the amount of work being done during one of two years, and that it is not fair to judge of regulations and their efficiency in less than five years, the figures being taken over that whole period?—I do not claim that my figures are conclusive. They only support my theory, and I think that they will be conclusive after a longer period.

14,633. With regard to paints that were used by the Austrian Commission in their tests, I understand you to say that zinc white and lithopone were used. Lithopone is not zinc white. It is zinc sulphide with barium sulphate, and zinc white is zinc oxide. Lithopone, we have been told, is not a good paint at all. If you mix zinc white with lithopone you will probably not get as good a result for outside work as by using zinc white alone. May that be a possible reason why some of the experiments of the Austrian Commission failed?—I wanted to say that lithopone is (by us) seldom employed in a pure state—not that lithopone is zinc oxide. Zinc white has also been used by itself for these tests, and I said so some time ago. I am quite willing to acknowledge that a number of these experiments are inconclusive, because the designation or trade names of paints do not actually show what the paint consists of, and any white paint which is free of lead may be designated as lithopone, although it may be anything. But it is equally certain that experiments with pure zinc white failed—in fact, no other medium than lead has given perfectly satisfactory results from my knowledge everywhere.

14,634. I suppose that Mr. Meissl is the person to be asked the composition of the paints that were used?—He certainly would have more experience on that point, and particularly with regard to Vienna.

D d 2

23 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

14,635. (*Mr. Sutherland.*) Like most of our witnesses, you locate the great danger in painting in the dry rubbing down. If this was abandoned and there was greater personal care on the part of the workers, would the risk of painting, in your opinion, sink to the normal industrial risk?—I think that other methods as well are necessary to bring the risk down to the normal industrial risk; I put this in as my answer:—

1. The duty of declaring lead colours.
2. Technical measures for the prevention of dust in the use of lead colours.
3. Personal prophylaxis, work clothes, observance of cleanliness, prohibition of smoking and eating.
4. The instruction of the workmen with regard to the danger.
5. An obligation on the part of the masters and also of the workmen to obey the rules and make use of the remedies.
6. Periodical medical inspection and the keeping of a register as to the condition of health.
7. Protective regulations for working and the exclusion of workmen with certain diseases from dangerous work.

14,636. Do you attach any importance to a statement made to this Committee that new paint gives off a volatile lead compound poisonous in its effects?—Volatile lead compounds are only possible at very high temperatures—temperatures like the boiling point of lead.

14,637. In a normal room you would not have such a temperature?—I refer to a temperature of two or three thousand degrees. I acknowledge the existence of volatile poisons in paint, but these poisons are chiefly benzol, and similar mediums used for mixing the paint. Benzol poisoning occurs particularly in ship painting. This danger is particularly intensive in the case of painting very small enclosed places. I have further experience on that point, I think.

14,638. Is it not likely that there would be an accumulating opinion on the part of workers and employers that would ensure a better observance of regulations, assuming that they were established?—I think that usage to the regulations and good information on the point will lead by itself to a strict obedience of the regulations.

14,639. Is it not likely that as the result of these regulations and the location of the danger to dry rubbing down the painting trade would find some other process in the place of dry rubbing down?—I think it very probable that you might find a process to replace dry rubbing down. This will be a question which Mr. Meissl will deal with.

14,640. Would not the mere fact of the wide distribution of instructions to workmen and the obligatory labelling of all the lead paints as poisonous put the workmen on their guard, and so tend to reduce the number of cases of poisoning?—That is my view. I think that lead poisoning would be reduced in this way.

14,641. Would not regulations for a period of, say, five years definitely determine their usefulness? The Government would then, if the regulations failed to effect a marked improvement, have public opinion strongly behind them for prohibition?—I think that public opinion would be on the side of the Government if the regulations had failed after five years; I think that five years would be quite a fair time to show whether the regulations could do some good, and only in the case of regulations not bringing about any reduction of lead poisoning would it be safe to assume that the regulations did no good.

14,642. Would it not be a serious step to take to close down a large industry like the making of lead, and throw some thousands of workers on to the world destitute, including the miners, because there would have to be a curtailment in that respect, as these men could not be diverted into other industries?—Yes. But I cannot presume to give a strict opinion on English economic conditions.

14,643. Do you realise what the prohibition of lead for paints would mean to England?—I have no opinion on the importance of white lead in England. I am only willing to give you my opinion with regard to Austria.

14,644. Do you know that in 1910 there was 325,497*l.* worth of zinc oxide brought into this country from Germany, the Netherlands, Belgium, France, the United States, and other foreign sources, as against 440*l.* worth introduced from British possessions? This is from the Statistical and Information Department, London Chamber of Commerce?—If there really is no zinc to be had in England, then the question of discussing the use of zinc oxide becomes quite impossible.

14,645. I am referring to zinc oxides. In the same period we had 71,000*l.* value in lead and 66,000*l.* from British possessions; so that in the two they balance, but in the other there is a great disparity?—I have some slight knowledge of English conditions, but I do not come here to lay down the law on English conditions to Englishmen. But if it is so, the conditions in England and in my country are very similar.

14,646. I will tell you, Doctor, that the National Association of Master House-Painters in this country have definitely passed a resolution (and they represent something like 1,500 master house-painters) that they would prefer a trial of regulations rather than the prohibition of lead?—If that is so, then the conditions in England are also in this direction very much like the conditions in Austria, and I was very much surprised to be told by the Chairman that the conditions in England are totally different from those in Austria.

14,647. (*Chairman.*) What Mr. Sutherland is giving you is some private information which I know nothing about. What I put to you was a fact within the cognizance of the Committee, namely, that several witnesses who have been examined by us have said that they would prefer prohibition to rules and regulations?—I am more surprised by your statement Mr. Chairman, than by Mr. Sutherland's statement.

14,648. (*Mr. Sutherland.*) With reference to the experiments which the Government carried out at Prague, did the Government lay down their own formulae?—The Building Department of the Bohemian Government decided in every case what kind of paint was to be used on any particular building.

14,649. But did they lay down the way in which it should be mixed first, or did they accept general paints, and then make an analysis?—The office laid down strictly of what composition the paint was to be in every case.

14,650. Have you those formulae?—The only instance of a formula which I can produce is the statement that pure zinc white was to be used in one instance.

14,651. You did not mix zinc white with lithopone?—In some instances a mixture of lithopone and zinc white was used.

14,652. Zinc oxide?—Yes. In other cases pure zinc oxide and other paints were also tried.

14,653. (*Mr. Gardner.*) In the cases of poisoning which have come under your observation, can you say if there were more cases among those workers who went into the trade as adults than there were among those who entered as boys and served an apprenticeship?—I think that the time spent at the trade does not make the man immune against lead poisoning, but the fact that the man has been apprenticed from his young days probably leads him to know the trade very much better, and the man who knows his trade thoroughly well is far less liable to lead poisoning than a man who is only an occasional worker.

14,654. (*Mr. Parsonage.*) Have you known any cases of poisoning or illness where painters were using so-called non-poisonous substitutes for white lead?—I have come across a number of cases of painters having used so-called lead-free paints, and those paints did contain lead and led to lead poisoning amongst the painters.

14,655. Have you had any complaints of illness other than lead poisoning, where they have been using these so-called non-poisonous paints?—I know of poisonous paints other than lead, as, for instance, chrome or

23 November 1911.]

DR. JOSEF RAMBOUSEK.

[Continued.]

arsenic, or any of these; but, according to my experience, pure zinc paints are quite non-poisonous.

14,656. You spoke of benzol vapour. Do you not think that the use of cheap substitutes for turpentine tends to increase the dangers of lead poisoning, because they give off a vapour?—I consider turpentine substitutes, particularly the so-called quick driers, very dangerous. I wish to add to this that poisoning by these quick driers, the benzol, for instance, always will be an instantaneous or acute poisoning, whilst lead poisoning always will be a slow and chronic lead poisoning.

14,657. Would it not be an advantage to add to the regulations the prohibition of the use of these cheap substitutes for turpentine?—I think such a prohibition very advisable, and the Board of Trade of Hamburg have actually issued the prohibition of quick driers—benzol and similar quick driers.

14,658. Would it not be much easier to prevent lead poisoning from the use of lead if its use is prohibited than to carry out the regulations governing its use?—I think it quite easy to decree the entire abolition, but I think that it will not be the slightest use unless with the decree you issue an efficient substitute for white lead. By "efficient" I mean that the substitute will be able to compete with white lead in price. I mean to say, as long as we have no substitute for white lead which is perfect as to price and usefulness, a white lead prohibition is impracticable.

14,659. (*Chairman.*) How many painters are there employed in Bohemia?—There are about a thousand.

14,660. (*Mr. Kinggate.*) With regard to paragraph 14,516, "Cases of lead poisoning," could you give any account of other industries in which these cases occur. I notice in 1907, 147 cases, only 18 cases of which are house painters, leaving 129 other cases of lead poisoning. Have you any statistics with regard to the industries in which those cases of lead poisoning occur, and particularly I want to know the number of coach painters?—There were 38 printers, 27 china workers, 14 stove factory workers, 18 painters, 11 glass workers, inclusive of glass painters, 5 potters (besides these there were a few very slight cases of lead poisoning amongst potters not included in this), 4 instrument makers, 23 workers in chemical works, 3 of them workers in nitrite works, 3 men soldering lead chambers, 17 workers in white lead, red lead and zinc white works, 1 maker of lead tubes, 1 shot polisher, 1 metal worker, 1 maker of organ pipes, 1 file cutter, and 1 cutter of garnets.

14,661. No cases of lead poisoning in any coach-making works?—Those are included amongst the 18 painters and brush hands.

14,662. (*Mr. Robins.*) Are we to recognise all through your evidence that you consider the painter's occupation is a dangerous one?—I consider all industries dangerous in some respect, and although at present there is a fairly high rate of professional poisoning amongst painters, I think that if the methods suggested by me are made law, and are strictly obeyed throughout, the danger for painters will drop to quite a reasonably low degree.

14,663. Do you not think that with these regulations where lead is used, restricted hours of work would be beneficial to the painters?—My measures include a maximum day for painters. I regret not having been able to read out my entire scheme. I think that your question brings up a point I have wanted to raise for some time. I consider that overwork is one of the greatest dangers for lead workers, and is greatly conducive to lead poisoning, and consequently a maximum should be fixed.

14,664. (*Chairman.*) What number of hours, on the average, do you consider that house painters and other working men should work?—The average would be eight hours, and the regulation is that no worker in Bohemia should do more than nine hours a day (not counting the intervals), but my observation is that most painters work as long as they can work and whilst they have light to see.

14,665. Do you think that seven hours a day would be sufficient for an ordinary painter to work?—I think

seven hours would be sufficient. The seven hours should be divided into reasonable intervals, so that the men get pauses in their work. The intervals are very important, because they should be used for cleaning.

14,666. Seven hours a day or 42 hours per week?—Yes. I think it important that these seven hours a day should include a number of intervals, so that the men can clean themselves.

14,667. I think that you would like to make an observation or two in connection with the dangers of inside painting?—Yes. I consider lead paints for inside purposes very dangerous, but I think that it would be no use prohibiting the use of lead paints for inside purposes, as the state after prohibition would be worse than before, because lead paint would be either used surreptitiously or else ignorantly, and consequently the lead paints might be used without the necessary care and without proper observance of the regulations, either on account of there being no control in the matter or else the men acting in the belief that the paints used are quite harmless.

14,668. What are your opinions concerning the necessity of labelling cans which contain the paint?—On the point of the declaration of paints containing lead being poisonous, I wish to emphasise the necessity of uniform method of designing the cans containing the paints. The Austrian regulation in that respect is bad, because it simply says that all paints containing lead must be labelled as such. I think it necessary that there should be a uniform way of denoting all vessels by putting on them, preferably in very striking red colour just these words: "Containing lead, and poisonous." And preferably putting above it the sign of cross-bones and skull to make it intelligible to the illiterate, because chemists who sell poison in bottles are compelled to put on them the cross-bones and skull. They label all bottles containing poisons for the benefit of illiterate people.

14,669. (*Mr. Sutherland.*) I gather that you think that if white lead was prohibited, paint would be sent out not as we buy it now but as mixed paint, and therefore would there be greater difficulty in detecting adulteration by white lead. If white lead is abolished, the practice of buying paint would change from buying it as paste white lead or zinc into buying it ready mixed for use, and with that form would come the possibility of adulteration with white lead?—I think it quite possible that the sale of ready mixed paint will open a door to adulteration.

14,670. (*Chairman.*) You have told us about the dangers of dry rubbing down. Would you like to add anything to that concerning any other dusts which are generated in the course of painters' work?—I think that there is a great deal of danger in the sale of dry white lead, which is then ground by the painters and mixed by the painters with oil. During this process a great deal of dust is made. I would like to see it made law that lead shall be only sold ready mixed with oil and never in the dry condition.

14,671. Would you like to add anything to your statement in connection with the duties which devolve on the employer?—It is very important that in case of any regulations being broken, not only the employer, but also the employee, should be liable to a heavy fine.

14,672. I understand that you would like to make a statement in connection with workmen suffering from certain diseases which are likely to pre-dispose them to lead poisoning?—It has been observed that certain illnesses pre-dispose workers to lead poisoning, and if these illnesses are combined with lead poisoning, the case is generally a very severe one. The illnesses which pre-dispose men to lead poisoning, and which are accelerated and made more severe, are tuberculosis in all its forms, hydrocephalus, epilepsy, alcoholism—all forms of mental and nervous diseases—rheumatism and similar diseases, and diseases of the kidney. All men suffering from such diseases should be advised not to enter any profession connected with lead.

14,673. (*Mr. Mason.*) Are those diseases caused by lead?—I am quite aware that lead poisoning may cause all or any one of the illnesses. If you have already had illness before you come into contact with lead, you are

23 November 1911.]

Dr. JOSEF RAMBOUSEK.

[Continued.]

far more likely to get lead poisoning, or the lead poisoning will make the illness very much graver and more rapid than before. I would like to say that if

at any time the Committee requires any further information on any point I shall be very pleased to communicate it in writing.

The witness withdrew.

Mr. ODO MARIA MEISSL.

Evidence to 14,688 handed in and taken as read; witness then called and examined (through an interpreter).

14,674. I am a master painter in Vienna, and have had over 30 years' experience. I employ some 300 to 400 hands, and have been entrusted with commissions for a number of public works of great magnitude, such as the Thulln bridge over the Danube. I have also studied the chemical composition of pigments.

14,675. I have given great attention to the question of lead poisoning among painters, and before there was any question of regulations took special measures of precaution in my own business; and I have for many years, by writing and by speeches, endeavoured to call attention to the dangers of lead poisoning and the best way of obviating them. In 1907 I was summoned by the Austrian Commission on Lead Poisoning as an expert to represent the Viennese master painters, and I may claim that a considerable number of the recommendations of the Commission's Report and also the regulations which were a consequence of it were made as a result of the information and advice which I was able to give as a man of long practice and experience.

14,676. Sufficient time has now elapsed to enable me to form an estimate of the working of the regulations which were issued on the 25th April 1908. They have been, speaking generally, properly enforced, and there can be no doubt as to the beneficial results which have followed from their operation. Anyone who, like myself, had many years of experience of the condition of things before the regulations were made cannot fail to observe the marked decrease of lead poisoning since the regulations.

14,677. From a practical point of view the regulations to a great extent are worked by the workmen themselves through their powerful trades union organisation. The painters of each of the 21 districts of Vienna have their own separate organisations (Verband der Maler und Anstreicher), and these are all part of a larger organisation of the building industries (Baugewerbe) of Vienna, which again are one group of the Baugewerbe-Genossenschaft for the whole of Lower Austria. The painters of Vienna all belong to a sickness insurance (Krankenkasse) to which there is a contribution by the worker and employer, as I understand is proposed by the health insurance legislation which has recently been introduced in England. As the trades union (Arbeiter Organisation) is of a somewhat social democratic character, and many of its officials are officials of the Krankenkasse, there is a strong tendency for the Krankenkasse to report every possible breach of the regulations to which its attention is called by a painter applying for sick pay, and from the employers' point of view the regulations are quite sufficiently enforced in this way.

14,678. I may say that I have, for a large number of years, spent a good deal of time and money in endeavouring to procure or make an effective substitute for white lead, but as I showed the Commission in my evidence, this is impossible, at any rate for use in outside painting.

14,679. In my judgment and experience white lead is indispensable for outside painting owing to its special properties and its exceptional durability and covering power, which are the result of the peculiar chemical combination which it forms with linseed oil. The chemical combination of white lead with linseed oil is such, that as the linseed oil oxidises when it is exposed to contact with the air, sometimes it forms a kind of lead soap which, when it hardens, remains elastic so that under variations of temperature it expands and contracts instead of cracking. Zinc white which is the next substitute for white lead makes in combination with linseed oil a different soap (zinc soap) which has far less resistance to the action of rain, &c., and changes of temperature. From a practical point

of view the "life" of pigments for outside use is determined by their power of resistance to the influence of water, and as one who is familiar with zinc white for outside use, I know that the effect of sunshine on zinc white is to make the zinc soap soluble in water; therefore it is far less able than white lead to resist the influence of water. For inside painting white lead has not so great an advantage over zinc white because white lead tends to turn yellow under the influence of sulphuretted hydrogen, but even for inside use white lead is indispensable for specially damp places.

14,680. The other great advantage of white lead is in respect of covering power. It is true that owing to the greater specific gravity of white lead the same weight of zinc white spreads over a larger surface than does the same weight of white lead, but zinc white has to be used with a much larger amount of linseed oil to make it sufficiently fluid to work. The result is that for the same degree of opacity more coats are needed for zinc white than for white lead. These circumstances show why it is much more costly to paint with zinc white than with white lead, since the use of zinc white increases the two chief items of the cost of painting: (1) the amount of linseed oil, and (2) labour. I calculate that the ratio of labour to materials in painting (at any rate in outside painting) is 60 per cent. labour and 40 per cent. materials, so that if it be assumed that three coats of zinc white have to be given for two coats of white lead, the greater cost is apparent.

14,681. From the point of view of those who have to maintain large structures (especially large iron structures), the greater cost of maintenance of buildings painted with zinc white is of even more importance than the greater initial cost of painting with zinc white. This is equally important for master painters who have to give a guarantee for maintenance. Surfaces painted with zinc white have to be renewed at least every three years, while surfaces painted with white lead will last for eight years. The cost of scaffolding, &c., for the purpose of renewal also becomes a heavy item.

14,682. From my special experience with regard to the painting of large iron structures, I was in a position to put before the Commission evidence showing that red lead (minium) is in a special way indispensable for this purpose.

14,683. These advantages may be summarised as follows:—

- (1) Minium is the only pigment used for such purpose which is soluble and forms a special combination with linseed oil (lead soap).
- (2) Minium is the only pigment which can be painted directly on slightly rusted and not properly cleansed surfaces, as it acts like a putty sticking on the loose parts of dirt, rust, etc., wherefrom other paint would peel off.
- (3) Minium sinks into all the pores of iron and enables a smooth even surface to be painted.
- (4) Minium makes the hardest ground paint, a fact of great importance, because it is found in practice that if the first coat be softer than the second, and therefore more elastic, the second coat is broken away.
- (5) Minium is the only paint which is not injuriously affected by water.
- (6) Minium is practically an air-tight paint.

14,684. I have made experiments myself with the object of finding a non-poisonous substitute for minium for painting on iron, and experiments have been made for this purpose by various bodies, such as the Royal

23 November 1911.]

Mr. ODO MARIA MEISSL.

[Continued.]

Railway Administration (k.k. Eisenbahnministerium), and by the municipality of Vienna, since the date of the Commission for the same purpose, but no such substitute has been discovered, for the reasons which I have indicated above, which were adopted by the Commission.

14,685. In my opinion one of the most important provisions of the regulations is the requirement of a declaration when a pigment contains lead. In the absence of such provision workmen and master painters handle substances containing lead which are even more poisonous than ordinary white lead without being aware of their danger.

14,686. My own experience causes me to emphasise the danger of smoking, especially cigarette smoking. I notice that, speaking broadly, apart from special predispositions to lead poisoning, the workmen who suffer most from lead poisoning are those who smoke cigarettes.

14,687. I also attach importance to the provisions to meet the case of those who have a predisposition to lead poisoning. It is well known that there are some persons who are peculiarly susceptible to it, and it is desirable that they should be altogether prevented from working with white lead. Originally it was proposed that anyone who once suffered from lead poisoning should not be allowed to work again, but I pointed out to the Commission the gross injustice of depriving a man of the employment in which he had perhaps been trained for years merely because he had one attack of lead poisoning, and in consequence of my representations the regulation was limited to requiring that no one who had been attacked by lead poisoning should again be employed as a painter until he had a medical certificate of complete recovery.

14,688. The point upon which the Report of the Austrian Commission lays most stress is the danger of the dry rubbing down of white lead paint. There can be little doubt that the dust created by this process was the chief cause of lead poisoning among house painters. I informed the Commission, and my statement was confirmed by other experts in the trade, that there was no process of the dry rubbing down which could not be done wet. The wet rubbing down, in many cases, gives a better result, especially for fine work, although, of course, it adds to the cost of labour.

14,689. (Chairman.) What substitutes for white lead paints have you tried?—The only thing which might be considered as a substitute for white lead is zinc white. It is the only white colour which comes into consideration.

14,690. Have you tried that extensively?—I have personally made extensive experiments with zinc white, and I have actually been for ten years representative of an English zinc white firm. I was compelled to abandon representing that firm because I found that zinc white did not answer the purposes as well as white lead.

14,691. What is the name of the firm you represented?—, formerly —, — was the inventor of lithopone.

14,692. How many years ago was it that you were agent for this firm?—It is about twenty years ago.

14,693. What substitutes for white lead have you used since then?—There is no substitute for white lead for outside work. The only thing which might be considered would be artificial barium sulphate.

14,694. What substitutes for white lead have you used for experimental purposes since you abandoned the agency of Messrs. —?—There are no other white paints than those already given, but I have made a number of experiments with zinc white with a number of different media.

14,695. Can you give us any illustration of the experiments you made with zinc white for exteriors?—As I found that linseed oil and zinc white did not give a durable coat of paint, I attempted to mix zinc white with varnishes or with resins. I made experiments on a very large scale, and in all cases the result was a negative one.

14,696. (Mr. Sutherland.) Was the result negative when you included varnishes?—Yes; they were found to peel off.

14,697. (Chairman.) For what length of time did these experiments extend?—These experiments have extended over a period of more than 20 years, and a number of these experiments were carried out at the instigation of the authorities.

14,698. When was the last experiment begun?—The last experiment on a big scale was made approximately three years ago, and the paint after one year came off like water paint.

14,699. We have never had anything quite as bad as that in this country, and we have had some examples which have been highly satisfactory. Have you heard of the Office of Works, a great Government department?—Yes.

14,700. They have made a trial of leadless paints on a large scale on the new Savings Bank buildings, and the result was so satisfactory after four years' trial that the Office of Works have decided in future to abandon the use of white lead in painting?—I have stated in the statement which I have prepared that the difference in my experience and the experience of the Office of Works is that most of my work was carried out on iron structures. Now, zinc white has to be used on iron structures in combination with very little oil; whilst in the case of painting zinc white on stone or wooden walls, it can be used with a large quantity of oil. Consequently a great part of the oil remains unsaponified, and consequently the result of zinc oxide on stone or wood might be very much better than on iron.

14,701. Do I understand that you have not made any experiments on a large scale on stone or wood?—I have made experiments both on stone and on wood, and found that zinc white would give quite satisfactory results, but on wood it required an additional coat of varnish. So the durability of the paint was the durability of the varnish and not the durability of the zinc paint.

14,702. Do I understand that your objection to zinc white is only as regards painting on iron?—Iron and wood. My experience is that on iron the whole of the oil is converted into very soluble zinc soap, while in the case of wood some of the oil remains unsaponified and might therefore remain for some time as a medium. But my experience is that for outside purposes it was not good enough, as the woodwork of some windows had been painted with zinc oxide and linseed oil, and when the windows were washed the paint came off as if it were chalk rubbed on with water.

14,703. In the illustration that I gave you of the Office of Works, a very large amount of the painting on the exterior was on wood, and that, they maintain, was highly satisfactory?—The difference in the experience in the English Office of Works and my Vienna experience might find its reason in the difference in climate. I think the strong sun over there is largely responsible for the different results, but in any case I would very much like you to read the exposé which I have prepared where I set out the reasons why zinc oxide paints cannot be durable.

14,704. Then with regard to painting on iron I would like to point out to you that we have had evidence from the South Eastern and Olintham Railway Company who told us that the railway bridges and station roofs at Charing Cross and Cannon Street Railway Stations were painted with coal tar, silica, graphite, and other such paints, and that they have been highly satisfactory. The same thing applies to a great many other railway bridges?—I would like to know for certain whether no red lead had been used previously for coating the iron before these other coats were applied; and also I wish to say that I cannot quite see how the comparison comes in, as graphite and tar are always black, and to obtain a white or grey paint you would have to add a considerable quantity of other white bodies. I quite acknowledge that there are very good black or dark colours for paint which will protect ironwork, as, for instance, carbon paint, or oxide of iron.

14,705. Will you tell us how the Austrian regulations are enforced?—One of the chief ways of controlling obedience to the rules is doubtless in the hands of the

D d 4

23 November 1911.]

Mr. ODO MARIA MEISSL.

[Continued.]

Trade Commissioners—those commissioners who attend only to one trade, and who inspect the larger workshop or factory at least five or six times a year.

14,706. Are those inspectors appointed by the Government?—Yes, like Dr. Rambousek. There is an Industrial Office in Vienna (called Gewerbe-Inspektorat), which has some 30 such inspectors, and every district has one or two inspectors on these lines, and these inspectors deal only with their own district, so that most workshops can be inspected five or six times a year.

14,707. Are the figures of these inspections available?—I may say that I have heard from other master painters that their workshops are inspected regularly, and my own workshop is inspected at least once every eight weeks or so, and then when the inspector finds anything he does not approve of he always insists on alterations. There is a further control by the insurance. It is a question of information in various districts.

14,708. You are speaking of your own workshop now, are you not?—Yes.

14,709. I want to know generally what the system of inspection is in Vienna. For instance, I find that there are 3,195 factories and workshops in one district of Vienna alone?—The master painters of Vienna number 800.

14,710. I am speaking of the number of factories and workshops which have to be visited by the inspectors?—There is in every district of Vienna an inspecting office. Every inspecting office contains more than one inspector—sometimes three or four—and every inspector has a certain number of workshops under his notice.

14,711. I understand that there are 3,195 factories and workshops to be inspected in the second district of Vienna, the district in which your works are situated, and that there were only 829 visits paid to those 3,195 factories and workshops in 1910, leaving 2,366 factories or workshops which were not visited at all?—That is not right. I still think it possible for painting workshops to be inspected five or six times a year, although only 829 visits were paid to 3,000 workshops, because amongst these 3,000 workshops are a great many workshops which do not require any inspection, because the work carried on there is not dangerous to health in any way.\*

14,712. If there are very few inspectors available it practically means that they utilise most of their time in visiting the master painters' establishments?—I wish to say that these inspectors practically confine their visitation to trades where the workers have to deal with poisonous substances, or where the trade is dangerous; but there is a further and very efficient control from the insurances (Krankenkassen). All these insurances are practically run by the Socialist force in Vienna; and as soon as only a few cases of lead poisoning occur these insurance officials give information so that inspection of the workshop takes place and the offending party is fined.

14,713. But how does the inspection arise through the insurance; is the factory inspector notified?—In case of such an inspection taking place on account of information by the insurance, a visit is paid as a rule by four persons—firstly, the district medical officer, the industrial inspector, a member of the magistracy, and a confidential person.

14,714. Do they each go separately?—No, the four of them go together. Every person employed in any workshop whatsoever must be a member of the insurance society.

14,715. How many cases of lead poisoning have occurred among your own workpeople since the regulations came into force?—About six or seven a year amongst 400 men.

14,716. You stated in your evidence that you employ between 300 and 400 painters?—Yes, in the

\* Later note added by witness:—

I do not know the reason why my workshop was so often inspected in the year 1911, in this year up to the present date (20.9.12) no inspection has taken place.

season, not in winter time. Now I have only 200, and in January about 120 or 130.

14,717. What is the average number you employ?—The average number is perhaps 250 to 280.

14,718. Is not six or seven cases a very high percentage?—Only very slight cases. If one has a little pain in his stomach or shows the blue line on the gum we send him to the doctor, and he writes "Lead sickness," because the insurance like to have as many lead poisoning cases as possible, so as to be able to start a new discussion and advertise the labour cause in the House of Parliament.

14,719. You have told us that your factories are inspected very thoroughly?—There is a triple inspection of the works: firstly, by the industrial officer, secondly, by the medical officer, and, thirdly, from time to time an inspection by the magistrate on account of danger from fire.

14,720. And yet the percentage of lead poisoning cases amongst your workmen is about 2.5?—There is a great deal of change in the personnel of the works, and a good many workers enter the workshop when they already suffer from lead poisoning. A good many of these cases which are put down as lead poisoning are only very slight cases where the men are absent from work only for a few days.

14,721. When does the medical examination of your workmen take place?—The regulation demanding medical inspection of the men is not strictly enforced. If the men miss the day on which they should go to the medical inspector they do not go until the next inspection falls due.

14,722. Do I understand you to say that your workmen, or some of them, are suffering from lead poisoning when they enter your employ?—I mean that a number of the men enter my workshop when they have lead poisoning in a latent form; that is, they have a certain quantity of lead, and the little quantity of lead which they may absorb there may bring out the lead poisoning.

14,723. But do not a certain number of men who may have lead poisoning in a latent form leave your establishment and go elsewhere?—Yes, I acknowledge that.

14,724. Does not one balance the other?—I think that these two quantities do not balance each other, as in my works about half of all the lead painting is done, and when men leave other painting shops they probably come to my workshop, but if they leave my workshop they would not go to other painters, but they would go to some other trade where they would be removed from the influence of lead. For outside work I do not employ regular or skilled painters, but only occasional workers who may have been at some other trade before, and who, when the painting season is over, go back to some other trade.

14,725. You lay stress on the danger of dry rubbing down?—That is the most dangerous process of all.

14,726. Can you dispense entirely with dry rubbing down of lead painted surfaces?—It is possible to do all kinds of rubbing down in the wet way perfectly satisfactorily, only the cost of doing it is slightly increased.

14,727. When a first or priming coat of lead paint has to be rubbed down before a second coat is applied, what would you use for rubbing down?—Pumice stone and water.

14,728. But would it not take a long time for the first coat to dry sufficiently to allow a wet rubbing process to be applied?—There is no reason why there should be any extra waiting, because, for dry rubbing down, you have to wait until it is absolutely dry and set hard, otherwise in rubbing down you would not obtain a polish, but a sort of smearing effect, whilst in wet rubbing down it is not necessary to wait until the surface is quite so hard. It must be hard, but not so hard.

14,729. In the case of a priming coat applied directly on new woodwork would not the use of a wet rubbing process involve a risk of raising the grain of the wood?—Rubbing down a first coat is only done with very fine work. In very fine work necessarily the first coat would be so thorough that the woodwork would not be

23 November 1911.]

Mr. ODO MARIA MEISSL.

[Continued.]

exposed in any way to water, and consequently the grain could not be raised, as the woodwork is entirely protected. Also the first coat for fine work must have a certain uniform thickness.

14,730. (*Dr. Collis.*) Could you tell me how long the cases of lead poisoning you have had in your works usually have been employed for a long time or a short time?—My experience is that the lead poisoning is strictly confined to men new to the work, who have been in the place only a short time. In my own case there are 19 men who have been employed for 25 years, one of them, a strong man, who has to rub up every year some 70 tons of red lead. None of these has ever shown the slightest symptom of lead poisoning.

14,731. Have the cases occurred mostly among the regular painters, or among the people who are taken on for a short period?—Most of the lead poisoning cases are amongst occasional workers.

14,732. Who may not have been employed before in painting?—No; they would be men who would have some previous experience of painting, but who would follow for some time the profession of painting, and at other times some other trade.

14,733. So that the idea that they come to you with lead in the system is hardly justified if they have been at another trade for some period before they come into your employment?—I hardly think that these men who come to me from other works would have had lead in their system, but there might be cases of men coming to me from ironworks where they might have been employed in the rubbing up of red lead. But the chief cause of lead poisoning, in my opinion, when you employ prepared paints, is lack of cleanliness or inexperience on the part of the workers.

14,734. Can you say what additional steps you consider should be taken in Austria, if your establishment is inspected four or five times a year, by three and sometimes four inspectors at a time, and yet you have a rate of lead poisoning among your workers which is very high?—I think that the figures of lead poisoning in my case are low, because it has to be considered that most other paint shops would do perhaps 25 per cent. lead painting, and the rest of the painting with other colours, while in my workshop lead paints almost exclusively are used. I also have the experience that in other workshops you get one case of lead poisoning for every 5 cwts. of lead paint used. In my own workshop you get one case of lead poisoning with every 13 tons of lead paint.

14,735. Then you consider that your workshop is better than the others in Vienna?—I claim that my workshop is better than other workshops in Vienna, on account of the regulations which I enforce.

14,736. You would consider that the effect of the regulations now established in Austria is fully shown in the health of the workers in your employ?—I do not think that my work is all carried out as it should be under those regulations, because in the summer, when most of the painting is done, out of 400 men in my employ as a rule some 300 men are employed outside Vienna, and many of these men may be employed at a distance of three or four hundred kilometres from Vienna, and some of these men are taken into employ out there. Consequently I or my foreman are unable to control the workers outside Vienna in the same way as they are controlled inside my own workshop. Inside my own workshop there are practically no cases of lead poisoning.

14,737. Yet the conditions under which your work is done are better than the average conditions in Austria under these regulations?—I claim, that my painters work, perhaps, under better conditions than other painters in the rest of Austria, but other painters frequently have more favourable conditions for enforcing the regulations than I have with my own painters. Most other painting workshops employ 80 per cent. of their men inside their own workshop and only 20 per cent. outside their workshop on outside work, while I employ only 25 per cent. of the men in the workshop in the summer, and 75 per cent. of the men on outside painting.

14,738. It is unlikely that the conditions of employment which you represent yourself, in any way differ

from the conditions of employment in England. I understand that under the regulations now in force in Austria you can only get the lead poisoning cases down to 2·5 per cent., which we should not accept. As an instance, I point out to you that in the pottery trade, where we only have an incidence of 1·4, a very important committee was appointed to inquire into the very high incidence of lead poisoning?—I think that I have proved by my exposé that if you prohibit the use of lead paints for interior work entirely, you can at once reduce the incidence of lead poisoning to a third of the present rate, and then lead poisoning would be 0·8 per cent.

14,739. But I understood that in Austria the use of lead for interior work was prohibited?—The prohibition of lead for inside paint does not affect my work much—only slightly—because my work is practically confined to outside painting.

14,740. We have people confined to outside painting in England in a similar way, and if we had similar regulations carried out to the best of our ability, as they are with you, you can only hold out to us the prospect of getting a percentage of 2·5, which, as I have already pointed out, is a great deal higher than we, in England, consider it should be?—I have an incidence of lead poisoning of 2·5 per cent. amongst my painters, who are almost exclusively outside workers working with lead paint. Amongst all painters there are 40 per cent. of outside painters. If these 40 per cent. of outside painters have an incidence of 2·5, then the whole of the painters will have an incidence of 1 per cent. I think that with further information to the working men it is possible to reduce the 1 per cent. to zero almost.

14,741. The percentage I gave in the potteries of 1·4 is 1·4 per cent. of the people exposed to the possibility of getting lead poisoning, and a percentage of 2·5 among outside painters of those who are using lead paints nevertheless remains extremely high?—I think it quite possible to greatly reduce the incidence of lead poisoning amongst workers by giving them further information. I think that in the case of interior painting the working man really has no protection against poisoning on account of the continuous formation of lead dust, but in the case of outside painting lead poisoning is invariably the worker's own fault, on account of lack of cleanliness.

14,742. With regard to inside painting, why should there be danger at all when you have abolished lead for inside work?—I would point out that the incidence of 2·5 per cent. refers only to outside painters; consequently, the incidence for all painters is 1 per cent., and as the incidence of lead poisoning amongst painters before the introduction of the regulations was 3 or 4 per cent., there is a great improvement, and I think with further information to the workers you can reduce the figures still further.

14,743. Yes, I quite follow that; but my point is this: that where these regulations have been carried out under the very best possible conditions in your factory, with an inspection occurring four times a year by three people specially set on one side to make these inspections, yet with regard to outside painters there remains a percentage of 2·5. The rest of Vienna we know has not kept so low. The 2·5 apparently represents the result of the regulations carried out by the best possible means under your own supervision to-day. That represents a very much higher figure than we can possibly accept in England?—The men under supervision as I should wish it represent only 25 per cent. of the men in my employ. 75 per cent. of the men in my employ are outside my supervision because they do not work in Vienna, and that is where most of the cases of lead poisoning occur.

14,744. You consider that most of the cases of lead poisoning occur outside Vienna?—Yes. Outside there is no inspection.

14,745. No inspection at all?—How can they be inspected? I am in London and I have workmen in Chatham or in Liverpool. How can they be inspected there?

23 November 1911.]

Mr. ODO MARIA MEISSEL.

[Continued.]

14,746. That is the question which I ask you?—It is impossible. No inspector can go on all the railways and bridges in the mountains. It is quite impossible.

14,747. (Mr. Sutherland.) What is the nature of your business—I mean what class of work do you do?—Mostly painting ironwork, bridges, viaducts, gasometers, and so on.

14,748. Railway stations?—Railway stations and roof construction, and railway work in general.

14,749. Can you tell me why zinc oxide ground in oil is packed in metal kegs and not in wood casks?—In the case of white lead with linseed oil you obtain saponification of a certain part of the oil by the lead, and the lead soap forms a mixture with the linseed oil and the lead; so that there is a complete mixture of one solid mass which is not likely to leave the cask, whilst in the case of zinc white, a certain amount of the oil is saponified by the zinc, but the remainder of the oil remains free, and is separated from the zinc white and the soap, and is likely to leak out of the cask.

14,750. Is not that a very great argument as to the value of white lead as against zinc. The white lead after a year's time in the cask would be better than it was when it was put in, but in the case of zinc you would have a solid body of zinc that you would very probably have to chisel, with a superstructure of oil?—Neither white lead nor zinc white are improved by age; but the white lead can still be used after having been kept for a year or more, whilst, on the other hand, zinc white mixed up with oil, after one year's keeping, cannot be used, because you have a solid hard mass of zinc white and a separate mass of oil. If you stir up the solid mass of zinc white again with oil you obtain a new pigment, which has practically no covering power.

14,751. Many master painters do order large quantities of white lead to put into tanks to store it, for the sake of its getting old, and therefore getting better value out of it?—I think that the buying of large quantities of white lead mixed with linseed oil is a mistake due to lack of information. I think that linseed oil alone improves with age, but not white lead. The white lead mixed with oil after some time gets tough. I think that the ideal way of proceeding is to buy a large quantity of linseed oil, let it lie for several years, and then mix it with white lead.

14,752. I do not mean in the mixing of paint, but in the grinding to a stiff paste. The point I wanted the Committee to know was this: that what happens if you put the oil and zinc in casks is that the zinc becomes a solid mass, and the same process goes on, does it not, in actual paint?—Yes.

14,753. The same affinity in the case of lead and oil operates to preserve the paint, and the less affinity between the zinc and the oil operates to make the paint poorer. Is that not so?—I wish to refer you to my exposé, where I have clearly stated that the great durability of lead paint is due to the formation of a very durable lead soap, whilst zinc white is not durable, because you obtain a zinc soap which is easily hydrolysed, and consequently you get a separation from the paint of the zinc plus the fatty acid, and consequently the zinc coat is not durable.

14,754. What would be the result on your own special branch of bridge painting, and railway stations, if zinc were substituted?—I wish to state that my experience is that zinc white paint is perfectly satisfactory if a durability of only two years is required instead of the customary five or six years' durability. If customers are satisfied to have all their work painted over again every two years, and are ready to spend so much more money on this repeated new painting than I am quite in favour of the introduction of zinc white, as it would give us so much more labour.

14,755. You refer in your evidence to giving an undertaking with regard to the maintenance of paint over a certain number of years. What kind of undertaking do you have to give?—In undertaking a contract I always guarantee that my paint will last at least five years. In case of the paint going bad before five years I have either to refund the money or put on another coat of paint.

14,756. Is it a common condition in Austria with regard to public work to guarantee that the paint shall last for a certain length of time?—Three years and five years. Some people are content with three years; some require five years. If they only want three we give a three years' undertaking only. It is better. The Government requires five. A good lead coat stands for eight or ten years, and zinc stands for two years. Therefore you must spend about five times the money if you use zinc instead of lead. So that in England where all painting costs in a year 10,000,000L., if you want to have zinc you must spend 40,000,000L. or 50,000,000L.

14,757. You do not object to regulation?—I think that regulation is absolutely necessary, because the disease must be brought down to a very small number. The stopping of lead poisoning is only a question of cleanliness and information to the workers. If the workers will always observe cleanliness, and are well informed as to the danger of lead, I think that lead poisoning can practically be stopped, and if employers will submit themselves to the duty of enforcing cleanliness and giving their workers proper information it will be quite safe then to permit lead for all outside work.

14,758. How long have your regulations been operative?—I cannot say exactly, but I think two years.

14,759. Do you consider that a sufficient time for all the workers and the master painters to have understood them?—No. I think that it will take at least another five or six years before these new rules will be quite understood and carried out everywhere, particularly in the provinces where they are not so directly under the influence of the Government officials.

14,760. Do you think that it would be dangerous to such structures as bridges and railway stations, if you were compelled to use zinc oxide?—I think that it is impossible to test whether there is any real danger in giving a railway bridge or similar structure a bad coat of paint, because there is a continuous inspection of railway bridges and other structures by Government inspectors, who always insist on a new coat of paint for every bridge or structure as soon as they see a deficient coat of paint.

14,761. What is the average time in which you have to renew?—Six or seven years.

14,762. Do you renew oftener with zinc than with lead paint?—Lead paint would stand perhaps two or three years longer. Zinc paint goes off in the second year.

14,763. You paint a lot of Government bridges, do you not?—I have painted more than 9,000.

14,764. You can give us the information we want. Have you had to repaint them before the regular period has expired?—I have never been compelled to renew a coat of lead paint before the contract time has expired, but it has occurred several times that I have had to renew a coat of zinc paint before the contract time has expired. My worst experience was with a coat of lead and zinc paint mixed. In this case I had to renew the paint before a year had expired. I removed it before I had been remonstrated with by the authorities, because I myself observed how badly the paint had worn. My opinion is that by having lead and zinc paint mixed you get an electrical influence which destroys the paint.

14,765. Are your bridges painted white or light colour?—The bridges in Austria are generally painted grey; but according to my experience the darker the colour the longer the coat lasts. I can give you the reason for that if you wish.

14,766. The substance of the paint is really lead?—The very darkest colours used on bridges never contain more than 8 to 10 per cent. of dark colouring matter and the lighter ones generally contain only 1 to 2 per cent. of added colouring matter.

14,767. Do you use genuine pure lead?—The basis of the paint is chemically pure white lead. I use 90 per cent. of such white lead, and I make a small addition of calcium carbonate, as a rule 10 per cent., for technical reasons. Then it stands longer than pure white lead.

23 November 1911.]

Mr. ODO MARIA MEJSSL.

[Continued.]

14,768. Do you mix your lead paints with any varnish?—Never for iron work. My experience is that if you add varnishes to lead paint you get a sort of solidification or gelatinisation, which makes the paint unfit for use. I use pure linseed oil.

14,769. Do you use boiled or raw linseed oil?—You cannot use the raw linseed oil, because it dries too slowly, and during the extended period of drying the paint might be damaged, either by dust or rain.

14,770. Do you use any special kind of linseed oil, or just the ordinary boiled oil of good quality?—The best process is to buy pure raw linseed oil, stock it for half a year, and then boil it with a small addition of lead or manganese. Stand oil is no good for the sun or against dampness.

14,771. Do you consider that zinc or other leadless paint in which there is a large proportion of varnish should be compared with paint mixed with linseed oil and turpentine?—To use turpentine is, in my opinion, no better than to use water, because pure turpentine should evaporate without leaving any residue. In fact the test for turpentine is to dip paper into it and dry the paper, there afterwards being no stain on the paper.

14,772. For zinc paints, do you mean?—For all paints. At times turpentine is used in conjunction with too rich oils.

14,773. You have not answered my question. I mentioned turpentine only incidentally. The question is, do you consider that zinc paint or other leadless paint, in which there is a large proportion of varnish should be compared with paint mixed with linseed oil?—I think that this would lead to a comparison of the media, but not to a comparison of the bases, and I think it an unfair comparison to make.

14,774. But I want your opinion, if you can give it. Which is the better paint?—If you have varnish it is all the same whether you put zinc or lead. Oil and varnish have quite different qualities. For outside work varnish is no good. Oil is much better.

14,775. I am speaking of outside work?—You do not get the elasticity with the varnish. I think that varnishes are not fit for outside use, because on account of insufficient elasticity they are likely to peel. For the highest quality of work, such as very fine coaches, no varnish whatsoever is used, but only linseed oil which has been stocked for some 20 or 30 years.

14,776. That is in Vienna?—Yes. If varnish has to be used for outside work a considerable percentage of linseed oil must be added to take away its brittleness. In the case of coaches the last coat of the 20 or 30 years old linseed oil is only there to give a surface polish. The colour and durability depend on the base and the first coatings. I also wish to state that I do not consider myself an authority on coach painting, but only on outside painting. I am not a coach painter, therefore it would not be fair for me to talk about it.

14,777. Would it not add very largely to the cost of the whole of the painting of this country if we had to abandon the use of linseed oil in paint and substitute a large proportion of varnish?—I think that the cost would go up a great deal if you were to use varnish instead of linseed oil, and although the cost would go up such a great deal, you would not attain your object.

14,778. You would not get the same protection?—No.

14,779. Do you know that, although the Office of Works have expressed their intention of abandoning lead, the Admiralty and the War Office are amongst the largest consumers of lead in the country?—I wish to state that four years ago the German State Railways prohibited the use of white lead on their carriages, and for all painting work. After two years this prohibition was recalled, and white lead was reinstated as the sole paint. Also the experts of the Austrian Navy decided that white lead was the only paint to be used for Austrian men-of-war.

14,780. You spoke of some experiments you had made in which the zinc paint after twelve months or so dusted off?—I divide paints into three classes, namely, paints which form a stable compound with linseed oil—

lead paints; paints which form an unstable compound with linseed oil; and zinc paints, and different paints, such as barium sulphate or iron oxide paints, which do not combine at all. The lead paints are the most stable, and the zinc paints the most unstable. In between these come the paints such as iron oxide or barium sulphate paint. In my exposé I have given a long dissertation on the durability of lead soaps, and I have also shown that the life of the paint depends only on the stability of the soap formed.

14,781. Have you great belief in the value of red lead?—Yes.

14,782. Would you tell the Committee why you hold that belief?—Red lead is of so fine a grain and the saponification of the linseed oil is so quick and so thorough, that when red lead is merely stirred with linseed oil it mixes so intimately with it that it forms rather a combination than a mixture. This can be clearly seen if red lead and some other kind of pigment in powder form is merely stirred up with varnish without the aid of any colour mill; the red lead immediately forms a homogeneous mixture like butter, while any other colour makes an uneven mass as if it were stirred up with sand. In consequence of the exceptionally fine distribution of the pigment in the case of red lead, it is obvious that in the skin of paint red lead lies so close and so finely that a thoroughly air-tight coating is formed which makes a foundation for a rust-protecting paint.

14,783. You do not think that you could dispense with red lead in the painting of ironwork?—No, never. You can, perhaps, mix lead but never dispense with it. My experience is that it is quite impossible to obtain iron quite free of rust. If any paint, excepting red lead, is put on to rusty iron the rust peels off and the paint with it, but red lead forms on top of the rust a cohesive paste and coat which cannot be peeled off with the rust, and then it is possible to put on top of the red lead coat any other paint which may be decided upon.

14,784. Do you think that graphite is a good substitute for red lead?—No.

14,785. (Chairman.) Would you agree that, owing to the difference in climatic conditions between England and Vienna, a paint that was not suitable for Vienna might be quite satisfactory for England?—The difference in climate might be held responsible for ordinary covering paints which are meant to give a colour, but for red lead the conditions in England and in Vienna would be precisely the same. Red lead is the finest main paint everywhere, both the English product and the Austrian product. Further, red lead forms with varnish a smooth compound, not merely a mixture, which will stick on to the iron perfectly well, although there may be rust on the iron, and, in fact, it will cement the rust on to the iron, and if there is any chipping, only a small flake of the red lead coat may be pushed off, whilst with any other paint the whole coat will be pushed off.

14,786. But excluding red lead, what do you say?—I think that a paint which will make a satisfactory coat in Austria will make a satisfactory coat of paint in England, and *vice versa*, only the durability or the life of the coat of paint might not be exactly the same in England and in Austria.

14,787. That is not quite an answer to my question. Excluding red lead, should you say that, owing to the different climatic conditions of England and Vienna, a paint that might suit England would not be suitable for Vienna, or *vice versa*?—I think it is all the same. In Austria, if I paint a bridge where there is much dampness and much heat and much mist, the coat stands only six or seven years, but when there is a bridge in a town between houses it lasts eight or ten years. If you paint a bridge near the sea, neither lead nor zinc stands any longer against salt water.

14,788. Your evidence is almost entirely in regard to the painting of iron bridges, is it not?—No. I do outside work in general—large factories especially.

14,789. But is not your evidence almost entirely confined to the painting of iron?—My experience is confined almost entirely to outside work, and chiefly to ironwork; but I have done the painting of big factories,

23 November 1911.]

Mr. ODO MARIA MEISSL.

[Continued.]

and this includes, of course, the painting of large walls and wooden surfaces.

14,790. Have you made any experiments with leadless paints on surfaces other than iron?—I have made extensive experiments with leadless paints on surfaces other than iron. Of my work, about 80 per cent. is outside work, and 20 per cent. inside work. All the inside work is carried out with zinc paint.

14,791. Have you made experiments recently on an extensive scale with zinc paints, outside, and on surfaces other than iron?—During the last few years I have used zinc paint for outside work only if it has been expressly stipulated for by the person giving the contract, because throughout the past I have obtained bad results with zinc paint for outside work.

14,792. Have you tried during the last two or three years, by extensive experiments, to obtain a leadless paint for outside work for wood or stone?—I paint every year some 30,000 or 40,000 square metres with zinc paint, only by express stipulation of the person giving the order, but whenever I use paint other than lead I decline all responsibility for the durability of the paint. I completed one big contract for the railway offices at Villach, and after one year the paint had to be renewed.

14,793. When was that painting done?—The painting was done two years ago, and last year the railway authorities asked me to renew the coat of paint at my own expense, as it had not lasted. I declined to renew the coat of paint, as I had stated on undertaking the contract that I declined all the responsibility concerning the durability of the paints.

14,794. Was that on iron?—In the case at Villach it was on iron, but I painted a large wooden fence at Vöslau with zinc paint, and after one year, when the fence had to be washed, all the zinc paint came off by washing as if it had been chalk.

14,795. Is that your only experience of zinc paints applied to wood?—There have been a great number of other cases where zinc paints were applied to wooden surfaces, and I have invariably found that for outside work within a year the zinc coat has given out.

14,796. But I want to know in what years these different zinc paints were applied?—It has occurred every year that outside wooden structures have been painted with zinc. Frequently this has been caused by confusion on the part of my employees who mixed up the paint which was destined for inside use with the paint which was destined for outside use. Invariably when zinc paint was used for woodwork outside the results were bad.

14,797. Is it possible that the paint used on the outside work might have been a cheap lithopone paint, which was only suitable for inside work?—It was in most cases a pure zinc white. It is always against the interest of the master painter to use zinc white instead of white lead in Austria, because white lead costs only 60 kronen for two hundredweight, while zinc white costs 90 kronen. A krone is 10*½*d.

14,798. (Mr. Sutherland.) 5*2s. 6d.* per two hundredweight for white lead. That is not mixed?—With lithopone you cannot do any good for outside work.

14,799. (Dr. Collis.) What are the respective costs of a litre of best zinc white paint and a litre of best white lead paint?—It is impossible to give an accurate figure on this point, as linseed oil everywhere has gone up from 70 kronen to 120 kronen in the last few years.

14,800. What would be the respective costs (because I presume linseed oil costs the same whether you are mixing lead or mixing zinc) of a litre of white paint ready for use made with zinc and a litre of white paint made with lead. You need not give the absolute figure?—Taking linseed oil at 100 kronen, the cost of a white lead paint ready for use comes to about 66 kronen per kilogramme, and a white zinc paint 94 kronen per kilogramme. The zinc paint goes about 1.4 times as far as the lead paint, so that the two paints in actual use cost about the same, the balance being slightly in favour of lead, because two coats of lead paint are equal to three coats of zinc paint.

14,801. Are the prices of the two paints very different to start with?—It is somewhat difficult to say. There is no great difference in the prices. The actual

prices work out at about the same. In addition to this I maintain that two coats of lead paint will do the same as three coats of zinc paint.

14,802. (Mr. Parsonage.) Do you consider yourself a practical house painter, doing a fair size of house in your painting work?—I certainly can consider myself a practical house painter, as I have done the painting work for the Imperial Castle. I do only two classes of painting work throughout, either work in very big quantities under big contracts, or else work of the very highest class. I have been paid 50 kronen for 9 square feet, because it was such fine work. I have painted a door for an Austrian Prince, and I have got 1,000 francs for it.

14,803. You said that you consider turpentine to be as useless as water to mix paint with?—No. I consider turpentine quite indispensable for painting work, particularly in conjunction with rich oils, or if you want to obtain a thin coat of paint so as to bring out the grain of the wood; but turpentine can only be considered as a thinner and never as a binding medium. Good turpentine should evaporate without leaving any trace of residue.

*Dr. Collis in the Chair.*

14,804. (Mr. Gardner.) I understand that you are a practical painter, and that you have been trained to the trade?—Yes; I think that I have learnt the trade from the beginning. Originally I was a chemist, and then I turned over to painting, and I have been occupied with painting for 30 years. I started painting with only two men in my workshop.

14,805. At the Austrian Commission you were the spokesman for the house painters in Vienna?—Yes.

14,806. Is there more outside house painting in Vienna than inside house painting?—About 60 per cent. of all the work is inside painting, and 40 per cent. outside painting. If you would have the kindness to read the exposé you would find it all.

14,807. The Commission prohibited the use of white lead for inside painting, because of its dangers, and they considered that the rubbing down process was very dangerous to the workmen. One would naturally conclude that the lead poisoning would be practically nil—that there would be practically none of it now in Vienna when there is no rubbing down and no white lead used for interior work?—As long as you have ignorant or careless workers you will have a certain percentage of lead poisoning. Theoretically, the prohibition of lead for inside purposes, and the prohibition of dry rubbing down, should stamp out all lead poisoning. The lead poisoning which occurs at present is only due to careless or unclean workmen.

14,808. But if a man has learnt his trade and been at it since he was an apprentice as a boy, he cannot be an ignorant workman. I understand that there is no rubbing down on outside paintwork, so from what do the present lead poisoning cases arise?—The reason of lead poisoning is chiefly the ignorance of the workers and their unwillingness to be taught. As a rule, the workers will not believe in the danger of lead poisoning until they have actually had the disease. For instance, in spite of all regulation men are too lazy to wash their hands before they go to their mid-day meal, and in spite of all precautions they will always smoke cigarettes on the sly whilst they are at work. It is impossible during the summer to be very strict on the point with the men, because the men know that there is an insufficient supply of labour, and if you remonstrate with a man too severely during the summer he throws up his work or threatens to throw up his work, because he knows that the master painter cannot do without the men in the summer. When a man has had one attack of lead poisoning he will believe in the reason for the regulations. Nowadays a second attack of lead poisoning for one man is extremely rare.

14,809. But these conditions would apply in 1904 just as they applied in 1910?—If there is a new law passed which involves information to the workers and employers, and the creation of inspectors to control a particular matter, it must necessarily take some time before these new measures have taken effect—namely,

23 November 1911.]

Mr. ODO MARIA MEISSL.

[Continued.]

until the workers and the employers have learned the importance of these regulations and the way of applying them.

14,810. Yes, but in 1904 all the work outside and inside was done with white lead; 60 per cent. of the jobs are inside, you say, and 40 outside. There were 197 cases of lead poisoning in 1904. You have dropped 60 per cent. of the jobs that white lead was used upon, and you are only doing 40 per cent. of the jobs with white lead, and you have still 138 cases of lead poisoning. You have only a reduction of 59 cases?—I think that in 1904, and before then, a great number of lead-poisoning cases were not identified as such by the insurance people, and by the hospitals. On the other hand, since these regulations have come into force there is rather a lead-poisoning scare, and a number of illnesses which really are not lead poisoning are put down as lead poisoning. In fact, if a painter or any lead worker has the slightest noise in his inside people call it lead poisoning.

14,811. You said that a large number of your men, and men employed by others, are employed in the workshop?—There is no such thing as a painters' workshop properly so-called; it is only an office which controls the work done. Most of the work is done outside, as it is impossible to bring a railway bridge into the workshop.

14,812. Do the majority of the men work outside?—Twenty-five per cent. of my men work under my own control in Vienna, or within the precincts of Vienna, and 75 per cent. work at such a distance as to be beyond my control.

14,813. White lead paint has been prohibited for interior purposes in Austria and Vienna, and you only use white lead for outside work, and there is practically no rubbing down on the outside of buildings. I presume that outside doors are of a highly finished character in Vienna?—Yes.

14,814. They are here. If you got an outside door to repaint, the first operation would be to wash and polish it down with pumice stone? That would be wet rubbing down?—The old paint would be removed by some chemical means if it was to be removed, and always with fine work. On oak you must never use removers containing water; the oak turns black. You use a mixture of pure alcohol and benzol. We do not burn in Austria; it is very dangerous. We remove all with the concentrated benzol and the concentrated alcohol.

14,815. No burning off is ever done?—No; it is not so good, and it spoils the wood.

14,816. Take a door which is not an oak door but a pine door; you have stripped off the old paint, and polished it down with pumice stone and water and given it a coat of paint. What processes do you adopt after giving it a first coat of paint?—If the first coat is a lead coat it is always done with pumice stone and water, but all doors are painted with zinc colours and not lead colours. On top of the final coat of paint there is always put a coat of varnish, which protects the paint. Consequently the non-poisonous paint may be used, and then dry-rubbing down may be resorted to. It is no use to paint them with lead, because if you varnish the door it is only the varnish that has to stand.

14,817. In that case zinc paint is quite good enough?—Zinc paint is quite good enough if a varnish is upon it. You can rub it dry or wet as you like. If you have fine work you will give a varnish over it. You can paint doors and windows and all kinds of woodwork with zinc if you give varnish, because the varnish is the last coat, and the varnish has to stand against the effects of the air. In this case it is quite useless to use lead paints. When you have a varnish you can paint with zinc paint quite well. There is a bridge in Roumania that cost 40,000*l.* to paint. It is some kilometres long. You cannot put a varnish over it, and varnish is not so good, and if it were so good you could not pay for it. That is why we must have lead paint. But not for fine work. If you paint houses or offices outside and use varnish you may have an enamel which contains zinc, and that is all right.

14,818. (Chairman.) Do I understand that in your opinion for the outside painting of houses where a varnish is used zinc will do perfectly well?—Perfectly well, or better even, because only the varnish has to stand against the atmospheric influence.

14,819. Therefore, to sum your evidence up, from your point of view lead is required for metal work?—Not only for metal work. I have painted this year 20 manufactories, one of which cost 2,000*l.* or 3,000*l.* Manufactories cannot be varnished. The people would not pay for it, and it is not so durable.

14,820. For other work than domestic house painting, you have thought it necessary to advise that lead should be retained; but, for ordinary house painting, in your opinion, zinc can be substituted, provided you use a varnish?—I do not want to speak of a business I do not understand. The carriage painters may also use whatever paint they choose, because they have varnish.

14,821. You state in your evidence that you stopped using zinc practically 20 years ago, but just lately you told us that you were still using zinc now and again. Is there not a large difference between the quality of zinc paint manufactured now and that manufactured 20 years ago?—I have discarded zinc white chiefly because its use for inside work does not give a sufficiently big market, but I maintain that the quality of zinc oxide is the same as that supplied 20 years ago. But there is a great improvement in the quality of the lithopone supplied.

14,822. (Mr. Sutherland.) The zinc oxide is a constant quality?—Yes, pure zinc oxide.

14,823. (Mr. Gardner.) I take it from your evidence that you consider that red lead is the only substance which can be used for protecting iron or steel surfaces?

In all cases where ironwork is exposed to the influences of the weather and where the coat of paint has to stand a great deal, red lead must be used, but in the case of transverse bearers or support beams where the ironwork is inside a house or is otherwise protected, and does not require to have much resistance against atmospheric influences, iron oxide paint can be used.

14,824. Have you any experience of ship work?—My only experience is that the Austrian navy uses nothing but lead paints.

14,825. If your men paint red lead over rust, do they never scrape the paint off again?—There seems to be a misunderstanding. I do not wish to state that you can paint with red lead over a thick layer of rust. You can only paint over a very thin film of what I call "fly rust"—small grains of rust which are difficult to remove. You never paint, of course, over a thick layer of rust.

14,826. You also think that red lead is the only paint which is not injuriously affected by water. Have you ever tried iron oxide paint on your work?—In Vienna they recently built a very big gasometer with a surface of over a million English square feet, and the part of the gasometer which is under water was covered with all sorts of paints for the sake of experiment. A few months ago it was inspected, and all the paint, with the exception of the red lead, had flaked off or had become scaly or spongy.

14,827. Have you ever heard of the Forth Bridge?—Yes.

14,828. You would not be aware that the Forth Bridge, which is exposed to sea air, is painted entirely with iron oxide?—No. I think that iron oxide is, next to red lead, the best paint. In the case of paint exposed to the influences of sea atmosphere it does not matter very much which you use, because no paint will last very long if exposed to that atmosphere. In the case of constructions like railway roofs iron oxide is superior to red lead, because the sulphurous gases in the smoke will affect the red lead but not the iron oxide.

14,829. What we call the bilge in vessels where all the dirty water collects is painted with iron oxide, even in war vessels. Is not that an additional proof of the value of iron oxide?—I maintain that Austrian navy experts consider red lead the only paint, and indispensable for under-water painting. As I said, no paint will stand the action of sea water for any great

23 November 1911.]

Mr. ODO MARIA MEISL.

[Continued.]

length of time, but red lead will withstand the action longer than any other paint. I further state that paints for ships are generally made with resin, and it does not matter very much what the base of the paint is if you use resin.

14,830. Are you talking of outside?—Yes.  
14,831-2. But I am talking of inside. The bilge is inside?—It might be done, because it is such a very big surface, and iron oxide is only a third of the cost of red lead, but it will not keep.

The witness withdrew.

## TWENTY-SECOND DAY.

Wednesday, 6th December 1911.

### PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Sir GODFREY BARING, Bart., M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.

Mr. J. PARSONAGE.  
Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. C. RICKER-DEVROEDE.

Evidence to 14,852 handed in and taken as read; witness then called and examined (through an interpreter).

14,833. I am a master painter, having my office and workshop at 14, Rue Montoyer, Brussels. I have been in business for 25 years. I am president of the *Chambre Syndicale des Entrepreneurs de Peinture de Décor de l'Agglomération Bruxelloise*. I am also *secrétaire-tresorier* of "*Le Journal des Peintres*" and acted as vice-president of the 7th Congress of *Fédération Générale des Entrepreneurs de Peinture de Belgique*, being the first International Congress (at which Mr. Sutherland was present as representing England), held at Brussels in July 1910. I formerly used to mix all my own white-lead colours; having a proper grinding and mixing machine, but since the Law of July 1910 I am not allowed to grind the white lead myself. I purchase the white lead in oil from G. Grove, Utrecht.

14,834. Zinc white is largely used in Belgium for interiors, and is a better white colour, but it does not incorporate the oil. If allowed to stand any length of time the oil comes to the surface and the zinc sinks to the bottom of the canister.

14,835. There is no efficient substitute for white lead for outside painting at the present time, and even for inside painting, in the vicinity of water or where the atmosphere is humid, zinc white does not stand so long as the lead.

14,836. So far as can be at present foreseen, there will never be a complete prohibition of white lead in Belgium. There was a great discussion in the *Chambre des Représentants*, extending from the session 1903-4 to 1909, in which the whole history of the use and abuse of white lead was gone into. In November 1903, Dr. Delbastée brought forward a proposition for the prohibition of the use of white lead in all house painting, under severe penalties. His introductory memorandum was almost entirely confined to the humanitarian side of the question.

14,837. Two thousand six hundred and eighty master painters signed a protest to the effect that, in their opinion, the efficiency of the work of white lead only could be guaranteed, that the harmful effects did not exist where this product was used with care and cleanliness, and that the adoption of this law would cause considerable prejudice to an industry already seriously prejudiced by the employment of materials which do not possess the lasting qualities found in white lead alone.

14,838. The proposed law was considered by the three sections of the *Chambre des Représentants*, three of which adopted and three rejected it. An exhaustive inquiry was begun by the central section in 1904, but

was suspended because the Government thought it desirable to deal with the matter under the Law of 2nd July 1899, regulating the security and health of industrial and commercial workers, and an *arrêté royal* was issued on the 13th May 1905, coming into force on 15th August 1906, concerning the employment of white lead in works of painting-buildings.

14,839. This *arrêté royal* imposed regulations upon the master painters requiring—

2. Notice to be given to the factory inspector of workshops where white lead was ground.
3. Grinding to be done in such a manner that the workmen did not breathe white lead dust.
4. Sealed receptacles for carriage of white-lead powder and watering floors.
5. No contact with the hands of workmen while mixing, &c.
7. Prohibition of rubbing down dry.
8. Working clothes to be provided.
9. Washing appliances to be provided.
10. Quarterly medical examination.

14,840. These regulations were found difficult to enforce in practice where men were working in private houses to which there was no right of access, by the inspector, and where the street was the principal workplace used.

14,841. These regulations, however, drew forth an emphatic protest on the 19th May 1907 from the Master Painters' Federation, who addressed a memorial to the Government and Parliament reiterating a resolution passed at their Liège Congress in 1905, that, although white lead was irreplaceable for certain work, they preferred a total prohibition of its use, making, or importation, to a regulation which they were unanimously of opinion was inapplicable to their workplaces.

14,842. In consequence of these criticisms the Section Centrale resumed their inquiries, and by their reporter, M. Verhaegen, presented their report on the 19th February 1908, being the result of four years' work.

14,845. The report split up the subject into headings:—

1. Is the employment of white lead in works of painting dangerous to health?
2. Can white lead be replaced by other materials?
3. Can the Legislature prohibit the use of white lead in works of painting?
4. Ought the Legislature to consider the question of indemnifying against loss the manufacturers of white lead?
5. How can the law be carried into effect?

6 December 1911.]

Mr. O. RICKER-DEVROEDE.

[Continued.]

14,844. The answers to the questions were:—

1. Yes.
2. The report confirms the conclusions arrived at by the Conseil Supérieur d'hygiène publique de Belgique in 1902, that white lead is replaceable for at least inside work by zinc white, which is, however, more costly.
3. Yes; the Belgium Legislature is justified in regulating, limiting, or even prohibiting the use of white lead for painting, provided there is a real necessity to do so relatively to the danger run.
4. No.
- 5.—(1) The transformation of white lead works to zinc white works, if possible.
- (2) If it were possible it would be useless, as the Vieille Montagne are the only producers of zinc in Belgium, and, in consequence, of zinc white.  
(NOTE.—It was afterwards shown that there are other small firms producing zinc in Belgium, but the Vieille Montagne are the only producers of zinc white.)
- (3) The industry could not subsist only on the white lead required for exterior painting.

14,845. The committee proceeded to recommend in this report the adoption of additional regulations rather than the prohibition of the use of white lead.

14,846. Dr. Delbastée and his friends directed their criticism to the conclusion of the Section Centrale contained in their fifth recommendation, on the ground that all the other recommendations pointed to the entire prohibition of white lead. The reporter, however, insisted that the section felt that the principal source of danger was by means of dust which was chiefly caused by the white lead in powder. It was found by the Section Centrale that 50 per cent. of the total production of white lead in Belgium was delivered dry. They also felt that if white lead were interdicted, then, logically, the employment of minium, massicot, litharge, American white zinc (which contains lead and arsenic), green lead, green copper, vermilion with mercury base, and of all the colours which were sources of danger to the workmen, should also be prohibited. It was also pointed out that Belgium ought not to go beyond what had then been done by way of regulation in France, Switzerland, Germany and Austria. Also, as was pointed out by the report of the Conseil Supérieur d'hygiène publique of the 28th November 1907, the wholesale colour merchant who is not a white lead manufacturer, and who grinds his colours under the best conditions, would be seriously affected by a complete prohibition.

14,847. The debate on the propositions of Dr. Delbastée and the Section Centrale commenced on the 28th May 1909, when the Minister of Industry and Labour gave the Government support to the proposition of the Section Centrale. The debate was continued on the 9th June 1909, when Mr. Verhaegen (the reporter) pointed out that an industry ought not to be suppressed except in the last extremity, and that the suppression of white lead would practically confer a monopoly on the Vieille Montagne, also that no other country had done more than regulate the use of white lead. He pointed out that the difficulties of inspection enforcement urged by Dr. Delbastée applied equally to a prohibition of white lead for paint. The Minister of Industry and Labour pointed out that the position of the white lead workers was not less favourable than of numbers of other workmen, and that one of the chief objects to be attained by regulations was the education of the workmen. He also emphasised the importance of the elaborate inquiry undertaken by the Canton of Geneva in 1907. At the adjourned debate on the 11th June 1909, it was arranged that Dr. Delbastée's propositions should be treated as proposed amendments to the report and proposals of the Section Centrale. Dr. Persoons pointed out at this session that designers of embroideries used white lead in transferring the design to the materials, also lace makers

for blanching purposes, and Mr. Verhaegen instanced china, glass, mastic, and gas-joint making as additional uses of white lead.

14,848. At the sitting of the 10th June a vote was taken, when an amendment of Dr. Delbastée to the Section Centrale's report was defeated, so far as the prohibition was concerned.

14,849. The second vote was taken upon the propositions of the Section Centrale at the sittings of the 7th July 1909, when the Government moved an amendment to Article 2, providing that the arrêté ministerial could prohibit not only the employment but also the sale and transport of other lead products. This amendment was accepted both by Dr. Delbastée and Mr. Verhaegen on behalf of the Section Centrale, and carried. The Bill was then put to the vote as a whole, and carried, 92 members voting for and 31 abstaining.

14,850. The Bill was then considered by the Committee of Industry and Works of the Senate, who made a report on the 22nd of July 1909, very shortly and ably summarising all that had gone before and indicating that the Government shared the views of the Section Centrale, and thought that their propositions would give great satisfaction. The committee supported the vote of the Chamber of Representatives on the ground that the Legislature ought not to use the remedy of prohibition except with the greatest care, and only when the necessity was absolute. The transport and use of white lead in powder and cakes for employment in painting works was undoubtedly the greatest danger, and ought to be prohibited, but the danger arising from white lead destined for other uses was not so great, and regulations as to the sale, transport, and employment appeared amply sufficient.

14,851. The Senate considered this report on the 5th August, and passed the law with discussion *nem. con.*

14,852. The law is dated 20th August 1909, and royal decree providing regulations in pursuance thereof is dated 25th July 1910.

14,853. (Chairman.) You are a master house painter, are you not?—Yes.

14,854. Can you tell us how many master house painters there are in Belgium?—About 4,000.

14,855. In paragraph 14,834 in your proof you say that zinc white is largely used in Belgium for interiors?—And a lot of white lead also. It depends on the master painter. There are master painters who only use white lead.

14,856. Are there master painters who only use zinc?—No, there are none who only use zinc.

14,857. You also state that zinc is more difficult to use than lead would be?—If zinc white only were used, the education of the painter would have to be recommenced.

14,858. Is that the only difficulty in using zinc white for interior painting?—Yes. At present many painters do not even know zinc white. That is talking of workmen, of course, and also of many masters.

14,859. But is the want of knowledge on the part of the painter the only difficulty in using zinc-white paints for interior painting?—Yes; it is the only difficulty.

14,860. Will you tell us in detail what are the difficulties you meet with in outside painting which you have not already overcome in inside work?—You are speaking of the use of zinc white?

14,861. Yes?—The principal difficulty is that zinc white does not dry as easily as white lead, and you cannot use the same driers as for white lead.

14,862. What leadless paints have you tried for outside painting?—Zinc white (meaning oxide of zinc), also sulphide of zinc.

14,863. What medium did you use?—Linseed oil or boiled oil. In Belgium no other oil is used. Also they use a certain amount of poppy oil for zinc white for grinding it, because otherwise it hardens in the cans when exposed to the air.

14,864. Did you try the addition of a small quantity of good copal varnish?—In the painting of buildings one uses enamels; one can also prepare zinc white with

See Appendix VII.

6 December 1911.]

Mr. C. RICKER-DELVROEDE.

[Continued.]

turpentine and also white varnish for colours which must dry quickly.

14,865. Then it is no good pressing you if you do not know. How long do you find white lead stands where the atmosphere is very humid, as in greenhouses?—Two to three years.

14,866. Would you be surprised to hear that zinc and lead have been found to be equally perishable under such conditions?—The painting of greenhouses is a special class of work and would probably be undertaken by a glazier.

14,867. But that is not the question I asked you. In your evidence you particularly mentioned the fact that zinc white did not stand well in humid atmospheres, such as greenhouses. Would you be surprised to hear that both zinc and white lead have been found to be equally perishable under such conditions?—I make no mention of that in my deposition. I speak there of "zinc white," not lead. I am persuaded that if the lead was properly applied it would last considerably longer under those circumstances than zinc white.

14,868-71. *The witness was asked if he was speaking only of iron, or of both wood and iron; but he states—in the correction of his evidence—that the point was not fully put to him (by the interpreter).*

14,872. Is that only a personal opinion of yours?—It would be the opinion of all the master painters in Belgium, and I cite as an example the fact that the re-painting of the greenhouses at the Royal Palace of Laeken, in Belgium, has just been put out for estimates, and it is specified that white lead must be used.

14,873. Are those greenhouses made of wood or iron?—More iron than wood.

14,874. In paragraph 14,836 you mention the motion brought forward by Dr. Delbastée, in November 1903 for the prohibition of the use of white lead in all house painting, under severe penalties?—Yes.

14,875. The fact of this motion being presented shows that the evil must be very serious, does it not?—I have never given any statistics applying to Belgium, although I was asked on several occasions to do so. It was rather a political question than otherwise.

14,876. Have you any definite statistics as to the number of house-painters employed and the number of lead-poisoning cases that occur amongst them every year?—In the whole of Belgium there are 25,000 to 30,000 painters. I know of isolated cases of lead poisoning, but there are no statistics of any kind.

14,877. (*Sir Godfrey Baring.*) Are there no Government statistics issued at all?—Neither Government nor otherwise.

14,878. (*Chairman.*) You are aware, I suppose, that the prevalence of lead poisoning amongst house painters in other countries in Europe is very great?—I do not know anything whatever about other countries, except possibly in France, where the method of painting is somewhat different.

14,879. Now, let us consider in somewhat greater detail the regulations which you summarise in paragraph 14,839. In England the dry grinding and carriage of dry white lead are almost unknown?—I do not know.

14,880. The precautions against lead poisoning arising from the handling of dry white lead may therefore be disregarded when we are considering the prevention of lead poisoning amongst house painters in this country?—Yes, I suppose so.

14,881. We are left therefore with the consideration of the remaining four provisions, namely, Nos. 7 to 10 in paragraph 14,839 of your proof: (7) Prohibition of rubbing down dry. (8) Working clothes to be provided. (9) Washing appliances to be provided. (10) Quarterly medical examination?—No. 5 should also be included.

14,882. That sort of mixing is not done in England, as I have just said?—It really applies here to ordinary painters.

14,883. In paragraph 14,840 you admit that the enforcement of these regulations is practically impossible in private houses, where the inspector has no

right of entry?—Yes, that is so. I can explain what does happen, and how the thing is actually enforced.

14,884. How then would it be possible to prevent the dry rubbing down of painted surfaces? Sixty per cent. of the working painters in Belgium belong to the unions, and the moment an employer attempted to make a man do dry rubbing down the fact would be notified to the unions by the workman.

14,885. Is that the only possible way of detecting any infringement of this regulation?—Practically speaking, up to the present I do not know of any other method. Already the various inconveniences of the law have been found, and they are being discussed at the present moment with a view to putting the thing in better shape; they are trying to find a way to get the inspector into private houses; they are endeavouring at present to ascertain how it can be done.

14,886. Now you lay stress on the danger of dry rubbing down, do you not?—Yes, it is very dangerous.

14,887. Can you dispense entirely with dry rubbing down of lead-painted surfaces?—No, for dry rubbing down can only be done with old paint. It would perhaps be just as dangerous with white zinc as with white lead.

14,888. What do you mean by that?—The effect of zinc white dust would bring about just as much illness, though possibly not exactly the same kind as white lead.

14,889. On what authority do you tell us that?—The old painted work has got not only the original materials that were put on to it, so to speak, but all sorts of dust and so on, which has gradually accumulated on it.

14,890. What do you mean by dust and so on?—General filth.

14,891-2. *The witness—in his corrections—states that these two questions were not put to him (by the interpreter).*

14,893. (*Chairman.*) Do you come here to tell us seriously that any form of dust is as dangerous as the dust generated by the dry rubbing down of lead paint?—For the interior it is less dangerous, because dry rubbing down is practically not done now.

14,894. I cannot leave the question like that. You have stated that zinc dust was just as dangerous as lead dust, and I want to know on what authority you make such a statement?—I refer to an article by M. Liber.

14,895. I will put one further question, and if you do not answer it I must leave the point. You have told us that in your opinion zinc dust is as dangerous as lead dust for workmen to breathe. Is that only your personal opinion?—I am willing to abide by the opinion of the gentleman who writes the article—M. Liber.

14,896. Can you dispense entirely with dry rubbing down of lead-painted surfaces?—Yes, entirely for old paint but not for new; the work would be better for it. The final result would be better for it.

14,897. Now, when a first or priming coat of lead paint has to be rubbed down before a second coat is applied, what would you use then for rubbing down?—The first coat never is rubbed down. (*The witness was understood to be referring to the enduit.*)

14,898. I am not speaking of the filling, but of the first coat of paint that is put on?—It is done dry on the first coat on top of the *enduit*, but there is no dust from fresh paint.

14,899. When a first or priming coat of lead paint has to be rubbed down before a second coat is applied, what would you use then for rubbing down?—I would wait till that first coat was dry, and then I would rub it down dry.

14,900. Would it not take a long time for the first coat to dry sufficiently to allow a wet rubbing process to be applied?—It would be a year or two before it would be in a state in which you could do that.

14,901. (*Sir Godfrey Baring.*) What do you mean by *enduit*, because a lot turns on that?—A white lead putty—chalk and white lead.

14,902. Made of white lead, oil, and a drier?—Yes, and chalk.

6 December 1911.]

Mr. C. RICKER-DEYROEDE.

[Continued.]

14,903. (*Chairman.*) I do not think you quite understand my question. I am assuming that a door has received its first coat. Now I ask, would it not take a long time for that first coat to dry so as to be sufficiently hard to permit of wet rubbing down?—One year at least. When the rubbing is done dry it is fresh paint, and consequently there is no dust.

14,904. (*Mr. Rice.*) Take a piece of white wood with nothing at all upon it, what do you put on that?—The first thing I would do would be to rub it down with glass-paper; then I would put on a coat of paint of two-thirds oil and one-third turpentine.

14,905. (*Chairman.*) What would you do then?—Then the next thing would be to fill up any small nail holes and so on with mastic—putty. If it is first-class work, the next thing that is put on is what I call *enduit*.

14,906. (*Mr. Sutherland.*) But that would not involve sand-papering?—For ordinary work I would not put on what I call the *enduit*.

14,907. (*Chairman.*) Do I understand that there is no rubbing down done at all up to this point?—No.

14,908. When does the rubbing down first begin?—If it is first-class work where the *enduit* is put on, there is rubbing down wet, and it is generally done three weeks or a month after. For good work it is absolutely necessary.

14,909. Does the *enduit* contain lead?—Yes, generally lead.

14,910. In what way can you make sure that working clothes or overalls are supplied to and worn by every worker?—The workman supplies his own clothes, and they are regularly cleaned every week.

14,911. How are you to ascertain that they are worn by every worker?—The employer goes round and sees these things himself on his visits to the work, and, in any case, in Belgium the workmen are very clean in their habits.

14,912. But you have told us that, generally speaking, it is practically impossible to enforce these regulations?—That refers only to the inspectors.

14,913. But that is what I mean. How are they to know that the men are wearing these overalls?—The employer himself goes round to the work, and would notice it.

14,914. But are we to understand that the employer in every instance goes round to every job to see that the workmen are wearing their overalls?—The employers do go round to all the work, and if the employer himself does not go, it would be a director who would go round.

14,915. Do I understand that the employers in Belgium have a sort of private inspection of their own?—Simply going round for the ordinary daily visit to see that the work is going on in the usual way of business. Doing that, he would notice if any workman did not wear overalls.

14,916. How can proper washing appliances be provided on every painting job?—When the ordinary materials for the work are taken round to the job, special buckets and soap are also included for the purpose of washing. The buckets must not be used for other purposes. And when a workman is first engaged he is always given a toothbrush, a nail brush, and a small metal cup and a towel for each man, and the latter is renewed every week.

14,917. I am quite sure that these different things are given out to the workmen, but I want to know how you are sure that the workmen use them?—Their companions on the job who did use the appliances and wear overalls would reproach them if they did not.

14,918. Article 7 requires employers to provide water and the requisites for rinsing the mouth, as well as for washing. How is this done when the men are working at a private house?—I repeat what I said just now as to water and soap and toothbrushes and so on being supplied by the employer. When the medical inspection is made every three months, the doctor questions the workmen on these points as to whether they have had the appliances and used them.

14,919. Do I understand that the only opportunity of ascertaining whether the men have rinsed their mouths is when the doctor examines the men once in three months?—Yes.

14,920. Article 7 also requires that the employer or his deputy shall see that the workman wash and rinse their mouths before taking food or drink, and before leaving the workshop. How can you be sure that this is carried out?—Nothing is done. These articles are posted up where the workmen can see them, and the workmen are old enough to know how to carry out the requirements. They are not children.

14,921. What is your opinion of the medical examination?—I would like to give it in a report which I have here.

14,922. I do not want a report. I want a short answer to my question. You may put the report in if you like. Is it the report of a medical man or is it your own?—It is a report initialled by the medical man. Each workman is in it.

14,923. I have here your letter which has been written on this question.\* I only want a short answer?—The medical inspection should be done in duplicate; that is to say, there should be two copies of this thing, one of which should be forwarded every year to a central office, presumably a Government office.

14,924. (*Mr. Rice.*) But what we want is your opinion on the thing as it stands?—It is not sufficiently severe. Shall I quote this report?

14,925. (*Chairman.*) I would much rather that you quoted a passage from your own letter. That will be a quite sufficient answer?—That is not my own opinion. I simply signed the letter as the president of the association who wrote it.

14,926. I understand that this letter was written and signed by you, in which you speak of medical examination in the following words: "Of all these regulations the most iniquitous is the medical inspection imposed on the operative painter. This provision, which is vexatious and humiliating, is without any effect"?—I have just explained that I signed this letter as the president of the association.

14,927. The Belgian Association of Master House Painters?—Yes, but it is not my personal opinion.

14,928. It is quite enough. It is rather unfortunate that you should have had to sign it. Is that statement, which you signed in the letter I have just read out, the opinion of the council of which you are president?—Yes, of the majority of the members.

14,929. Is this association of which you are president the same as the federation to which you refer in paragraph 14,841 of your evidence?—No; the federation is the federation of all the master painters in Belgium.

14,930. I want to get it quite clear which is the federation of all the master painters. Is it the one of which you are president?—It is the *Chambre Syndicale*. It is the painters' section of the Brussels Chamber of Commerce, of which I am president.

14,931. Does that painters' section embrace all the master painters?—No, not even half.

14,932. What does the federation embrace?—The federation is an association of all the painters' chambers in Belgium; therefore, the *Chambre Syndicale* of which I am president would be a part of the federation.

14,933. (*Sir Godfrey Baring.*) Do all the chambers of commerce make one federation?—Not all the chambers of commerce, but all the painting sections of the chambers of commerce.

14,934. (*Chairman.*) In paragraph 14,841 you state that the Master Painters' Federation (that is the society that embraces the whole of Belgium, I take it) passed a resolution at Liège in 1905 stating that they preferred the total prohibition of white lead to the application of regulations?—Of the 4,000 master painters in Belgium only 800 are members of the federation.

14,935. You can put that as an addition to your answer, but I want to know whether that resolution was passed?—Yes.

14,936. The same view was set forth in the Master Painters' Federation Memorial of the 19th May 1907, and again repeated in the letter dated 30th September 1911?—Yes.

\* Appendix XVIII.

6 December 1911.]

Mr. O. RIJKER-DEVROEDE.

[Continued.]

14,937. I want to clear up the question of the numbers that these different corporations represent. Both these societies have passed resolutions in which they say that they prefer prohibition of white lead to these regulations. I want to know about how many of the painters in Belgium are included in these two organisations?—800 out of 4,000.

14,938. Have the other 3,200 master house painters made any declaration one way or the other?—No, they were neutral.

14,939. What is the protest?—It was made before the regulation of the use of white lead. It is a protest of 2,800 master painters in Belgium.

14,940. Have the balance of the 4,000 made any move one way or the other in favour of prohibition or in favour of regulations since then?—Nothing beyond this.

(*Sir Godfrey Baring.*) Some of the balance of the 3,200 have signed this, I understand.

14,941. (*Chairman.*) Did the balance of the master painters, namely, 3,200, in any form make any protest against the regulations or in favour of prohibition?—No, nothing beyond this. This is not a protest against the regulations.

14,942. Was not this protest produced and signed before the regulations were put into force, and consequently before the irksomeness of the regulations was understood?—Yes, that is so. It was several years before.

14,943. With regard to the 800 firms that belong to this federation, are they the principal firms of master house painters?—Yes, most of them.

14,944. Could you tell us how many men they employ?—It is really a very difficult thing to say, but, taking an average of 20 workmen for each, say about 16,000.

14,945. I want to know whether the 800 firms employ as many men as the balance of firms who do not belong to this federation?—The 3,200 altogether employ 9,000 to 15,000. That makes the 800 employ more than half.

14,946. We may take it that more than half the men employed in the house-painting trade belong to the 800 firms?—Yes; that is what I mean.

14,947. Do I understand that a committee of the Belgian Government in 1909 proceeded to adopt additional regulations, though the Master House Painters' Federation had stated in a memorial in 1907 that they would prefer prohibition of the use of lead?—Yes; that was the substance of the report of the Section Centrale to Parliament.

14,948. The Belgian Government proceeded to pass a royal decree adopting additional regulations, notwithstanding the protest of the 3,200 firms who put forward the fact that there was no danger in using lead in house painting?—Yes.

14,949. The report of the 19th February 1908 admits that the employment of white lead in painting is dangerous to health?—Yes.

14,950. You have no definite statistics, but if they were collected for the whole of Belgium, I suppose that the number of lead cases would be very large?—The cases are very rare.

14,951. Why should Belgium be immune from lead poisoning when other countries are not? Is the process of painting different?—I do not know anything of what happens outside Belgium.

14,952. But may we not take it that Belgian painters are just as subject to lead poisoning as painters in other European countries?—Yes, I suppose so.

14,953. Then presumably the percentage of lead-poisoning cases in Belgium would be about the same as they are in England, Austria, and so on?—I cannot say—not necessarily, because the process is not always the same. For instance, in France, the man who puts on the *enduit* (the filling) takes the stuff in his hands, and so on.

14,954. (*Sir Godfrey Baring.*) Whereas in Belgium he fills in with a knife?—Yes.

14,955. (*Chairman*) (*to the witness.*) You admit that the prohibition of the use of lead would be the simplest solution?—For myself I would prefer to see

the medical inspection, which would be the best and simplest way of getting rid of the whole trouble.

14,956. (*Sir Godfrey Baring.*) Made much more rigorous? You said that it ought to go beyond what it does now?—At present it is not enforced as it should be.

14,957. (*Chairman.*) At any rate, the majority of the house-painter employers in Belgium prefer the prohibition of the use of lead?—I am convinced that it is not so. It is not possible to judge by a protest made by some of the master painters only.

14,958. At any rate, the Corporation of Painters would prefer the total suppression of white lead to regulations?—With regard to the statement that the Corporation of Painters would prefer the suppression, that refers to the federation. I explain that the federation consists of 200 master painters out of 900. At the meeting at which that letter was signed 60 were present, and 40 were in favour of the letter and 10 were against; so that it is the opinion of 40 out of 900.

14,959. (*Mr. Rice.*) That is in Brussels?—Yes. I am not speaking about the provinces at all. The letter refers to only the Brussels section.

14,960. (*Chairman.*) How many men do those 200 employ?—There are large firms and small firms, and there are large firms which are outside. It is a difficult thing to say how many. I have no figures that I can give. Certain of the employers consider that the *Chambre Syndicale* is more or less a political body, and they will not join it.

14,961. But I understand that you are president of this society?—It is not really a political organisation, but there are master painters in Belgium who will not associate themselves with it because they think it is a political organisation.

14,962. (*Mr. Rice.*) Of the number present, would 40 represent the council? Was it a general meeting or a council meeting?—It was a general meeting.

14,963. (*Sir Godfrey Baring.*) Everyone was summoned to it?—All the 200 were summoned and 60 attended.

14,964. (*Chairman.*) Do I understand that when they were summoned they knew what the meeting was about?—Yes. It was on the agenda paper.

14,965. So that practically we may say that the people who stayed away assented to the resolution. They knew what was going to be put before the meeting?—There are always a large number of people who remain absolutely indifferent until the thing is done, and then they start to shout. It is unpleasant to say it, but true.

14,966. At any rate, a large majority of them voted in favour of it at the meeting?—Yes, 40 against 20. I said 10 in favour, but it appears that it is 20—2 to 1. The principal reason of the 40 was because of the medical inspection costing them money.

14,967. I understand that the Belgian Parliament reserve the right to prohibit the use of white lead if they find that there is any real necessity to do so?—No, that is not so. The article only refers to dry white lead in powder.

14,968. You agree, no doubt, that injury to health is more important than the possibility that the customer might have to pay a little more for the more frequent painting of his buildings, if lead were prohibited and substitutes did not prove so durable?—The answer to that question would be very long. There is a whole list of comments that I would like to make on a question like that.

14,969. But surely it is a very simple point?—Admitting that a client would be willing to pay a little more, in my opinion the painting work for exteriors would become impossible simply with zinc white, and would cause very considerable trouble in the case of public buildings, and railways, and so on, particularly for painting on metal. What I say is so true that, although at the commencement of this law, which was passed in 1909, only white zinc was used for the State railways of Belgium, within recent months we have had so much trouble with zinc white that an order for 60,000 kilogrammes of ground white lead has been placed by the works at Malines, the largest workshop

6 December 1911.]

Mr. C. RICKER-DEVROEDE.

[Continued.]

of the State railways in Belgium, about 3,500 workmen being employed there.

14,970. How many of these are painters?—At least 500 would be painters.

14,971. Notwithstanding this opinion of yours, up to the 30th September 1911 they could only collect 20 master painters to vote against the total prohibition of lead in all painting operations. How do you account for that?—I have already explained why. You must take into account the Belgian character. They object, generally speaking, to regulations of any description.

14,972. The manufacture of white lead is a very important industry in Belgium, is it not?—Very important. The principal manufacturers in the whole of Europe are probably Debbaudt Frères, at Brussels.

14,973. Is the manufacture of white lead confined to a few firms in Brussels?—There are about five important firms.

14,974. In Belgium?—Yes. Debbaudt Frères export thousands of kilogrammes to the United States.

14,975. Now, the decision of the Belgian Section Centrale not to recommend prohibition was dated 19th February 1908. It was not until 1909 that France adopted prohibition?—Yes.

14,976. Do you not think that the Section Centrale might have come to a different decision if they had reported after 1909?—I do not think so. The Belgian law, as a matter of fact, was only voted after the French law.

14,977. The Belgian law in favour of regulations and against prohibition?—Yes.

14,978. You refer in paragraph 14,847 to the danger of one company in Belgium securing a monopoly of the supply of zinc. How is it that they are monopolists?—I do not say that at all. It is M. Verhaegen, the Belgian rapporteur, who says that.

14,979. Do you agree with that opinion?—Yes, it is my opinion also, because in Belgium and even in Holland it is the Vieille Montagne Company which exports the most.

14,980. Of what do they hold a monopoly?—Zinc white in powder.

14,981. How does the output of zinc ore from the mines with which they are connected compare with the output of zinc ore of the whole of the rest of the world?—I cannot say.

14,982. If they are not monopolists of zinc ore what are they monopolists of?—It is a question of Customs duty on the stuff entering.

14,983. A monopoly means something that you can control. What do they control? If the Belgian firm had the right of collecting all the zinc from all the zinc mines in the world, then they would be monopolists of zinc: that I can understand; but unless they have a patent form of manufacture or a monopoly of the zinc ore how can they be monopolists?—It is recognised that the zinc white they turn out is the best. It is also recognised in France, where the Vieille Montagne Company, have also works, and the company's product which is sold in Belgium is superior to that sold in France.

14,984. Do I understand that they have a superior method of manufacture?—Yes, it is a process of manufacture which is superior.

14,985. They have a monopoly in that particular respect?—It is doubtless a manufacturing secret, because they will not allow anybody to go near their works. Two years ago a party from the School of Painting at Brussels went to visit the works of the Vieille Montagne Company, and they showed them the whole of the works except that part in which zinc white was manufactured. They make other things besides zinc white.

14,986. (*Lord Henry Bentinck.*) If the opinion in the chamber of commerce is 2 to 1 in favour of total prohibition, do you not consider it likely that the opinion of the employers outside the chamber of commerce is equally strong in favour of prohibition? What reason have you for thinking that the opinion outside is not equally favourable to prohibition?—Simply my knowledge of the trade and of the people themselves.

14,987. (*Dr. Collis.*) Do I understand that you desire that the quarterly examination should be made more strict?—That is so. Each time the workmen are

examined it is found that they have improved so far as the questions of cleanliness are concerned.

14,988. Do you find that they have improved as regards health or only as regards personal cleanliness?—I am speaking simply of cleanliness.

14,989. Do I understand that you consider that cleanliness is the most important thing in reducing the danger to the workers of contracting lead poisoning?—It is the most important thing to the workers, and it is recognised by all the reports which have been made up to the present date.

14,990. Do you consider it more important than the question of dust?—Yes, much more important.

14,991. You speak entirely for yourself and not for others, I presume?—Yes, I speak simply for myself. I cannot speak for everybody.

14,992. You do not speak for any of the Belgian doctors?—Do you mean as to the relative importance of the dust and so on?

14,993. Yes?—The doctor says the same thing. Each time that the doctor visits my works he looks first of all at the man's nails, then at his teeth, and then he makes the man stretch his hands like that (*describing*).

14,994. But surely you could not expect the doctor to look at the dust?—The principal point is that a workman does not continue to sand-paper all day. It is only a very small portion of his time that he is doing it.

14,995. If the medical examination was to be made more thorough, and I presume more frequent, how then do you suggest it should be held?—Once in three months is enough, having these registers in duplicate, and having one each year sent up to a central office.

14,996. But how would that affect the doctor's examination? It would not make it more careful, and it would not make the men more careful?—Under those circumstances it would be done with regard to everybody. At the present time every painter is not examined.

14,997. Is it not the law that they shall be?—Yes, it is the law that they shall be, but it is not carried out. I am speaking of the small employers who actually do work themselves. Those are the people who do not pass a medical examination.

14,998. A man who does not employ any men?—Not necessarily. He may employ men, but there are plenty of employers who are also practical workmen themselves, and, being employers, they do not have to pass the medical examination—they or their sons or members of their family.

14,999. All the painters themselves are to-day examined, are they not?—In the large businesses the medical inspection is properly done, because the men are collected at a certain time in order to meet the doctor, but in small businesses—employers, for instance, who have only one or two workmen—it is difficult. They escape from medical examination. They do not happen to be there when the doctor comes in. The whole thing is not organised in the same way, and as a matter of fact they are not examined.

15,000. Is the medical register open to the inspection of any Government official who has to look after these workshops and factories in Belgium?—Yes. The register must always be kept at the disposal of the Government inspector.

15,001. Then if the Government inspector finds that a person is employed whose name is not down in the register as having been examined, surely he can prosecute the occupier?—Yes. The occupier has to have at the disposal of the inspector two registers, the medical register and also a register of the workmen whom he employs, and if the inspector finds workmen in one and not in the other, he would have him fined.

15,002. What is the charge that the medical inspection imposes on the occupiers? How much is the doctor paid? Is there a Government scale?—Five francs for the first ten, and 1 franc for every succeeding ten. So that if you had 50 you would pay 9 francs and 14 francs for a hundred.

15,003. That is a good deal less than ours. Ours is 25s. for 50. Is that considered a fair fee to offer a medical man for examining such a number of men—

E c 2

6 December 1911 ]

Mr. C. RICKER-DEVROEDE.

[Continued.]

9 francs for the medical examination of 50 men?—Considered by whom?

15,004. By the Belgian Government?—Yes, it is considered enough. It is done very quickly. The doctor does not take an hour to examine 50 men.

15,005. Does he take about a minute to examine each man?—The first time that a man is examined it lasts longer. Particulars are entered in the register at each three-monthly examination, and the doctor, if he does not remember a man, can refer to his own remarks on the previous examination. The first time it takes considerably longer. It depends necessarily upon what happened three months before as to whether it takes long or not.

15,006. Do you in Belgium consider a doctor working hard for an hour reasonably paid at the rate of 9 francs an hour?—I sum it up by saying that we have had no complaints from the doctors. I have the list of doctors here.

15,007. How many Government inspectors of factories and workshops have you in Belgium?—You do not mean medical?

15,008. No; factory inspectors?—I do not know anything about it, because I have nothing to do with factories.

15,009. (Mr. Sutherland.) Why did the Belgian State Railways abandon the use of zinc paint?—They have not entirely abandoned it, but they found it necessary to take up white lead again.

15,010. For what—for their rolling stock or their stations?—For first coats on the rolling stock and the preparation of the *enduit*, the filling.

15,011. Does that apply also to their structures and stations?—No, it does not apply to them, because the work in connection with stations and buildings is done by contractors. It is all put out to contract.

15,012. But do they specify in the contract for lead or for zinc?—No, they do not do so nowadays. At the present time prices are being asked for a new station at Ostend, where there will be more than 100,000 francs worth of painting work, but no mention is made of white zinc or, for that matter, of white lead. The contract will be actually given out to-day.

15,013. (Lord Henry Bentinck.) It is not specified that it shall not be zinc white?—No, it is not specified at all.

15,014. It does not specify white lead?—No.

15,015. (Mr. Sutherland.) How is the specification framed?—Simply so many coats of paint in colours to be decided by the architect.

15,016. Your objection to zinc paint is that it does not stand like lead? You do not object to the use of zinc except on the ground that for outside work it does not stand?—For outside work it does not last. It is not solid. Nobody would contest that. In Belgium even the adversaries of white lead did not contest the point that white lead is much more durable and lasts longer than zinc white.

15,017. For outside work?—For outside work.

15,018. You are of opinion that to strengthen zinc paint by the addition of varnish would add considerably to the cost of it?—You are speaking of exterior painting?

15,019. Yes, exterior painting?—Enamel does not stand in any case out of doors, as has been shown by experiments.

15,020. I am not speaking of putting it into the category of enamels, but I am speaking of using varnish with it?—The question of price does not come in except from the point of view that you would have to have more coats of paint, but in any case the use of varnish with white zinc for exterior work would be disastrous from the point of view of the durability of the work. Varnish would crack.

15,021. Even good enamels are not suitable for general use over broad surfaces?—You are still speaking of the outside?

15,022. Yes?—They are not used for outside at all. The use of enamels outside is quite impossible, principally on account of the rubbing down. It would have to be done so very much better, and so on, in order to hold.

15,023. Your opinion is that, for a basis of comparison between lead and zinc, we can only compare them as mixtures with oil and turpentine?—I quite agree that you can only compare them if they are with linseed oil.

15,024. The question has never really been put before the master painters of Belgium, has it, as a definite question, except in the case of the Brussels section of the chamber of commerce?—Do you mean officially?

15,025. I mean has anything been put before the master painters officially by the federation with regard to whether they would prefer prohibition or regulation?—No.

(Chairman.) Let me read this to you from paragraph 14,841, because it is very important: "These regulations, which drew forth an emphatic protest on the 19th May 1907 from the Master Painters' Federation, who addressed a memorial to the Government"—

15,026. (Mr. Sutherland.) I meant has it been put before the whole of the master painters of Belgium by any organisation whether they would prefer prohibition or regulation?—It has not been officially or semi-officially put before them.

15,027. (Chairman.) Are there any means of putting it officially before them?—No. Even if the Government officially sent out a questionnaire to them all, I am quite sure that at least 80 per cent. would not reply.

15,028. (Mr. Rice.) I understand that you are only speaking for Brussels. I see that you are president of the *Chambre Syndicale* of Builders and Painters in Belgium?—Only for Brussels. I was vice-president at the seventh congress of the General Federation of Master Painters in Belgium.

15,029. Was this question of prohibition raised at that seventh congress?—No.

15,030. And therefore no vote was taken on that?—The question had already been done with, so to speak. The rules were already in force.

15,031. Yes, but I did not know whether they protested at this time?—No. The congress was an international one, and this was simply a national question.

15,032. In Antwerp, and other towns such as Ostend, you have *chambres syndicales*, I take it?—Yes, and there was a special protest in 1906 sent by the master painters of Antwerp to all the parliamentary representatives of the district of Antwerp. It is a protest against the suppression of white lead. You will see therefore that Antwerp, although their chamber is affiliated with the National Federation, are not of the same opinion, because they are absolutely against the suppression of white lead.

15,033. Can you tell me the voting of the Antwerp federation? What were the proportions?—Unanimously.

15,034. Unanimously against?—It was unanimously voted that a letter protesting against the suppression should be sent to all the Parliamentary representatives.

15,035. How many members are there?—One hundred and thirty. It is the most important of these organisations outside Brussels.

15,036. One hundred and thirty members of the Antwerp Painters' Society, or whatever you like to call them, met together and they were unanimous in signing this protest against the suppression of white lead?—Yes.

15,037. Do you know anything about other towns? Take Ostend, for instance?—They have taken part in the whole.

15,038. In Brussels they are 2 to 1 against the continuance of white lead, and in Antwerp they are altogether in favour of white lead?—The first part of the proposition was that they would prefer the suppression to regulations which they objected to; that was because they could not stand the medical inspection and the cost of it.

15,039. (Chairman.) Are the 130 members of the Antwerp section included in the total of 800 given to

6 December 1911.]

Mr. C. RICKER-DEVROEDE.

[Continued.]

us as members of the Master Painters' Federation?—They are.

15,040. What is the date on which the Antwerp section of the Master Painters' Federation made their protest against the prohibition of lead?—1906.

15,041. But on the 19th May 1907 the Master Painters' Federation, which included the Antwerp section, addressed a memorial to the Government in which they said they preferred a total prohibition of lead to the regulations which were being introduced?—Yes, but it must be remembered that each town has the right to only three delegates, and a town which had, for instance, 20 master painters in all, would have the same representation as the city of Antwerp.

15,042. Did the Antwerp section of the Master Painters' Federation make any protest to the main body when this emphatic protest was made to the Government on the 19th May 1907?—They protested all through.

15,043. In what form did they make their protest?—Verbally at the meetings.

15,044. But that is hardly evidence. Have you any evidence to produce that the Antwerp section of the Master Painters' Federation objected to this declaration which was made on the 19th May 1907 to the Government, in which they said they preferred total prohibition to regulations?—Yes, in the minutes of the federation.

15,045. Would you kindly send us those minutes?—Yes, I can produce them.

15,046. (Chairman.) How many medical inspectors are there in Belgium?—One for each province, that is, nine.

15,047. (Mr. Gardner.) I understand that there is a good deal of zinc white used for interior work?—There is a great deal used, but not so much as there is of white lead.

15,048. There are no special men employed for painting with zinc white?—No.

15,049. Can you explain why you said that if white lead was to go out and zinc white was to be used, the painter would require to begin his education over again?—Only one painter out of twenty is capable of properly applying zinc white. Those who put it on and are not accustomed to putting it on, do poor work.

15,050. It is just a matter of custom, then. How long would it take a man to learn to paint with zinc white?—A very good man would probably be able to learn it in six months, but the average individual with the ordinary average intelligence would take a couple of years.

15,051. Do the painters in Belgium serve an apprenticeship to the trade or do they enter the trade after they are adults?—There are apprenticeship schools, but they are not obliged to go through those schools.

15,052. Do they go to the trade as boys and be trained?—They begin about 14 or 15. Most painters you find have been through all sorts of jobs, not only building and so on. But those who have been at it all their lives began about 14 or 15 years of age.

15,053. I will take a painter who has been trained to the trade and who spreads all sorts of material, oil paint, flat paint, varnish enamel, and distempers. How many years would it take him to learn to spread zinc paint?—Six months to two years.

15,054. But an ordinary painter spreads a dozen different materials, and each one of these requires different treatment. How would it take from six months to two years to learn to spread zinc?—The majority of painters use white lead, and a lot of it, and the use of white zinc is only a small proportion.

15,055. The use of enamel is a small proportion of a painter's trade, but if a painter is expected to be able to spread enamel, and he can spread enamel, why cannot he spread zinc?—It is a totally different thing; and who says that any ordinary painter can put on enamel?

15,056. I do not?—There are few that can put on enamel.

15,057. I am referring to men who have been trained to the trade—the trained painter. I am not

speaking of the man who has gone into the trade as a last resort. Every man can put on paint in that sense?—It is a question principally of the making up of the zinc white paint. Zinc white paints at the present time, when flat surfaces are required, take a large amount of turpentine, and it is very easy to spoil the work with zinc white by putting a little too much turpentine or a little too much oil. It therefore comes to a question of mixing. If I could discuss the thing for five minutes with someone who completely understood the trade I could explain it, but it is a long technical question.

15,058. Do they mix zinc paints in exactly the same manner as they mix a white lead paint?—No, not at all. You want much more oil in the white lead.

15,059. Do they use ordinary raw linseed oil?—One does not usually use boiled oil with zinc white.

15,060. Then the answer is that they use ordinary raw linseed oil?—Yes.

15,061. Those who have used zinc successfully use refined boiled oil, of which I showed you a sample?—The more you refine linseed oil, the more it loses its quality.

15,062. That is a matter of opinion. Dry rubbing down has been prohibited in Belgium. Does that include sand-papering or glass-papering between the different coats of paint?—It refers to the whole thing to all the coats.

15,063. Then there is no sand-papering between coats at all?—No, dry rubbing down is entirely prohibited legally, but as a matter of fact the prohibition is not carried into effect for freshly-painted surfaces, which you cannot rub down otherwise.

15,064. I understand that in Belgium, in Brussels in particular, outside doors the main doors of houses are finished in a rather high-class manner. Are they brought up with white lead, and are they varnished as a finish?—In general the main entrance doors are finished with the same perfection as a carriage would be. They are of two kinds: first of all those which are treated simply with varnish after the fashion of varnished wood, and then there are also painted doors, which always have applied to them at first underneath coats of white lead.

15,065. And are they always finished in varnish?—Emmels are never used outside, and there is no varnish in the paint. The natural wood doors are varnished and done in the same way as polished furniture. For a painted door if it is left white no varnish at all is used, but for doors otherwise coloured a small quantity of varnish is put into the paint for the outer coat.

15,066. (Mr. Fell.) Do you speak both for house painters and carriage painters?—No; I only speak for the house painters. I have a certain knowledge of the whole subject and can answer questions.

15,067. Have you carried out any experiments with regard to painting vehicles with non-lead paints?—The only experience I have of the question is with regard to my own automobile, on which I do not use any lead at all. It happens to be the fashion in Brussels at the present time to use brown ochre, which is made up principally with turpentine, and seven or eight coats are put on before the wet rubbing down.

15,068. Do you anticipate any difficulty in connection with using zinc white, say, instead of lead on work of that description?—Coach-building is not my trade, but I do not think that lead is used any more at all for coach-building.

15,069. Is it not a fact that at the present time a very large number of Belgian vehicles are exported to this country, which are painted with lead?—I do not think so.

15,070. Do you know anything about Messrs. Van den Plas's factory?—Yes, I know the firm quite well, and the porter of my house is a grinder in that business.

15,071. Is it not a fact that that firm uses white lead and not a substitute?—I am quite sure that they use very little white lead.

15,072. Do they reserve all the white lead for vehicles which are sent over here?—I do not believe

6 December 1911.]

Mr. C. RICKER-DEVROEDE.

[Continued.]

that there is any difference between those that are made for Belgium and those that are sent over here.

15,073. (*Mr. Mason.*) Following on a question of Mr. Gardner, I would like to ask you whether enamelling is a different branch of the trade from ordinary painting?—The application of enamel is done by all master painters just the same as ordinary painting, but they all have special workmen for that particular work.

15,074. That is what I mean, it would be a different man who would apply enamel from the man who applies ordinary paint?—Yes.

The witness withdrew.

Mr. EUGENE EXPERT-BEZANÇON.

Evidence to 15,103 handed in and taken as read, witness then called and examined (through an interpreter).

15,078. I am the principal partner of the firm Eugene Expert-Bezanson & Co., which has its head office at Aubervilliers, near Paris, and its principal works at Saint André, near Lille, where we manufacture both white and red lead. In 1909 we succeeded the firm Ch. Expert-Bezanson & Co., of which also I was the principal director. This company had important works in Paris, where it also manufactured zinc white from 1903 to 1909.

15,079. I have very closely followed the agitation in France during the last ten years for the prohibition of the use of white lead. The Law of 20th July 1909 applies to "factories, workshops, buildings in course of construction or repair, and generally in every work-place where painting work is being done on buildings." The important sections are:—

"Article 2. At the expiration of the fifth year from the promulgation of the present law, no white lead, linseed oil containing lead, or special product containing white lead shall be used in any painting operation of any kind carried out by working painters, either on the exterior or interior of buildings."

"Article 3. A regulation of the public administration, issued after conferring with the Consultative Committee of Arts and Manufactures and with the Commission on Industrial Hygiene, shall, if necessary, specify special operations which may be exempted from the preceding provisions."

15,080. I would first remark that the law does not come into force until the 1st January 1915. Secondly, it only prohibits the use of white lead by house painters, that is to say, as far as buildings are concerned; it does not prohibit any other use of white lead, e.g., by coach painters. Thirdly, Article 3 authorises the Minister to allow "derogations" in the application of the law.

15,081. A perusal of the Parliamentary debates proves that there were two motives for this last attenuation of the prohibition: (1) To lessen the injury inflicted upon the manufacturers in order to justify the refusal of an indemnity to them; (2) to avoid inconveniencing the consumers by an immediate complete cessation of the production; and to make it possible for the Government to retrace its steps or to shut its eyes if the enforcement of the law appeared to be impossible.

15,082. The Law of 1909 has up to now had absolutely no effect. All master painters are already well acquainted with zinc white. When the industrial manufacture of this product was discovered about 1846, everybody believed that it would replace white lead, its qualities being evident, and its defects, i.e., especially its durability, not being immediately apparent, while the price of zinc, which is now always higher than that of lead, was at that period very advantageous. The white lead manufacturers themselves believed that their industry would disappear. Several of the more important consented to make an agreement with the Vieille Montagne, and there was a question of proposing to the Government the prohibition of the use and the manufacture of white lead; by way of indemnity the manufacturers would receive the monopoly of the

15,075. (*Mr. Robins.*) Is it not the fact that zinc white is much easier of application than lead to the painter?—I think quite the contrary, and that is the opinion of everybody who follows the calling of painter.

15,076. Is it not a fact that the disastrous results might be from the improper mixing of zinc white as with white lead?—Yes.

15,077. I take it that the failure of zinc white is from the improper mixing. That is the main point?—I have already said that—and the quality of the zinc white itself, which does not combine with the oil, whereas white lead forms a whole with the oil when ground with it.

manufacture of white zinc, which monopoly they resold in advance to the Vieille Montagne. This combination failed by reason of the refusal of my grandfather to associate himself therewith, and also of the protests presented to the Government by painters, colour merchants, lead refiners, etc. However, all master painters had willingly tried the new product; but they soon perceived that, in a great number of instances, zinc white did not cover, dried very slowly, and had little resistance. They continued to use it as well as white lead, but only in work which did not necessitate great opacity or permanency.

15,083. A law sets the seal upon progress, making it general, but in France, at any rate, the law cannot bring about progress by force. If the greater number of painters, although well warned, do not commence to apply the law until such time as it becomes obligatory one can affirm that its application will not be enforced on the 1st January 1915. Now painters are, in fact, not abandoning white lead. If the consumption of zinc white has slightly increased it is because of an increase in the general consumption of paint as the interior decoration of apartments in light shades is by degrees becoming more general.

15,084. In the absence of official figures, my personal experience gives me reason to suppose that the consumption of white lead in France at present is from 23,000 to 25,500 tons, almost exclusively for painting buildings. The consumption of oxide of zinc must be about 7,000 to 8,000 tons, of which 5,000 to 6,000 are used in painting. That of lithopone is about equal to that of oxide of zinc. These figures have scarcely varied during the last three years. Master painters are asking for the same quantities of white lead because they cannot do without it.

15,085. When the Parliamentary Commissions made their inquiries they heard—

- (1) Doctors.
- (2) Working painters.
- (3) Master painters.
- (4) Architects and engineers.
- (5) Manufacturers.

15,086. (1) Amongst the doctors opinions concerning white lead were not unanimous. Ex-Senator Treille, who considers that clean, sober and prudent workmen are not exposed to the malady and who opposed the prohibition, is a distinguished doctor. The celebrated Dr. Armand Gautier has fought lead poisoning for 40 years, but, in spite of this, he does not consider it necessary to prohibit the use of white lead. Dr. P. Carnet, Professor of the Faculty of Medicine of Paris, has strongly criticised the law (*Journal "Le Progrès Médical,"* 11th September 1909). I only mention the best known. I might also mention, among other well known names, Dr. Lucas-Championnière, Dr. Bouclardat, and Dr. Barth.

15,087. (2) As regards working painters, the commissions of the Chamber and Senate practically only listened to M. Craissac and his comrade, M. Robert, who represented the National Federation of Painters, which in reality comprises only a few hundred workmen.

Almost all the workmen remained indifferent, and to an impartial observer their abstention sufficed to

6 December 1911.]

Mr. EUGENE EXPERT-BEZAÇON.

[Continued.]

prove that the workmen themselves did not demand prohibition.

15,088. (3) Master painters in general made the mistake of assuming indifference. Many are small people who do a great deal of work and have not the time to give to such questions, they thought that the manufacturers of white lead were sufficiently well placed to defend them. Finally, many of them, no doubt, thought that if all their competitors as well as themselves were legally obliged to do costly and fragile painting, this would not by any means be against their interests. M. Diolé, M. Ciroux, and M. Montot, large master painters in Paris, Bordeaux, and Dijon, defended white lead, but the authorities were not willing to accept their evidence. 1,620 less important master painters of Bordenaux and Dijon sent their written testimony and that of 6,000 workmen, but they were not taken into account.

15,089. (4) A thorough inquiry should have been made amongst competent architects and engineers, but private architects were not questioned, and their opinions were looked upon with suspicion. The most important association of architects, the "Société Centrale des Architectes Français," on several occasions manifested its opposition; on 22nd April 1909 it ratified the report of M. A. Vaillant, who concluded definitely against the adoption of zinc white out of doors, but a deaf ear was extended to this society of such standing and independence.

15,090. As to the engineers, the Government confined itself to questioning those in the service of the State; and as the Minister of Public Works, their chief, had already indicated on many occasions that his opinion was decided, independence and courage would have been necessary on the part of those engineers to combat it. During the ten years that white lead has been prohibited in public works no report of the practical results obtained has been required of the engineers.

15,091. (5) The manufacturers of white lead were heard several times at the Chamber of Deputies and the Senate, but it was too late. The question had been decided in advance; the condemnation of white lead had become for many legislators an indisputable dogma, and the Socialist party had seized upon the white lead question as an opportunity to create a precedent.

15,092. The Socialist Deputy Breton, one of the principal authors of the law, who had originally made a report almost without an examination of the question, was too intelligent not to listen to the protests of interested parties: he was obliged to issue new reports and to enter into lengthy studies in order to combat our arguments. I do not call in question the sincerity of his convictions, but his convictions were at the start firmly anchored in his mind, and whenever contrary arguments were put before him he stubbornly contested them. His arguments were subtle but not profound. He never refuted the scientific opinions of the great Belgian chemist Stas (Report of the Jury of the Paris International Exhibition, 1855, Class 10, Chemist, Member of the Belgian Royal Academy, reproduced in the report of the Chamber of Deputies by M. Breton, 1907, annex, page 775). His own laboratory experiences were accurate in themselves, but his practical conclusions were incorrect. They were contradicted by the work of M. Lenoble. Pamphlet entitled "Study of the relative value of the covering Power of Zinc White and White Lead," by E. Lenoble, a Lille doctor of Science (reported in the Breton Report, 1907, annex, page 786). The French Parliament eventually approved M. Breton, but this cannot be a final judgment, particularly for other countries. In Switzerland, the Grand Council of Geneva very carefully studied this question after considering all the French documents and reports, and the report of the Grand Council of Geneva is the best refutation of the French Parliamentary Reports.

15,093. It follows from what precedes that the French Parliament had considerable difficulty in seeing daylight in this affair. How could political men properly appreciate such contradictory evidence? A better method would have been: (1) From the medical point of view, to consult official statistics; (2)

from the technical point of view, to have practical experiments carried out. The Parliamentary Commissions did indeed seek these sources of information, but the following is the deplorable manner in which it was given.

15,094. (1) Up to 1907 the Government had followed the question without instituting precise medical inquiries. They produced press articles, lectures and speeches of doctors, some of whom were indeed eminent men, such as Dr. Brouardel, Dr. Laborde, &c., but as none of them carried out any methodical inquiry, the Geneva "rapporteur," M. de Morsier, was able to say of their statements—"they are drawing-room statistics." Dr. Armand Gautier, President of the Academy of Medicine, has also studied this question for many years from the statistical point of view. His opinion, reproduced in the Annex of the Parliamentary Report, is that hygiene of the painters has already made considerable strides, and that it can progress further under Parliamentary measures, and while not ignorant of the danger, he persisted in combatting total prohibition (for exterior work).

15,095. The reason of such vague discussions is that in France there are no complete official mortality statistics. The administration of the Assistance Publique has established certain statistics for Paris and the Department of the Seine, and the Prefecture of Police has done likewise; but a perusal of the discussions (annexed to the Parliamentary Reports) shows that no definite basis for information is to be found therein. In any case there is no information concerning the provinces.

15,096. In 1906 the Government entrusted Dr. Dieulafoy (Professor at the Faculty of Paris) with the work of explaining the medical question to the Senate. Dr. Dieulafoy had no statistics, and it was thought that the Senate would commence consideration of the white lead question within a few days. Dr. Dieulafoy therefore addressed to the director of every hospital in Paris a telegram asking, "How many lead-poisoning cases have you in hospital at this moment? How many lead poisoning cases came to the hospital to-day for admission, or as out-patients?" The replies gave 31 painters as being treated and 12 out-patients—i.e., 43 painters suffering more or less from lead in the Paris hospitals on July 7th, 1906. This was the principal argument used by Dr. Dieulafoy before the Senate. In the course of the discussion M. Poirrier, senator, said: "43 cases in one day, that would make in each year  $43 \times 365 = 15,065$  cases!" M. Poirrier did not reflect upon the fact that cases treated at the hospitals remain there at least 15 days, and that the out-patients, if really ill, come back again later for further consultation. It is also known that painters suffering from chronic lead poisoning were brought up from the provinces and, with others who could simulate lead poisoning, were rushed into the hospitals on that one day.

15,097. The Government never realised the inaccuracy of such information. One of the Ministers, however, who followed one another at the Ministry of Commerce had endeavoured to obtain more precise documentary evidence. By a decree of 3rd November 1905 he instructed Dr. Mosny to make a complete inquiry in all the hospitals in France, which was completed within a year. But no notice of the work of Dr. Mosny was taken by the succeeding Minister, and the new "rapporteur" of the Senate, M. Pedebidou, in his report of June 1906, confines himself to saying "the results of Dr. Mosny's investigations are too incomplete to allow us to take cognisance of them." In 1908 the white-lead manufacturers in vain asked for news of Dr. Mosny; neither the Minister nor the Parliamentary "rapporteur" ever spoke of them again.

15,098. (2) The same scrupulous Minister wished to elucidate the technical question. By a decree of 1905 he had appointed a commission to make a comparative study of white lead and zinc white, presided over by M. Pascal, member of the Institute. This commission held several sittings, decided upon its method of procedure, and asked for a small credit in order to carry it out. But the Ministry changed; the Government showed an entire lack of interest in the affair; Senators have no right to propose credits; the Chamber

E c 4

6 December 1911.]

MR. EUGENE EXPERT-BEZANÇON.

[Continued.]

was occupied with other matters at the moment. The commission was forgotten and the Parliamentary "rapporteur" in 1908 naturally did not mention it.

15,099. Other experiments without official value served as arguments for the enemies of white lead. In 1902 a non-official society, called the "Société de Médecine Publique" made experiments in the buildings of the Pasteur Institute (annex). In spite of defective white lead and improper proportions of oil and turpentine, white lead had the advantage. In one of these tests (on plaster) the white lead resisted the atmosphere, whilst the zinc white flaked off heavily (I produce a photograph of this). When in 1909 it was found that the Government and the "rapporteur" had forgotten the official commission, the Société de Médecine Publique passed a resolution to the effect "that white lead and zinc white are of equal value," and the Parliament adopted these resolutions as though they were official.

15,100. I should next like to examine in a few words the consequences of the error into which the French Parliament was misled. Zinc white manufactories have not yet been developed. A number of attempts have been seriously made to manufacture zinc white and have, generally speaking, failed. When I succeeded my father, I gave up this branch of my business, the financial results of which were mediocre, although our product was held to be very good. One of the principal white lead manufacturers of Lille has had a zinc white factory for some five years, where experiments are still going on, but there is not yet any production. The Société de Malfidano owned a zinc white works (Department of Pas de Calais), but it was shut up in 1905. I could cite other examples.

15,101. The Société de la Vieille Montagne has, in actual fact, a monopoly. Practically only the New Jersey Zinc Oxide Company, and one other company which imports entirely from Holland, sell zinc white in France. So far as the white-lead manufacturers are concerned, they do not dare to accumulate stocks and manufacture actively. They live from day to day. If in summer the consumption experienced somewhat exceptional activity, this was because of a scarcity of supply; the intermediary merchants are in a most embarrassing position: zinc white is sometimes not to be had at all, and the master painters do not know what to do.

15,102. The question arises as to what would happen if the whole of the world's market were suddenly thrown back upon zinc white. What will happen if countries like England, Germany, the United States, who consume much more paint than France, prohibit white lead? The lowest price of zinc that we have known is 15*l.* and lead, 10*l.* The highest we remember were zinc, 29*l.*, and lead, 20*l.* But the periods during which these price limits were reached were simultaneous for both metals. It is our industry that is the most important from the point of view of the consumption of the metal in its final form. If lead is abandoned and the consumption thrown back upon zinc, we shall see lead at 10*l.* and at the same time zinc at 30*l.* or perhaps more. White lead will be worth 13*l.*; zinc white will be worth 35*l.* The consequence will be inevitable frauds and a serious increase of the danger owing to the clandestine use of lead.

15,103. My conclusion is simple: we have made a mistake in France. Our neighbour would do well, before imitating us, at least to wait and see what is going to happen in France.

15,104. (Chairman.) You are a white-lead manufacturer?—Yes.

15,105. And as your business depends on the use of white lead, your desire, naturally, is to protect the industry in which you are engaged?—From the point of view of France, I am naturally interested in the manner you suggest; but from the point of view of England or any other country, I am entirely disinterested, for the reason that probably it would be best for the manufacturers of white lead in France if all the countries prohibited the use of white lead. It would bring about an extraordinary situation which would necessarily entail a reversion to the use of white lead.

15,106. You are only expressing your own opinion when you say that, I take it? I give my opinion, but I have not come here simply for the purpose of protecting the industry, seeing that I do not know that it is really to my interest to do so.

15,106a. Now, in paragraph 15,080 of your proof you state that the law in France prohibiting the use of white lead applies only to buildings, and not to the painting of coaches and the like? That is so.

15,107. May not this be because the French Government recognised the difficulty of enforcing regulations among house painters, whereas it is easier to secure the observance of rules in factories where coaches and similar articles are painted?—By no means. The principal reason why coach-building and other industries using white lead were not included was in order to provide a reply to the demand of the white lead manufacturers for an indemnity; and whilst, as a matter of fact, 90 per cent. of their output goes for ordinary house-painting, it did leave them something. It was not enough, but it was sufficient for an argument for the Government. Also, secondly, the Government came to the conclusion that for coach-building white lead was absolutely necessary. I point out that the organisation of carriage-builders wrote to the Minister to ask whether the law applied to carriage-building. The Minister answered it did not; and the organisation stated when publishing the Minister's reply: "We are satisfied that the trials which have been made for replacing white lead by zinc products have given very discouraging results."

15,108. You point out that house painters are still using white lead?—Certainly. The consumption has not diminished so far.

15,109. I did not speak of the consumption. I say you point out that house painters are still using white lead exclusively?—Yes, just as much as ever.

15,110. Do you not think that they are relying on the long period of grace allowed them?—There are still three full years before the prohibition becomes absolute. The law has already been in force for two years, and there is no indication whatever of the slightest change in the general customs of painters, so far as concerns the use of white lead.

15,111. Is it not likely that they regard this further period of three years as ample time in which to adopt a substitute for white lead, without having troubled to look for one up to the present?—Probably the majority of them are quite indifferent, and do not give the subject much thought at all. Many of them certainly think that at the end of these three years it will be necessary to extend the period.

15,112. But in the meantime they are doing nothing to find a substitute?—By far the greater number of them have not done so. There are a few exceptional cases in which painters are now only using zinc white. The majority say that it is best to wait until the moment when substitution must be made, and then they will see.

15,113. There are some master painters in France who have accepted the law as it stands, and are using exclusively zinc white?—I only know one firm which uses zinc white exclusively. There are a few others who use a considerable quantity of zinc white, but still a certain amount of white lead.

15,114. Now, it is very good of you to come here to-day and give us your opinions, but we are bound to assume that the French Government were serious in passing the law of 1909 in the form in which it was accepted by both Houses of Parliament. We cannot, therefore, allow the views of one gentleman, however eminent, to weigh with us very much when he is in opposition to the settled decision of the French Government.—First of all, the discussion of the question took eight years. It commenced in 1901, and the final law was not passed until 1909, and it was not passed without the very greatest difficulty, there being a very important minority. It is not only my opinion, but it is also the opinion of many gentlemen of much greater standing than myself—I would instance the case of M. de Morsier, the rapporteur of the Swiss Inquiry. Another eminent individual whom I would quote is Dr. Armand Gautier. Although he does not

6 December 1911.]

Mr. EUGENE EXPERT-BEZANÇON.

[Continued.]

say definitely in his report that the Government has done something exceedingly stupid, it is quite simple to read between the lines.

15,115. In paragraph 15,086 you refer to the differences of opinion among doctors concerning the evils of white lead. Such differences are not unknown in England; but I know of no medical expert in this country who would say that a clean, sober, and prudent workman runs no risk of lead poisoning? The opinion, nevertheless, is the opinion of Dr. Gautier, as well as Drs. Carnot, Lucas, Championnière, Bouchardat, and Barth. I want to add that these doctors whose names I have given do not deny the fact that there are certain individuals, perhaps one in a hundred, perhaps one in a thousand, who are specially susceptible; but what they do assert is that an industry should not be ruined on account of these few.

15,116. If a susceptible man, for instance, breathes lead dust, which he may get from dry rubbing down or from any of the other sources of general dust in the room where he is working, how can he avoid the risk of lead poisoning simply by personal cleanliness in washing and the like after his work is done?—Obviously, a man who is very susceptible to lead poisoning could not avoid it by the precautions of ordinary cleanliness and so on, but when he realised that he was indisposed owing to lead he should go to the doctor, and it might be necessary for him to change his occupation.

15,117. It appears from your evidence, and you have told us so this afternoon, that the agitation regarding lead poisoning among house painters in France has been going on for a long time. Have the master house painters ever agreed to take organised action in regard to this question?—The great majority of the master painters have remained entirely indifferent to the question of white lead, but exceptions are to be found in the case of the *chambres syndicales* in Bordeaux and in Dijon. That is a master painters' association. In this case it has nothing to do with the chamber of commerce. Bordeaux collected the signatures of 1,600 master painters, who protested against any change, and the signatures of 6,000 workmen.

15,118. In paragraph 15,088 you speak of evidence tendered against the proposed prohibition. In view of the decision of the French Government, I suppose we must assume that the evidence on the other side was stronger?—I am obliged to say that during the whole inquiry the authorities were very unjust to us. When a manufacturer gave evidence the reply was always that he was an interested party and no reliance was to be placed upon his evidence. When a master painter gave evidence it was always suggested that his evidence must be taken with suspicion, because he was in the pay of the manufacturer of white lead. It was even said that the master painters who purchased their white lead from the white-lead manufacturers owed the latter money, and consequently they were entirely in the hands of the manufacturers of white lead.

15,119. I want to point out, with the greatest respect to yourself, that a very great deal of your evidence has been devoted to the belittling of the evidence on which the French Government acted, and I can only repeat that this Committee, in view of the fact that they only have two or three witnesses from France, should be guided by the action which the French Government decided upon after weighing all the circumstances of the case put before them?—I cannot of course individually oppose or place myself against the decision of the Government, but time alone will tell, and I can at any rate cite a similar opinion on the part of the gentlemen already mentioned, Dr. Armand Gautier, M. de Morsier, and so on. Besides that, one might mention very important occasions when the French Government has been entirely wrong, one being *l'affaire Dreyfus*.

15,120. Do you want that put in evidence?—I sincerely consider that the two errors of the Government are comparable.

15,121. Now I gather from paragraph 15,090 of your proof that the use of white lead has been prohibited for public works in France for ten years?—Yes.

15,122. Then, surely, if this prohibition had proved detrimental to the Government buildings in France, its

effect would have been exposed, would it not?—I am persuaded that it has been bad in many cases, but it must be remembered that the Government official pays for the work not with his own money but with the money of the taxpayer, and if the work costs more, as it undoubtedly does, either through the cost of the material or the fact that it has to be re-done more often, there is nobody to complain. I desire to put in an official circular of the Minister of War, being a technical instruction on the employment of various zinc paints. In this paper the Minister of War recognises that a coat of zinc paint covers less than a coat of white lead, and consequently the cost is more.

15,123. What is the name of the Minister of War?—It has changed often since, and I could not say.

15,124. When was that published?—In 1902.

15,125. That is a long time ago. Can you tell us from your own knowledge whether the buildings that were painted with non-poisonous paints were perfectly safe?—There is a famous example, namely, the Garabit Bridge, in Auvergne, which had to be re-painted at the end of one and a half years. I must say the advocates of zinc white stated in regard to this bridge that the material used was of poor quality. But in all such constructions as iron bridges, although no white lead is used on them now, an additional coat of red lead is put on, and consequently really the danger to the workmen is very little less.

15,126. (Mr. Sutherland.) You mean before the white zinc is put on?—Yes.

15,127. (Chairman.) But does not the prohibition of poisonous paints in the case of Government buildings apply to red lead?—It is not leadless paints; it is white lead.

15,128. Have you any other instances to give us where Government buildings have been rendered unsafe by the use of leadless paint?—No. I might mention the Metropolitan, the Paris Underground Railway, where a zinc white paint has been used, but in this case there were first of all two coats of red lead, and secondly a certain amount of green was added to the zinc white in order to arrive at the desired colour, which green is a compound of lead, and consequently the whole protection of the ironwork of the Metropolitan is really in the hands of lead.

15,129. Now, in paragraph 15,094 onwards you refer to the absence of statistics of lead poisoning in France. Have you no definite statistics to offer us with regard to lead poisoning and the number of house painters employed in France?—The only official statistics are those of Dr. Armand Gautier, which the rapporteur of the Chamber of Deputies would not accept. He was favourable himself to zinc white. Beyond that there are the statistics collected by the Master Painters' Association of Bordeaux, already mentioned, which contain the signatures of 1,600 master painters and 6,000 workmen, of the whole of whom about 740 stated they had had a touch of lead poisoning, not merely in any one year, but during the whole of their life. All the others were safe.

15,130. (Mr. Sutherland.) The workmen?—It includes the whole—the workmen and the masters.

15,131. (Chairman.) What do you mean by "a touch of lead poisoning"?—An attack.

15,132. Severe, moderate, or slight?—Including severe and slight. It is 143 out of 7,600. But these figures are not official and are not complete.

15,133. In paragraph 15,096 of your evidence you call attention to the 43 cases of lead poisoning under treatment in Paris hospitals on a certain day, and you point out that it is unfair to multiply this figure by 365 to get the number of cases in a year?—Yes.

15,134. Now, if we adopt your own suggestion that 15 would be an average number of days for such cases to remain on the books of the hospitals, we should have 43 multiplied by 24; in all 1,032 cases in the year in Paris alone. The estimated number of cases for the whole of Great Britain is only about 1,000 per annum?

—I would point out that I have also stated in my evidence that this number 43 was abnormal. For instance, previously to the day in question M. Craissac recruited a number of painters who had suffered from the effects of lead in the provinces, and it is known.

6 December 1911.]

Mr. EUGENE EXPERT-BEZANÇON.

[Continued.]

that he offered them money to come forward and attempt to get themselves accepted at the hospitals as suffering from lead poisoning. In addition, Paris, because of its large population and the prevalence of alcoholism and bad sanitation, would be likely to show the greatest number of cases.

15,135. I will ask you in a moment what your authority is for stating that these cases were manufactured, so to speak, and sent to Paris. Even supposing that the explanations are reasonable, it would still mean that the amount of lead poisoning in France is appalling?—No. The figures for 1905 and 1906 were without any doubt falsified.

15,136. Which figures do you mean?—The number of cases.

15,137. The number of cases in the Paris hospitals in 1906?—The proof of the fact that the figure was falsified and that people were brought from the provinces lies in the figures given by Dr. Armand Gautier. With regard to the total cases of lead poisoning in Paris hospitals, they were in 1902, 87; in 1903, 48; in 1904, 72; and in 1905, 153.

15,138. Were not those figures rejected by the French Government?—The figures were not refused by the Senate. Dr. Armand Gautier himself gave evidence, and put in his figures before the Senate Commission. What I meant before was that sufficient weight was not given to them. I would like to say that the white lead question was very much to the fore during the years that I have referred to, and doctors were more disposed than usual to put down cases amongst painters which presented a certain amount of difficulty in diagnosis, to lead. I would mention particularly nephritis, which can presumably be caused by lead, but which is also well known to be brought about by other causes. In a painter it is more often put down to lead than it should be.

15,139. How did Dr. Armand Gautier collect his figures?—Dr. Armand Gautier was especially nominated by the Police Department in Paris to officially collect these figures, and consequently had access to the registers of all the hospitals in Paris.

15,140. But I suppose that there must have been a very large number of cases which were not in the hospitals and which, therefore, he did not come across?—Necessarily the figures would not include any cases which did not come to the hospitals, but Dr. Gautier said in one of his depositions that the majority of the cases probably did come to the hospitals, and this can be verified through the number of fatal cases.

15,141. The figures which you have given only refer to house painters, do they not?—The figures that I have given refer to painters only. At the foot are given the figures for the whole of the lead poisoning in all trades.

15,142. I note, however, that the French report on the use of lead compounds in painting for 1907 quotes statistics of the mortality of painters in Paris?—Yes.

15,143. The tables given on page 719 of the report, for example, seem instructive?—Yes.

15,144. If we take the figures for men over 40 years of age, it appears that the death rates are as follows: deaths from phthisis among painters, 1,213; deaths from cerebral hæmorrhage and paralysis among painters, 237?—The death rate where?—I do not understand?

15,145. In the city of Paris from 1893 to 1899?—What was the total death rate from phthisis?

15,146. Among all males over 40 the death rate from phthisis in Paris during that period was 776, and the death rate from cerebral hæmorrhage and paralysis was 177?—I should not care to say anything with regard to figures which have just been put before me for the first time.

15,147. Were not you cognisant of these figures?—No.

15,148. It would appear, from these cases that I have cited here, that the mortality amongst painters is materially greater than amongst other male workers?—I have not made any study of these figures, not having seen them before, but I would only remark that it is not reasonable to compare painters' figures with the relative figures for all males. They should be compared with the figures of another trade.

15,149. But how can you account, then, for this increased mortality amongst painters other than by the fact that the painters use a highly dangerous material, namely, lead?—I cannot see how lead can have any influence on those diseases mentioned, with the exception of the second and last, that is to say, cerebral hæmorrhage, paralysis, and nephritis, in which it plays a certain part, but probably not much. In other words, a good many of these cases have nothing to do with lead, or are not caused by lead.

15,150. It is a curious thing, is it not, that the figure for painters should be so very much higher than that for all males?—I cannot say more without looking further into the matter.

15,151. They are specially interesting, from our point of view, from the fact that they coincide precisely with similar figures for the United Kingdom?—I suggest that in both cases a comparison should be made with other industrial occupations and not with all males. It must not be thought that lead is the single material used by painters which is noxious, because almost every material which is employed by the painter has an injurious effect.

15,152. Could you tell us some of the elements, other than lead, which are injurious?—First of all an element of every paint, turpentine, then other materials as lead colours, and so on.

15,153. (Dr. Collis.) You have knowledge of the publication of the French Government (I refer to a dossier in connection with the inquiry made by the French Government) upon which the law was passed prohibiting the use of lead, and in which your own name appears on several occasions—or I presume it is your name?—It was myself and my father jointly who did it.

15,154. You have quoted the figures of Dr. Armand Gautier. You are aware, I presume, that these figures were controverted in the report I have referred to, and those of M. Bertillon were stated as against them?—Would you let me look at the report for a moment, please? (The report was handed to the witness.) M. Bertillon never denied the exactness of the figures of Dr. Armand Gautier so far as they went, because they were figures of cases, not deaths, but the discussion between M. Bertillon and M. Treille was on the figure of the number of deaths.

15,155. M. Bertillon quotes cases to 1903, 4,078, where Dr. Armand Gautier gives 2,071, and he proceeds then to explain why his cases are more numerous and a more just estimate of the number of cases which occur in the city of Paris?—I can only say that Dr. Armand Gautier was officially nominated, and therefore he had the entrée into all the hospitals, to all the hospital registers, and so on, and he had to make his reports officially; and Dr. Armand Gautier, as an individual, is an eminent person, which is not the case with this gentleman (M. Bertillon), with regard to lead poisoning. I would also point out that this is not an official publication. It is simply a report of a Committee of the Chamber of Deputies, a Parliamentary Committee.

15,156. As there seems to be some dispute in France over the figures of Dr. Armand Gautier and the figures of M. Bertillon, which are also controverted further, it is hardly possible for us to accept the figures which you have put in merely based on Dr. Armand Gautier?—I ought to point out that I have never stated that the figures of Dr. Armand Gautier are absolutely exact. I can simply say that these figures are the only ones which have been officially collected. There are numerous other doctors who have given figures, but none of them are in any way official.

15,157. Yes, but that is hardly my point. I suggest to you that as these figures were controverted in France, and apparently rather strongly so, we are hardly in a position to enter into the dispute which took place there with regard to these figures, and, therefore, we are not in a position to judge whether the figures you place before us are absolute?—That is so; but what I wish to point out is that without question there were the most extraordinarily exaggerated figures and statements made with regard to lead poisoning during the whole course of the inquiry, and in any case

6 December 1911.]

Mr. EUGENE EXPERT-BEZANÇON.

[Continued.]

I would express the opinion that, even taking one of the figures given by M. Bertillon, if there were 500 painters who had attacks, slight or severe, of lead poisoning, due mostly to their own lack of ordinary precautions, that would not provide sufficient argument to altogether modify the whole industry, seeing that in comparison with this 500 you have thousands upon thousands who are not affected by lead.

15,158. But how many painters are there in the city of Paris?—There are no statistics, but most people say 15,000 to 18,000.

15,159. Do you not consider a case incidence of 500 among 15,000 to 18,000 high? I would point out that these figures are not all painters. They include painters, but they are for all industries.

15,160. Taking the same proportion that we have already taken, it gives us 400 among the 15,000 house painters roughly. I am sorry to trouble you on the point, but I wish to point out that there was before the French Government another set of figures presented in addition. I notice that your dossier is quoted in this report in reference to the existence of lead emanations. Have you carried out any further experiments since the two authorities which you quote in your dossier, namely, in 1855, and the opinion expressed by Dr. Armand Gautier in 1903, to meet the experiments carried out by M. Heim and M. Hébert, M. Breton, M. Trillat (in his experiments on guinea pigs), and Dr. A. Marie. They are quoted in support of the statement that lead emanations are given off?—Dr. Heim himself refutes M. Breton. The experiments carried out by M. Breton have an interest purely scientific, that is to say, the results showed that if there were any lead emanations they were something so exceedingly small that, practically speaking, they would be ignored. M. Heim has come to the same conclusion.

Mr. FELL in the Chair.

15,161. (Mr. Sutherland.) You know the Maison Leclaire, the celebrated firm of French house painters?—Yes.

15,162. Leclaire was the first man who devoted himself, on humanitarian grounds, to making the use of zinc white practicable as a paint?—Yes.

15,163. He, more than any other Frenchman, popularised its use, did he not?—Certainly.

15,164. Notwithstanding this fact, you say that his firm are large users of white lead?—Up to the year 1903 or 1904, the firm of Leclaire used about 15,000 kilos. of white lead each year.

15,165. How many tons is that?—It is about 15 tons a year. The director of the Leclaire firm admitted it, but he gave a very natural explanation—that they had cases in which architects specified that they had to use white lead. But in view of the capital that was made out of that fact during the inquiry in France, they gave up using it, and probably ever since they have not used any white lead.

15,166. They resented the capital that was made out of it?—Yes.

15,167. By whom—by the lead manufacturers?—Yes, by the lead manufacturers.

15,168. I was going to ask the reason for the use of the white lead. You said that architects specified it. Now that suggests another question, and that is that architects have more confidence in white lead than in zinc?—Certainly, that is so; and in confirmation of that I would like to put in the evidence of M. Nénot before the Senate. M. Nénot being a very well known architect, the architect of the Sorbonne and other large public buildings. He stated that this firm of Leclaire had a personnel composed of workmen accustomed to dealing with this product (meaning zinc), and in spite of all these guarantees it is observable that exterior painting work executed by this firm offers less resistance to atmospheric influences than work done with white lead. In resumé, zinc may, perhaps, by law succeed lead, but it will never replace it. He means that it will never really be an efficient substitute.

15,169. What is the nature of the Government buildings painted with leadless paint in the last 10 years? There must be more than the bridge that you

cited?—I speak of all public buildings of any kind such as the hospitals, schools, and so on.

15,170. Are they all painted with leadless paint?—Yes.

15,171. I gathered from a reply which you made to the Chairman that the question of cost does not enter into consideration, because it is Government work?—Exactly.

15,172. What, in your opinion, are the alternative paints to white lead?—I know of no substance which can entirely replace white lead. The only substitute of which I have any knowledge, and which is considered of comparative value, is zinc oxide, and that certainly can take the place of white lead under certain circumstances, but not generally. For the exterior certainly zinc white cannot be used, because of its inferior lasting powers. This also has to be taken into consideration, that it is extremely difficult to apply zinc white properly, and that fact accounts for the extraordinarily divergent opinions on zinc white which have been given by different employers. In Paris there are a few master painters who have made a speciality of zinc white, and have carefully trained some of their workmen up to the use of zinc white; but this is quite another thing from supposing that the large mass of workmen could properly apply it.

15,173. (Dr. Collis.) Would you explain to us what is the character of the monopoly that the Vieille Montagne Company has with regard to zinc ore?—The Vieille Montagne Company is not favoured by the law. It has no legal monopoly. It was founded at the beginning of the nineteenth century, and at that time possessed most of the zinc mines. In 1848 Leclaire sold his process for manufacturing zinc white to a company, which immediately re-sold the process to the Vieille Montagne Company. The company has therefore a fifty years' reputation behind it. They have a trade mark which is known, one might say, over the whole world, and those who might desire to enter into competition with them would have to fight, of course, against this. They originally had a capital of 9,000,000 francs. The company has been exceedingly prosperous, and has extinguished its capital. It has very large reserves, and it makes an annual profit of something like 10,000,000 francs. Clearly it is an exceedingly difficult thing to fight against such an organisation, and I have myself, unfortunately, experienced it.

15,174. Have they any control of the zinc ores suitable for making zinc oxide?—No. The Vieille Montagne Company works two processes; one consists of burning the metal, and that only is carried out in France. In Belgium the company make zinc white by the direct process, but they do not own any mines the product of which specially lends itself to the manufacture of zinc white. There are none in Europe of this particular kind of zinc ore. It is all in America, and controlled by the New Jersey Company.

15,175. The direct process?—Yes.

15,176. Is there not another large company or trust in Germany?—There are several other companies in Germany and Belgium, and they form with the Vieille Montagne Company a trust which affects zinc, not zinc white, but necessarily that has an indirect effect also upon zinc white.

15,177. Are the American company in harmony with them? Do they work with them?—I cannot state definitely that that is so.

15,178. Are there certain zinc ores which are not suitable for the production of zinc oxide?—Certainly; it is obvious that a zinc ore which contains a very large proportion of zinc is used for the production of metal zinc, and the ores which are used for the production of zinc white are those which are poor in zinc, and those poor or low-grade ores are difficult to treat on account of the presence of a number of other materials, largely lead. The ore treated by the New Jersey Company is the only one that does not contain any lead. The difficulty of abstracting the lead provides the reason why such companies as the Maestricht Company sell zinc white with not less than 4 per cent. of lead. For the last ten years many attempts have been made to produce a process by which zinc and lead can be

6 December 1911.]

Mr. EUGENE EXPERT-BEZANÇON.

[Continued.]

separated, notably in Algeria and Tunis, but so far without any effect.

15,179. Does it make any difference what ore is used when zinc white is prepared by the indirect method?—Do you mean so far as the quality of the product is concerned?

15,180. Yes?—The effect on the ultimate product of the ore would depend upon the amount of lead that there was originally in the metal treated. Where you have more lead there would be more lead in the ultimate product, and, consequently, from the strict point of view, that would make it inferior, but as a matter of actual practice we know that oxide of zinc with a certain percentage of lead in it is for some special purposes superior to the other product.

15,181. As a paint?—Yes.

15,182. But it is not accepted as a pure zinc, is it, with lead in it?—Formerly in specifications a half per cent. only was allowed for impurities that is, lead, in white zinc, but in recent years several companies, particularly the Maestricht Company, who manufacture by the direct process zinc white containing a certain percentage of lead, have made great efforts to obtain a modification of this, not only in Belgium but in France, and successfully. One very grave result of this should, however, be noted. The method of testing whether a paint contains lead is by adding a small quantity of sulphide of potassium or sodium. If this turns black it shows that lead is the basis of the paint; but if a certain amount of lead is allowed in the white zinc paint it is clear that this no longer constitutes a control, as such quick method does not allow one to distinguish a paint containing 3 per cent. lead from another one containing 10, 20, or 30 per cent. Under these circumstances it is obvious that inspectors cannot make sure that lead is not being used, and this necessarily opens the door to fraud.

15,183-6. That is not quite what I wanted. We have large supplies of zinc ore from Broken Hill, Australia, and that is sent to this country, but not for making zinc oxide?—Of course, it might be used for producing oxide; but in Paris, for instance, they use largely zinc that has been taken from houses which have been demolished.

15,187. Do we understand that any form of spelter can be used for making zinc white by the indirect method?—Zinc white is also manufactured from the residue from galvanising works. The zinc bath is thrown away after a certain time when it becomes impure for galvanising purposes, but it still has 87 per cent. of zinc in it, and that is used for manufacturing by the indirect process. But I desire to point out that if the white lead were suppressed entirely, and it was necessary, therefore, to make zinc white in very much larger quantities, there would be difficulties, because such sources of zinc as supply now what is necessary would not be sufficient. I am talking about the direct residue from galvanising and so on.

15,188. Has either of the companies, the German or the Belgian or the American, any control over the ore from Broken Hill, Australia?—I could not say, but I should imagine that the Broken Hill authorities belong to the Zinc Trust. My reason for thinking so is that recently the representatives of the other European zinc organisations were in Paris for the purpose of a conference, and they were awaiting the arrival of representatives from Australia.

15,189. You think that they have some control over it?—Yes, I think they are in the trust.

15,190. (Mr. Parsonage.) Have not the Zinc Corporation, a British corporation, bought the residue of the ores belonging to Broken Hill? The original owners were unable to treat the zinc ore at Broken Hill, so they sold it?—I have no special knowledge of the Zinc Corporation, but I should imagine that it is included in the Zinc Trust, of which I have spoken, my reason for thinking so being that the rise in the price of zinc which has taken place during recent months was foretold by the zinc people in Belgium and Germany. personal acquaintances of my own, a couple of years

since, and they did not attempt to hide the fact that there would be a rise.

15,191. (Mr. Fell.) But you do not know of your own knowledge?—No.

15,192. (Mr. Parsonage.) You spoke of a firm who use zinc white exclusively?—Yes.

15,193. Can you tell me how it is possible for this firm to compete with other firms using white lead when your own statement is that they have to train the workmen specially to use zinc white, and also that it is not so durable, and that it is more expensive than lead? When you speak of zinc white being more costly the question necessarily arises as to who pays the extra price, and on consideration you will see that it is the customer who would pay it. In high-class work,—and the Leclaire firm is a firm which does principally the best work, a firm of very good reputation—the question of covering power is necessarily not so important. For instance, a plastered wall to be prepared in light colours in an interior would not have a number of black spots and discolorations upon it, and therefore three coats would be sufficient. On the contrary, if an architect wished to have a room painted white instead of the original colour, brown, a master painter who used white lead would say that two coats were sufficient. The Leclaire firm would say that three coats necessarily of zinc oxide would be required; and seeing that the architect probably had worked in the past in connection with the Leclaire firm, he would not refuse the three coats when he would know that in any case neither firm would lose because they would not pay the extra cost but the proprietor of the house. Necessarily the higher the class of the work, the less the customer would be likely to perceive the difference.

15,194. (Mr. Sutherland.) It would meet Mr. Parsonage's question if you told him that Leclaire's are a firm of such eminence that they practically command their own prices?—One could say that it is about the first house of the kind in Paris. I should desire to add to what I said before that one of the conditions of the sale of the Leclaire process to the Vieille Montagne Company was that the Leclaire firm should always buy their zinc at a lower price. That was one of the conditions when the process was sold in 1850. Probably during the recent inquiry in France, when the Vieille Montagne Company would naturally have an interest in the success of zinc oxide as against lead, they would during that period allow a still greater discount in order that the work done with it might bear a better relation from the point of view of cost to white lead.

15,195. With reference to the question of the men being rushed into the hospital on a certain day, you said that a telegram was sent on one day to the hospital asking how many men were suffering from lead poisoning at that moment. You said that men were rushed into the hospital from the provinces. That would suggest that prior notice was given that a telegram was going to be sent on a certain day to enable them to send these men in. Surely you do not ask us to accept that. (*This question was not translated and put to the witness.*)

Sir ERNEST HATCH resumed the Chair.

15,196. (Chairman.) I do not think we can question the findings of the French Committee, and therefore I do not think that the point ought to be gone into any further. You stated that the men were bribed to come into the hospital. I wish to know who were the parties interested in making out a case against white lead, and who you suggest found the money for bringing in these men, seeing that zinc manufacturing firms were not developed in France at that time with the exception of the Vieille Montagne Company. Is it suggested that that firm were finding the money to get these men?—Obviously I cannot definitely prove this, but I have a firm conviction that Craissac received money from the Vieille Montagne Company. My reason for this is that my father and one or two other manufacturers thought it would be useful, during the course of the inquiry, to obtain some details in regard to Craissac, and had him shadowed. Craissac was formerly a painter, but has

6 December 1911.]

Mr. C. EUGENE EXPERT-BEZANÇON.

[Continued.]

not done any work for the last seven or eight years. As a result of this shadowing it was found that Craissac daily visited, not the head office of the Vieille Montagne Company, but one of their principal representatives. After the white lead inquiry was over an article was published in the "Figaro" in connection with troubles amongst stable lads in the racing stables, which suggests that he lived on money which was obtained in this manner, and in addition during the course of the white lead inquiry a paper which is called "L'ouvrier Peintre," which is a workmen's journal, and copies of which I have sent to senators and others interested, definitely accused Craissac of being in the pay of the Vieille Montagne Company. It was published in 1908, and openly accused him. I do not fear any criticism on it, because I have the absolute conviction myself, having been through the whole thing.

15,197. (*Mr. Kinggate.*) How did the Government arrive at the conclusion that it was absolutely necessary to use white lead in coach-painting?—I have no special knowledge of that subject, but it is well known that the coachmakers are quite unanimous on that point.

15,198. Is that simply the view of the employers? There was no inquiry made of any description with regard to the use of non-poisonous paints in coach-painting?—No.

15,199. You stated that the Government arrived at this conclusion. I want to know whether it was simply from making inquiry from the employers or whether any special inquiry was held?—I have no special knowledge.

15,200. It is in your evidence. With regard to the list of lead-poisoning cases in hospital, does it differentiate between house painters and coach painters?—Coach painters are included in Dr. Armand Gautier's figures.

15,201. (*Mr. Robins.*) What is the average number of hours per day that a French workman works in the manufacture of white lead?—The general practice is 11 hours per day.

15,202. Has the State any control over the number of hours worked in those works?—There are no special rules for white lead works, but they are under the general rules of the Government, which fix the limit at 12 hours for all industries, with one or two special exceptions.

15,203. (*Chairman.*) Does the 11 hours usual in white lead works include meal times?—No. They come at six and they go at half-past six, and they have an hour and a half for meals.

15,204. (*Mr. Robins.*) Do I take it that there is never any excess of hours worked over the 11 hours?—They have no legal right to work over 12, and if, as occasionally happens, it is necessary to keep a few workmen for some special purpose, they allow them to come late the next day in order to make up for it.

I would like to add one word. In what I have said about the Government I do not accuse them of bad faith, but simply that they were deceived. The whole thing commenced in this way: In the year 1900 a Paris paper published under a heading which may be translated as "Divers Facts" a story about some children who had been playing with some pots of paint with the most disastrous results. This sensational story was published in all the papers of Paris, and it was from that date that the whole agitation started. My father made an inquiry to the authorities into the whole thing, and the answer was, that it was a pure fabrication, and that the painter whose paint-pots the children had got hold of as a matter of fact did not exist.

15,205. (*Mr. Parsonage.*) Neither the painter nor the paint-pots?—Exactly. Naturally, the public never knew the truth.

The witness withdrew.

## TWENTY-THIRD DAY.

Thursday, 7th December 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Sir GODFREY BARING, Bart., M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary*).

Mr. NOOIJEN.

Evidence to 15,218 handed in and taken as read; witness then called and examined (through an interpreter).

15,206. I am a member of the Guild of Dutch Master Painters (Bond van Nederlandsche Schilderspatroons) and secretary of its insurance fund; delegate to the congress held at Sheffield in 1909 by the National Association of Master House Painters and Decorators of England and Wales.

15,207. I have closely followed all the work of the Dutch Commission appointed in 1903 to investigate the extent to which white-lead paint could be replaced by zinc white, and the reports and counter-reports in respect thereof. Taken as a whole, my guild does not object to the accuracy of the final conclusions of the Commission, having regard to the materials used by it for its experiments; but it is generally considered by the master painters in Holland that the zinc-white paint prescribed was too thick to work with, and that, in fact, the zinc-white paint used was frequently diluted with oil with or without the knowledge and consent of the persons supervising the tests.

15,208. The universal opinion in Holland among the master painters is that it is much better to paint the outside of buildings with white lead, as it resists the atmosphere much better than zinc white. The one disadvantage is that in the neighbourhood of bad-smelling or dirty water, which gives off sulphuretted hydrogen gas (H<sub>2</sub>S), the white lead is liable to discoloration.

15,209. I have tried all the known substitutes for white lead, and have painted my own house with zinc white mixed with stand oil only, and it lasted three years at the south-west side and four years at the north-east side. White lead mixed with stand oil or boiled oil lasts several years longer. White lead is not used in Holland for finishing interior painting. Zinc white is largely used in Holland for interior decorative work owing to its retaining a pure white colour better in comparative; dark positions when mixed with linseed oil, and to its resistance to

7 December 1911.]

Mr. NOOIJEN.

[Continued.]

sulphuretted hydrogen gas, which is given off by the bad-smelling water of the canals, such as at Delft, Leyden, and Haarlem, where the large factories let their dirty water into the canals and spoil the fresh water.

15,210. Zinc white is nearly always used for interiors mixed in stand oil, so as to produce a kind of an enamel similar to Ripolin, Velours, &c. The interior of my house, painted nine years ago with this paint mixed with stand oil, is still in excellent condition. White lead, whether mixed with stand oil or linseed oil, when not exposed to light is apt to turn yellow in interiors.

15,211. Most decorators in Holland mix their own paints, procuring the dry material and the colouring matter. For first-class work for shining surfaces stand oil is used in the mixing. Stand oil is linseed oil boiled a very long time, and is of two kinds, thick and thin. The thin stand oil is most suitable for inside work and the thick stand oil for outside work, as when used inside it has a tendency to turn yellow. Zinc white mixed with stand oil forms a very strong paint for the outside, but must be thinned with raw linseed oil. Zinc white mixed with stand oil forms a very strong shining paint for interior works, but must be thinned with turpentine (not oil).

15,212. White lead mixed equally well with stand oil, and mixed and thinned with linseed oil, makes the best of all paints for the exterior apart from its liability to turn colour when attacked by sulphuretted hydrogen. It is impervious to atmospheric changes, and the oil forms with the white lead an elastic coat which expands and contracts instead of cracking with variations of temperature. Zinc white, on the contrary, is simply held in solution, and is unable to offer the same resistance to damp and humidity, it is not elastic, because it hardens very much. When mixed with stand oil it will last for three years in exterior painting as against the five years of white lead in the same circumstances. The price of stand oil is, however, high, being at present about 1s. 6d. a kilo. It forms a fine varnish which protects the zinc white from the ravages of the weather and makes its use possible out of doors.

15,213. Zinc white varies very much according to the atmospheric conditions. Sulphurous acid ( $H_2SO_4$ ) is fatal to zinc white, even when mixed with stand oil, as was proved in the trial painting of bridges at Amsterdam and Utrecht. At Amsterdam, where the smoky and humid atmosphere causes sulphurous acid, the zinc white only lasted one year, but at Utrecht, where it is clear, it lasted four years.

15,214. A ship must be painted, for the outside, under the water-line with red lead mixed with linseed oil, and above the water-line with iron minium mixed with linseed oil, with a large quantity of driers in it and again covered with zinc white. A great many painters in Holland use one-third white lead for putty (filling), but it can be replaced by zinc white.

15,215. In my business I mix all my own paints, and have a gas engine to work the mixing machine in my workshop. I buy all the white lead dry, as I find it very difficult to test the quality when it has been mixed with oil. All proper precautions are taken against dust, and I have never had a case of lead poisoning among my workmen. There is, however, a very large and growing consumption of white lead ground wet in oil—i.e., the white lead, being ground in the manufactory, is mixed there by a special method with water during the process to prevent all danger from dust. The water is driven away when oil is mixed with the white lead.

15,216. In Holland it is the practice to rub down old paint wet, and remove the residue whilst still wet. We do not use any dry process, except among the ship painters, where there is the greatest danger of lead poisoning, because they remove the old paint by dry scraping the old white lead and red lead coats which causes lead dust. Very little turpentine is used in the preparation of zinc-white paint by me, but we use poppy-seed oil in addition to the stand oil for flat surfaces.

15,217. At present no regulations of any kind exist in Holland, but it is understood that as a consequence of the findings of the White Lead Commission in 1909 some regulations are likely to be issued.

15,218. White lead is used in very large quantities in all the departments of the Government.

15,219. (Chairman.) We are very much obliged to you for coming over to place your opinions at the disposal of this Committee. You will understand, of course, that the Dutch White Lead Commission must carry greater weight with us than any individual opinion, seeing that the report, dated October 1909, embodies the final conclusions of the Commission, who presumably were in a position to obtain and judge of the best available evidence?—Yes.

15,220. Can you tell us what led up to the appointment of the Dutch White Lead Commission in 1903?—I am very sorry, but it has been a political question. The question to my mind was a political one, as some of the members of our Parliament felt inclined to take it up on behalf of the workmen, although the master painters were fully convinced that there was actually no lead poisoning at all. So it was on behalf of the Government that the thing really started, and the master painters in Holland were opposed to it, because they were sure that there was no lead poisoning at all. That is what I want to explain to you. That is the reason why the workmen asked them to have a Commission to find out if there was really lead poisoning at all or not.

15,221. But I understand that no instructions were given to the Commission to inquire into the existence of lead poisoning at all? No. They asked the Commission to get another paint instead of white lead.

15,222. But I suppose we must assume, from the fact that the Commission was appointed, that lead poisoning did exist amongst house painters in Holland?—It is my opinion that, as a matter of fact, it does not exist.

15,223. The Government appointed a very important Commission, including some of the leading men in Holland, such as professors of the Polytechnic School at Delft, the chief engineer of the navy, the first lieutenant of the staff of the artillery, a civil engineer and architect, and others. Do you suggest that the Government appointed this very important Commission without any knowledge, or in the belief that there was no lead poisoning at all in the country?—The agitation caused in the Chamber by the labour members had something to do with the Commission coming about. I am decidedly of opinion that what is called lead poisoning in Holland is not always lead poisoning.

15,224. That is always stated in every country. Do I understand you to say that there is no lead poisoning at all in Holland?—In our painting shops; I do not say anything of the painting of ships.

15,225. But is there any lead poisoning amongst painters?—Yes, there is lead poisoning, but not amongst house painters.

15,226. Are there any statistics published of the incidence of lead poisoning amongst house painters?—No, not yet.

15,227. Did the Government know how many cases of lead poisoning had occurred in Holland amongst house painters in any particular year?—I do not know a case in the Hague.

15,228. But did the Government have any figures showing the amount of lead poisoning that had existed in any one year in Holland?—No.

15,229. Are there any published tables of the mortality amongst house painters in Holland?—Nothing more than you can find here in the report.

15,230. Are there any figures published, of any kind, of lead poisoning in Holland?—No, not more than you can find here in the report.

15,231. Then I shall confine my questions to you entirely to the final conclusions of the Dutch White Lead Commission. The first two clauses read as follows:—"Taking everything together, the Commission are of opinion that their labours lead to the following conclusions: (1) Zinc-white paints are much better able to withstand the action of

7 December 1911.]

Mr. NOOIJEN.

[Continued.]

" sulphuretted hydrogen gas than white-lead paints, which soon become motley and black. Where such gas occurs much, that is, near stinking canals in our cities, zinc-white paints can be substituted for white-lead paints with good results. (2) Zinc-white paints are not so well able to withstand frequent recurrent action of vapours containing sulphurous acid as white lead paints are. As the vapours occur in coal smoke of locomotives, steamers, tall chimneys, &c., zinc-white paint which is much exposed to such smoke, for instance, in railway stations, &c., will soon become corroded, and is certainly not able to replace white lead there." The Commission found that zinc-white paints did not stand well when exposed to the vapours of sulphurous acid?—Yes.

15,232. Would the same objection be valid against other substitutes for lead, such as iron-oxide paint, bituminous paints, graphite paints, silica paints?—There are no other substitutes than zinc oxide and zinc sulphide. We do not use graphite paint in the Netherlands. It is used in England.

15,233. I want to know whether the same objection would be valid against other substitutes for lead. I gave you a list of several substitutes. If you do not know, you had better say you do not know? White lead is an oxide paint, and zinc white is an oxide paint. They are both oxides. One is oxide of lead and the other is oxide of zinc.

15,234. Do you wish to say that the other paints are different things and do not compare with zinc and lead?—They are different things altogether.

15,235. What paint would be used in the instance where you say vapours and coal smoke of locomotives, steamers, and tall chimneys prevail? You say that zinc-white paint which is much exposed to such smoke will soon become corroded. Do you use white lead for such purposes?—For locomotives and such things you must use white lead, and not zinc white, because the zinc white may be black very soon.

15,236. I understand that white lead is used in railway stations in Holland?—Yes.

15,237. I understand that these substitutes are not used in railway stations?—That is right. You cannot use zinc white in stations, because the zinc white may be black very soon with the acid.

15,238. It is quite enough if you simply say that the paints I have read out do not compare, and you cannot give an answer. Clause 3 of the "Conclusions" reads: "Zinc-white paints applied on zinc, Portland cement, or iron (the latter having previously been provided with first coats of red oxide of lead or iron) are able to withstand the action of the open air during five years quite as well as white-lead paints, and can entirely replace the latter, provided they are not exposed to the action of vapours containing sulphurous acid"?—Yes, that is true.

15,239. Conclusion 4 states: "Zinc-white paints applied on wood, iron, zinc, Portland cement, and plaster, remain in an equally good condition in the interior of buildings as white-lead paints, and can entirely replace the latter there, provided they are not exposed much to vapours containing sulphurous acid or to great dampness." In conclusion 4, sulphurous acid is alluded to again, and a new difficulty is mentioned, namely, that of great dampness?—It is true what is here, but you cannot have an air without having sulphurous acid in the air. It is always in the air. Here in the cities you have sulphurous acid in the air. You will always have damp in the air. You will always have something in the air to take away the zinc white. I think that zinc white will not stand in the open air on account of the acids which are working into the zinc white.

15,240. Then you do not agree with the finding of this Commission?—No, I do not believe in the report.

15,241. Do you agree with conclusion No. 4?—I agree with that.

15,242. How long do you find white lead stand when the atmosphere is very humid?—I think five years.

15,243. Would you be surprised to hear that zinc white and lead paints have both been found to be equally

perishable under such conditions?—No, I am no surprised.

15,244. Is there a considerable amount of painting done in interiors where there is exposure to great dampness in Holland?—No.

15,245. Would it not therefore be only a small proportion of such interior painting which would be exposed to excessive humidity?—In my opinion, with inside work you never get the dampness that you get outside.

15,246. That is not what I have asked. I want to know whether there is any question of excessive dampness with regard to inside work?—No, there is no excessive dampness in inside work.

15,247. Conclusion No. 5 reads: "Zinc-white paints applied on wood, if not exposed much to the action of vapours containing sulphurous acid, will in many cases remain, during five years, in an equally good condition in the open air as white lead paints, and can replace the latter with good results. But in all places where accumulations of water remain during a long time, such as on window sills, the lower side of cornice work, &c., they will, even after three or four years, deteriorate in the course of a short period to such a degree that re-painting will become necessary for the preservation of the wood. In this respect, therefore, they are inferior to white lead paints"?—It is my opinion that this conclusion of the Commission was wrong concerning the first part of the question. I have seen the tests they have made.

15,248. Can you tell us how long the zinc-white paints and white-lead paints respectively will stand where they are applied on wood and exposed to excessive moisture, such as window sills?—You must make a difference between the north, south, east, and west sides. On the north side you never have the sun. The zinc white is not elastic, and white lead is elastic. Where you put zinc white on the north side you have never the sun, and it will stand in a wet country three years; but on the south side it will stand only one year and a half or two years. That makes a difference. You understand the north side of a building is always in a better condition—three years or two and a half for zinc white, and three or four years for white lead.

15,249. In what way are zinc-white paints inferior to white lead in these specially exposed positions?—Zinc white goes away; it does not keep the oil; the oil goes away, and after two years you have only powder, and you can brush it off with a dry brush.

15,250. Can you tell us what proportion of the whole of the paintwork will consist of painting on exterior woodwork which is liable to be exposed to accumulations of water? The Commission say that it is good, with the exception of window sills and cornice work. What proportion of the whole of the exterior painting do the window sills and the cornices form?—I think a sixth or an eighth part of a building.

15,251. The following is the text of conclusions 6, 7, and 8:—(6) Zinc-white paints such as the White Lead Commission have used successfully, cover at least equally well as the white-lead paints customary in this country. The zinc-white putty used by the White Lead Commission is quite as serviceable as ordinary white-lead putty. (7) Painting with zinc-white paint, such as the Commission used on new woodwork in the open air, is not dearer than painting with the white-lead paints customary for that purpose. (8) Painting on existing paintwork, so-called re-painting, in the open air, with zinc-white paints, such as the White Lead Commission used, is dearer than with the white-lead paints hitherto in use, inasmuch as the wood painted with zinc-white paints involves a greater expense in rendering it fit for the re-painting than does wood painted with white lead in rendering it fit for further painting with white lead. In the case of painted wood which is exposed to the open air, the possibility is moreover not excluded that where such wood is in an unfavourable condition of humidity (see under V.) (that is the window sills and cornice work) "it may have to be re-painted sooner than if it had been painted with white-lead paints. In these circumstances the cost

7 December 1911.]

Mr. NOOIJEN.

[Continued.]

" of maintenance of wood painted with zinc-white paint, and exposed to the open air, is further increased in connection with this shorter duration as compared with wood painted with white-lead paint." Is the increase of expense referred to in conclusion 8 a particularly serious one?—It is about a third more. The total extra cost is a third.

15,252. (*Mr. Sutherland.*) That includes labour?—Yes, wages.

15,253. (*Chairman.*) Do I understand that the increase of cost which would be entailed by the use of zinc white for outside painting arises entirely under three heads: (1) the additional preparation required on surfaces to be re-painted; (2) the possibility of earlier re-painting being necessary where the work is exposed to unfavourable conditions of humidity; and (3) the increased cost of maintenance of wood painted with zinc-white paint as compared with that painted with white lead?—Under No. 1 there is an increase in labour. It is a third.

15,254. What about No. 2?—White lead will stand five years, and zinc white three years.

15,255. What do you say with regard to No. 3?—My opinion is that this question is not of so much importance as Nos. 1 and 2. I cannot see that there is so much difference between painting with white lead and painting with white zinc. It cannot have much influence.

15,256. On what figure do you base your reply to question No. 1, that it will be a third extra cost?—They cannot put zinc-white paint on old white-lead paint unless they have first a special preparation for the paint to put it on. That is what I base my one-third of the cost on.

15,257. But if you use zinc-white paint entirely, the extra cost disappears?—Then there is no extra cost.

15,258. Conclusions 9 and 10 read: "(9) Lithopone paints cannot replace white-lead paints in the open air, because they have proved to be altogether unfit in this respect. (10) For paint work above water, first coats of oxide of iron have, during five years, proved to be quite as good and serviceable as first coats of red oxide of lead. For coats of paint under water, oxide of iron cannot be used. Coats of oxide of iron paint are cheaper than coats of red oxide of lead paint. When oxide of iron is used for the first coat much more technical ability is required for the painting of the covering coats than is the case when red oxide of lead is used for the first coat." The Commission tell us that oxide of iron cannot be used under water. Could not bituminous paints be used in such positions?—I do not know.

15,259. We have been told that the Orient Steamship Company and other shipping firms use a leadless paint on surfaces that will be ordinarily under water?—It is possible. I do not know.

15,260. I understand that you do not agree with the findings of the White Lead Commission?—No, not the 6th finding.

15,261. You say that you do not agree with the findings of the Commission in their final conclusion No. 6. What evidence did they take before they arrived at that very important decision?—The Commission made tests on black painted boards.

15,262. Do I understand you to say that the Commission did their work inadequately?—The Commission supplied paint to the workmen, and this paint was so thick that an ordinary painter in Holland could not use it. So my opinion is that it was not done in a practical way. The test may have been all right, but it was not done in a practical way as it was done by the painters in Holland.

15,263. How long was this Commission sitting?—Seven years.

15,264. Do you mean to say that during those seven years they did not give reasonable trials to leadless paints?—With the buildings? Yes, generally they made good tests. We believe that the workmen whom they put on the zinc-white paint given by the White Lead Commission (the workmen upon the ladders) put oil in it, because the zinc-white paint of the Commission was too thick to work with. We have

told our Minister that it is not possible to paint with the zinc-white paint of the Commission.

15,265. This Commission must take the findings of the Dutch Commission and weigh them very closely before they accept the opinions of a gentleman, however eminent he may be, and however sincere he may be, as conclusive where they are in conflict?—I only told you my opinion, and it is not only my opinion, but I can assure you that it is the opinion of the Association of Master House Painters in the Netherlands of more than 1,500 men, and all those men say the thing that I say now to you.

15,266. Did the Master Painters' Association have an opportunity of giving evidence before the Royal Commission?—No. The Commission did not ask us to come there.

15,267. Did you make any suggestion that you should be asked to give evidence?—Yes; we tried to get into the Commission to give our explanations.

15,268. And were they refused?—Yes, they were refused.

15,269. Did you have no representation on the Commission?—Only two, Mr. Kippel and Mr. Smith-Azn are master house-painters.

15,270. Did they sign the report?—Yes.

15,271. Did these members represent you on the Commission?—No.

15,272. Are they responsible men?—Yes.

15,273. And they signed the report?—Yes.

15,274. And they apparently agreed with the findings of the Commission?—They represent only their own opinions.

15,275. But apparently they agreed with all the findings of the Commission?—Those two master painters, Mr. Kippel and Mr. Smith-Azn, have done all the work in the seven years. I have seen it. I have often spoken to several members of the Commission, and they told me: "It is such a difficult thing for us that we must believe what the master painters say on the Commission." It is true what they say; it is a difficult thing. I have spoken to Mr. Metzelaar and other members, and they have told me that it is such a difficult thing. "We know nothing about the white lead question, but the master painters know all."

15,276. Are these master house painters very experienced men?—Yes.

15,277. And they are highly honourable gentlemen?—Yes.

15,278. And they have signed this report so much against the interests of your business?—Yes.

15,279. (*Sir Godfrey Baring.*) In fact, according to you, they inspired the report. They were the only two men that understood it, as I understand. Those two master painters practically drew up the report. Is that what you say?—Yes, that is true. Article VI., which I condemn so much, is signed by those two master painters, but it does not represent the ideas of the master painters of Holland.

15,280. (*Chairman.*) What made them sign a report which is so much opposed to the opinions of the majority of their fellow master painters?—I cannot say.

15,281. I understand that the Dutch Government contemplate issuing regulations to protect the workers from lead dangers?—They will make regulations, but they have not yet made regulations. They will come.

15,282. Have you any idea what those regulations will be?—Yes; I think the first will be that the dry white lead must be mixed with oil in the white lead manufactory. In Belgium it is forbidden to have dry white lead in the shops of the painters. They must mix it with oil in the white lead manufactory. That will be one regulation.

15,283. Would you prohibit dry rubbing down of painted surfaces?—Yes, certainly, because it makes dust.

15,284. When a first or priming coat of lead paint has to be rubbed down, before the second coat is applied, what would you use for rubbing down?—Pumice-stone wet in water—or you can do it in oil.

15,285. Would it not take a long time for the first coat to dry sufficiently to allow the wet process to be applied?—No; it is the same time, whether you do it wet or dry, and I should say that in a wet condition it

7 December 1911.]

Mr. NOOIJEN.

[Continued.]

is quicker. You have only to put your pumice-stone in the water.

15,286. But would not that rub the wet paint off?—No.

15,287. Have you ever tried rubbing down the first coat with the wet process?—Yes.

15,288. How long after the paint has been put on?—The following day.

15,289. But you could not do it before the following day?—No; the coat must be dried off. It takes 24 hours to dry. Where you have a white-lead coat, it will dry enough the next day for rubbing off with wet pumice-stone.

15,290. Then I suppose you would have to provide washing appliances for the workmen?—Yes.

15,291. Can you always supply towels and soap and nail-brushes?—Yes; that we do in our shops.

15,292. But when they are out on a job?—There is a law (I think it is a local law—it is a law of the Hague) that as soon as we begin to work in the house we must have water in the house for the w.c.'s and for washing the hands of the workmen, and the workmen tell their association if the master painter has forgotten it. He has only to say it to a policeman of the building police and the master painter has the same day a letter from our local government to do it. It costs nearly nothing. I have to pay for water in such cases to our local government  $4\frac{1}{2}$  guilders in three months, and then I have water enough.

15,293. (Mr. Sutherland.) On all your jobs?—Yes.

15,294. (Chairman.) Have you any factory inspectors in Holland?—Yes; factory inspectors come to see the workplaces.

15,295. How can they be quite sure that these rules will be carried out in private houses?—The workman is our friend. The workman is ordinarily the friend of the master. If the rules are not carried out the workman brings it to headquarters of the building police and the master is compelled to do it. The workman and the employer are not always at one. The workman knows that it is to his own interest that the rules should be carried out, and if they are not he will bring it before the building police, before whom it should be brought.

15,296. But are there any means of inspecting the work done in private houses to ensure that these rules are carried out?—Yes; a great lot is done. I see plenty in the Hague.

15,297. How many factories and workshops would these men have to inspect?—I cannot say. They are always walking in the streets, and they go in a place where they see workmen and they look, "Is all in good condition here?" and if it is not in good condition you have soon a letter from the local government. There may be 15 or 20 men.

15,298. Would you arrange to have a system of medical examination of the workers to see whether the men are suffering from the effects of working in lead dust or working with lead? In England and in other countries it is obligatory on the part of the employers to see that each of their workmen is examined once a month or once a quarter to see whether working in lead is affecting his health. I want to know whether that is one of the rules that it is proposed to introduce into Holland?—I cannot say.

15,299. Have proposed regulations, that would be applicable to the industry, been discussed by the master painters?—No, not yet. I hope that will come very soon, but we have none to-day.

15,300. I suppose the Government will take care that the special rules applied to the building trade would be as complete as those which are in vogue to-day in the potteries in Holland?—Yes.

15,301. (Dr. Collis.) I understand that you consider that this Commission was appointed because of political influence brought to bear by the working men?—That is my opinion.

15,302. Surely the working men had some reason for pressing the Government for this inquiry?—Yes, the white-lead poisoning. We have in the Netherlands white-lead poisoning, it is true, but it is not with the painters; it is the sailors. There are cases in Amsterdam and in Rotterdam where you have ships, and when

a ship comes from the sea and the sailors have nothing to do, then the captains of the ships say to the men, "You must remove the old paint"; and they do that work in a dry condition. It is dangerous work and they get white-lead poisoning. In the hospitals in Amsterdam and Rotterdam, you will find cases of white-lead poisoning among those sailors.

15,303. Have you any figures pointing to that fact? We want figures to prove the point?—No. I can get them for you when I go back to Holland.

15,304. (Chairman.) You said that there were no statistics at all. If you have any, I should like to have them?—Very well.

15,305. (Dr. Collis.) You think that the working men had some definite knowledge in their minds that made them press the Government to appoint the Commission?—There are those cases of white-lead poisoning that I told you of. Workmen do not talk about those questions. They know they do not apply to painters but to seamen. Do you know what I mean?

15,306. It appears to me that the working men must have proved to the Government of the Netherlands that there was an evil to be remedied, before the Government appointed the Commission, and that the danger was taken as proved in 1903?—The danger existed in 1903, and they have taken different precautions in manufactories and everywhere where white lead is used; and now all those precautions are taken the workmen are compelled to obey them.

15,307. Precautions in the manufacture of white lead, do you mean, or in the use of the paint?—In my workshop, when I have white lead to mix with oil, there is only one workman who does it, and for 20 years the same workman. He wears a respirator before his face. That man has been at work 20 years, and he is as well as we are. The only dangerous moment in my shop that can give lead poisoning is the moment when the white lead is taken out of the cask to put it into another one to mix it with oil. Then you can have white lead dust. That is the only moment, and for that moment I provide this respirator.

15,308. That is what I wanted to know. The Government were first acquainted with the danger before they appointed the Commission?—Yes.

15,309. (Mr. Sutherland.) You are connected with a large organisation of master painters?—Yes.

15,310. How many members are there?—1,300 or 1,400.

15,311. How many men, roughly, do you think they will employ?—I think 10,000 men.

15,312. An average of about eight men in each shop?—Yes.

15,313. You have a large insurance society in connection with your organisation?—Yes.

15,314. And you insure the men yourselves against accidents?—Yes.

15,315. Is white lead poisoning an accident under the Dutch law?—Yes, when poisoning is caused by accident.

15,316. You are the secretary of that insurance society?—Yes.

15,317. If you had any cases of white lead poisoning amongst the workers employed by your members, they would come under your notice?—We have not had one.

15,318. But if you had one, you would have to certify the accident?—Yes, and we would have to pay.

15,319. And your association is under the approval of the Government?—Yes.

15,320. It is really a private association connected with the State?—We deposit certain moneys with the Government, and they administer the insurance society. The Government pay, and then the society reimburses the Government.

15,321. Have you had any cases of lead poisoning out of these 14,000 men?—No. In the last nine years not one case has come to me.

15,322. They cannot get compensation without it comes through you?—It is impossible, because I am secretary, and I must sign.

15,323. For how long has lead poisoning been an accident in Dutch law?—Since 1903.

15,324. Did the Dutch White Lead Commission consider the question of lead poisoning?—Yes.

7 December 1911.]

Mr. NOOLJEN.

[Continued.]

15,325. But they had no instruction to consider the use of lead in relation to lead poisoning?—No.

15,326. Then the value of the evidence lies in the conclusions that they formed as to the value of different paints?—The aim of the Commission was to find something equal to white lead to prevent the use of white lead.

15,327. Now you have a very large experience of white lead and of zinc oxide?—Yes.

15,328. In your opinion, as a master painter with very large experience, can zinc oxide or lithopone take the place of white lead for outside work?—No, never.

15,329. Would you say that it could take the place of white lead if it were fortified or strengthened by the addition of varnish?—When you mix your zinc white for outside work with stand oil, then you make your paint stronger. You will have a very good paint, but it is always inferior to white lead.

15,330. And without the addition of varnish or stand oil, there is no comparison between the two paints?—No; it is absolutely impossible.

15,331. There is no alternative to white lead except zinc oxide and zinc sulphide for very light work?—No.

15,332. Have you any resolution of your members, in connection with your organisation, against the findings of this Commission?—Yes, that is what I told you.

15,333. Yes, but we understood you to say that that was the opinion of your members, but not a definitely passed resolution?—I have a resolution here in Dutch. The resolution was signed by the president and secretary of my association.

15,334. Was it passed after the report had been issued in 1909?—Yes, after that report. We have had two reports.

15,335. (Chairman.) What action was taken when the Commission was appointed, and while the Commission was sitting?—While the Commission were sitting, our association made the same tests as the Commission were making, and did not agree with the Commission's results. They got different results.

15,336. Did they communicate with the Commission, as a representative body, while they were sitting?—No.

15,337. Can you show us the resolutions?—Yes, I will let you have them.

15,338. Will you tell us how many people attended the meetings, and so on?—Yes, I can give you all that information.

15,339. (Mr. Sutherland.) The Chairman asked you, with regard to woodwork, as to the proportion of window sills and cornices, to which the Commission refer in their report; is it about an eighth?—When you have a house built with our Dutch bricks, then you have another proportion different from when you have a house as you have here.

15,340. With stucco?—Yes.

15,341. Though the proportion might be small, the window sills and cornices are places where the wet collects, and it is very important that they should be protected, and the Dutch Commission say that zinc paint is deficient on these very points?—It is important, although the proportion is small.

15,342. Do you not think that this report of the Commission is qualified very much by all sorts of reservations? For instance, "If not exposed much to the action of vapours containing sulphurous acid, zinc white paint applied on wood will in many cases remain during five years." That is a very important and serious qualification. In large cities like London, Manchester, Sheffield, and Birmingham, sulphurous acid is abundant in the air, and you could not put zinc paints outside without their being exposed to the action of the acid. In positions like stations, which they exclude, where you get the smoke from locomotives; they say that zinc will not stand. Therefore this report is a weak report for zinc, in my opinion, because it is qualified at all points with "if this and if that do not exist, then zinc white will do." I want to know your opinion as a master painter on that point?—Yes, it is very much qualified, and that is the opinion of all the members of our association.

15,343. (Chairman.) Were the two master painters on the Commission selected by the Masters' Association?—No, by the Government.

15,344. (Mr. Sutherland.) Would you tell the Committee what is the action of the sun on zinc paints on the outside, for instance?—When it has been there for a year and a half, the oil has gone away, and what you have over is a dry powder of zinc white, and, with a brush or your hands, you can take all the zinc white away. That is not the case with white lead—never.

15,345. Does not zinc-white paint also strip off?—Yes, because zinc white is not elastic. White-lead paint is always elastic. Zinc white is too strong, and, therefore, cracks.

15,346. The conditions of atmosphere in England are very much like the conditions in your own country, Holland?—Yes.

15,347. And we may take it that what would stand there, or otherwise, would be much the same here?—Yes.

15,348. Generally speaking?—Yes, generally. You have the same wet weather as we have.

15,349. When you said that the extra cost was a third more, did not you include the extra cost of the material—the paint?—The paint is not expensive, but the salaries of the men are expensive, and it is that that costs the money.

15,350. But zinc oxide in this country is very much more expensive than lead, and zinc oxide takes a great deal more oil and turpentine than lead takes?—Yes, but the wages are the most.

15,351. I am dealing with the materials now. With us, roughly, there is an increase of a third in material apart from the labour of applying the paint. Does that obtain with you? Do you get zinc white as cheaply as lead?—No. I think that zinc white will always be more expensive, because you must give more coats.

15,352. But I mean the raw material per hundred-weight?—Then it is not so expensive as white lead.

15,353. That is contrary to experience in this country?—The extra cost is not in materials.

15,354. Then the cost comes on the additional labour involved?—Yes, the wages.

15,355. Assuming that the work was painted with zinc white and had to be re-painted, is that any more expensive than painting with lead on lead?—You must always remove your old zinc white coats, because the old coat is hard and does not hold to the new coat.

15,356. So that, really, a great deal of the cost is in the preparation?—Yes, in the preparation.

15,357. You have had a very large experience of zinc paint, have you not?—Yes. We use zinc paint always for interior work. I think that I use 4,000 kilos a year of zinc white for interior work; and of white lead for exterior work, 6,000 kilos.

15,358. The painting in the Hague is very well done, is it not?—Yes. The places in the Netherlands where the best work is done are not Amsterdam or Rotterdam, but the Hague, Haarlem, Utrecht, and Arnhem.

15,359. The best painting work is done there?—The best painting work is done there.

15,360. You are quite convinced that there is nothing to take the place of white lead amongst white paints?—No; that is my opinion.

15,361. For outside work?—For outside work.

15,362. (Mr. Gardner.) We have been told that, in a country where the use of white lead was prohibited for inside work, we would never be able to see, so long as a man was using white lead outside, that he did not put it on inside. In the Netherlands they use zinc white inside and white lead outside. I want to know if there is no danger of the two things being mixed?—You cannot use the white lead inside for the last coat, because it is yellow in a few weeks. White lead asks a strong light. You can feel the difference. There is such a difference between the one and the other that the workmen cannot make a mistake.

15,363. Do the workmen in the Netherlands find any difficulty in manipulating zinc white as against white lead paint? Do the same workmen use both

7 December 1911.]

Mr. NOOIJEN.

[Continued.]

paints?—It is possible. I call at the work; it is a beautiful day: I say to my workmen, "Stop the work inside; we have sunshine now; you go outside," and the same man does it.

15,364. He changes from white lead to white zinc without the slightest difficulty?—Yes.

15,365. The one man uses both paints?—Yes.

15,366. We have had evidence that it takes two years to train a man to use zinc white?—No, that is not so.

15,367. Are your workmen trained from boyhood to the trade, or do they come into the trade as adults?—Yes. My father was a painter, and I was born in a painter's shop.

15,368. But are all the journeymen trained to the trade from boyhood?—Yes.

15,369. Still referring to the question of zinc white, you say that you cannot put zinc on the top of white lead without special preparation?—No, you must always take off the hard coat so that they shall properly unite.

15,370. But I am not speaking of putting zinc on zinc, but of putting zinc on white lead?—I understand. Some preparation has to be done to make the two go properly together, one on top of the other.

15,371. I understood from you that white lead paint was always elastic, no matter how old it is?—Yes, if you compare it with zinc white. I speak always in comparison with zinc white.

15,372. In painting with zinc white, your preparatory coats must always have zinc. You do not use white lead for bringing up the work before putting zinc on it?—We use white lead always for the first coats for inside and outside, and for inside after the second coat we continue with zinc white, and outside with white lead. The first coats are always white lead inside and outside.

15,373. You bring up the work from the beginning with white lead and then you change to zinc?—Yes, and we put white lead in our filler-up—in our putty.

15,374. I am rather interested to learn, I being a working painter, that you have had no lead poisoning among the painters in the Netherlands. You said that the work was highly finished. You have a good deal of sand-papering between coats?—I do not use sand-paper.

15,375. Glass-paper?—It leaves too much mark. It does not give a smooth surface.

15,376. How do you smooth down between the coats?—We take artificial pumice-stone and put it in water, and then we rub it off. I do not use sand-paper. I do not like sand-paper. I use Schumacher's Bimstein (artificial pumice-stone).

15,377. You find that it works quite well on the top of a coat of paint 24 hours' old?—Yes; but you must always use your white lead very thin. That is a rule, is it not?

15,378. It is not always done?—Thick work is bad work, is it not?

(Mr. Sutherland.) Yes, I should think you are quite right.

15,379. (Mr. Gardner.) You use a good deal of stand oil. It is what we should call fat oil. You use a good deal of it?—It is a very good material. In every Dutch shop you will find it. We make our enamel colours with it. When you mix white lead with it, you have the best exterior paint you can think of. It will last seven or eight years.

15,380. Has this oil been boiled?—Very, very long boiled. It is linseed oil.

15,381. It is really a boiled linseed oil exposed to the action of air?—Specially boiled.

(Mr. Sutherland.) It is specially boiled; steam boiled, I think.

15,382. (Mr. Gardner.) Then it would not be so thick. It practically comes to this, that that oil is almost equal to varnish, so that when you put on paint with stand oil in it is practically putting on a varnish paint?—No, that is not varnish. Varnish is made of other things.

15,383. Yes, I know, but for wearing power that is almost equal to a varnish, though there is no gum in it?—No gum.

15,384. Paint made up with that oil is practically a varnish paint?—You would not call it varnish.

15,385. But practically it is a varnish?—No, it is not a varnish practically. When you put this on a coat of colour your colour will change colour directly, and that is not the case when you have varnish. You must mix it with your colours. There is thick and thin stand oil.

15,386. Are they both boiled?—Yes; the dark one is longer boiled.

15,387. (Mr. Parsonage.) Zinc white takes longer to dry than lead paint?—Yes.

15,388. Considerably longer?—We always use driers.

15,389. Zinc white takes considerably longer to dry?—Yes.

15,390. And still between coats of zinc white you can rub down wet in 24 hours?—I have spoken of white lead, not zinc white. Zinc white is fat, and you must give to zinc white a longer time to dry, because it is fat.

15,391. In rubbing down interior work, that only applies to the first coat of white lead, where you can rub it down within 24 hours?—Yes.

15,392. After that coat, you cannot rub down within 24 hours on the zinc?—No. You would have to give it a longer time to dry.

15,393. You would have to leave the rubbing down altogether, or rub down dry with some fine paper?—No, always wet. When you have your zinc white of very good grade, it is not necessary to rub.

15,394. Do you find zinc white finer, when it is laid on, than lead, or a little coarser?—I have Belgian zinc white, and it is very fine.

15,395. But is it finer, in that it does not show the brush mark?—I have my machine, and it goes in the machine, and when it has passed the machine it is fine.

15,396. But is zinc white thinner in the brush work than white lead?—I can hear whether a man has zinc white or white lead, because white lead is dull in the brush and zinc white not. White lead makes a noise when he works with it; but zinc white not.

15,397. But can you get a better finish off the brush with zinc white than with white lead?—The best work to look at you make with zinc white. We mix our white lead with thin oil for the last coats for outside work. When you mix the stand oil in the white lead for outside work you get enamel paint, and you have also the same fine-looking work as zinc white for inside.

15,398. (Mr. Fell.) Have you done any carriage painting?—It happens that I do a little carriage work, but I am not a carriage painter.

15,399. Have you made any experiments in substitutes for white lead on carriages?—No. That is another branch of the trade. I will give you these papers (*handing some small green books to the Committee*).

15,400. (Mr. Robins.) I take it from you that the Dutch Commission was sitting for seven years?—Yes.

15,401. And during that time they made very careful experiments with white lead?—Yes.

15,402. In the course of your evidence you mentioned, with regard to the experiment with zinc white, that the zinc white was given in too thick a condition for the workmen to make good experiments?—Yes.

15,403. Seeing that the Commission sat for seven years, had it not time, after finding that such a blunder had been made, to make a good experiment with regard to zinc white, as careful experiments had been made with white lead?—We have in those two books told our minister that it is not possible to carry out the experiments with the thick paint.

15,404. How was it that such careful experiments were made by the Dutch Commission with white lead and such careless experiments made with zinc white, seeing that from your evidence the zinc white was not in a condition for the workmen to use, and the workmen had to add some other matter to it?—But the Commission did not say that. We say that. There is a great difference. Our association in the Netherlands say to the Dutch Commission that it is not possible to use the zinc white as it is said to have been used in the experiments.

F 1 2

7 December 1911.]

Mr. NOOLJEN.

[Continued.]

15,405. The Dutch Commission sat for seven years. When did it come to the knowledge of the Dutch master painters that these imperfect experiments had been made?—Here are the formulae of the paints. Some of the tests by the Government the master painters never saw.

15,406. (Chairman.) But is it not the fact that the Commission contained some very able representatives of the master painters?—Yes, that is true.

15,407. And would it not be the ordinary course of events for the Commission to consult the master painters on the Commission?—Yes.

15,408. Then do you think that the master painters on the Commission would have agreed to have a formula used which was not an accurate one?—In point of fact it is true that the formulae they used are unusable. I cannot say why they did it, but my opinion is that what they used is unusable.

15,409. Then do you mean that the master painters on the Commission were not paying proper attention to their duties? If this formula was wrong, why was it passed by the master painters on the Commission?—I do not know the reason.

15,410. The Commission drew up their final conclusions after they had received these two documents which you put in?—There are two preliminary reports and these are answers.

15,411. After these had been printed and sent to the minister, then the final conclusions were issued in 1909?—Yes.

15,412. Do you wish us to infer that the final conclusions which the Commission issued were based on a wrong formula?—Yes, that is my opinion. They did not think it necessary to refer any more to the matter, because they had already explained their views.

15,413. Notwithstanding that they were informed by these documents that they were going on wrong lines, they persisted in going against the advice they had received?—Yes.

15,414. (Dr. Collis.) Would you tell me how the right to compensation is established in the Netherlands when a man is suffering from lead poisoning?—If caused by an accident he has 70 per cent. of his wages weekly.

15,415. How does he establish his right to that 70 per cent.?—There is the insurance law.

15,416. How does he prove that he has a claim?—The doctor has to do it.

15,417. What doctor?—His doctor. When the doctor says, "You have white-lead poisoning," he has only to write a bill to get the compensation. It goes to the post office; it goes to Amsterdam, to the insurance fund of the Netherlands. Every week he has, on the declaration of the doctor, 70 per cent. of his wages.

15,418. Is it the certificate of his own private doctor?—The doctor of the Government comes and inspects.

The witness withdrew.

Dr. COLLIS in the Chair.

Mr. ALBERT ROBERT RIVET examined.

15,437. Do you attend to-day as the representative of Messrs. T. and W. Farmiloe, Ltd., of Rochester, N. York?—Yes.

15,438. What is Messrs. Farmiloe's business?—We are colour manufacturers and paint grinders, and also merchants, of course.

15,439. Is your firm not represented by the witnesses nominated by the Colour, Paint, Oil, and Varnish Trades Association?—No. We belong to no association whatever in the paint and colour trade.

15,440. Is that why your firm wish you to give evidence to-day?—Yes. We are quite independent of any association.

15,440a. Do you grind both lead and zinc paints?—Yes.

15,419. Does the Government doctor see the man?—Yes.

15,420. If the Government doctor disagrees with the private doctor's opinion, would the man get compensation?—No. There is a court, and he can claim there.

15,421. It goes then before the court in that case?—Yes.

15,422. With regard to compensation, I understand that the Government pays the compensation, and you pay the money back to the Government?—Yes.

15,423. Does the Government issue any figures of the number of cases for which such compensation is paid?—Yes, every five years.

15,424. Do they separate the various trades?—Yes.

15,425. Can we have these figures?—Yes. I will send them to you—of the illnesses.

15,426. Are there other accidents, besides lead poisoning, that compensation must be paid for?—Yes, trade accidents. When a business comes after an accident it is paid.

15,427. Lead poisoning is an accident?—Yes.

15,428. I suppose that mercury, and phosphorus, and arsenic poisoning are also accidents?—Yes. There are accidents and trade illnesses.

15,429. Our law is just the same. We look at lead poisoning as an accident in the same way exactly under the Workmen's Compensation Act. What do you say with regard to arsenic, and phosphorus, and mercury? When we get the Government figures which you will send (I want to know exactly the figures referring to lead poisoning for the Netherlands), will the figures tell whether the lead poisoning occurred in the pottery trade or the house-painting trade, for instance?—Yes.

15,430. Have you looked at those figures at all?—I have them in my home, but it is such a big book that I have not had time to read it.

15,431. You do not know whether, outside your association, there have been cases of lead poisoning amongst house painters?—No. Nearly all the house painters in the Netherlands are members of our association.

15,432. (Mr. Sutherland.) Outside Amsterdam?—Yes, outside Amsterdam.

15,433. (Dr. Collis.) It is possible that those figures may contain casual painters, such as you have spoken of, as seamen painting a ship or some place on the dock?—Yes.

15,434. I want to make that quite clear?—Amsterdam is excepted.

15,435. Since 1903 has your practice in painting been as you now describe, to use zinc chiefly inside and lead chiefly outside?—Yes, always. In my father's shop it was so when I was a boy.

15,436. There has been no alteration since 1903, when the Compensation Act was passed?—No.

7 December 1911.]

Mr. ALBERT ROBERT RIVET.

[Continued.]

15,444. Both have increased, but, roughly, does the proportion remain the same?—Roughly, it is about the same.

15,445. Are these enamels all leadless?—Not wholly. We make an enamel that is not leadless. It is a white-lead enamel as a matter of fact. It is a comparatively new article with us, but we have done very well with it up to the present.

15,446. Are the leadless enamels mostly built up from zinc oxide?—Yes, practically all the good-class enamels are built up from zinc oxide. A certain number of enamels contain lithopone which is another form of zinc.

15,447. (Mr. Parsonage.) That is a question of cheapness?—It is merely a question of cheapness.

15,448. (Dr. Collis.) That is not lead oxide?—No. It is a double precipitation of sulphide of zinc and sulphate of barium. The lithopone usually used is 30 per cent. That is what is called red seal. Some use the cheaper seals containing 15 and 20 per cent. We only use the 30 per cent. We do not use it so much for oil paint as for water paint. A large amount of lithopone is used for water paint.

15,449. Are you at liberty to say where you obtain your zinc oxide from?—Yes.

15,450. At home or abroad?—Wholly abroad. I only know one manufacturer of zinc oxide in England, and he has not been manufacturing it for very long. He has been manufacturing zinc oxide for nearly two years. The samples he submitted to us we did not think were equal to the foreign.

15,451. You have not used it to any extent?—No. Our impression is that it is not as good. We get samples submitted to us. We are approached by manufacturers of every kind.

15,452. You have not found any manufacturer of zinc oxide in England whose product you considered satisfactory?—They cannot touch the Belgians or the Germans for quality, or the Americans for price.

15,453. Is the price of American zinc oxide below that of the German and Belgian?—Yes, it is below the price of zinc.

15,454. Do you think that if the demand for zinc oxide increased, it would not be possible for America to meet the demand?—Not at the price they sell it at now. At present American zinc oxide is about 23l. 10s. to 23l. 15s. a ton, against German red seal of the fair average quality, at about 30l. That is a syndicate price. There is an international syndicate that controls the price practically.

15,455. In your opinion, if the demand increased, the Americans could not continue to supply the material at the present price?—No; and I do not think they would if they could. If they had a wider market for that, they would probably put up their price. It is the ordinary question of supply and demand.

15,456. Are the American makers in any way controlled by the zinc combine?—That I could not say, but their agent in England is one of the agents of the combine.

15,457. You think that there may be a connection?—There may be a connection. The American zinc oxide is inferior in quality to the German. Sometimes it contains a certain proportion of lead. It is a leady zinc.

15,458. When it contains a certain proportion of lead what is the effect?—That is bad. It spoils the colour and does not improve the body.

15,459. How much lead is there in the American zinc?—It varies.

15,460. Have you an idea of the proportion?—It varies from  $\frac{1}{2}$  to 2 per cent. Sometimes you get American oxides practically free from lead—99 $\frac{1}{2}$  per cent.

15,461. As far as you are aware, 2 per cent. would be an upward limit?—So far as our experience goes. A lot of this stuff goes for export, and we do not do an export zinc trade; 95 per cent. of our trade is home trade with the painters of this country.

15,462. Do you consider the mixing, or knocking up, of paints by the painters to be a dangerous process when they are using lead?—Yes, I think it is open to a certain amount of danger to painters. It adds to the

danger. There is danger in handling lead, undoubtedly, and the more they handle it the greater the danger is likely to be.

15,463. How would you remove that danger?—I certainly think that if the painters were to purchase the paint ready mixed it would minimise the danger to a certain extent. There is a much larger market now in ready-mixed lead paints than ever there was. A good many people have taken them up. We were one of the first to offer a ready-mixed paint for decorators; that is to say, an absolutely genuine paint, and we are selling a very largely increased quantity of it.

15,464. What is the proportion of pigment, either zinc or lead, that you sell in ready-mixed paints, as compared with the amount that you sell dry?—We do not sell any dry. In oil, you mean—in paste form?

15,465. Yes?—At present I should say we sell about 20 per cent. ready mixed.

15,466. Ready for use?—Yes. Two years ago we did not sell more than 10 per cent., but our trade in ready-mixed paint we find has increased very considerably. Taking roughly the figures for the last three years, without giving any amounts, they are as 5, 8, and 11. It has practically doubled in two years.

15,467. The amount of ready-mixed paint has doubled?—Yes, it has doubled. That is largely lead paint, but not wholly.

15,468. Has the sale of paste paint diminished in the same proportion at the same time?—That has not diminished in the same proportion, because our trade has rather increased, taking it all round. You must allow a certain amount for the general increase of trade. Taking two years ago, I should say, speaking roughly, we sold about 12 $\frac{1}{2}$  per cent. Now we sell, roughly speaking, about 20 per cent. We have sold double the quantity of ready-mixed paints, but it has not doubled the percentage, because our general trade has increased also, and that must be taken into consideration. Had the increased sale of ready-mixed paints meant doubling the percentage, the figures would have gone from 12 $\frac{1}{2}$  to 25. I am only giving rough figures.

15,469. Is it your opinion that for certain outside work lead is the most satisfactory paint?—Undoubtedly. Where a white paint is required, without the slightest doubt, in my opinion, white lead is, for outside purposes, for protective purposes, putting the question of decoration on one side, the best paint.

15,470. On what ground do you make that statement?—We base it on several grounds. If you go back to the last committee that was held about 18 years ago, I understand that the opinion of the committee then was that white lead for outside purposes was best. My own experience covers, roughly speaking, those 18 years. I am speaking of the committee of 1893. I have a copy here of the report.

15,471. You mean the Departmental Committee on Various Lead Industries?—Yes. May I read out the findings?

15,472. Yes?—“With regard to all these so-called ‘substitutes’ (this is referring to white lead) ‘the committee have invariably found that on closer inquiry of persons competent to judge, and unprejudiced on either side, the substance in question was in some particulars inferior; and they have come to the conclusion that there is at present no substitute that can take the place of carbonate of lead made by the old Dutch process.’” That was the finding of the committee. I can speak from 1893; that practically covers the period I have been connected with the trade. Naturally, we have our own experiments with white lead and with zinc white. We have experimented very largely.

15,473. What comparative trials have you made?—We made comparative trials on boards on our building at Westminster. One portion was painted wholly with white lead paint; another portion with a mixture of white lead and zinc paint, half and half; another portion with a mixture of 25 per cent. of zinc and 75 per cent. of lead, another with 75 per cent. of zinc and 25 per cent. of lead, and another wholly with zinc. That is to say, five different portions. After

7 December 1911.]

MR. ALBERT ROBERT RIVET.

[Continued.]

the work had been exposed for what we considered a considerable time, that is to say 15 months, we examined the building, and in our opinion the white lead had undoubtedly stood the best. This was at the top of our own factory at Westminster, a place which is certainly subject to a very considerable amount of dirt, dust, and smoke. The next best was the pure zinc. The various mixtures we found were bad. They were the worst of the lot. There was not much to choose between the different proportions. The 50-50 was fair, but the other two were bad. After white lead the zinc was the next best.

15,474. (*Mr. Sutherland.*) Zinc oxide?—Pure zinc oxide, mixed with linseed oil and turpentine and the proper driers. We did not use lead driers. The reason why we made these experiments so thoroughly was that eight or nine years ago an interest was acquired by some Americans in two firms in this country, and they put on the market paints which they described as being scientific combinations of lead and zinc. They sold a pretty considerable amount of this. Our travellers heard of this and reported it to us, and we made these experiments accordingly. We found, 15 or 18 months after, that our customers were persistently asking us, where our white lead paint was concerned, whether it contained any zinc or lithopone—mainly whether it contained zinc. They asked the question to such an extent that we ultimately put a guarantee on our white lead paint that it contained no zinc, lithopone or any other admixture. We found that we had to emphasise it, because there was a considerable amount of trouble over these mixed zinc and lead paints, and the customers were continually asking about it. Both these firms that I have referred to informed me (I do not know whether it is fair to give their names, the information being given in conversation) that, so far as their outside paint was concerned, they had dropped the zinc altogether and substituted for it nothing else but a pure white lead paint.

15,475. (*Dr. Collis.*) Would you say that the pure zinc paint and the pure lead paint gave somewhat similar results?—No. I say that the lead was undoubtedly the best, but the next best was the zinc. The pure zinc was better than the mixtures, but not so good as the lead.

15,476. What was the comparative price of the two paints as used by you at Westminster?—Roughly speaking, the comparative price was 22s. a cwt. and 34l. a ton. The difference is accounted for by the question of oil and turps.

15,477. Which is which?—22s. a cwt. lead, and 34l. per ton zinc.

15,478. Could you give us a figure in gallons of paint ready made up? Lead weighs heavier than zinc. Or a comparison per square would suit us better?—Do you mean per square with one coat or the solid job?

15,479. Taking these tests, what do you say?—I could not give the exact figures out of my head.

15,480. They are no good unless they are correct?—I could not give correct figures, but I can answer in this way—that per gallon the zinc would have cost more money, because there was more oil in it. I could not give the exact difference offhand.

15,481. You exposed these for 15 months, you say?—Yes.

15,482. (*Mr. Sutherland.*) From when?—They started in July and finished in October the next year.

15,483. July of what year?—I could not give you the exact year. It covered 15 months. It covered the whole of two summers and one winter. That was our object. We were not testing covering power then, but testing durability.

15,484. (*Dr. Collis.*) Other witnesses have said that it is possible to make satisfactory paints without lead?—Yes, there are plenty of satisfactory paints without lead, particularly if they are not white. Oxide of iron will give very satisfactory paint for ironwork.

15,485. But if you are dealing with white paint, do you think it possible, though not at the same cost?—I think it quite possible, but not at the same cost, and not with the same durability. One of the reasons why zinc white costs more than white lead is, that it is

bound to take more oil. You cannot work zinc white with the same amount of oil as you can white lead. You cannot grind zinc white with the same amount of oil as you can white lead. You can grind white lead with as low as 7 per cent. of oil, but you want from 12 to 14 per cent. for zinc white. At the present time and for many years past now, the price of oil has been considerably higher than the price of lead. I cannot say that it has been above the price of zinc.

15,486. We would like to get, if possible, at the comparative prices of the zinc white paints, such as you say you used in your tests, and the lead white paints; and then we would like to know the respective values of these two paints for protective purposes outside. Could you give us details with regard to how soon a surface painted with pure zinc white and one painted with pure lead white would require renewing?—It would be impossible to give anything like accurate details, because the conditions vary so very, very largely—conditions of position, conditions with regard to sun—whether north, south, east or west.

15,487. Imagine for this purpose that the conditions are the same, how long would good zinc white paint last outside under similar conditions compared with good lead white paint, taking a north exposure or exposure to the south, or whatever you like?—That is beyond my province. I cannot tell you.

15,488. I will not press it. If the Committee should consider the evidence strong enough to justify them in prohibiting or closely restricting the use of lead, how would that affect your firm's business?—It would not affect us.

15,489. Would it not?—I suppose it would at first, if the Committee did that. At first, there would be an internal disorganisation; but so far as the market is concerned, it would not affect us at all.

15,490. Is the machinery required for grinding zinc paint different to any extent from the machinery required for grinding lead paint?—Not to any great extent. There would be a difference in the speed of the rollers, and you would have to use a different kind of pugging mills. An ordinary pug mill will do for white lead, but for zinc white the most satisfactory way is to use an edge runner pug mill. To turn our white lead machinery into machinery to deal with zinc white would certainly cost us a certain amount of money.

15,491. Would it be a large consideration, taking the capital invested in the works?—That depends on what you call a large consideration. It might cost up to 1,000l. to alter the whole lot.

15,492. That may be a lot to some, but not to others; not to you, for instance?—No, I do not suppose that 1,000l. would mean much to us in a sense, but it would cost a certain amount to make the alteration.

15,493. (*Mr. Mason.*) Could you give the percentage, taking the present value of the machinery?—It would mean, roughly speaking, a lot of machinery; I should say 25 per cent.

15,494. (*Dr. Collis.*) Twenty-five per cent. on the present capital value of the machinery?—I should think so.

15,495. Have you studied the relative covering powers of zinc and lead paints?—Yes. It all depends on what you mean by covering power. We do not understand spreading power by covering power, but we understand obliterating power, that is to say, the number of coats or the amount of stuff required to make a solid job. If you treat white lead and zinc white in identically the same fashion as a paint, roughly speaking, in our opinion we reckon five coats of zinc white equal to three coats of white lead. I am not speaking of enamels. The cost of putting on five coats would be considerably more than the cost of putting on three, and the labour is perhaps the biggest item in painting. After a little experience a painter could possibly put on a coat of zinc as well as he could white lead.

15,496.-7. If you cover a surface with a coat of lead paint or with one of the five coats of zinc paint that you are speaking of, coat for coat, which costs the

7. December 1911.]

MR. ALBERT ROBERT RIVET.

[Continued.]

more?—Coat for coat, I should say the zinc white costs more.

15,498. Then there is the labour of putting on five coats as against three?—Yes.

15,499. Have you any opinion on the covering power of zinc sulphide?—Absolutely pure zinc sulphide by itself, which is not really a commercial article at present, has a bigger obliterating power than white lead or any other pigment I have ever seen. I could not speak as to its durability. Some time ago a syndicate was formed for the starting of a sulphide of zinc factory in this country, and they submitted samples of the pure sulphide, which we tried and tested in our ordinary manner. So far as the obliterating power is concerned, the zinc sulphide had bigger obliterating power than white lead, but its colour turned very badly immediately. Whether that was because it was manufactured on a small scale or not I could not say, but the sample we tried lost its colour and turned a sort of peculiar grey. I am speaking from information which I have not had long. I have not gone into it.

15,500. (Mr. Mason.) How soon did it turn colour? You say immediately. Was it in two or three days?—It turned to a kind of grey colour in about a couple of days. That is pure zinc sulphide. I know of nobody manufacturing it at all. The only people I have heard of, I heard of from the man who offered it to us. He said that Sollvay, of Belgium, had taken it up. I have heard since that they have dropped it, but whether that is true or not I could not say. I simply say that sulphide of zinc by itself has greater covering power than white lead, but its cost would be considerably higher than that of ordinary zinc oxide.

15,501. (Dr. Collis.) When combined with other things like barium sulphate, what is its covering power then?—It is poor. That is lithopone pure and simple. They generally use 30 per cent. A mixture of 30 per cent of zinc sulphide and 70 per cent of barium sulphate has nothing like the covering power of white lead and the covering power of zinc oxide.

15,502. (Mr. Sutherland.) You are speaking of obliterating power?—I am speaking of obliterating power. At the same time it does not keep its colour.

15,503. (Dr. Collis.) Are you speaking of inside or outside?—Inside only. I have never heard of lithopone being used largely for outside. Some lithopone loses colour very rapidly. That is due to the fact of the free sulphur, I have always understood. Lithopone is found to be a very unsatisfactory article altogether. There are many makes on the market.

15,504. Your experience of mixtures of white lead and zinc appears to suggest that zinc paint does not gain at all by the presence in it of lead?—That is so. In our opinion, if you want to use a zinc paint, you should use a pure zinc paint; or if you want to use lead paint, you should use a genuine white lead. We have always held the idea that a pure article is better than a mixture of any kind, and the object of mixing white lead with zinc white I do not quite see. If you want to use the paint in a place where there is gas or anything of the sort, the presence of white lead will turn it black.

15,505. It has been suggested to us that the presence of lead in zinc paint adds a certain amount of the qualities that lead possesses to that paint without deteriorating it, but your experience is to the contrary?—Our experience is to the contrary, and there is the experience of the two firms that I have spoken of. In both cases they started with scientifically combined mixtures of zinc and white lead, and in both cases they dropped them for outside use.

15,506. If you were preparing paint without lead, would you have great difficulty in obtaining the various tints and colours that are required for decorative purposes?—You are speaking of wholly without lead, doing away with lead chromates?

15,507. For the moment?—You would find great difficulty in getting satisfactory colours, and they would be more fugitive. You can get any colour you like with aniline dye, but it will not last.

15,508. Suppose, however, lead was allowed to be used to the extent of about 5 per cent. solubility. Do

you know the Thorpe test of the solubility of lead?—No, I cannot say that I do.

15,509. Various lead pigments act differently with regard to solubility. Pure lead chromate has only about 1 or 2 per cent. of solubility?—It is fair to take a pure lead chromate.

15,510. Some of them have something else in them?—I am speaking of the best quality. You may get any quality you like with barytes.

15,511. If you were allowed to use a 5 per cent. solubility lead, would you then be able to obtain most of your colours required for decorative purposes?—Do you mean if you use chromes?

15,512. Five per cent. solubility would allow you to use pure lead chrome as freely as you wished. Red lead, on the other hand, has 100 per cent. solubility, and you could only use 5 per cent. of that?—That would bar the reds very largely.

15,513. Orange lead is to a similar extent soluble?—That would make it impossible to produce a range of reds without falling back on aniline dyes. It would mean fugitiveness. All the vermilionettes and Persian reds and permanent reds are made with a basis of orange and red lead. Alizarin aniline colours are rather less fugitive, though they are practically all fugitive.

15,514. The reds would be your difficulty?—A great difficulty. If you could use as much chromate as you liked, that could certainly deal with the yellows and the greens.

15,515. What do you say with regard to the nitrate?—That is used in the manufacture but not in the colour.

15,516. Have you had any cases at all of lead poisoning in your works?—Yes, from time to time we have.

15,517. You are under the regulations for the manufacture of paints and colours?—Yes.

15,518. Have you had much trouble in seeing that those regulations are fully carried out, not only by yourselves but by the workmen?—No, no difficulty at all.

15,519. With regard to the wearing of overalls and the medical examination, does everything run quite smoothly?—Yes, everything runs quite smoothly. All our men employed in the paint and colours, even if it is packing, are provided with overalls, and always have been. The bulk of the workmen are supplied with overalls; the paint and colour men with white overalls; and the others with blue overalls.

15,520. You have exhaust fans to remove all the dust?—Yes. We have had one or two cases of lead poisoning, but nothing very serious for years past.

15,521. You ascribe that to the care with which the regulations are carried out?—Undoubtedly.

15,522. From your knowledge (which, as you are entirely makers of lead paints, may not be large) do you think that it would be possible to enforce a similar code of regulations, modified, of course, by considerations of the trade, to the house-painting trade?—I should certainly think so, if the regulations are not made unnecessarily worrisome, so to speak. I should think that there would be no difficulty whatever in applying regulations, particularly with regard to the periodical medical inspection, which I think is the most important thing of the lot.

15,523. You know how difficult it is sometimes to get men to follow out regulations which are laid down even in their own interests; washing for one thing, and the wearing of overalls for another. Do you think that it would be possible to ensure that these two points were as fully followed out in the painting of private houses as it is possible to do in your factory?—I should think so. If the regulations are commonsense regulations, certainly 99 per cent. or more than that of the men would conform to them without any difficulty, I should think. We find no difficulty whatever with our workmen. They fall into them just as a matter of course once they understand them. One should not necessarily imagine that, because a regulation is made, workmen will kick against it. That is not our experience.

15,524. With regard to such a point as dust removal, do you think that that could also be dealt with?—Do you mean with regard to rubbing down?

F f 4

7 December 1911.]

Mr ALBERT ROBERT RIVET.

[Continued.]

15,525. Yes?—There is not a huge amount of rubbing down done in the painting trade. I do not understand very much about the coach-building trade. In many cases, if it is wet-pumiced, I should think it would produce as good an effect.

15,526. Some of the master painters have told us that they do not see their way to getting rid entirely of dry rubbing down?—That is largely a question of producing a fine job. I do not think that the difference between a job produced by wet-pumicing and a job produced by dry rubbing down is so great that there would be much objection to doing away with dry rubbing down altogether.

15,527. They have rather said that they do not see their way to do it. Under those circumstances, do you think it possible for the dust to be removed under regulations in the same way as it is removed from the atmosphere in your factory?—We use a fan to remove it. I do not think it possible to fix a fan on all jobs to remove the dust. The men might be made to wear a respirator, as our men have to do when they are dealing with dry white lead.

15,528. The men want watching a bit to see that they do that?—Yes; but the number of cases where dry rubbing down is absolutely necessary and cannot be done away with is so small that it would be possible to have a reliable man to do the work, or to have it done under the foreman's eye.

15,529. (Mr. Sutherland.) Your firm have no special interest in either zinc or lead?—No, none at all.

15,530. And except for the internal dislocation of your works, if lead were abolished, you could turn to zinc?—Yes. We naturally have a greater interest in lead in a sense, because we consider it a superior article, and that is backed up by the opinion of our customers. We cater very, very largely, for what you might call the competitive painters' trade. If you take the midlands, or the south, or the east, or the west (not the north, because north of Liverpool we are not very well known) we go into practically every painters' shop in the country. They have to do competitive work. They have to do a job satisfactorily. They get so much for it, and in two or three years' time or four years' time, as the matter may be, they do it again. We have found no tendency on their part whatever to ask for zinc-white paint to replace white lead. If we had found it, we should have catered for it. We do a certain amount of zinc white and always have done, and should be quite willing to cater for any change. If we really thought that zinc was superior to lead with regard to cost and durability we should certainly push it.

15,531. Is not that the common judgment of the trade? Is not that an enormous factor in the case—that they have found and proved by prolonged experience that lead is the best thing?—That is certainly what our customers bear out. I am not speaking of the man who works under the specification of an architect, and who has to do what is put down in the specification, but of a man who has free choice in doing a job in white. He will use white lead.

15,532. Taking it broadly, the architectural profession specifies "Genuine white lead, pure linseed oil, and American turpentine"?—Yes, that is the architectural specification.

15,533. Generally, that is so?—Yes.

15,534. So that the judgment of the painting trade is reinforced by that of the architectural profession?—Yes.

15,535. Does the use of ready-mixed paints add to the cost of paint?—In our opinion, no, particularly where a small job is concerned. If you take the large contractors who have their own grinding mills, and so on, and practically a small paint factory, it probably pays them to make their own paint, but the ready-mixed paint costs the small painter no more if he buys it ready mixed, allowing for the time that it takes to knock-up the paint, than if he buys white lead and knocks it up. In fact, it costs rather less. Our "Nine Elms" paint is genuine white lead, pure linseed oil, pure American turpentine, and the best driers. It is a paint such as the painter mixes for himself with the articles if he buys them. The sale of that has

increased in the proportion of 5, 8, 11 in three years. It has more than doubled in three years' time. That goes to prove that the painter has found it just as cheap to buy the ready-mixed paint as to knock it up himself.

15,536. Do you think that a number of the well-known proprietary paints that are on the market could absolutely displace white lead? I am speaking of leadless proprietary paints?—No, I do not think they could, not without adding very largely to the cost.

15,537-9. When you spoke of American zinc oxide, were you referring to the product of the ————?—I do not know. We only get it on this side through the London agents.

15,540. You do not know if it is the ———— at all?—No. I wrote to America for the information, and I expect it every day, but I have not had it yet.

15,541. With regard to the trials on your buildings, you said that the white lead was the most satisfactory of the lot. Was there any defect, and if so, what was the defect?—There was no defect except the question of discoloration.

15,542. The substance was there?—Yes, the skin was there, the protection was there.

15,543. The experience of the Master House Painters' Association is that lead is the worst for colour in most cases, but the best for preserving?—Yes.

15,544. You say that five coats of zinc are equivalent to three coats of lead?—Yes, that is our experience. Anybody can put on a thick coat, but you do not get a satisfactory job with it. I am speaking of properly put-on paint. There should be a thin coat to begin with so that it binds properly together, and dries thoroughly right through. If you put on a thick coat, you get it all ropy to begin with. It does not dry properly, and with a further coat on it it will not bind.

15,545. That is an axiom in all good painting shops?—Thin coats, and many of them; because they dry thoroughly, and give better protection.

15,546. Now zinc sulphide, you said, is not a commercial article to-day?—Pure zinc sulphide is not offered commercially to the painting trade.

15,547. It is not put on the market?—It is not put on the market at present; whether it will be or not I do not know. A process was talked about, but the only people who took it up were the Belgian people, and they have since dropped it, I understand.

15,548. Did I understand you to say, in reply to the Chairman, that you prefer zinc oxide as a more stable paint without any lead in it whatever?—Yes; pure zinc oxide produces a better result in our opinion than a mixture of zinc and lead. It has its uses as a paint. One or two customers buy it. We sell it. In gasworks, particularly, near a gasometer, where they have an emanation of gas, they use it because it retains its colour better than lead paint under the circumstances.

15,549. We have been told by witnesses that 5 per cent. of lead in zinc oxide gives stability to it?—When you say 5 per cent. of lead, do you mean white lead?

15,550. Five per cent. inherent in the oxide. I am speaking of the direct process?—The Germans put a lot of that on the market, not so very long ago, made from the tailings of the zinc mines. It contained from 5 to 6 per cent. of sulphate of lead. We experimented with the product very largely, and our opinion was that it was no good, or not as good as zinc oxide. It was bad in colour and bad in body too. It was offered at a very low price, but undoubtedly had it possessed the marvellous qualities that they certainly tried to make people believe by the lectures that one or two of the German professors came and gave over here, I do not think that they would have sold it as cheaply as they did. They were selling it then under the price of white lead. They were offering it at 19l. a ton.

15,551. As against what for lead?—Lead is 20l. a ton now. It was then about 18l. or 19l. It was practically the same price. I do not think that there was anything in that lead-in-zinc question.

15,552. What do you think about 5 per cent. of oxide of lead?—The only oxides are the red, the grey, and the orange.

7 December 1911.]

Mr. ALBERT ROBERT RIVET.

[Continued.]

15,553. So far as I have gathered it has not been the suggestion to add 5 per cent. of lead to pure zinc, but to retain the natural amount of lead that is in. What do you say about adding 5 per cent. of white lead?—The addition of 5 per cent. of white lead is absolutely useless from the point of view of a paint.

15,554. It would not give stability to the zinc oxide?—It would not have any effect at all. With regard to the naturally produced leady zincs, they are bad as regards colour, and bad as paint, as I say.

15,555. In your opinion, is the extra cost of zinc paint over lead paint to be found in the larger amount of vehicle that it absorbs?—It is found in many things. First of all the cost of the dry material itself is larger, and if you remove white lead the cost of the dry material is likely to be larger still.

15,556. I was going to ask you about that?—At the present time linseed oil is very much dearer, and it has been, than white lead or zinc. You have to use a larger percentage of linseed oil to grind the zinc to produce the pulpy state, to produce the paste state, and secondly to thin it. A zinc paint ready for work contains more oil than lead paint ready for work.

15,557. Much more oil?—Much more oil.

15,558. Have you formed any idea what cost the oil would add to zinc paints over lead paints?—It depends entirely on the price of oil.

15,559. In either case the percentage would remain the same?—If oil is 35*l.* a ton at present and zinc is 30*l.*, you have 5*l.* a ton difference. If there is 25 per cent. of oil in the paint, that increases it about 2*s.* a ton. If you took lead paint with only 20 per cent., it would only increase it 1*l.* a ton. The difference between the price of oil and lead, and oil and zinc, being a varying quantity, the percentage would vary with the difference in price between lead and oil and zinc. If oil at any time were to go below the price of zinc (as it was in the old times—15*s.* a cwt.) zinc paint would probably come out cheaper than lead paint, but I do not think that we are likely to see oil down to 15*s.* That is one item. The price of dry zinc is higher, and always has been to my knowledge, than the price of dry lead.

15,560. (*Dr. Collis.*) Weight for weight?—Yes.

15,561. It goes further?—But it obliterates less. One cwt. will not cover so much as 1 cwt. of white lead. The opacity of white lead compared with the opacity of zinc white is greater than the proportion between the specific gravity of white lead and the specific gravity of white zinc. Although the specific gravity has a good lot to do with the opacity, that has not wholly to do with it. In the case of barytes the specific gravity is higher than that of zinc, but it has no opacity at all.

15,562. It is transparent?—Yes.

15,563. What in your opinion would be the position if lead were prohibited? What would be the effect on the paint trade?—If lead were prohibited, we should be entirely at the mercy of the foreigner so far as our raw materials were concerned. We should be entirely in the hands of foreign producers of zinc white. It would kill the English white lead industry, and we should have to depend on abroad for zinc. We cannot get away from the zinc white people. Wherever you turn they hold the mines. They hold the mines in this country. The Vieille Montagne Zinc White Company hold the mines.

15,564. What zinc mines have we?—There are several in Cumberland.

15,565. Not extensive?—No.

15,566. (*Mr. Sutherland.*) We have a source of supply in the Broken Hill Company?—The Broken Hill Company is already in conjunction with the German syndicate so far as the lead is concerned. The lead of the Broken Hill Company is sold in this market entirely by the Agent of the Metall-Gesellschaft in Frankfort. There is a combine, and all the mines are combined together. America is an exception. There is an agreement for working with them. The result of the prohibition of lead, in my opinion (it is merely an opinion), would be to kill the English factories, and would not replace them by anything at all.

15,567. Would it be impossible for us to get what we require for our industry here, unless there was a very long interval allowed between the pronouncement of prohibition and the operation of the law?—There would have to be a pretty considerable interval. Undoubtedly, this country absorbs a large amount of white lead. The figures are given at 68,000 to 70,000 tons a year for this country. I do not know the exact figures. I do not think that the zinc white manufacturers, without considerably extending their plant, could supply the market at once.

15,568. Are you speaking of the import of 68,000 to 70,000 tons?—I am speaking of what is used by the painters and grinders. A considerable amount is exported. I believe that the import is about 18,000 tons a year, the remainder being British production.

15,569. What is it worth?—At the present time it is worth about 300,000*l.* It varies very much.

15,570. The amounts that we get from our British possessions and from abroad practically balance?—White lead?

15,571. Yes?—We get no white lead from British possessions.

15,572. Yes. Statistics supplied by the London Chamber of Commerce show that they practically balance?—They must be wholly inaccurate.

(*Dr. Collis.*) Those were statistics of lead ore.

15,573. (*Mr. Sutherland.*) Yes. The imports of lead ore from foreign countries and from British possessions practically balance. The imports of zinc oxide from British possessions represent 400,000*l.*, and the other figure is about 376,000*l.* That is for 1910. Assuming that prohibition were put into force, what do you think would be a reasonable time to allow to make the necessary arrangements for coping with it?—I should say from three to five years.

15,574. If lead is prohibited, we shall have to have inspection to see that the prohibition is observed?—I should think so, certainly.

15,575. Would it not be better to try regulation and inspection before abolition, to see what effect that has on the mortality and cases of lead poisoning?—Undoubtedly. I think that the experience of lead factories, at any rate so far as we are concerned, is that regulations keep the lead poisoning down to very, very low limits indeed. I would suggest regulations if they are made simple, provided that they include the periodical medical examination, which I think is the most important part, and I certainly do not see very much difficulty in that, particularly as under the Insurance Bill every workman is going to have his own doctor.

15,576. Who were the Committee who issued the 1893 Report. Thomas Oliver was one?—James Henderson was the Chairman. He died. The members were Thomas Oliver, Arthur Pillans Laurie, Edward Gould, Henry James Cameron, and Harold John Tennant. Mr. Henderson died on the 13th July 1893. Mr. Laurie tendered his resignation on the 13th May 1893.

15,577. (*Mr. Rice.*) Do you think that the regulations which have been suggested to you, would increase the cost of the work?—I do not think that they would, to any great extent, once they were thoroughly got working, provided they are made simple. That is the only thing. If they are commonsense regulations, I see no reason why they should not be got to work quite easily.

15,578. You are aware that it is suggested that the expense of the medical examination, to which you have referred, should be borne by the employer?—I do not see the necessity of that. Under the Insurance Bill the man has his own doctor. I should have thought that it could have been grafted on to that.

15,579. (*Dr. Collis.*) That does not cover it?—I know that it does not cover it, but I do not see why it should not cover it. Surely in the case of lead poisoning, in a good many cases, if a man has slight traces and takes no notice of the symptoms, they will get worse. It seems to me that it would be saving money under the Insurance Bill if he went periodically to the doctor. If he had a book, and the doctor certified that he was free from lead poisoning, and he

7 December 1911.]

MR. ALBERT ROBERT RIVET.

[Continued.]

went to an employer; the employer could employ him. If he was not free from lead poisoning, he could be put to work where no lead is used. Some men have an absolute tendency to lead poisoning. We know from our own experience that some men, if they are in a factory for a few days, start getting the symptoms at once.

15,580. (*Mr. Rice.*) I understand that your answer to my question, "Are you aware that the expense of the medical examination will fall on the employer?" is that you do not see why it should, and that it should come under the Insurance Bill?—I was not aware of the fact that it was to be borne by the employer, but I say that it could be included in the duties of the doctors who attend the men under the Insurance Bill.

15,581. Are you aware that the employers would be compelled to supply overalls to the men, which the men supply themselves with now?—I was not aware of that. In our own factory we supply the men with overalls free of charge.

15,582. Are you aware that it is suggested that overalls should be supplied by the employer and periodically cleansed at his expense?—I was not aware of that.

15,583. Are you aware that it is suggested that hot water for the washing of hands should be provided on every job where a painter goes?—No. We are under one of the most stringent regulations with regard to the provision of hot water.

15,584. I am speaking of hot water for every job where a painter is working; so if you send him to paint this ceiling, you must make proper provision for hot water?—Or else make use of the existing hot water arrangements.

15,585. Now do you think that if regulations on these outlines were enforced, it would add to the cost of painting?—Yes, if they were carried out as you suggest, they would add to the cost of painting.

15,586. (*Dr. Collis.*) Your answer to me was hardly correct. I took it for granted that you knew that the employer would have to provide the overalls, and provide hot water, and pay for the medical examination and the installation for the removal of the dust. You answered that you thought it possible that these could be applied to the house-painting trade without difficulty. Would not you like to modify your answer?—I was not thinking of the question of expense then, but of the question of the possibility and difficulty. For instance, I understood that the master painters did supply overalls free to the men.

15,587. (*Mr. Sutherland.*) The men supply them?—I have no intimate knowledge of the subject. I never gave it very much thought, but I should have thought that the master painters did supply them.

15,588. (*Mr. Rice.*) It is not the custom to supply them, and it is not the custom to supply towels to any large extent, and soap and nail-brushes?—I believe that some firms do supply towels, and some do not.

15,589. These regulations, as outlined by me, must increase the cost of the work?—Undoubtedly, if you put it that way, they must.

15,590. Does it occur to you that in every case and every circumstance these regulations can be applied, such as the provision of hot water and nail-brushes?—Yes.

15,591. Cannot you conceive any case where hot water cannot be obtained?—That is rather a wide question. There is usually provision made on all jobs for cold water at any rate, is there not?

15,592. But hot water is the point?—I should have thought that if it is possible to have a temporary cold water supply on the place, it would be possible to have a temporary gas supply to provide the hot water.

15,593. And that would mean money?—Yes.

15,594. Then there is the question of a meal room being set apart. You have that?—Yes.

15,595. These regulations provide for a separate meal room for the men, so that they shall not take their meals in the rooms where they work, and shall not put their clothes where they work?—With regard to the majority of jobs, I take it that they are sufficiently near to the ordinary public means of getting food to get their meals.

15,596. That is going out for meals?—Yes.

15,597. Do you think that an employer would be fulfilling the regulations by pointing to a coffee house opposite as a means of complying with them?—I take it that the foreman would have to see the men off the job.

15,598. Does it not occur to you that there might be some difficulty about that in certain places and conditions?—Undoubtedly there would be difficulty in some conditions.

15,599. So that the regulations, now they have been explained to you, are not quite so easy to carry out as you at first contemplated?—I do not think that they offer any insuperable difficulties.

15,600. But my question is, are they quite so easy to carry out as you at first contemplated?—That is rather difficult to say. I say that there is no insuperable difficulty. I said it was possible before. I did not mention any degree of ease at all. Undoubtedly regulations of any kind entail trouble and a certain amount of expense.

15,601. My point is, are they quite so easy as you at first contemplated when you answered the Chairman's question. You have said already that you were not aware that the overalls had to be supplied at the employer's expense?—That is not a question of ease, but of expense. Perhaps I may say that they are not so easy as they seem at the first blush. I certainly think that the cost of painting would be greatly increased if you prohibited white lead.

15,602. (*Mr. Parsonage.*) A great deal of your mixed paint is supplied to retail shops to sell again?—The bulk of our trade is done with decorators. I am speaking now of our absolutely genuine white lead paint with a guarantee on it.

15,603. You supply a great quantity of ready-mixed paint to retail shops?—Yes, but not what we call a genuine white lead paint.

15,604. Do you supply house-painting firms in London with ready-mixed white paint?—Yes, very largely.

15,605. Firms in the West End of London?—Yes, several firms in the West End of London.

15,606. You are not a practical painter?—No.

15,607. And have no knowledge of how painting work is carried on?—I would not like to say "no knowledge."

15,608. Very little?—I have no technical knowledge, or no trade knowledge.

15,609. And yet you say that dry rubbing down is a very small quantity of the work, and can be dispensed with. Is that an idea, or have you any practical knowledge to go upon when you make that statement?—That is the opinion I have had from such painters as I have asked.

15,610. Recently?—Yes, recently. I am speaking of ordinary painting and decorating.

15,611. It is an impossibility to rub down newly-painted surfaces by the wet process. There must be dry rubbing down?—But it is not necessary to rub down in every case, is it?

15,612. In nearly every case for inside work, if it is to be decent work, you glass-paper down between the coats. With regard to regulations, you think that there should not be great difficulty in carrying them out?—It all depends on what you call great difficulty. I do not think that there should be any insuperable difficulty in carrying them out in a large number of cases.

15,613. Supposing that dry rubbing down was entirely prohibited, how would you be able to prevent it?—I take it that it would rest with the master painter to see that the instructions were carried out.

15,614. But it would be to his interest to use it?—You mean that he would break the law?

15,615. It is the master painter we want to deal with?—I see.

15,616. (*Dr. Collis.*) We have different factory inspectors to see that paint and colour people do not break the law?—Yes, but I do not know that they are very necessary.

15,617. (*Mr. Parsonage.*) An inspector could not enter a private house?—Is there no possibility of giving him power to enter a private house?

7 December 1911.]

Mr. ALBERT ROBERT RIVET.

[Continued.]

15,618. (*Chairman.*) Did you see recently the outcry on the Insurance Bill when it was suggested that inspectors should have the power to enter private houses to see whether any persons were employed there?—Yes.

15,619. You saw the rapidity with which that was modified in the Bill. It was immediately modified?—But still it seems to me that when men are going in and out of premises and work is being carried on, an inspector going there would not be objected to very much.

15,620. (*Mr. Parsonage.*) But in the season in London there are hundreds of painting jobs going on. Some only last two or three days. Sometimes a shop is painted at night after it is closed, ready for opening the next morning. How would the inspector know where work was being done?—I do not say that it is impossible to avoid regulations; it is always possible to avoid any regulations, but if the master painters were under penalty they would see that the regulations were carried out.

15,621. If the master painter has 20 to 40 jobs at a time, he will not go round to see that the regulations are carried out, especially if it is to his own financial interest not to carry them out?—I would not like to express an opinion on that—if he deliberately, for his own ends and purposes, broke the law. I have not such a bad opinion of the master painters as all that. I think that they would do their best to carry the regulations out.

15,622. (*Dr. Collis.*) I would suggest the precedent of factory inspectors. Whenever a law is passed, a great deal of care is taken to see that the law is carried out. It is no good asking Parliament to pass regulations if we do not at the same time say how they can be enforced. The precedent of factory inspectors must be the one to which we turn. Do you think that it would be possible, as I asked you originally, for regulations to be enforced in the house-painting trade in the same way as they are enforced within factory walls? I think you answered my question rather hastily?—Do you mean by means of inspectors?

15,623. Could the whole scheme be enforced in the same way in the house-painting trade as it is enforced within factory walls?—I certainly think that, if everybody did his best, there should be no difficulty in enforcing them. If people deliberately start out with the intention of evading them, it is always possible to break the laws.

15,624. If you are right, the whole of the factory inspection staff could be dismissed to-morrow?—As far as our experience goes, in factories at any rate, regulations go on automatically once the men understand them.

15,625. But prosecutions occur annually, in no small numbers against both employers and men for breach of regulations in factories?—Yes.

15,626. (*Mr. Gardner.*) You expressed the opinion that dry rubbing down could be done away with. Of course, we find it necessary to rub down between coats. Would you say how long, in your opinion, it would take a coat of oil paint to dry so that pumice-stone and water could be applied to it?—No; I am not a practical painter. I could not give an opinion on that. That is a purely technical question.

15,627. You spoke about applying a thin coat of paint. Do you mean by that that it would be thinned up by the medium?—No; I mean brushed out thin.

15,628. I wanted to make that point clear. If we say to ordinary people a thin coat of paint, they think it is thinned paint?—No, I do not mean a thinned-down paint.

15,629. That would kill the body?—Yes. I mean a paint brushed out thin.

15,630. (*Mr. Robins.*) You said that, if lead was prohibited, you thought that three to five years should elapse. In your opinion what time should elapse before the abolition of the use of dry white lead?—Dry white lead is very little used in this country by painters, surely.

15,631. But that will have to be prohibited along with white lead. Would you make any difference in the time for the abolition?—No. I take white lead to cover both the dry and the paste lead. It has to be made dry before it is made into paste, in nine cases out of ten, not in every case.

15,632. It is brought into the painter's shop. Dry white lead is used by the painter?—Not in the south of England, surely.

15,633. It is used by a considerable number of coach-makers?—I was not speaking of them. That is so in the case of flake white, for instance.

15,634. What time should elapse?—The use of dry white lead in a shop should be abolished altogether except under very stringent regulations.

15,635. At once?—Undoubtedly. It is a very, very dangerous thing for anybody to handle unless he has the apparatus that we have ourselves.

The witness withdrew.

## TWENTY-FOURTH DAY.

Wednesday, 13th December 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman.*)

Lord HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. O. FELL.  
Mr. O. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (*Acting Secretary.*)

Mr. ALBERT ROBERT RIVET recalled and further examined.

15,636. (*Mr. Sutherland.*) Your firm have supplied materials to the Office of Works?—Yes.

15,637. I do not know how far your experience goes, but could you inform the Committee what you have supplied during the present year, and where you have supplied it to?—You mean with reference to white lead only?

15,638. Yes?—104 cwt. 1 qr. 3 lbs., equal to 5 tons 4 cwt. It was delivered to the following places:

the Menai Bridge, 98 cwt. 1 qr. 3 lbs.—4 tons 18 cwt. 1 qr. 3 lbs.—and 6 cwt. to their own stores. That is so far as the Office of Works is concerned personally. The general Office of Works contract is held by a contractor, who started (the new contractor) and took over the contract in April this year. The contractors were changed. We obtained the contract from the contractors for the supply of colours, glass, and other things. We supplied them with white lead, 5 tons

13 December 1911.]

MR. ALBERT ROBERT RIVET.

[Continued.]

15 cwt., between the beginning of April and the end of November. I have not taken the December figures out, because I did not think it was necessary.

15,639. Is that the London district?—The London district pure and simple.

15,640. (*Mr. Parsonage.*) Would this lead be for the Office of Works?—Yes; it was delivered to the Office of Works jobs absolutely.

15,641. The contractors have other works?—Yes. The Office of Works have special forms. We have supplied the contractor with other white lead, but that would refer to his own jobs. This went on to the Office of Works jobs, and was signed for by the foreman in charge.

15,642. (*Mr. Sutherland.*) Have you a list of the places that they were delivered to?—Yes. I will read them out as I have them down: "The British Museum; Horse Guards; Victoria and Albert Museum; Church Street, Islington; King Edward VII. Buildings; Tower of London; Regents Park; Savings Bank; Somerset House."

15,643. (*Chairman.*) Where was the Savings Bank?—I could not say. I thought it was one job. I did not take a note of the address: "Chelsea Hospital; Buckingham Palace; St. James' Palace; the Royal Mews, near Buckingham Palace." That comes under a special job. "Natural History Museum; Hyde Park Store Yard; the General Post Office; the Houses of

"Parliament; Hercules Buildings; Custom House, Greenwich; and Kensington Palace."

15,644. 5 tons 15 cwt. amongst the whole of those places?—Yes—from April to November, it is 5½ tons.

15,645. (*Mr. Sutherland.*) Do you supply the contractor with all his stuff for his jobs?—I could not say. We supply them with a large number of small orders, but whether they get the whole from us I could not say. The preceding contractor used to draw from his own store, and I know we never had the whole of his supplies then.

15,646. You simply deliver to him?—Yes, we simply deliver to him.

15,647. In the orders for these, does the Office of Works operate in special compartments, or does it all come under one administration?—With reference to these contractor's orders?

15,648. Yes. Do they come through the contractor only?—They come through the contractor only.

15,649. On the Office of Works forms?—Yes, on the special forms for the Office of Works jobs.

15,650. (*Mr. Parsonage.*) Can you give us the dates at which these deliveries were made?—They are practically daily deliveries between April and November this year.

15,651. Have there been deliveries in the last month?—Yes, and also in December. I did not include this month, as a matter of fact.

The witness withdrew.

MR. KENNETH WELDON GOADBY, D.P.H. (Cambridge), M.R.C.S., L.R.C.P., examined.

15,652. (*Chairman.*) Are you a consulting pathologist, of Hurley Street, London?—I am.

15,653. Have you devoted special attention to questions of lead poisoning?—Yes, I have, in a number of directions, both from the clinical side and from the experimental side as well, in various large lead industries. In one of the lead industries I am appointed surgeon; and also in the progress of my ordinary professional work, I have had a considerable amount of consulting work to do with regard to lead poisoning in painters, quite apart from the work in connection with the appointment of surgeon of which I have spoken.

15,654. You have practical knowledge, then, of lead industries generally?—Generally.

15,655. To what extent have your investigations been published?—The investigations so far—the first resumé of my pathological work on lead poisoning—was published in the "Lancet" three years ago. I also published papers in the "International Congress of Medicine" at Buda Pesth two years ago, and in the "Congress of Hygiene" at Leeds; and there is a considerable amount of my evidence as appendices and otherwise in the report issued by the Committee on Lead, &c., in Potteries, of which you were chairman. Besides that, there are a number of original papers in the literature, which I do not think I need make a list of. In addition, at the present time I am engaged in the publication of a work on lead poisoning in conjunction with Dr. T. M. Legge, who is H.M. Medical Inspector of Factories. The book, as a matter of fact, is in manuscript at the present time, and I hope that it will shortly be published.

15,656. Have you carried out special investigations as to the causation of plumbism among painters?—I have done so, and these investigations have been carried out both chemically and pathologically.

15,657. Did your inquiry include examination of mixed paints as used by the painter?—Yes.

15,658. What paints did you use in your experiments?—White lead paint, lithopone, zinc sulphide paint, zinc oxide, and basic lead sulphate paints, the latter commonly known as Purex.

15,659. Did you also experiment with the constituents of those paints separately?—Yes. It was found necessary in the course of the experiments to determine, if possible, by direct physiological and chemical experiments, which particular constituent of the paint was responsible for the poisoning that was

produced when paint fumes were inhaled by animals under certain definite conditions.

15,660. Did your chemical investigations deal with the question of emanations?—Yes, most decidedly. The attempt was made first of all to find if emanations were given off at all, from paints generally, and from special forms of paint, that is to say, the paints that I have premised two questions back; and the nature of the emanations given off. There were two main types experimented with lead paint and zinc paint of definite composition.

15,661. Did you also experiment with the metallic bases of paints?—Yes. The base of the paint, that is to say, the metallic salt, as for instance, lead oxide or litharge, hydrated lead carbonate or white lead, zinc oxide, and zinc sulphide, were tested by themselves, and also in combination with each of the constituents of which the paint was compounded, so as to have the experiments as little vitiated as possible by the intercurrent.

15,662. What constituents did you test besides the metallic salts?—Turpentine and linseed oil; various forms of turpentine, in fact, and the driers, turpentine and lead acetate, particularly the combination with lead acetate. I also tried (it comes under the next heading) certain volatile organic compounds which are used as paint removers, and many of which are used also to mix with paint—that is the various types of petrol. It is rather important that they should be mentioned as belonging to the constituents of paint.

15,663. In the chemical investigations, did you attempt to collect any emanations given off in the drying of paint, and to determine if those emanations contained lead?—I did.

15,664. Will you describe the apparatus with which your chemical experiments were made?—The apparatus consisted of a long tube similar to that made use of by Professor Baly—a glass tube 5 feet 6 inches in length, and about 3 inches in internal diameter. This was closed at either end by a tightly-fitting cork. The tube was filled with the substance tested—white lead and oil, zinc and oil, as the two bases of paints. The tube was then put inside a second tube, round which was wound an electric wire, so that the tube could be heated by means of an electric current, and by interposing resistances in the circuit, the temperature could be raised to anything desired. To make quite certain that the temperature was constant, a thermo-couple was inserted into the tube.

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

15,665. (*Mr. Sutherland.*) Did you say a thermo-couple?—Yes, one consisting of two metals soldered to a wire, which, when heated, gives a small current of electricity, and that current is measured by a galvanometer. The galvanometer was specially calibrated, and graduated in degrees centigrade, so that one had an exceedingly delicate thermometer connected with the interior of the tube. With the ordinary method of using thermometers pushed down inside the tube, the temperature is apt to vary, owing to the thickness of the glass and the various local conditions in the tube, and it is quite impossible to read it inside the tube which is coated with the paint. So that the temperatures given are the actual temperatures of the internal portion of the tube. The tube was then set up, the electric current passed, and air was drawn through the tube by means of an exhaust pump (a filter pump).

15,666. Are you speaking of the inner tube and the air drawn over it, or of outside the inner tube?—It is drawn over the lead. I will give you a sketch of the apparatus (*handing a sketch to the Committee*).

15,667. (*Chairman.*) At what temperature did you conduct your experiments?—The temperature of the inner tube was 59 degrees centigrade. Experiments were also made at the ordinary room temperature as well.

15,668. What does 59 degrees centigrade correspond to on the Fahrenheit scale?—138 degrees Fahrenheit.

15,669. How was the chemical examination of the air carried out?—The air passing over the paint was drawn through slowly, or bubbled through caustic potash, nitric acid, sulphuric acid and water, and the solutions used were varied in their order. In addition, alcohol was also used, the idea being that if there was a volatile compound of lead it would be an organic compound; it would not be in the metallic form; as it is known there are organic compounds of lead excreted, in the urine for example, which are very difficult to analyse. It is necessary to break up such a compound first of all by means of very strong acid. To do that, concentrated acids would have to be used, and the air bubbled through at a very slow rate. The solutions were subsequently tested by various methods.

15,670. Will you please explain if the conditions under which you made this experiment were strictly comparable with those under which a painter would work?—No. The test in this case was to determine whether any volatile compound was given off from lead and oil at any temperature, at the normal temperature or at an abnormal temperature. Experiments were also made with paint at the normal temperatures in a similar manner, but, in this particular experiment I am describing, the materials used were merely the lead and oil that are used as the basis of paint, and from which Professor Baly said he had got emanations. I agree with him that there are emanations, but not containing lead; these emanations are given off from a mixture of lead and oil to a much greater extent. These experiments are not the ones which are comparable with painting.

15,671. Have you made experiments comparable with the conditions under which painting is done?—I have made such experiments. The electrically heated paint experiments were devised as a preliminary study and served as the basis of others. It was essential to first determine if the constituents of lead paint themselves react on one another under normal or abnormal conditions.

15,672. (*Mr. Sutherland.*) The conditions of these would be more severe?—Much more severe—60 degrees centigrade. The ordinary hottest temperature that you might get to work with in the sun is not more than 43 degrees centigrade. It was 43 degrees centigrade in the sun on Lake Maggiore this summer. That is the bright Italian sun, so the temperature is far above that of Italian sunshine.

15,673. Sixty degrees centigrade is a tropical temperature?—More than tropical.

15,674. (*Chairman.*) What results did you obtain?—I obtained no lead at all; none whatever. From my original experiments on animals with paint itself, I expected to find lead present, and I set out expecting

to find traces of lead in the solutions through which I passed the air, but I have not been able to obtain any lead. I obtained distinct evidence of organic matter which could possibly be termed emanations. I found substances which had been given off during the drying or the interaction of lead and oil, and the interaction of zinc and oil, but I have not succeeded in getting any lead in the intercepting solutions. I discussed the matter with Professor Baly, who, as you know, has done a good deal of work in this way. Professor Baly stated that he obtained emanations. I agree that emanations are present, and I found, in my experiments, more at the higher temperature than at the lower, but certainly some at the lower temperature—all sorts of organic compounds were intercepted by the various solutions through which the vapour passed. And amongst these organic compounds the presence of aldehyde was demonstrated, a substance which would give absorption spectra when examined with an absorption spectro-scope. The presence of aldehyde is a very important matter. I also demonstrated the presence of formic acid in small traces, and also various compounds, smelling of "paint," and then, later on, in the train of the tubes, rather an ethereal ester-like smell. But I was unable to find lead. In the case of white lead and oil a definite vapour was obtained, using the ordinary mixture such as is manufactured in the white lead works, and in that, at ordinary temperatures, the curious pointy smell was observed even in the water condensation. But when zinc oxide was used instead of white lead the curious pointy smell was scarcely discernible at all. On the other hand, when the temperature was pushed up to 59 degrees centigrade the smell in the lead tubes was pronounced, and it was difficult to detect any increase from that of the ordinary temperature experiment, whereas in the zinc and oil compound the higher temperature gave a very distinct "paint" smell. Then, when the temperature was raised to such a point that charring took place in the lead tube (and that was a temperature of 150 degrees centigrade, which is much above boiling point, and a temperature that might easily be reached in the distillation of lead) acrolin was given off. That is a decomposition product of the glycerine present in the oil. That has a curiously penetrating odour.

15,675. Are we to understand that at a normal temperature a mixture of zinc and oil would produce no noxious vapours at all?—I will not say noxious, but practically no vapour at all condensable.

15,676. No bad smelling vapour?—No bad smelling vapour. Noxious means poisonous, and these were not poisonous.

15,677. How do you account for the fact that white lead and oil gave off this bad smell, while zinc and oil gave off no such vapours?—Because of the chemical reaction that took place between the lead and the oil. There is a degree of chemical reaction that had evidently taken place. Though I am not a technical lead chemist, it is a fact that lead is one of the few substances which form the curious compound known as limonate. Apparently the zinc oxide and linseed oil do not interact at normal temperatures. Carbonic acid gas is also given off, which shows definitely that the white lead has entered into combination with the oil, and has so thrown off carbonic acid, which is an integral portion of white lead.

15,678. But you still assert that there is no lead?—No lead at all.

15,679. Then you differ from the conclusions of M. Breton, Dr. Heim, M. Hébert, and Dr. A. Mario?—Absolutely. Their methods were all improperly controlled.

15,680. Do I understand that you dispute the reliability of the test described by M. Trillat?—That is so. I find in going over his work in the results he describes his quantities show a variation of 60 per cent. in the figures from which he derives his answers, and that the variation is well inside what he admits is the experimental error of his reagent. I have also attempted to use this reagent and failed to find it reliable.

15,681. Would it not be useful to ask the principal chemist of the Government laboratory to give his

18 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

opinion on the reliability of that test and of any results obtained by its use?—I should think it would be a most excellent thing, because if this particular reagent is of any value, all of us physiologists, chemists, and so on, will welcome it. In my hands, when attempting to determine small quantities of lead, I found the reagent (tetramethyldiphenyl-methylen) absolutely useless. I should be one of the first to welcome it. When it was first described I made the reagent. Here is a sample (*producing the same*). I ought to say why the test is unreliable and worthless. The difficulty is this: the substance used to turn the lead into the peroxide condition also gives a blue colouration of the reagent, a blue colouration is taken to indicate the presence of lead, and the limits of the reaction are so close that it is extremely difficult to get rid of the substance which is added—that is hypochlorite—and the amount of the substance that is left is so exceedingly minute that it is practically impossible to eliminate error of non-removal of hypochlorite in dealing with these very small quantities. I should have been very pleased indeed to use the test for the digestion experiments for the estimation of lead. I had a good deal of experience last year in attempting to determine the amount of lead present in the tissues of persons who had died of lead poisoning, and in the tissues of persons who died of other diseases whilst employed in lead works. I have not been able to find that this reagent has given me any reliable information, the test showing the presence of the blue colour in substance free from lead. Further, it is only a test for peroxide, and any peroxide will give the test. It is not a test for lead, and I hope that I make that point particularly clear—that it is in no sense a specific test for lead. It is merely a test for the peroxide of lead.

15,682. And yet the foreign experts, in their investigations, which were very complete and very thorough, assert a diametrically different opinion?—But they did not assert it to be a test for lead, but only a test for peroxide of lead, and I dissent that the experiments were properly controlled.

15,683. Yes, but in the experiments they made they found lead?—Yes, what they considered a lead reaction, and the observer said that lead fumes were given off at ordinary temperatures, that ordinary metallic lead was volatile at ordinary room temperatures, and according to his results the volatility did not increase until quite a high degree of temperature was obtained. On behalf of Dr. Legge and myself (I think I am not committing any breach of confidence) a very well-known chemist in a lead factory made some experiments to determine the temperature at which lead fume is given off. We wanted to know the temperature at which lead fumes rise from the surface of an open bath of molten lead, and from lead which has not been refined, or which contains zinc. Practically nothing at all was given off from the surface of molten lead until a temperature of 760 degrees Centigrade is reached.

15,684. That has a bearing on the question?—Certainly. The point is this: that if metallic lead is heated no fume is given off until very high temperature is reached, and yet, by means of this particular reagent, the investigators in question have claimed to have obtained lead at ordinary temperatures.

15,685. Did you say just now that practically no fumes were given off?—None at all that you can estimate with the ordinary methods, which are sensitive from 1 in 500,000 to 1 in 1,000,000. It has not been tried by the Trillat method, but that is so unreliable that no chemist would base an opinion upon it.

15,686. You said practically nothing; that is why I asked?—No fume that could be detected by the ordinary methods, which are very delicate. It can be heated to 740° C. without finding any trace of lead in the air aspirated over from the surface. 1,000 litres, when concentrated by passing through solutions capable of absorbing lead, gave no chemical tests for the metal, *i.e.*, not 1/500,000 gm. in 1,000 litres. If a metal gives off emanations at ordinary temperatures, the emanations are increased when the metal is heated. That is the function of all metals. If lead gave off emanations at the rate that Dr. Heim says it does, no

ordinary sheet lead would last on the surfaces of houses for more than 50 years, because the rate of discharge would be so great, and yet specimens of Roman lead are common. It would exhaust itself. I am sorry you take a strong view of this particularly uncorroborated and questionable work.

15,687. We are bound to take notice of it?—I am speaking entirely *ex parte* and on scientific grounds.

15,688. The French commission sat for eight or nine years. They investigated this question most thoroughly, and all the medical opinion, or the majority of the medical opinion, is diametrically opposed to yours?—I am very sorry. I was in that position on a previous occasion with the inhalation of lead dust before the Committee on China and Earthenware, and the position I then maintained is now generally accepted. With the organic compounds condensed, from the tube experiments explained above, a blue colour was obtained with Heim's reagent, but this blue colour was given in exactly similar quantity in the control experiments without the presence of lead.

15,689. In your physiological investigations; did you use an apparatus similar to that described in connection with your work for the Committee on Lead, &c. in Potteries?—In part of the experiments, yes; but, in the testing of the emanations direct, the apparatus naturally had to be modified.

15,690. Will you please describe, then, the apparatus you used for your tests upon animals?—The apparatus in the animal tests differed with the particular form of experiment in progress. The present one that we are discussing is the one in which air was passed over lead paints heated or not heated. The first series of experiments were made with the fumes given off from painted surfaces at the ordinary room temperature. The apparatus used in the experiments was the cage that was used for estimating the effect of dust on animals, as described in the appendix to the Report of the Committee on Lead, &c. in Potteries. But as I was not using dust, it had to be modified slightly. Three compartments were used in a large cage, and these compartments were separated from one another. I will draw it roughly (*making a sketch and handing the same to the Committee*). The cage was just a box with glass sides, and the roof of the cage was separated off with galvanised wire netting. The front pane of glass in the glass door was removed for a distance of 3 inches from the floor, to allow of efficient ventilation.

15,691. (Mr. Sutherland.) In all the compartments?—In each compartment.

15,692. (Mr. Mason.) You say 3 inches. What was the over-all dimension? We have no idea?—Each cage contained 9 cubic feet of air. That is about 2 feet 6 inches square, roughly. The glass was cut away 3 inches from the floor. This space was made at the bottom to allow of ventilation. Every morning boards freshly painted with paint were pushed into the cage above the wire netting, where the animals could not in any way get at them to lick them, eat them, or scratch them, and any fumes given off from the paint would be the fumes as given off from ordinary painted surfaces. First of all, white-lead paint was used in the whole three. The painted surface was on the top side.

15,693. (Lord Henry Bentinck.) Where was the ventilation?—From the side at the top—two plugs in each, and the 3 by 2·6 opening along the side.

15,694. It was possible for the smell to have gone out of the ventilating holes?—Yes, quite possible. A good deal of it got into the laboratory.

15,695. Was it possible for the smell to go downwards?—Yes, it did.

15,696. You are sure of that?—I take it so from the results on the animals. The effect on them was the same as in the enclosed cages. I tried later on artificial ventilation entirely, with the whole of the air drawn off from the bottom. The ventilation was perfectly efficient. The difficulty was that unless we had an opening at the bottom, or exhaust ventilation, the animal exhibited symptoms of carbon dioxide poisoning. The boards were put in every day, painted with white lead paint.

13. December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

15,697. (*Chairman.*) What results did you obtain by these experiments when the animals were exposed to white lead paint?—The animals became very ill. The first symptoms showed within a few hours from going into the cages. They were only exposed during eight hours a day. They were taken out at night and put into other cages, and put back again in the morning into the inhalation paint chamber. The animals showed salivation, progressive emaciation, and two of them became so emaciated and so ill altogether that it was necessary to destroy them at the end of about two and a half months, or rather less. The third cat did not die. The experiment was stopped, as the other animals were showing distinct signs of poisoning. The animal was removed and allowed to recover, which it did thoroughly, in a very different way from the cats exposed to white-lead dust in the Potteries inquiry. The two animals that were very ill were chloroformed and a *post-mortem* histological examination was made of the tissues of the animals. Certain curious facts were noted. In my previous work I have described the hemorrhagic condition which is found in the capillaries. Microscopical hemorrhages are constantly associated with lead poisoning. The hemorrhagic condition described in lead poisoning was not found in these animals. The hemorrhages present (and there were hemorrhages present) were of a grosser type. There was no hemorrhage, however, in any of the nerves, although the animal was showing generalised emaciation. The animals, further, did not develop paralysis, but they lost a very great deal of their body weight—considerably more than half. An animal weighing 2,900 grammes went down to 1,850, a loss of over 1,000 grammes. So that there was something exceedingly poisonous given off from the white lead paint on the surface. This was the ordinary white lead of commerce. The animals showed distinct changes in the structure of the kidney. The kidneys were inflamed. They had tubal nephritis, differing from the cats which had definite lead poisoning, as reported in the Potteries inquiry, which had interstitial nephritis. It is the difference between the kidney of chronic alcoholism and the kidney of Bright's disease.

15,698. What results did you obtain from paints made with zinc oxide, zinc sulphate and lead sulphate?—Very similar results. The animals showed progressive emaciation and salivation. The rapidity, however, of the effect on the cats was less for the zinc paint than for the lead paint. The symptoms of salivation came on early in both cases. They dribbled and their eyes ran, and they coughed. The emaciation did not commence until a later period than with the lead cats, but when it did commence it went on in very much the same way, and the ultimate effect produced was very much that described with regard to the lead cats. The least damage was produced by the ordinary zinc oxide; the next by the lithopone paint; the next, in order, by the lead sulphate paint; and then came the white lead.

15,699. Was there any difference in the severity of the symptoms?—The ultimate result was practically the same with regard to the emaciation of the cats. They lost over a third of their body weight. On the whole the animals exposed to the lead paint showed severer symptoms than those exposed to zinc paint alone.

15,700. Then if people are in the atmosphere where any paint, whether lead or zinc, is used with turpentine, are they in all cases liable to illness?—It depends on the susceptibility of the individual person, but they may be liable.

15,701. Of course it depends on that, but you are telling us about the effect on the cats?—I think that, as far as the effect of the turpentine from the paint goes, the turpentine effect is produced practically as quickly from the zinc as from the lead. But the later changes, those that are produced by oxidation of the oil and lead, are more pronounced in the case of lead than in the case of zinc.

15,702. Would you say that the vapours that emanate from a mixture of zinc and turpentine and linseed oil would be as pronounced and as dangerous as those which emanate from a mixture of lead and

turpentine and linseed oil?—In the first stages, in the first few hours, yes; but later, no, because changes of a chemical nature take place between the oil and lead, and such compounds as aldehyde and formic acid are given off, although in minute quantities.

15,703. Then, does this turpentine illness affect similar organs to those affected by lead?—Yes, it does; and more so in some instances than lead—more rapidly, particularly the kidney.

15,704. Are you aware that M. Breton obtained different results with guinea-pigs?—With paint or with turpentine alone?

15,705. With paint?—Possibly.

15,706. Do you know that a guinea-pig exposed to vapour from a mixture of linseed oil, turpentine, and zinc, for 27 hours, remained perfectly well?—It is quite possible.

15,707. Although another guinea-pig exposed, under exactly similar conditions, to vapour from a mixture of linseed oil, turpentine, and lead, died after one night's exposure?—Quite possibly. They are not my experiments, and without seeing the full experimental details I can express no opinion on them.

15,708. Is it possible, then, that a cat is susceptible to lead, zinc, and turpentine, in different proportions, as compared with a guinea-pig?—I think it highly probable. I have other experiments which bear on that point, namely, those made originally by Professor von Lehmann in dealing with the turpentine question. He found there that rabbits were much less susceptible than cats, and that the dog was more resistant also than the cat. I used cats particularly because they are animals which are very susceptible to lead poisoning.

15,709. Could you possibly say whether a cat or a guinea-pig is more nearly comparable to man?—A cat undoubtedly.

15,710. What reason have you for saying that?—It is a larger animal; it has larger lungs; its diet is different; one is a herbivorous animal and the other is carnivorous. Perhaps you would hardly call man carnivorous; man is an omnivorous animal. The cat is much more nearly comparable with man for physiological reasons. One uses the tissues of the cat in ordinary physiological work for demonstrating to students, but one would not use a guinea-pig. The guinea-pig has basophile granules in its blood, which in man is a sign that blood destruction has gone on.

15,711. Is that the normal condition of the guinea-pig?—Yes. Guinea-pigs are able to put up with a much larger percentage of carbonic acid than other animals. They huddle together and lie quite close in a position where they get probably very much more carbonic acid gas in ordinary breathing than even a cat would stand.

15,712. (*Dr. Collis.*) Can you explain the difference of the reaction with regard to these two guinea-pigs in the case of the zinc paint and the case of the lead paint? They were both otherwise comparable substances, except one was linseed oil, zinc, and turpentine, and the other was linseed oil, lead, and turpentine, mixed in the same proportions?—You are rather unfairly asking me to give an opinion on what someone else has done.

15,713. No. Can you suggest an explanation?—I offer no explanation, and I am afraid, without reading the experiments myself, I am unable to form a conclusion. You are giving me an idea of the experiments from a lay point of view, and not from the scientific point of view.

15,714. (*Chairman.*) I am giving them from a scientific point of view; I am giving the experiments made by a scientist of great authority?—They differ from mine. I am afraid that we are at issue. I do not understand his results; there may be explanatory circumstances.

15,715. I am sure that you appreciate the position that we are in; we are bound to consider all these investigations?—Certainly. It is a scientific question.

15,716. (*Lord Henry Bentinck.*) How long were the cats kept in cages? Was it three weeks?—About 2½ months. I have a cat now that I have had four years.

13 December 1911.]

MR. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

15,717. In a cage?—Yes. These cats come out every day for a run. In the laboratory we used to keep the animals in that way.

15,718. Do not they deteriorate?—Not at all. They maintain a definite weight. If you weigh a cat in a cage every day regularly for a year, you will find that he will go rather steadily up. They are emaciated when we get them first of all. We keep them for two months before using them to get them to the standard laboratory weight. At the end of that time they do not vary 100 grammes a week for a year or two. They remain perfectly friendly and happy. There is one thing, and that is that a cat kept in confinement does not clean itself, which is a great advantage from the point of view of dealing with dusty things.

15,719. (Chairman.) Did you follow up these experiments by examinations of the separate constituents of the paints causing illness?—Yes, I did.

15,720. I will ask you about the effect of the constituents one by one. Will you describe the experiments made with white lead paste and linseed oil?—Yes. It was free from lead acetate. The tube which I have already described in the earlier part of my evidence was made use of, but, as in this case it was necessary to modify the physiological apparatus, a new cage was constructed, with a glass door, zinc lined, and mechanically ventilated. The tube from the apparatus previously described was led into the cage, and discharged at half the distance between the top and the bottom. The cage content was about 9 cubic feet. As it was impossible to aspirate air through the cage by means of a water pump, a bellows driven by an electric motor was made use of, the air passing first of all into a pressure chamber, with which was connected a manometer. The tube passed directly from the pressure chamber into the cage. The pressure was three inches of water, and about 100 c.c. of air was driven through the tube every 10 seconds, at the rate of about 10 c.c. a second. The tube was filled with white-lead paste, as in the chemical experiment, and the animal was placed in the cage. The animal was placed in a cage for about eight hours a day, with slight variations, sometimes it was eight, sometimes it was six; the average was, we will say, six hours a day. At any rate, the animal passed in one case 380 hours, and in the other 370 hours, and in the third experiment 250 hours in the cage.

15,721. (Lord Henry Bentinck.) Were they all subjected to the same treatment?—Yes, they were all subjected to the same treatment. First of all I did one animal with lead in a cage, and then an animal with zinc.

15,722. (Chairman.) Will you please keep to the case of the cat exposed to lead, first?—The animal had 380 hours at daily intervals, and exhibited no symptoms whatever of lead poisoning.

15,723. Did the animal exhibit any symptoms at all corresponding to those given in your previous answer?—It varied a little in weight, as cats will do, some 100 grammes; but the final weight of the cats was in each case the same.

15,724. Did you make similar experiments with zinc-oxide paste?—Exactly.

15,725. What conclusions did you draw from these two experiments?—That there was no emanation given off of a poisonous nature affecting the cat from the lead or zinc pastes when heated to 59 degrees centigrade, or at the normal temperature.

15,726. Was there any difference at all between lead and linseed oil and zinc and linseed oil in this respect?—No, none whatever.

15,727. Did you then investigate the effects of the other main constituents of the paint?—Yes, I did.

15,728. What apparatus did you use for that purpose?—A cage similar to that used in the physiological experiments I have just described. I will call it cage 3. In the first compartment was placed a bottle of linseed oil containing 100 c.c., in the second compartment a bottle containing 100 c.c. turpentine, and in the third a bottle containing 100 c.c. turpentine and lead acetate, which was supplied to me as an ordinary drier, constantly added to paint. The apparatus was further modified in such a manner that air could be

bubbled through the various solutions at a measured rate. The cages were also efficiently ventilated by means of exhaust ventilation.

15,729. What was the effect on the animal exposed to the linseed oil?—It exhibited no symptoms whatever. It went to sleep.

15,730. What was the effect on the animal exposed to turpentine only?—It showed signs of acute illness, and at the end of the two hours was so ill that it had to be removed.

15,731. What was the effect on the animal exposed to lead acetate and turpentine driers?—The animal exposed to the acetate and driers showed signs of illness at the end of four hours.

15,732. Was the illness of the animal exposed to turpentine only as severe in all respects as the illness of the animals exposed to ready-mixed white-lead paints and ready-mixed zinc-oxide paints?—It was much more severe.

15,733. Were these experiments repeated?—Yes. Seven experiments were made with the turpentine on animals.

15,734. What conclusions did you draw from these experiments?—They were quite opposed to my own expectation, and until I had read up the literature on turpentine poisoning I was very astonished at the acute symptoms produced. I found that turpentine acted first of all as an irritant poison to the mucous membranes; that is to say, salivation was produced; secondly that it acted as a most distinct nervous poison, in that it produced what we call ataxia; that is inability to walk straight—practically drunkenness; inflammation, an early and rapid effect on the brain shown by the divergence of the animal's pupils; and finally, that it acted as a distinct irritant on the spinal cord, by the position in which the animal was thrown by the contraction of its muscles, which is known medically as opisthotonos. This was quite an unexpected effect of turpentine, and I took occasion at once to look up the literature on turpentine poisoning, and I found that there had been some experiments on turpentine poisoning by Professor Lehmann. I, therefore, was inclined to attribute the symptoms which I had found in the animals exposed to lead paints and zinc paints to the turpentine content. The animals were only exposed for two hours at a time. It was found absolutely impossible to continue the exposure to turpentine vapour for longer than two hours, as on one occasion an animal was exposed for 2½ hours and it died suddenly.

15,735. I want to ask you, first of all, what was the amount of turpentine in the air of the cage in the case of the animal exposed to turpentine only?—The amount varied from 6 to 10 milligrammes per litre there.

15,736. Would that correspond to the average amount of turpentine that might be given off by the paint of a room which was being painted?—I calculated out about what that would mean. I am unable to say the quantity of turpentine that is used in a room. That is for practicable people to say. It comes to this: that in a room 20 feet long by 10 feet high and about 15 feet wide it would be half a pint of turpentine.

15,737. Used in the paint to cover that surface, do you mean?—No. It would mean that there would be half a pint of turpentine vaporised and filling the whole of a room of those dimensions. It would contain about 8 milligrammes of turpentine per litre. I say "about" because it is difficult to estimate the turpentine. The room I have described is a good big room.

15,738. If you have regard to the smallness of a cat compared with the size of a man, would the amount of vapour that emanated from the cage be a comparable amount with that which might be given off by the paint in a room which was being painted?—I think it would. Both myself and my laboratory assistant suffered from some curious disease, whilst we were doing these turpentine experiments; that I can only put down to the turpentine. I suffered from nausea, and attempted to vomit on two or three occasions. My laboratory assistant had similar symptoms. When exposed to the vapour of the cage I got acute headache.

13 December 1911.]

Mr. KENNETH WELDON GODDBY, D.P.H., &amp;c.

[Continued.]

15,739. Do you think then that a man, if exposed to the paint in a newly-painted room, would suffer to the same extent as a cat?—No, I do not. That is quite another story.

15,740. That is important for us to know?—I say that the amount in my cage was equal to the amount in a given room, but I do not draw the conclusion from it which you put to me. The concentration of turpentine that an animal breathes, if it gets to 8 milligrammes per litre, is sufficient to produce symptoms of poisoning. It did in myself and it did in the animal. If you shut up a room which has been freshly painted, I believe it is a fact that people suffer from all sorts of queer symptoms which are put down to the new paint. I have done so myself. The special circumstances about the disease that is produced by smelling fresh paint are the headache and also the nausea, and that is exactly what we developed. We also suffered from anorexia. The cats showed this distinctly. They were off their feed after their exposure to turpentine, and they frequently attempted to vomit. The question is concentration. If a man is painting a room, it is not necessary to have the whole of the turpentine volatilised throughout the room, providing the concentration at the point at which he is working is sufficiently high. In putting paint on a surface, turpentine may be vaporised from that surface, and if the concentration at the point at which he is working reaches 8 milligrammes per litre, he is likely to suffer from headache. I am speaking in general terms, of course. I think that my experiments show that the commonly noticed symptoms of headache and nausea, and also colic of a type, that is to say, stomach-ache complained of by people from the smell of paint, are explainable on the turpentine hypothesis.

15,741. Did you make a *post-mortem* examination of the animal which died from exposure to turpentine?—I did. This is the condition found, *post-mortem*, of the animal which died suddenly, which had been exposed for two hours a day for 16 days; it was exposed for 2½ hours on the 16th day by mistake, and died in a fit. It was noticed during the exposure that the symptoms of salivation and divergence of the pupils were always more pronounced when we put fresh turpentine in, and that the older turpentine did not have the same effect. Fresh turpentine was put in the day this animal died. There was bloody mucus round its mouth. It had multiple ulcers in the ileum; it had melena; the kidneys were in a state of acute congestion; the lungs were also in a state of acute congestion, and smelt of turpentine strongly; the liver around the gall-bladder was deeply stained with bile, and also smelt of turpentine, as the lungs did. There were a few patches of local hemorrhages in the lung, and the bases of both lungs were congested; the heart was flabby; there was nothing of note about it otherwise; the blood vessels in the surface of the brain were in a state of acute congestion, and particularly the inter-ventricular plexus. A histological examination was made of the lungs, heart, liver, and kidneys.

15,742. It would be more valuable to have the account of a cat that had not died from an overdose?—This one was exposed 2½ hours. I do not know that you can call that an overdose. It is rather longer. It only had half-an-hour longer of the same thing as the other animals had.

(Chairman.) It had longer to breathe it in, so that it had more than the others, and therefore an overdose.

15,743. (Mr. Sutherland.) Does not that show that that is the breaking point, and that the hurtfulness comes from the turpentine, in that it can be sustained up to a point, but, pass that, and death ensues?—The animal was very bad on each occasion. The point is this: this particular animal had been exposed for the longest time, and had always recovered, if therefore immunity was produced or tolerance to turpentine by regular exposure, it was reasonable to suppose that this animal should have withstood an extra half hour's exposure. One animal died after two-hours' exposure, another after only 75 minutes. Two hours is as much as we find a cat will stand yet.

15,744. From the turpentine?—From the turpentine. The first animal I am discussing had withstood

16 exposures of two hours each—32 hours—so that it had had all along preliminary dosage, and it ought to have been able to stand an extra half-hour, if there is anything in immunity.

15,745. (Chairman.) Will you tell us the number of hours that all these cats were exposed before they died?—One animal had been exposed for 32 hours, and died at the end of an exposure of an extra half-hour. Another animal is still alive, and has had exposure for 30 hours. A third animal died after two hours' exposure. They are roughly the same amounts. The variation was between 8 and 10 milligrammes per litre. I cannot go nearer than that. It is very difficult to estimate. A sixth animal had been exposed for 16 hours, and it is still alive. Those are the times of exposure.

15,746. (Sir Godfrey Baring.) Are we to understand that some cats are more susceptible than others?—Yes, I should think so apparently.

15,747. And that, given that the same quantity of vapour could be breathed by men in a room, they would die equally?—I should think so, but I do not know. You cannot argue absolutely with regard to fatal doses from man to animal. All you can argue is that if symptoms of changes in the tissues are produced in an animal, such tissue changes are invariably produced in man by the same thing.

15,748. If these experiments are not comparable as between cat and man, given the same conditions, they are practically of no use at all?—All I can say is that I got a very uncomfortable headache from breathing the air. I was not inside the cage. I was only outside it. I do not propose to get inside the cage to determine the further point.

15,749. You see my point?—Yes.

15,750. I want to know whether this is comparable?—These cats weigh 2·7 kilogrammes. A man weighs, say, 60 kilos. The relation, if you take it merely on body weight, is 30 to 1, roughly. So that at that rate you would want a very much larger dose for death, but not necessarily for the other symptoms. The turpentine is taken into the blood, where it produces changes in the composition of the blood, and it is excreted by the kidneys. You can smell it. Taking a painter's urine where he has been working for a long time in the presence of turpentine, it smells of violets a curious smell always related to turpentine. And further, in my animals at any rate, I found curious changes produced in the intestine, and a symptom of turpentine poisoning is diarrhoea. Dr. Collis has had the opportunity of examining my histological specimens of the turpentine cat that I have been describing, and he can bear me out as to the very curious hemorrhagic effects. They differ from the effects of white lead. I think he will bear me out.

(Dr. Collis.) They are quite different. The chief symptom which these cats showed even when only exposed for an hour and a half was kidney change. The animal which died after exposure of only one and a quarter hours still showed kidney changes, and the intestine was full of frothy mucus—not blood—whereas the one exposed for a longer time (77) had ulceration, and blood in the motions. This cat showed frothy mucus and acute patches of inflammation starting in the intestine, but to no great extent. That suggests that turpentine is excreted by the intestines as well as by the kidneys.

15,751. (Chairman.) Is it possible that animals might become immune to turpentine vapour?—I have been doing my best to get immunisation, because I see the great importance of that, and the importance of the question of the establishment of immunity in man. If turpentine acts on the kidney as one has shown that it does (and one knows that lead does), it is highly important. So far no immunity has been produced.

15,752. Can you distinguish between a kidney acted upon by turpentine and a kidney acted upon by lead?—Yes, I think so, in the early stages. The turpentine produces tubal nephritis. The inside of the tubules is damaged by turpentine. In lead it starts with interstitial hemorrhage, and the hemorrhage that takes place in the kidney in these animals in the lead is very distinct. There is excessive excretion. My animals so far have broken down that I have been

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

attempting to immunise. I have not obtained true immunity yet.

15,753. Did you also make inoculation experiments, and with what result?—Yes, as a control to the experiments which I had previously made with regard to breathing emanations from lead paint and emanations from zinc paint, and the basic compound of the paint, that is the metallic salt. Inoculation experiments were performed to determine the relative poisonousness of the compounds and their absorption by the tissues direct. I found by these inoculation experiments that the metallic constituent of the paint, when inoculated subcutaneously into the tissues of an animal, underwent definite absorption, and in each instance produced some change resulting in a diseased condition of the kidney. Even zinc salts, the oxide and sulphide, produced death of the animal, when only 0.1 grammes per kilogramme body weight were inoculated. This is merely testing the virulence, you understand.

15,754. As a matter of practice, would a painter be likely to get inoculated either with lead or with zinc?—No.

15,755. Then your only point is that inoculation with zinc is dangerous, just the same as in the case of nearly all metals?—Yes. It was necessary to determine this, and the inoculation experiment always gives you the answer to this question: Is the definite salt of the metal experimented upon absorbable by the tissues themselves when it gains definite access to such tissues?

15,756. But are there any metals that would not have that effect?—Yes.

15,757. What are they?—You can inoculate with iron. You may get that effect, but different in degree.

15,758. What are the metals that you can inoculate with that would not have the same effect as zinc?—I have not tried. So far all the heavy metals I have tried have produced the result.

15,759. Then this experiment of yours is only to show whether all metals have the same effect?—It might have been possible that zinc would prove non-poisonous, and differ from other metals. There was quite the chance.

15,760. You did it for that reason?—Yes. This is a question of determining whether or not zinc was poisonous in common with other metals, and it was.

15,761. Did you also expose animals to dust such as painters would be liable to breathe in the dry rubbing-down process?—Yes, I did.

15,762. Did you conduct these experiments in a method similar to that employed in your work for the Committee on Lead, &c. in Potteries?—No.

15,763. Will you describe the apparatus used?—The apparatus was the apparatus described in the experiments for investigating the emanations given off from heated paints. It consisted of a hermetically-sealed cage with a glass door. It was modified so that the air could be blown over the compound to be tested. In the experiments for the Committee on Lead in the Potteries the compound to be tested was dropped into the cage, and it was dropped in in fairly large quantities over a couple of hours.

15,763a. The material in the form of dust?—Yes; as dust. In the case of the experiments with paint materials, the animals were situated in the cage in such a way that they were all breathing dust-laden air. The air was blown over the compound by bellows, and therefore it was possible to leave the animal exposed to small quantities of lead in the cage for long periods, instead of, as we did in our experiments in regard to the potteries, to larger quantities for a shorter period. The animals in this case remained in the cage for the whole of the day, being taken out at night and put in an ordinary cage.

15,764. What dusts did you experiment with?—Two metal salts were used, one of them being white lead, and the other zinc oxide.

15,765. What quantity of dust was suspended in the air during the exposure of the animals?—The quantity in the case of zinc was slightly in excess of the quantity in the case of lead. The average quantity of dust in the air for the lead cases was 0.004 gramme

per litre. It was probably a little less. In the case of the zinc it was at least four times this amount. The lead content was very small, so small that it could only just be recognised.

15,766. Would this make the atmosphere of the cage comparable with that of a room in which dry rubbing-down is being done?—I should think entirely. I have no facts with regard to direct examination of the air from the dry rubbing-down process, but I take it that the dust given off would be of the very finest description, and therefore it would be the finest dust that one would wish to experiment with; that is to say, the dust which would be carried over from a gentle current of air rather than when large quantities of lead are dropped into the cage in front of a fan.

15,767. What was the result of the exposure to white lead?—The animal showed signs of poisoning at the end of a fortnight.

15,768. What was the result of the exposure to zinc oxide?—There was no symptoms whatever except the loss of body weight.

15,769. Notwithstanding that the quantity of dust used was four times as much as in the case of lead?—Quite.

15,770. Have you made *post-mortem* examinations of the animals experimented upon?—I will give you the result of the *post-mortem* examination of the zinc cat as against the lead cat. Both cats were exposed for a month. At the end of a fortnight the white-lead cat was showing symptoms of poisoning, and at the end of a month it had got symptoms of paralysis, so it was quite time to deal with it. The zinc cat at that time showed no symptoms of paralysis at all; it was exceedingly lively; but it was necessary to kill it to examine it as against the other one. The cats were chloroformed. Taking the white-lead animal first: the loss of weight was from 4,050 grammes to 2,050 grammes—half weight again. The *post-mortem* signs were those which I have usually found in lead poisoning; that is to say, there were old and fresh hæmorrhages in patches in the lungs, heart, liver, spleen, and kidney. In the intestines there was some injection, and a number of ulcers (small erosions), quite different from the turpentine effect. The whole of the cæcum (that is the lower part of the intestine) was stained black. In this black staining, I was able to recognise lead by the usual chemical tests. Histological examination of the tissues showed the ordinary typical signs, namely, interstitial microscopical hæmorrhages, discharge of the lead particles from the surface, and the deeper layers of the large intestine; hæmorrhages in the smaller intestine, and ulceration. It conformed in every particular with what I have described in various places as the typical signs of lead poisoning. So that a small dose of lead over periods of, roughly, six hours a day (it is bigger than man gets) is distinctly serious. Now we come to the *post-mortem* on the zinc cat. The zinc cat started at 2,800 grammes weight and it finished at 2,500 grammes weight, so that the difference in its loss of weight was very small. It only lost 300 grammes. At the same time it looked very thin, but it was exceedingly lively. There was no dark staining in the intestine; the heart muscle was rather flabby; the liver was congested and firm; the kidney showed no hæmorrhages. On the other hand, the spleen showed a number of recent hæmorrhages of an ordinary type, rather suggesting that particles of dust had gone into the lung and had passed as solid material. That I have not been able to investigate yet. There were infarcts in the spleen. The rest of the organs were apparently quite normal, with the exception of the lower part of the ileum, which showed congestion. There was therefore some slight evidence, or more than slight, there was distinct histological evidence that the metal which had been taken in by the cat's lungs had been circulating in the blood, and was being discharged. The kidney, on section, showed that there was early inflammation taking place. There was also congestion and a suggestion of recent inflammation in the small intestine. There is very little doubt, therefore, that it is not a good thing for an animal or for a man to absorb even zinc oxide dust.

18 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

15,771. Would you go so far as to say any metal dust?—I am not prepared to say that. I am only prepared to give you what I know, and what I have done. I should be very pleased to try any metal dusts or any dusts that are likely to be met with, and I think it important, but one cannot generalise. I could express an opinion, but it is only an opinion, after all. It is of no value, because it is not based on evidence.

15,772. Exactly; please give only the facts you have ascertained?—The difference between the white-lead cat and the zinc cat is very marked.

15,773. Have you examined the blood of the animals experimented upon?—I have made a large number of examinations. In the case of these investigations particular attention has been paid to the blood examination of the animals experimented upon. The change in the red blood corpuscles, known as basophilic staining, was found—a symptom in both turpentine and white-lead poisoning, and even the animals exposed to zinc oxide and to zinc sulphide showed the presence of a few basophilic granules in the blood.

15,774. Was the basophilia so marked in the case of the zinc as in the case of the lead exposure?—I should think that the lead showed if anything the excess.

15,775. Is basophilia never found in a normal cat unexposed to any poisonous influence?—Unexposed artificially, yes, but it may have suffered from some intercurrent disease which would determine it. Basophilia is not a symptom of blood destruction at all. Basophilic staining, so-called, consists of the appearance of small granules in the red blood corpuscles. This basophilia is the result of the change in the development of the cells which is going on all the time in one's red bone marrow, and it is the remains of the nucleus which is left behind. If there is great and rapid hæmorrhage—if you bleed an animal of two-thirds of its body blood and examine its blood afterwards, you find the same day enormous quantities of basophilic granules present. There are many other diseases which produce basophilia. That was controlled by examining the animals beforehand to make sure that there was no basophilic condition in the animal.

15,776. But is there no case of basophilia whatever in a normal animal?—Yes, it may occur, but basophilia did not occur in these experimental animals.

15,777. But it is possible?—Yes. If you got a cat which had just undergone parturition, you would definitely find basophilia.

15,778. When you examined the cats first of all, there were no signs of basophilia?—None at all.

15,779. And after the inhalation of dust and turpentine you found them?—Yes, very small quantities. The basophilia in the animal, the cat, is less pronounced than in man in lead poisoning. So far, in my experimental work, I have found a small number of basophilic granules in the animals.

15,780. Have examinations of the blood of men exposed to lead dust also been made?—Yes. That does not bear on my answer as to the basophilia in animals. It is rather important as bearing out what I said with regard to blood destruction if you expose an animal to lead poisoning such as the animal exposed to white-lead dust. I examined that cat during the whole of the time and it showed no basophilia whatever, and the animal died without there being any basophilic staining present.

15,781. Neither before nor after?—Yes. The animals exposed to lead poisoning for a short time and then removed from its influence showed basophilic staining.

15,782. As the result of what?—As the result of exposure to lead poisoning for a short time, then being allowed to recover, and I had the same sort of thing in the case of the zinc. It is not an early symptom in experimental animals. It is rather thought that in man it is an early symptom. It may be because the so-called hæmo-poietic mechanism of man is different from that of animals.

15,783. What deduction do you put before us as the result of finding basophilia in both sets of

animals?—It is a symptom of blood regeneration after blood destruction.

15,784. Caused by what?—Caused by the toxic influence of both lead and zinc.

15,785. You have spoken of examinations of the blood of men exposed to lead dust?—Yes, I have, in several directions. The investigations have been carried out with regard to this basophilic staining, which I was explaining a little while ago, and also with regard to other changes in the blood which take place, the important matter being to get some method by which early lead absorption rather than lead poisoning could be recognised, so that such a case could be treated or removed from the influences which were producing the poisoning; and, as often happens in doing so, the man not only is protected from the disease at that moment but becomes more immune than a person who for the first time is exposed to lead poisoning. I think that there is no doubt, from my experimental work and from clinical observation, that persons do become immune to dosage with lead; and I think that Dr. Collis will be able to bear me out in that respect—that immunity may be established by continued exposure to lead.

15,786. Would you say immunity or that some subjects are not so susceptible?—Diminished susceptibility, otherwise what we know in drugs as tolerance. We know quite well that, if a person takes morphia over a long period, he is able to support huge doses which are impossible for a normal person to take; and the same with alcohol. In fact, if it were not so, it would be a very serious thing with regard to all lead trades. Men are frequently met with who have been exposed to lead poisoning to the same extent as others and who never show any signs of it at all, and those people may be regarded either as less susceptible or as having become diminished in susceptibility. One makes use of it from the practical point of view in the ordinary routine treatment of men employed in white-lead works where a man shows early signs of absorption. I distinguish between lead absorption and lead poisoning. They are two very distinct things. Lead absorption may go on for a period without producing any clinical symptoms, and there should be a direction to certifying surgeons to distinguish between those two points. Lead poisoning and lead absorption are not synonymous terms. The literature with regard to the potteries makes the statement that certifying surgeons are to observe that.

15,787. What would you consider to be the difference between the two?—One is ingestion by the lung, or by the alimentary tract of quantities of lead which are subminimal poisonous doses. They are sufficient to produce some change in the body, but that change is one that the body is able to deal with. To carry it a little further, the damage, by stress to the body, is slightly increased; but it is not increased beyond that amount that the body is able itself to deal with and repair. Carry the dose beyond such a point, and the body is no longer able to deal with the quantity, and the whole of the previous quantity of lead which is present in the body may then act as a toxic amount.

15,788. But is it not the case that some bodies are able to resist the influence of lead better than others?—Certainly, and even a susceptible person in many instances may become less susceptible by constant exposure.

15,789. Do you consider the effect of turpentine a matter which calls for serious investigation?—I do, most decidedly, and as it is concerned with lead paints so much (or all paints I prefer to say) I think it comes within the scope of the Committee to consider. From my point of view, although it is not lead, it is undoubtedly a constituent of paint which may operate very seriously.

15,790. Could you tell us whether the symptoms created by turpentine are similar to those complained of by persons who smell fresh paint?—Yes, most decidedly. I have experienced it myself. I have also inquired into and seen cases of poisoning or illnesses produced by inhaling the fumes of fresh paint, and such

G g 2

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

illnesses are always more nearly allied in their symptoms to those of turpentine poisoning than of lead poisoning. In fact, I think it is quite easy to distinguish.

15,791. Then your conclusion is that there is a definite illness from turpentine not easily confused with lead poisoning?—Not easily confused, but I think that it has been confused a good deal, because it has been associated with paint.

15,792. You consider that turpentine produces symptoms which, in a *post-mortem* examination, would be readily distinguished from lead poisoning?—In acute poisoning; but I am not able yet to say what the symptoms would be in the more chronic cases.

15,793. I asked about *post-mortem* examination?—That is obviously acute. It might not be readily distinguished. You might have to distinguish between turpentine poisoning and lead poisoning in a case which had died after exposure to lead for a long period and then to a severe dose of turpentine. Then it would be very easy. I will illustrate by what actually occurred. I had, for an insurance company, to see a man who had been exposed to sand-papery large surfaces of paint for flating, and the question that arose was whether that man's illness was due simply to his sand-papery the surfaces, or whether, as he had been engaged mixing paint previously and stirring it in turpentine, that had predisposed him to a second dose of poisoning by means of the sand-papery. Is that clear?

15,794. Yes, quite. You say, in fact, that turpentine introduces the danger of a new illness?—I think so.

15,795. In addition to the lead poisoning which we are now investigating?—I think so.

15,796. I will not say a new illness, but a new danger of illness?—Previously unconsidered we will say. It has probably existed all the time. These investigations rather suggest that there is such a thing.

15,797. Do you think that this would make the men more prone to take lead poisoning?—That is such a vital point, because from the point of view of the painter it is a very serious matter. Having no direct evidence on it at present, it is difficult for me to give a direct answer. *A priori* (if you wish me to express an opinion) I should say yes, because of the effect of the turpentine on the kidney.

15,798. Let me remind you that you found in your previous experiments for the Committee on Lead, &c. in Potteries that alcohol, given in addition to other food, renders the system much more prone to an attack of lead poisoning?—Certainly.

15,799. Did you attribute that to the fact that both alcohol and lead have to be eliminated by the kidneys, and that these organs are apt to break down under the double strain?—Yes.

15,800. As you have found that turpentine also produces kidney disease, would it not seem probable that the exposure to turpentine would greatly increase the risk of lead poisoning in the same way that alcohol does?—That is a conclusion that it would be fair to make, I think; but without experiment it is impossible to make a definite statement.

15,801. In any case your discovery that turpentine is an additional dangerous element in the work of the house-painter might account in some measure for the high incidence of Bright's and other diseases of the kidneys amongst those workers?—Yes, I entirely agree with that; if you will allow me to say that it is not absolutely my original work in this case, although it was after I had completed my experiments that I became aware that other work had been done on the question. It is original from that point of view, but Lehmann's work was published in the "Archives for Hygiene" in 1899. Unfortunately, I was not aware of that when I did my work.

15,802. For example, Bright's disease causes three out of 100 deaths in the general population, and eight out of 100 deaths in painters?—Yes.

15,803. So there must be some contributory cause for that large increase?—Yes, and turpentine is a

substance which, as a result of my recent examination, I should look on with the greatest suspicion.

15,804. The comparative figures of lead poisoning amongst house-painters are as follows: The average number of deaths during the last 10 years is 30, which is equivalent to about 1,000 attacks each year?—Is that 30 per 100 or per 1,000?

15,805. Thirty is the absolute number of deaths per annum, on the average?—Taking the relation of attack-rate to death-rate, it is quite fair to estimate the probable attack-rate amongst painters as you have done, providing the amount of infection in the two cases is about the same. It is a very fair sort of deduction to make—that, for 1,000 cases of lead poisoning in industrial conditions, you might get 30 deaths.

15,806. (*Dr. Collis*.) That is the usual proportion?—The fatal lead poisoning figure among house-painters, the actual figure being 30, the chances are that that 30 is due to somewhat the same causes, at any rate, as would produce a general attack-rate of 1,000 cases per annum.

15,807. That is a very serious condition of affairs, is it not?—Yes. Are those deaths certified as from lead poisoning?

15,808. Yes, they are taken from the Registrar-General's figures?—What is the total number of deaths from all causes amongst house-painters?

15,809. That is given in the last Decennial Supplement?—What is the relation to the total deaths amongst lead workers? (*Some figures were handed to the witness*.) Using the term in a technical sense, entirely, and not in an antagonistic sense, a crude death-rate estimated upon an assumption is a difficult figure to deal with. That figure might be contributed to by the turpentine poisoning.

15,810. Each death is tabulated on the result of a coroner's inquest, at which expert medical evidence was taken in regard to lead poisoning?—Yes, but I believe it is a fact in the case of the Potteries, that if any disease of the kidney at all is found it is ascribed to lead poisoning at once. If there was kidney disease, that would be taken as evidence. I have noticed that in reading the reports of coroners' inquests which I have been collecting for four or five years. Probably great stress is laid on that question, and I am a little uncertain yet as to how far kidney disease alone is such a serious feature of lead poisoning. That is not only from my own work, I find, with regard to a very large number of persons who have done experimental work with animals, that the difficulty has been to reproduce chronic kidney lesion. It is a matter probably more of scientific interest, but I think it a point to raise.

15,811. Your point being that some of these deaths attributed to lead may be attributable to causes other than lead?—Yes, which it is difficult to distinguish.

15,812. If a few mistakes are made in regarding as lead poisoning what may really be turpentine poisoning, will there not, on the other hand, be at least as many cases attributed to other causes which should be ascribed to lead?—That is an argument. It is not quite as likely.

15,813. It is not as good an argument as yours?—No. There is always a tendency, recently at any rate, to bring in a verdict of lead poisoning if possible. I think that that is the general tendency.

15,814. What makes you say that, because you know there is a medical referee?—Yes, I know. I know several medical referees, and they each of them take this view, and I am not criticising their view—that in a case of doubt where the evidence is almost evenly balanced, and there is evidence of the man having been employed in a lead industry in which he might have contracted lead poisoning, it is common justice to give the benefit of the doubt on the point of lead. I think that is right, but for the purpose of statistics it is a little disturbing.

15,815. But that opinion of yours would not apply to lead industries where turpentine was not used?—I am talking of all lead industries. I think that that is the general point of view that a referee would take. I should take it myself if I was acting as referee. I

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

think that it is a fair one, but it is disturbing with regard to statistics, however fair it may be. Thirty deaths is rather a small number to go on alone.

15,816. (*Dr. Collis.*) That is an annual average for 10 years?—There is rather an important point that I would wish to make. I had blood submitted to me by Dr. Collis, who obtained it from persons employed in the painting of furniture, and who were, therefore, presumably exposed to lead dust. I did not know the source of the blood, except that it was obtained from people who had an opportunity of being exposed to lead dust in the air from sand-papery. I found, taking the particular line which I have been laying down as the one to take when estimating changes taking place in the blood probably due to lead, that a number of these persons probably had suffered or were suffering from lead absorption. I have not the figures with me, because I thought they were rather of a private nature, but I sent the results to Dr. Collis, and I think that they bear out rather strikingly the fact that it had been possible by means of this blood examination to pick out a number of men who had been exposed. I picked out all the blanks which were put in. I only had the numbers of the bloods. I picked out all the blank bloods, which were of normal persons, clerks and so on.

15,817. (*Chairman.*) What does "blank bloods" mean?—Blood from a person not exposed to lead infection. They were put in amongst the series. By examining these bloods in the way I have described, I was able to pick out those who were not exposed, and certain people who definitely had been exposed; and some of them in those instances were showing symptoms of lead absorption. That was with regard to sand-papery workers. In a case a little while ago, in which the Home Office was concerned, I had submitted samples of blood obtained from people who had been exposed to lead sulphate dust, or basic sulphate of lead, and again, at my own particular request, the names were not indicated to me. Each was labelled with a number. Numbers 1 and 2 were lead suspected persons; 3 was a normal person, a clerk; 4 was a lead blood; and so forth right away up. The samples were mixed. I succeeded in picking out not only people not affected, but the very ones who were admittedly cases that had been reported as lead poisoning from the works. The only blood which I queried was one of the samples which came from a presumably normal person. He had been suffering from some curious form of anaemia. So that, as far as those samples went, all the persons who were suffering from illness were definitely determined.

15,818. Did all the persons who had had any connection with lead show it in their blood?—Yes. By examining, microscopically, I was able to make a selection and say: "This is probably lead blood; that is 'probably normal blood.'"

15,819. Were you correct each time?—I was correct in every case. The method that was adopted was not only the basophile staining—and that is why I wanted to refer to this question again. A good deal has been done recently with regard to basophile staining, and at the recent exhibition in Dresden a method was suggested which had been adopted for finding out whether the lead workers were affected with poisoning or not, and they used only the basophile granules. I have shown you that basophile staining may occur in turpentine poisoning. It may occur also, presumably, in zinc poisoning. The point is that that curious staining in the red cells is not a symptom of lead poisoning alone, and it must not be regarded as such. It is only a symptom that blood is being formed at a greater rate than the normal, and it is being made so fast that it does not get properly formed, and bits of the process are left in the red cells. At the same time, if a person is also suffering from the effects of poisoning, changes take place in the blood in the number of certain other constituents, namely, the white blood corpuscles of a certain type. The white cells of the body are divided for practical purposes into four main classes (A, B, C, and D). A is generally about 63 to 65 per cent., up to 70, of the corpuscles. If you examined 100, you would expect to find 63 to 70 of one sort, all being white, 15 to 20 of another sort of white, and so on. One of

these types of white cells is apparently always increased in lead poisoning, and that, taken together with the curious staining in the cells, seems to be, and has been in my hands, so far a means of detecting a sample of lead-worker's blood when shuffled with a number of other samples, and I think it is one that might be made use of in the detection of the early absorption of lead, so preventing the more serious symptoms of paralysis and so forth occurring. Paralysis and all these maiming diseases which follow lead poisoning only come on in the majority of cases after very long continued exposure. I do not consider lead poisoning by any means an unpreventable disease. I believe it might be a preventable disease if it were recognised in the earlier stages in which these changes were going on in the blood. It is not enough to take the change in the red cells alone, because it occurs in pernicious anaemia; it occurs in benzol poisoning; it occurs in aniline poisoning; and it occurs in turpentine poisoning, as I have shown. Turpentine therefore comes into relation with other forms of poisoning which are known to show what I have been describing. This is lymphatic leucocytosis, otherwise an increase in the particular form of white blood cell known as lymphocyte. If this is present up to above 30 per cent. in addition to the alteration in the red corpuscles, together with a diminution in the red colouring matter of the blood (haemoglobin), there is very strong presumptive evidence that what is happening is a form of metallic poisoning, and if the person is working in lead it is practically certain that it is related to the trade. Therefore I think it is worth considering that as a method of determining lead poisoning, and therefore eliminating many of the more serious forms. But it is most important that such an investigation should not be undertaken by anyone unless he be a competent person in doing blood examination. It cannot be done, I am afraid, by the man who is in general practice in the ordinary way. He has not the time or the facilities for doing a rather technical operation of that sort.

15,820. What do you mean by facilities?—Facilities in every way—both the apparatus and the manual dexterity of his fingers, and also, what is still further important, the judgment to determine which is the basophile-stained cell and which is not. If Dr. Collis thinks that I have over-stated it or under-stated it, he will tell you. That is purely technical, but it is a thing I thought well to bring to the notice of the Committee. I think that I have under-stated it, if anything. It was a considerable question in the prosecution which was undertaken by the Home Office in the particular instance to which I am referring.

15,821. Would you go so far as to recommend, supposing the Committee decided to issue rules governing the trade, that in the medical examination an analysis of the blood should in all cases be insisted upon?—Always where any question of illness occurs, and, in addition, I would like to recommend that once a year the blood of all persons employed in lead industries be examined, as I suggest, and by an expert.

15,822. (*Dr. Collis.*) With reference to the point on which you have just been speaking, what do you think about the possibility of a painter rubbing down paint composed of a zinc pigment, absorbing by that means sufficient of the zinc to cause alterations in his blood. You have stated that such alterations may occur when zinc is injected under the skin, and I wish your opinion on the possibility of such changes occurring?—If he is breathing a zinc dust, the amount of basophilia produced in such a person is less than that produced in a lead person, and, further, so far in animals (and I have only animal experiments to go upon yet) I have not observed any lymphatic leucocytosis occurring.

15,823. Not from the inhalation of zinc dust?—No.

15,824. I ask this because I want to get clear the position of master painters if lead was restricted, or possibly if they were working entirely without it and one of their men fell ill and made a claim for lead poisoning. Could this test be applied to distinguishing between the form of illness of which he was complaining and any other illness?—In such an instance you would be attempting to lay more stress on the test.

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

than I suggested, and I think perhaps in that way if it was used as an absolute test it might break down.

15,825. But it might be of assistance?—It would be of very great assistance, and the absence of any marked basophilic staining and the absence of lymphatic leucocytosis together with the diminution in the red colouring matter of the blood being by no means in relation to the lymphatic leucocytosis would be very strong presumptive evidence that the man was not suffering from lead poisoning, but to make it an absolute test by which to say whether a man has or has not lead poisoning is asking too much for such an experiment.

15,826. It may be of value in helping to distinguish?—Of great value. It would be the very greatest presumptive evidence, I agree, that he was not suffering. I made that statement just now, I think.

15,827. May I try to see if I have understood correctly the position which we now have before us from evidence given by the French report, and by yourself and Professor Baly. I am correct, I hope, in assuming that, if the lead dust alone is used, all the authorities agree that lead poisoning may be produced?—Yes.

15,828. The French have claimed that lead vapours come off lead filings and can be recognised?—At what temperature?

15,829. They do not speak of the temperature being more than ordinary temperature?—That is a French statement?

15,830. Yes, that is a French statement. With that statement at any rate you, for one, disagree?—I absolutely disagree. My researches have negated it in every particular.

15,831. The same French authorities state that, using carbonate of lead, they have found that the growth of microbes is impeded. This is a point that you have not attempted to to prove or disprove?—Not with carbonate of lead, except in conjunction with linseed oil.

15,832. I am coming to that by and by. I want to take the lead alone first?—I have not performed that experiment with lead alone. A number of experiments can be easily devised with regard to micro-organisms that may or may not give you evidence on the subject. The growth of bacteria is notoriously inhibited by variations of an exceedingly minute nature in the composition of the media in which they are grown. I am familiar with bacteriological work, and I have found that a difference of alkalinity in a given solution so slight as the difference of 1 cubic centimetre of normal soda per litre of medium is sufficient to eliminate the growth of certain organisms. Carbonic acid gas might be given off from the surface of lead carbonate at ordinary temperatures—I do not know—and that would certainly have an inhibiting action on some organisms, not all.

15,833. According to the report, this statement is backed by three separate sets of observations, those of M. Heim, M. Hébert, and Dr. A. Marie. I only mention this in passing. I am not holding a brief for any observations which I am at present pointing out. I only wish to get clearly how our evidence goes, so I am asking you if you can give us help on each point, from your point of view. Have you a translation of the French?—No. (A copy was handed to the witness.) 50 grammes of powdered white lead were put under a bell jar. He used fluid media for No. 1, and Agar plates for the typhoid in the other. He found that the typhoid was inhibited in growth. He does not give any controls grown under absolutely normal conditions. He does not give the number of colonies. He simply says that the development was very quick and apparent in No. 1, and it was not so great in No. 2, and it was evidently much decreased in No. 3. Unfortunately for bacteriological work, those experiments are hardly worth talking about. I am sorry to disagree in that way. When one makes bacteriological experiments for determining the inhibition of the growth of micro-organisms, one must control with the greatest of care the actual number of organisms per cubic centimetre growing. He does not even say how his plates were made.

15,834. There were three separate observations made, not by the same individual, but by three separate people, all working on different types of organisms?—All of them suffer from the same defect, that they really do not tell us the number of organisms. My own feeling is, that those bacteriological experiments are ones that would probably give quite a different result if they were made in another way. There is only the general appearance of the plates to go on with regard to whether the things are growing or not. My experience has been that I cannot get inhibition of bacteria, and I have tried, by means of white lead.

15,835. Then, when we come to lead and oil, Professor Baly obtained certain absorption spectra?—Yes.

15,836. The reason for this perhaps he will tell us later. It was an absorption which was not obtained from lead alone or oil alone. The French savants here claim a much more marked effect with regard to microbic and mould growths. Have you yourself any evidence on the point of using oil and lead alone?—No, none at all. They mix the oil and lead, do they not?

15,837. Yes?—They actually mixed the cultures together.

15,838. No?—Then they got a growth of all sorts of other organisms present, which they did not put in to start with. When they used oil, they got the bacillus prodigiosus.

15,839. They were exposing in exactly the same way as in the last case?—Then they got air organisms. Evidently the experiments broke down.

15,840. They got the inhibition of the growth with which they had inoculated the plates?—I am a bacteriologist.

15,841. Yes, I know?—I have not made those experiments. To me, as a bacteriologist, those results are not convincing.

15,842. I quite accept your point, but on the other hand they have not been traversed, have they, by your experiments?—No, they have not been traversed, and I do not think that they are worth traversing, as a matter of fact.

15,843. Then, when we come to the influence of the whole mixed paint, the French again speak of emanations, and they claim that they have found lead in them?—Yes.

15,844. You yourself have produced certain effects upon animals which you consider to be due to the turpentine which the paint contains?—Yes. I could not find any evidence in my animals of lead.

15,845. There was a slightly quicker effect produced when a lead paint was used than was the case with a zinc paint?—Yes; and when the oil thinnings and turpentine alone were used. I forgot to tell you that I exposed a cat to oil thinnings and turpentine without any lead and without any zinc—just with the plain stuff, quite apart from blowing air over.

15,846. (Mr. Sutherland.) Did that have any effect?—It had a turpentine effect.

15,847. (Dr. Collis.) Your opinion on the point (correct me if I am wrong) is that when oil and paint are mixed an emanation possibly of the aldehyde group is given off?—And carbonic acid gas.

15,848. Which may, as far as the French work goes, have been a cause of the inhibition of the growth of microbes?—Yes.

15,849. Do you think that such emanation from the oil would in any way have any effect upon a less delicate organism than moulds and microbes?—What do you call a less delicate organism?

15,850. Higher in the animal scale, and therefore possessing greater power of protection, such as cats and human beings?—It did not have any effect.

15,851. None that you were able to trace?—Yes.

15,852. You examined the blood of these animals?—Yes, and there was no basophilia.

15,853. And no other recognisable effect. Then you come to the turpentine effect, and that you consider to be marked?—Yes.

15,854. Such an effect that it might lower the general resisting power of the organisms, as in the case of alcohol?—It might, undoubtedly.

13 December 1911.]

Mr. KENNETH WELDON-GOADBY, D.P.H., &amp;c.

[Continued.]

15,855. When you were speaking of your carbonate of lead and oil aspiration experiments, you said that you used carbonate free of acetate?—Yes.

15,856. What lead did you obtain for this?—Three different leads.

15,857. Were they all acetate-free?—No. One did contain acetate, I think, but I am not sure. I am afraid I cannot answer that straight off.

15,858. It occurred to me as possible that lead carbonate, especially as made in France by the chamber process, or by the Stack process, contains acetate, and that the French observers were working with lead carbonate containing acetate?—One of mine was a Brimsdown lead, one was a Millwall lead, and one I bought in a paint shop.

15,859. There may be an agreement after all, if the French contained acetate and yours did not?—The materials may have been the same possibly.

15,860. As most white leads are not acetate free, it is better to work with the lead containing acetate?—Yes. I used lead acetate and turpentine in the animals' cage. They did not show any signs, but they were not exposed for any great length of time. They are still being exposed. I have dealt with acetate of lead in a previous report, but not on the emanation question.

15,861. Turning to the question of turpentine, we expect that there would be a considerable effect from exposing animals to the turpentine vapour; but I am a little uncertain as to whether bubbling air through turpentine is quite a fair test. The point, I believe, that has caused Professor Baly to repeat his work is the possibility of small particles being drawn over mechanically?—That is small quantities of lead.

15,862. When you bubble air through turpentine, it is possible that not merely vapour is coming off in the air, but definite particles of the turpentine are being disturbed; in fact, it is very probable?—Yes.

15,863. I am referring to Dr. Baly's aspiration experiments. The exposure is quite different in that case from exposure to vapour coming off from the painted surface of a wall. Do you think that if the turpentine had been mixed with oil, in the same proportion as is used for paint, and the surface of the cage had been painted with that in the same way as in the first series of experiments, you would have obtained a much better comparative test?—I got the effect from paint with turpentine.

15,864. You were narrowing it down?—I narrowed it down in this way; paint containing turpentine produced salivation and effects which we will call turpentine effects, and which were definitely found ultimately to be associated with turpentine. That produced illness. The various other paints, zinc, lead sulphate, and so on, also mixed with turpentine, produced effects which I came to recognise as turpentine effects. Lead acetate, oil, and turpentine painted on the boards produced the same effect, only it was more pronounced, finally when we vaporised the turpentine, by passing air through it. There was a device at the side of the cage to catch any splashing, but there did not appear to be any marked degree of splashing, and as the apparatus for the turpentine was in one corner of the cage, I do not think that the whole of the air would become impregnated with splashing. It would be only local and high up in the cage away from the animal.

15,865. A witness who is appearing before us tomorrow makes a very great point, in his proof, of this spray in the air, and the way in which it will travel, and the substantial impossibility, having once disturbed the atmosphere by making a spray, of getting it out of the air again?—But the turpentine may be in the form of spray when it is evaporating from the surface—small microscopical bubbles bursting. The whole thing may be a question of fine spray and not gas. That I am not prepared to say.

15,866. Fine spray caused by the evaporation?—Yes. Take, for instance, water vapour in the air, we find it in the form of droplets. The turpentine may be in the form of droplets. It is rather a physiological question.

15,867. I quite agree, but experiment on the last point, with regard to getting exposure to turpentine

and oil in the same way from evaporation off the surface of the wall, has not been carried out?—Yes; I did it with turpentine and thinners, the oil and the turpentine.

15,868. But not the turpentine and oil alone?—Yes, turpentine and oil; oil and turpentine and acetate.

15,869. Did you use turpentine and oil painted on boards?—Yes.

15,870. With nothing else?—Nothing else at all.

15,871. That is the experiment I want to know about?—That has been done. I got the effect so much quicker by using the turpentine alone bubbled. It was the same effect. The more ventilation one gave the animal, the less was the effect, obviously.

15,872. Have the animals exposed to turpentine and oil used in this way and those exposed to turpentine, oil, and lead, and turpentine, oil, and zinc, been respectively subjected to *post-mortem* examination?—Yes.

15,873. Have you details of the three series?—I do not know whether I read the details or not, but I said they were all the same. They all had the same type of symptom with regard to turpentine, varying in degree with the length of exposure and the quantity of material.

15,874. Now, you mentioned that you got your turpentine effects more rapidly if you were using fresh turpentine?—Yes.

15,875. Turpentine is, after all, a complex body; do you think that there are possibly any constituents in turpentine which are more likely to cause ill-effects, other more volatile substances, which might be removed?—It is quite possible. In fact, my observation rather suggests that that is so. My observations would allow of that deduction, but as to what they are and whether it is possible to remove them, one could not tell without further experiment.

15,876. It seems to me a very important point to find out whether there are certain constituents in the turpentine which cause the trouble when inhaled, and which possibly the painter could do quite well without?—If it is the wish of the Committee, I shall be very happy to continue the experiments to try to solve those points. I have the apparatus still.

15,877. You mentioned that turpentine particularly acts on the mucous membrane of the bowel, in places at any rate, did you not?—That is a wrong deduction, I think. I found, associated with turpentine poisoning, lesions of the intestine.

15,878. In all the animals?—Yes, in all the animals. It may be some compound of the turpentine. It looks as if the turpentine or some poisonous substance was being excreted. But I have not recognised turpentine in the intestine.

15,879. I will put it differently. The effect of turpentine on the animal body is to produce lesions of the intestines?—Yes.

15,880. I expressed myself badly?—Yes. It is a question of medical expression. You know quite well what I mean.

15,881. Yes. It is also true, is it not, that lead is largely excreted from the body by the bowels?—Yes, under conditions of lead absorption without illness.

15,882. If an individual were exposed to lead absorption without illness, and then to turpentine vapour, might it not affect the normal path of lead excretion from the body?—Yes, but I think that it would be more likely to produce kidney trouble than bowel trouble.

15,883. For this point it is quite immaterial what trouble it would produce. Would it not, therefore, be liable to precipitate symptoms of lead trouble?—I think so. That is a point that I have been discussing, and it is one on which the Committee require further information than I can give them.

15,884. Looking at the point conversely, if the exposure to turpentine vapour is sufficient to cause transient symptoms, and therefore may be considered to be affecting to some extent the path of excretion through the bowel, if a man is exposed to lead he may suffer from illness which he would not suffer from where the paint that he is using is, let us say, possibly, zinc paint?—That is arguable, but before

G g 4

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

giving an answer I should prefer to have experimental data to go upon. It absolutely suggests itself from my experiments, and you have really put your finger on a very important point. Although one might express an opinion, and that opinion might be correct, it is a matter of such extreme importance that it should be investigated.

15,885. You see my point?—I see your point clearly.

15,886. If we could not get rid of turpentine, but we saw our way to modify the amount of lead in the turpentine vapour which possibly produces the transient and not marked pathological effects, it would be an advantage?—Yes.

15,887. The presence of lead is a large element in the danger?—I think it is, no doubt.

15,888. I quite grant that we want further light on that point?—Yes, I am absolutely in agreement. That is why it strikes me as being a matter of some importance to ascertain whether if the paint, say, be limited to a content of 5 per cent. of soluble lead, as is adopted for glazes, that quantity of lead may be just sufficient in the presence of turpentine to cause disease. I think that is a matter that the Committee would want further evidence on.

15,889. You cannot take the percentage quite as a safe percentage, but an increased percentage is more likely to cause illness?—My point is whether 5 per cent. is a minimal dose.

15,890. Yes. With 5 per cent. there would be a material gain, but whether we should have got to the minimal point is another thing?—Yes.

15,891. It might be necessary to drop below it?—Yes, from the point of view that we are discussing.

15,892. The whole thing requires further light thrown upon it?—It requires further light thrown upon it.

15,893. I only want to get clearly before the Committee the line which such inquiry should take?—Yes.

15,894. (Chairman.) I hope that your experiments may be made comparable with the conditions under which working men come into contact with the risk of breathing lead dust, if it is possible?—That should be done in the way of cutting down the exposure of the animal to such a limit that it will not be exposed to more dust, within reason, than might be expected to be met by a painter. That can be done with a new apparatus.

15,895. I notice you say that in some of your experiments you only used 1 milligramme of lead in 10 cubic metres of air, and it produced poisoning?—Yes; for a long-continued time.

15,896. We had the air in some of the coach-builders' rooms tested by Mr. Duckering, and in the dry rubbing-down process it varied from 3 to 1,000 milligrammes per 10 cubic metres?—Estimated as Pb. O.?

15,897. Estimated as Pb. Dr. Kaup quoted, in evidence which he gave before the Committee, amounts of lead in the air varying from 10 up to 250 milligrammes per 10 cubic metres of air?—I follow.

15,898. (Dr. Collie.) Would you allow that there is a point, with regard to vapour of turpentine, below which the body can deal with anything that is inhaled, in the same way that the body can deal with a sub-minimal dose of lead?—I have not had sufficient experience of turpentine poisoning yet to be able to tell. Turpentine is rather different from lead in that way, being a volatile substance. Excretion through the kidneys sets up rapid changes. These animals that have only been exposed for, at the most, four hours, show well-marked tubal nephritis. They are probably excreting a great deal. It looks as if it was highly irritating.

15,899. The animals exposed to the complete paints did not show such acute symptoms?—No, but the amount of turpentine there was presumably much smaller.

15,900. There might be a sub-minimal dose?—There might be a sub-minimal dose. Whether turpentine vapour is a substance that the kidneys could establish a tolerance for or whether they would break down

under small doses, is a thing one could not say without further experiment. It is a very important point.

15,901. (Mr. Sutherland.) Have you made any experiments with fumes from burning off paint?—No, I have not done so. It is a little too dangerous.

15,902. Is that a scientific answer? Do you wish that to go on the minutes?—Certainly; I am afraid it must. The point is this: that in dealing with all fumes you have to heat up your substance, and you have to get off sufficient material.

15,903. Did you understand my question? I meant burning off paint with a torch?—I have not done it.

15,904. You do not regard that as very dangerous?—I do not know. I should find it exceedingly difficult to find any laboratory method of burning off paint which I should consider safe to employ my laboratory assistant at.

15,905. Are you frightened of the explosion of the lamp or the fumes of the lead?—I am frightened of the Employers' Liability Act.

15,906. Do you think, if considerations should arise that should decide this: Committee to recommend regulations and not prohibition of lead, the promulgation of strict regulations would not have a wholesome effect on the operatives engaged in the trade?—I think that it might be possible to devise regulations for practically cutting down the poisoning to nil, and I think that in examining the men from time to time in the way I have suggested you would put your finger on the weak point—on the men who were careless; and also the susceptible people. That is what we have done in the white-lead works. There are certain people who ought not to be employed in a lead trade, because they are susceptible to lead. There are many intercurrent diseases. There are many men with kidney disease, not due to alcohol, but to old rheumatism or scarlet fever. If such a man presented himself at lead works he should not be employed, because he would be dealing with a poison when his tissues are already half-poisoned with something else. I think that much might be done with regard to painting in that way.

15,907. Did you form any idea with regard to the point at which a painted surface ceases to evaporate or throw off turpentine?—No, I have no evidence yet that will give me any information on that point. That is one, I think, that is rather foreshadowed by the sub-minimal dose of turpentine. In attempting to get the evidence in the way that Dr. Collie suggests we should absolutely cover that point, I think.

15,908. It is a common thing for painters to use wet hay. It is supposed to attract the smell. With regard to the size of room that you mentioned when you spoke of the half-pint of turps, I worked it out that if we get a surface of wall, allowing for windows and openings, of 60 square yards, 12 lbs. of paint would cover that with one coat, and of that 12 lbs. of paint 2 lbs. would be turpentine. We should not evaporate half a pint of turpentine out of that?—You are using 2 lbs. of turpentine, and I used 10 ounces, which is equal to half a pint, as the maximum dose. You are using only in your paint for that size room three times as much turpentine as is necessary to saturate the room, so that if you get a third of your turpentine given off from that surface it is sufficient to bring it up to the saturation point that killed my cats.

(Mr. Parsonage.) In the ordinary way the turpentine would be twice the quantity of the oil, and not the minimum quantity.

15,909. (Mr. Sutherland.) For a flatted surface?—That is only for one coat. If you have four coats of paint it would be more.

15,910. It will not evaporate through the coats that you put on it?—The question is whether you get more evaporation from a zinc surface than from a lead surface. I do not know that yet, I think that on the whole there is more evaporation from zinc paint than from lead paint in that way.

15,911. There is more oil?—You get the skin formed over the surface pretty equally with lead paint. The drying with lead paint is much quicker than with zinc paint, so that you have with zinc a longer interval during which turpentine can be given off.

13 December 1911.]

Mr. KENNETH WELDON GOADBY, D.P.H., &amp;c.

[Continued.]

15,912. (*Mr. Parsonage.*) There is much more turpentine in lead than in zinc paint?—This is a very important point. If you will let me have the figures I can devise the experiments to correspond exactly.

15,913. (*Chairman.*) Perhaps you will give us the comparative amounts of vapour from each process?—Yes.

15,914. (*Mr. Gardner.*) A flatted room would have no oil except what was in the paste lead?—In Switzerland they have noticed turpentine poisoning. Lehmann says that he has noticed paralysis taking place in industries where no white lead was used at all. He describes the possibility of some of the forms of paralysis that are met with in painters as due to turpentine. He points to the fact that bisulphide of carbon produces paralysis by absorption through the skin.

15,915. (*Mr. Parsonage.*) With regard to the different experiments with painted boards, was one board tried without turpentine?—Yes.

15,916. With lead and linseed oil?—Yes.

15,917. Was there any result from that?—No, none at all.

15,918. (*Mr. Mason.*) Do I understand you to say, with regard to the French experiments, that owing to the reagent being unreliable the whole of these experiments are practically valueless?—The ones that rely on Heim's reagent I should regard with the greatest degree of suspicion. I have myself attempted to conduct experiments on their lines with the reagent. I welcomed it to begin with as a solution of many of our laboratory difficulties, but I found the reagent so absolutely unreliable that I was compelled to give it up; I got such discordant results. When I examined the French results, I found that the figures they gave varied within what they admitted was their own experimental error, so they were hardly worth regarding seriously under the circumstances. Curiously enough, the experimental error given in the physiological experiments and that in the chemical experiments show the same variation of at least 60 per cent., and a variation of 60 per cent. is unthinkable. That is in a published document.

15,919. You exposed one animal to turps and lead acetate, which you represent as liquid driers, I understood?—It was given to me as such.

15,920. That consisted mostly of turps. As a result you found that the animal subjected to this stood it twice as long as the cat subjected to turps alone?—Yes.

15,921. Would not you have expected an equally, if not more, pronounced effect from the turpentine plus lead acetate?—Yes, unless the acetate had had some action on the turpentine.

15,922. Would continued exposure to turpentine, even if the amount of turps was rather less than the amount used with the cats, show the same effect on the human system?—Presumably, yes. I have no absolute experiments. Dr. Collis raised that point just now. I have said that we have not sufficient evidence on the minimal dose of turpentine yet; but, in the smallest doses that I have given so far, effect has been produced. I have not yet got a dose of turpentine which will not produce definite changes in the animal's kidneys, and that is a point I have made a note of for further experiment.

15,923. With regard to the bubbling of air through turpentine, producing turpentine drops, would not you get the same effect from brushing paint on a wall?—I do not know how far paint sprays in that way. If you brushed turpentine on alone I suppose you would

get the same effect, but I do not know the quantity of spray given off; say, from stippling in the corner of a cornice. That is a point of considerable importance, of course. The viscosity of oil paint being so great, the question is how far is it given off in that way—whether fine spray is given from the surface, I do not know.

15,924. You say that you would not like your laboratory assistant to try burning off. Do you suggest that he is less immune than the ordinary painter who does this sort of thing every day in his life?—No; I should say he is distinctly more immune than the ordinary painter, because he has already suffered from lead poisoning on two occasions in helping with experiments. He had definite colic when I was doing the experiments.

15,925. If the more volatile constituents of turps as well as dry rubbing could be got rid of, would the lead itself be comparatively innocuous? May I deduce that from what you say?—I think so, as far as I have gone, but it is a mere expression of opinion.

15,926. (*Chairman.*) Is it not a question of what the other dangers are?—Do you mean from painting alone? Splashing, I presume, is included with dry rubbing down. There is no volatile compound, that I have been able to detect, given off from a painted surface, provided that is not disturbed.

15,927. But there may be other operations where dust is generated?—If you can get rid of the dust and the turpentine, you get rid of the poisoning.

15,928. (*Mr. Mason.*) I intended to include all dusty processes?—That is what I thought was meant. If you eliminated all the dust from lead paint, you would still have turpentine poisoning left. If you eliminated that, I think you would have very little poisoning.

15,929. (*Mr. Robins.*) Have you seen much actual painting done, because in the course of a conversation which was not for the shorthand notes you mentioned the manipulating of dry white lead. I would ask if you have really seen the thing accomplished, or is it imagination, because in over 35 years I have never seen a painter yet manipulate dry white lead with his hands. It is always done with the knife?—I saw it absolutely done by a painter, unfortunately. I have seen a good deal of painting one way or another. I am very interested in painting. I have done quite a lot of amateur painting myself.

15,930. I should think it is the exception and not the rule?—I think it is the exception, but it is evidence of extreme carelessness. A painter can create dust from dry white lead; if he has it to deal with, but if he has not got it to deal with he cannot.

15,931. I have seen hundreds of painters, but I have never seen that?—I am not suggesting that it is the usual method.

15,932. Some stress has been laid on the disastrous effects of lead poisoning from the uncleanly habits of the workmen. You will admit, I suppose, that the workman of to-day is more cleanly and intelligent than he was 10 or 15 years ago; how comes it, then, that there is such a large increase of lead poisoning?—Is there a large increase of lead poisoning, or have we better statistics now of poisoning? The only figures we have had to-day show a difference of between 28·6 and 30.

15,933. (*Chairman.*) The statistics show an increase?—There are many factors. Work is on the increase, and I do not know whether men are more or less careless now than they were. Any opinion I might express on the point would be only a pious opinion after all.

The witness withdrew.

## TWENTY-FIFTH DAY.

Thursday, 14th December 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.  
Mr. A. L. C. FELL.

Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*)

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

Evidence to 15,966 handed in and taken as read; witness then called and examined.

15,934. I am a fellow of the Royal Society and Professor of Chemistry at the City and Guilds of London Central Institute. I am the author of several works on chemical subjects. I have recently made an extensive study from the chemical point of view of noxious vapours of turpentine and other similar substances.

15,935. My attention has been directed to a lecture given on "The Toxicity of White Lead" by Professor E. C. C. Baly, of the University of Liverpool, to the Liverpool Section of the Society of Chemical Industry, on 3rd May 1911, a report of which has been published in various trade journals, but which has not yet been published in the journal of the society.

15,936. The purpose of this communication appears to have been to suggest and prove that volatile matter containing lead is given off from white lead paints in drying, and that white lead paint is specially dangerous on this account. Professor Baly proceeded on the assumption that, "If, as painters insisted, some lead compounds were given off in drying white lead paint, there would be absorption of light when light was passed through the vapour into a spectroscope." It was natural that he should make experiments in this way rather than look at the matter as a chemist, because he has devoted his attention almost entirely to spectroscopic work in the past.

15,937. Professor Baly appears to have taken photographs, with the aid of a spectroscope, across the interval provided by tubes 2 feet long coated inside with various mixtures in such a way that any vapour inside the tube could exercise its effect on light on the way to the spectroscope. There was evidence of light being absorbed when the tube was one coated with white lead and linseed oil, but not when either zinc white or "Purex" (basic lead sulphate) was used. These experiments were repeated in various ways, at various temperatures, practically always with the same result.

15,938. Professor Baly's conclusion, therefore, was that the painter, in using white lead paint, is exposing himself to volatile compounds. He then proceeded to make experiments to determine what these compounds were. To this end he distilled white lead—by which I understand he means the paste of white lead and oil used by painters—in various ways, and obtained distillates containing lead.

15,939. The final conclusion Professor Baly arrived at was that a definite volatile lead compound is given off in the drying of white lead paint. He appears to think that this behaviour is peculiar to basic carbonate of lead, and that it is an explanation of the prevalence of lead poisoning among painters using white lead; he further suggests that it may explain the symptoms often exhibited by persons after sleeping in a room recently painted with white lead paint. According to his statements this objection does not apply to "Purex" (basic lead sulphate).

15,940. I have no objection to make to Professor Baly's statement based on spectroscopic evidence that vapour of a volatile compound is given off during the drying of white lead paint—but his experiments prove

nothing more than this. Almost any vapour of an organic substance would produce the effect he observed and recorded in his photographs. It is well known that the drying of white lead paint is attended with a variety of changes likely to give rise to volatile products. Judging from our knowledge of the chemistry of lead, however, it is eminently improbable that these volatile products contain lead.

15,941. But the statement cannot be disregarded that Professor Baly found lead in distillates from white lead. I do not dispute the accuracy of this statement, having made similar observations on repeating his experiments. But I do dispute entirely the inferences he has based on his observations, and deprecate the haste with which, and the evidence on which, he has assumed that volatile lead compounds can be produced, and are actually produced, in practice when white lead paint dries.

15,942. At the outset of my own experiments on this matter, I not only had Professor Baly's results before me, but also observations made at my request by Mr. C. A. Klein, that when steam was passed into a mixture of white lead and oil mixed with lead acetate, a distillate was obtained which contained lead, though when the acetate was not used lead was not present in the distillate.

15,943. I had no difficulty in confirming Mr. Klein's result, and yet I felt that it must not be interpreted as evidence of the volatility of lead compounds or of the formation of a volatile lead compound, long experience having taught me that the difficulty of preventing materials from being carried forward mechanically during distillation with steam (or what engineers call priming) is very great indeed. It has taken me a long time, however, to satisfy myself that I was right. We tried in my laboratory, in all sorts of ways, to prevent spray from being carried forward, and also to prevent liquid from the still creeping along the surfaces of the apparatus leading to the condenser, but to no purpose; we were at last convinced, however, that lead was carried forward mechanically on observing specks to form in places where their presence could not possibly be accounted for in any other way. I then came to the conclusion that spray was being projected forwards and carried forwards, and that perhaps also liquid films were sometimes forced forwards along the surfaces of the apparatus by the eddies and sharp currents set up by the steam in the upper part of the distilling apparatus. This view was confirmed subsequently on using as connecting and condensing tube a length of block-tin tube, nearly half-an-inch in diameter, simply bent at an acute angle about 1 foot above the distilling flask. Very little lead was detected in the distillate when this was substituted for the elaborate glass head (provided with traps) we had used previously when a very sharp current of steam was passed into or generated in the distilling flask; when a moderate current of steam was used, lead could not be detected in the distillate with certainty. Similar results were obtained with white lead and "Purex."

15,944. I had a similar experience a year or two ago in connection with an analytical process in which

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued]

steam is passed into a solution of caustic soda. It was found that soda always passed over, though elaborate precautions were taken by introducing traps to prevent the spray from being carried forward; satisfactory results were obtained only when the simple arrangement above referred to was used. I may also refer to the well-known fact that sea-water spray is carried long distances inland.

15,945. It is to be noted that lead appears in the distillate only when lead acetate is added to the white lead oil paste before passing steam into it. The acetate appears to act in two ways—it seems to emulsify the paste so that this breaks up into fine particles when steam is passed in; but probably the chief reason is that when a solution of lead salt is present fine particles of the liquid are carried forward as spray with the steam.

15,946. The appearance of lead in the distillate when white lead paste is distilled *in vacuo* may be accounted for in the same way. The distillate consists mainly of water mixed with a little volatile oily matter. When the paste is heated the escape of steam and other vapours, with some carbonic acid gas from the heated mass, involves the production of spray, formed by the bursting of bubbles at the liquid surface, and presumably the lead is carried forward in this spray.

15,947. The change which takes place when white lead is heated, involving the escape of water and carbonic acid, cannot occur when zinc white or "Purex" is used, as gas is not given off from these; but even in their case spray may be formed by the bursting of bubbles.

15,948. No such spraying effect or mechanical separation of particles as is observed in distilling white lead paste can occur during the drying of paint under the conditions of ordinary practice, and therefore these experiments have been carried out under much more rigorous conditions than obtain in practice.

15,949. Passing to the consideration of the question of vapours given off from paint in drying, Professor Baly makes the remark: "Everyone is familiar with the characteristic smell of white lead paint when drying upon a newly-painted surface, which is described by painters as the smell of lead. Painters have long ascribed this characteristic smell to lead, and it is noticeable that there is no such smell from zinc white paint."

15,950. Professor Baly has been at no pains to consider how the smell of paint arises. The paint as used contains not only the lead and the oil in which it is ground, but also turpentine, and boiled or raw oil, which are added to reduce the paint to a proper consistency for painting. The smell described as that of paint is merely that of turpentine modified and increased by that of boiled oil, and there can be little doubt that the smell of which people complain when interior painting is done is principally due to that of the turpentine thus modified. Turpentine is a quite volatile substance, and the first stage in the drying of paint is due to the rapid evaporation of the turpentine.

15,951. Turpentine is also used with zinc white, Purex, &c. All paints containing turpentine, therefore, suffer from the same objection that during the earlier stages of drying they give off vapours of this substance which are productive of headache and other symptoms in persons unaccustomed to them. Painters, apparently, are accustomed to turpentine, and are not, as a rule, affected by the vapour; they usually work in rooms with open windows, moreover, so that the effects are minimised.

15,952. Boiled linseed oil has a distinct and characteristic odour. A mixture of white lead and boiled linseed oil, therefore, has a distinct and characteristic smell, but this smell is nothing like so strong as that of paint proper containing turpentine, and is not productive, I believe, of headache or similar effects.

15,953. A paste of white lead and unboiled oil has a smell similar to but much fainter than that of paste containing boiled oil; in some way the white lead appears to promote changes in the unboiled oil, but these also take place in the unboiled oil alone on exposure to air, though less rapidly than when it is mixed with white lead.

15,954. The smell of a mixture of lead sulphate (oxysulphate; Purex, &c.) with unboiled oil, or of zinc white with unboiled oil, is faint in comparison with that of the white lead mixture, because these substances do not promote changes in the oil to the same extent, if at all, that white lead does. It is well known that when white lead is mixed with linseed oil, especially boiled linseed oil, a product is obtained which dries more readily than any other paint; this is doubtless due to some change which does not take place with an equal degree of readiness, or to an equal extent, when other substances are used in place of white lead; it is on this account that white lead is of such special value. But the changing substance is known to be the oil, and the volatile substances which produce the smell are, I fully believe, nothing more than products from the oil. There has never been reason to suppose that they emanate from the lead, or contain lead. The function of the lead compound is to promote change in the oil, the mixture of lead and oil being one which dries well, and at the same time gives off the vapours which are characteristic of the changes taking place when an oil or paint dries.

15,955. The test used by Professor Baly as proof of the emission of vapour is very costly and difficult to apply, and not practical. In studying the production of vapours from oils I have applied a far simpler test, which anyone can use, and which, moreover, has the great merit that it is a physiological test. In other words, it is one in which the effect observed is that of the vapours on living material, and is therefore akin to that which is produced on the human subject.

15,956. I expose leaves of the ordinary spotted Japanese Laurel or aucuba over the substance to be tested. If vapour be given off which is capable of diffusing through the cell walls, the leaf turns black. This behaviour of the lead has been fully discussed by me in a recent communication to the Royal Society.\* When the leaves are put into a bottle together with a few drops of turpentine, blackening is soon noticeable, especially if the temperature be at all high and approaching blood heat. At this last temperature the leaf is often completely blackened within an hour or so, some effect being visible after very few minutes. The vapour of turpentine is therefore very active in causing what may be termed physiological breakdown within the leaf.

15,957. The leaves may be exposed alone or over water, often during many weeks, without blackening.

15,958. To test the effect in the absence of turpentine three different purchased samples—bought retail in London, genuine in quality—of white lead mixed with oil were put into separate jars with fresh leaves. No change was apparent within 24 hours at room temperatures. The bottles were then kept in a heated chamber at about blood heat; the leaves in all three jars were entirely black after a further interval of about two days, which was clear proof that a volatile substance was given off from each mixture. The leaves were removed and strips of moistened filter paper substituted for them. After six days the papers were tested with sulphuretted hydrogen, but no lead could be detected. Had a volatile lead compound been formed, it is to be supposed that it would have been indicated.

15,959. Jars were then charged with the following:—

1. Linseed oil (the linseed oil used throughout was the best Baltic oil).
  2. Linseed oil and white lead.
  3. Linseed oil and sublimed lead (basic lead sulphate of French manufacture).
  4. Linseed oil and lithopone.
  5. Linseed oil and barytes (natural).
  6. Linseed oil and zinc oxide (free from lead).
- (These pigments had been analysed and all found to be of the best quality.)

15,960. No visible effect was produced during a day at room temperatures, but after two days' exposure at

\* Proceedings of the Royal Society, 1910. Series B, vol. 82, p. 588. See also "Annals of Botany," April 1911, vol. 25, p. 507.

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

blood heat the leaves over the white lead and basic sulphate mixture were black; signs of blackening here and there were obvious on all the other leaves except that over linseed oil alone. After two days' further exposure all the leaves were blackened to a considerable extent, except that over linseed oil alone. When leaves were exposed over a similar series of mixtures containing turpentine in addition they were blackened considerably within an hour, showing that all paints made up with turpentine give off vapour readily.

15,961. Mixtures of linseed oil with "Purex," with lime, with baryta, with various commercial driers (including manganese driers) all affected the leaves after more or less prolonged intervals, and even linseed oil alone eventually blackened the leaves.

15,962. After making a great number of experiments such as described, I am convinced that the production of vapour is in no sense special to mixtures of white lead and linseed oil such as are used as paints, but that lead and zinc compounds generally, indeed almost all the various finely divided substances that are mixed with the oil to form paints, have the property of more or less hastening the change, whatever it may be, which takes place in linseed oil on exposure to moist air. Nor is linseed oil peculiar in this. Sunflower oil, crude and refined soya bean oil, menhaden oil, and even olive oil, exposed with white lead, give off vapours moderately rapidly; castor and china-wood oils seem to be much more slowly affected. But I imagine that much depends on the age and purity of the oil. I feel sure, however, that any oil that will dry and can therefore be used in paint will be found to give volatile products as it dries.

15,963. Proof that volatile matter is given off from oils on exposure to air is also obtained when they are placed in open dishes over oil of vitriol in a closed chamber. The colourless oil of vitriol gradually becomes coloured by the vapour.

#### Conclusions.

15,964. The conclusions to which I have arrived are that there is no reason whatever to import any new element of danger into the consideration of the question of paints. Lead paints are to be objected to only in the sense that they may enter into the system through careless handling or in the form of dust such as is produced by rubbing down old paint. There is no reason to suppose that the vapours given off during the drying of the oil are objectionable under ordinary conditions, and further, they are not found to contain lead; they are products formed during the drying and oxidation of oil, and are produced entirely from that source.

15,965. The rate at which vapours are produced (not the total amount) is determined by the rate of drying. Lead paints dry more rapidly than others—the presence of vapours can be detected in less time when lead paint is examined than in other cases.

15,966. The vapours from oil are produced so slowly and in such small quantity that ordinary ventilation is bound to remove them. Turpentine undoubtedly produces marked effects, but the workers seem to grow accustomed to these, and they are transient; moreover they are easily guarded against.

15,967. (*Chairman.*) I note that your proof is largely devoted to criticism of Dr. Baly. Have you been in touch with him, and are you fully acquainted with the methods he used?—I have not been in communication with him in regard to this, but I am fully aware of the methods he used, because a few months ago I was up at Liverpool and saw the apparatus, and I know it from when he was using it in London.

15,968. We have had opinions like yours expressed to us by Mr. Goadby, who said he differed also from the results found by M. J. L. Breton, Dr. Heim, M. Hébert, and Dr. Marie?—Those are with reference to the physiological effects, are they not?

15,969. Yes. Do you think that the various tests used should be very carefully criticised?—Certainly.

15,970. We, of course, cannot enter into polemics between different chemical experts. Would it not be as well to ask the principal chemist of the Govern-

ment laboratory to express an opinion of the various tests which have been used, and to estimate the scientific value of the deductions based upon the different experiments?—Yes. I should see no objection to that whatever.

15,971. You found a material difference in the behaviour of white lead in your experiments, according as lead acetate was or was not present in the white lead?—With regard to lead being carried forward in currents of steam, yes; but not in other respects.

15,972. Is acetate of lead not generally present in white lead as used by a painter?—In some cases it is; and in some cases care is taken to remove it. It is there in small quantity, much smaller quantities than we had present, I think, in our experiments.

15,973. Is acetate of lead, known as sugar of lead, frequently contained in liquid driers as sold to painters?—I do not know enough of the composition of driers to say that, but it is quite likely.

15,974. Your conclusion as to lead particles being carried over in your experiments, was that the detachment from the painted surface was purely mechanical?

—Yes. I want to emphasise that point very strongly, because Professor Baly states that there is a volatile lead compound, not a substance which is carried forward mechanically in any way. There is no mechanical action possible in his earlier experiments when he took photographs through the vapour. The mechanical action was eliminated, and therefore what we were dealing with when we were passing currents of steam was in a sense eliminated. I have been dealing in the one case with the mechanical carrying forward, and in the other case with volatilisation, but those two require to be distinguished very carefully, I think. I do not for a moment question vapour being given off, but the question between us is as to what that vapour is, whether it contains lead or no.

15,975. Exactly; what is your conclusion?—We say that on no occasion is lead vapour given off.

15,976. But have you confined your determinations to lead vapour?—No, but I mean that our experiments show that, if lead is carried forward, it does not go forward as vapour, but is mechanically carried forward, which is quite a different thing.

15,977. Is there not generally some mechanical detachment from newly painted surfaces?—I should think not. I have been in the habit of observing paint, and painting myself all my life, and I do not see how mechanical detachment is to arise, except, of course, splashing from the brush.

15,978. I was going to ask about splashing?—That might arise if a painter is careless.

15,979. In any case, your evidence would seem to point to considerable danger from fine spray, such as we are told arises (1) in the painting of ceilings with deep moulded designs; and (2) in stippling?—For the moment I do not deny that in so far as concerns mechanical distribution of lead paint, whether at the time of application or at the time of rubbing down, it may occur; but I merely wish to be clear on the point of there being any emanation, anything which would affect people who went into the room after the painting had been done.

15,980. You mean in connection with lead vapour?—Yes.

15,981. Now you say that all paints containing turpentine give off the same vapours. How do you account for the absence of the characteristic lead paint smell when zinc paints are being used with the usual mixture of linseed oil and turpentine?—I think that there is a lead paint smell to some extent, but that lead paint smell seems to arise mainly from this oxidising action which takes place much more readily and rapidly when the lead is present. It is a product of the oxidation of the boiled oil apparently—particularly of boiled oil. It takes place in the case of unboiled oil, but so slowly that you do not perceive it. No paint changes so rapidly as lead paint. It is a question of the rate at which the paint changes, I think.

15,982. You probably are aware that practical painters say that they can tell whether a fresh paint contains lead or not, even in the dark?—It may be.

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

15,983. Do you think that that is likely?—I think that that is quite likely—with the expert nose. It is a very good judge of small differences always.

15,984. Would you read paragraph 15,953 of your evidence? I do not understand it?—“A paste of white lead and unboiled oil has a smell similar to but much fainter than that of paste containing boiled oil; in some way the white lead appears to promote changes in the unboiled oil, but these also take place in the unboiled oil alone on exposure to air, though less rapidly than when it is mixed with white lead.” The white lead seems to have a very marked influence in hastening the rate of change, the rate of drying of the paint, and you get the peculiar smell produced to a greater extent on that account apparently.

15,985. Now with regard to the distinction you draw between the behaviour of boiled oil and unboiled oil when used with white lead, have you actual experimental evidence bearing on this point?—I have tried mixtures of the two with white lead, and got quicker effects with boiled oil.

15,986. Both as to smell and drying?—I have not done it with regard to the smell in particular, but with regard to the effect produced as tested by those leaves (*producing some leaves in jars*).

15,987. (*Mr. Sutherland.*) It is a commonplace that boiled oil dries much quicker than raw?—Yes; that is the object of boiling.

15,988. (*Chairman.*) But I understand from the paragraph you read out, that you assert that white lead promotes changes in unboiled oil at a more rapid rate than it does in boiled oil?—No; it is the other way. It is the last sentence that has misled you a little.

15,989. It is not quite clear. I will put it in another way: Do you assert that white lead promotes no change in unboiled oil?—It promotes change, but the change is slower. The boiling has the effect of rendering the oil much more sensitive, much more oxidisable. It is a process of atmospheric oxidation.

15,990. In the paragraph 15,966 of your evidence you say that the dangers of turpentine poisoning are transitory, and easily guarded against. Will you tell us first of all in what way they are transitory?—In the sense that the vapour is absorbed, and easily eliminated from circulation, I think. It is not like lead, which is known to be a solid material, and known to be cumulative in its action. It is known to pass out in the urine.

15,991. You further state that the workers seem to grow accustomed to these smells?—Yes.

15,992. In what way do you mean? Do you mean to say they become immune to the dangers?—They do not notice it, and they grow accustomed to it apparently, and it is very much, as I understand, a question of the individual. I had a painter in the house a fortnight ago, whom I have known all my life, and I asked him whether he ever suffered. He said that he had never had a headache in his life. I know myself that I have had headache at times if I have been exposed to turpentine vapour, but it has passed off very quickly. I had a great deal to do with turpentine a good many years ago. I used to watch all the qualities of turpentine that came into the London market for the chief importer.

15,993. But do you think that, though you yourself were partly immune, as you were not affected, it might be serious to other men?—I do not think it is ever serious. I think, at the worst, you get headache from it.

15,994. Is not that a sign that something is going wrong in the constitution?—It is a slight sign, but it is not necessarily serious. I do not think turpentine, in the quantity that can be inhaled, is to be regarded in any way as a poisonous substance. You see, it is very slightly volatile. You do not get much into the air.

15,995. You would not say that it might seriously impair the constitution, and affect the kidneys, for instance?—No, I do not think so.

15,996. Have you any authority for saying that, or is it only your personal opinion?—That is my personal opinion.

15,997. Perhaps you would not like to give a definite opinion on the question with regard to the physiological side?—No. I know that it has been given in quite large quantities to animals, and has been recovered again in the urine in combination. It does not come out as such, but it comes out in combination.

15,998. You finish up your evidence by saying that the evils of turpentine, whatever they may be, are easily guarded against?—Yes.

15,999. In what way do you mean?—Opening the windows.

16,000. Simply that?—Nothing more.

16,001. I notice that you have brought some test glasses with you. Have you any important point which you can illustrate by those?—I thought that you would like to see the way in which these things are indicated. No doubt you are familiar with this leaf. It is a very common garden shrub (*indicating a leaf*). It is the Japanese spotted laurel, the *aucuba*. That becomes black under the influence of all kinds of vapours which can get into the leaf, and one can use it as a test for comparing the extent to which vapours are given off in this case. The first jar contains a mixture of white lead and linseed oil, unboiled oil. The leaf in that jar has been in there 48 hours at blood heat, and it has been left in an ordinary room since.

16,002. Would you describe what you consider the change in the leaf to be?—You see that almost the whole of the leaf there has become black, showing that there has been very marked action indeed. Now the next jar contains simply oil alone (*producing another sample*). No change is visible after 72 hours at blood heat—against almost complete change in 48 hours when the lead is present. That about illustrates as well as one can illustrate the remarkable effect that the lead has in hastening the change in the oil.

16,003. (*Mr. Sutherland.*) In hastening the oxidation?—In promoting drying; and, in the process of drying, there is volatile matter given off, which acts upon the leaves.

16,004. (*Chairman.*) Do I understand that in neither case is there any turpentine in the mixture?—There is no turpentine there.

16,005. (*Mr. Sutherland.*) Is it raw linseed oil or boiled?—That is unboiled oil. The temperature, you will see, is a little above the ordinary. I have quickened it by putting it at blood heat.

16,006. What do you deduce from that?—It simply illustrates the giving off of vapour from the mixture and shows that the rate of change is hastened by the presence of the lead. Now, the next is a similar vessel containing zinc white and oil as a paste—the same oil as in the other. The change is only just beginning to show there after 72 hours. It is very slight indeed.

16,007. (*Chairman.*) This jar contains zinc white plus unboiled linseed oil?—Yes. There is the same weight in each, but you get a greater bulk of mixture in the case of the zinc white.

16,008. (*Mr. Sutherland.*) Is the lead in that one held in solution?—It is merely mixed with it as though it were paint, but there is rather an excess of oil. If I poured off that, the paint consistency would be more at the bottom you see.

16,009. (*Chairman.*) What deduction do you make from this leaf?—That the zinc oxide has much less influence in promoting the drying. One knows that zinc is not good in that respect. Driers are used with zinc white in order to make the paint dry. Zinc white and oil together do not give a good paint. You have to put in driers.

16,010. (*Mr. Parsonage.*) One has been 48 hours, and the other 72 hours?—Yes. The first was exposed for two days and these for three days. *This is another jar with turpentine in (producing the same)*. I put that in only just before coming down here at half-past 10, and it has begun to blacken. In the course of an hour that leaf would be entirely black. The vapour is given off from the turpentine much more readily.

16,011. What is in that glass besides turpentine?—Nothing but a few drops of turpentine. The leaf is in air, of course, and turpentine.

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

16,012. (*Mr. Sutherland.*) The point then is the rate of oxidation?—Yes, very much hastened by the presence of lead, and by the lead oxide apparently in the white lead.

16,013. In the carbonate of lead?—Yes.

16,014. (*Dr. Collis.*) Did you expose any leaf to the influence of oil and manganese driers?—Yes.

16,015. What was the effect of that?—Not quite quite so rapid as with the lead. You get the vapour given off much more rapidly in the presence of driers than when no driers are present.

16,016. I presume that you tried the obvious control of white lead alone without the oil?—Yes. There is not the slightest effect produced with white lead, but there is with oil alone after a considerable interval.

16,017. Are you familiar with the bacteriological experiments, or rather the experiments with growths of bacteria and moulds, which were carried out in France on the same point?—Yes, I have read the account of those.

16,018. Do you consider that this test would be more delicate than theirs?—I think that it is quite as delicate.

16,019. They obtained a retardation of the growths of moulds and microbes with lead carbonate alone, you may remember?—Yes.

16,020. Your test does not show that?—No. Of course that sort of experiment has to be made over and over again to be quite clear.

16,021. Theirs were repeated by three independent observers with three independent forms of organism. I do not know whether one can draw the conclusion that their test is more delicate, in that they obtained a result when working with white lead alone, while your test gives no reaction?—I should like to control those experiments. I am not prepared to accept those results without very careful repetition and study. My own belief is that this method is quite as sensitive. It is altogether remarkably sensitive. If there is a very minute quantity of vapour present, the leaf blackens sooner or later.

16,022. Yes, but the blackening of the leaf after all is not of necessity an indication of the presence or absence of lead in the vapour, is it?—No, not at all. It has nothing to do with it necessarily. A very large number of volatile substances, in fact all volatile substances, produce the effect. It is a test of the presence of a vapour.

16,023. Precisely, but it in no way is an indication of the presence or absence of lead in that vapour?—Certainly not.

16,024. After all, that is the point that we have to consider, or rather one of the points. We quite understand that lead has an action upon oil which zinc does not. I think we understood that before. This demonstrates it in a very pretty way, but I do not think that it has carried us any further on the question of the presence or absence of lead in the vapours which come off?—I do not contend that it does, but if there were a volatile lead compound, that would produce the effect, I contend. Therefore, the absence of any change in the leaf is, to my mind, proof that there is no volatile lead compound there.

16,025. But you do get a change in the leaf when you have the lead and the oil mixed?—Not in the case of lead alone.

16,026. The lead alone could not give an organic vapour, could it?—The proof that there is no volatile lead compound has to be got in other ways. It is not got in this way. Given the production of a vapour, then you have to consider what evidence there is to prove that lead is present in that.

16,027. Exactly, but at present (I hope I do not misunderstand the evidence) we do not seem to have got any nearer the point. We are rather working in a circle. The presence of a vapour coming off from a mixture of lead and oil has been demonstrated to us very prettily, but we are no nearer the point as to what the constitution of that vapour is?—Except that it is not producible from the lead alone.

16,028. But you could not expect an organic vapour from lead alone?—I agree with you there. I do not

suggest for a moment that this test gives evidence of lead, but it is material with regard to the fact, that a great deal of vapour is given off. Professor Baly said that vapour was given off, and that that vapour was the vapour of a lead compound.

16,029. But this does not seem to controvert Professor Baly for a moment?—I do not say that it does. I say that he had no right on that evidence for one moment to assume that it was vapour of a lead compound.

16,030. But he did not assume it on that evidence. He only assumed by his spectroscopic analysis that he had a vapour, and you have demonstrated to us in another way, that it is not given off by zinc and oil. After that he attempted to aspirate the air containing the vapour, and to test it, I believe. At present he is repeating his experiments, and is not prepared as yet to give a definite opinion as to the constitution of that vapour; but it seems that you and Professor Baly are really in substantial agreement?—I agree with him as to there being vapour given off.

16,031. (*Chairman.*) If a vapour, as you assert, does come off, may it not assist in carrying off mechanically some of the lead?—No, not under paint conditions, I think.

16,032. Are you quite sure of that?—Yes, I should say so. You see the difference between my experiments and Professor Baly's is this: that I do not agree with Professor Baly that lead alone gives rise to vapour. I say vapour comes whenever you make a mixture with linseed oil, whether you use zinc-white, lead-white, or any of the other substances, and that the only difference is in the rate at which the vapour is given off.

16,033. (*Dr. Collis.*) But Professor Baly did not maintain that he got a vapour from lead alone?—He does practically. He says that Purex did not give any vapour.

16,034. But it is always lead and oil, or Purex and oil, or zinc and oil?—Yes. I say when mixed with oil.

16,035. Just now you omitted that?—I am speaking of the influence of these various materials upon oil—the behaviour of different paints. Whenever you make a paint, whatever material you use, from linseed oil, then that paint invariably will give off vapour sooner or later: sooner in the case of lead; later in the case of zinc white.

16,036. Pursuing the point further, you are doubtless aware of the work that was done in France on the same point. The French observers, after very careful repetition of their experiments, and after being attacked and criticised, and again repeating their experiments, make the extremely definite statement that they have conclusively shown that vapour containing lead does come off. Have you read those?—Yes, but I am not satisfied that that is the case. I cannot myself find any evidence. I can only say that.

16,037. Do you know Trillat's re-agent?—As a matter of fact, I have forgotten it at the moment. I have not read the subject up recently.

16,038. The whole question of the certainty of the French conclusions turns on Trillat's re-agent, and you would hardly like to criticise the French results without having acquainted yourself with the use of that, would you?—I am simply going on my own experiments. I say that, from my own experiments, I am not satisfied myself that there is any volatile lead compound given off. I am not dealing with theirs.

16,039. But some four or five years ago a scientific work, well known in literature, was published, and surely it is necessary for every scientific observer to acquaint himself with work previously done, to test the old observations to show whether they are correct or not, and to show how his new observations, when they do not agree with the old ones, differ. Otherwise it is hardly a scientific investigation. Possibly both sets of observations are right, but they are done in different ways. One may adopt one process and get a certain result, and you adopt another and get a different result?—I am putting this forward as an especially delicate test for the production of vapour. I am not concerned with the other experiments at all. I do desire to take up that attitude with regard to it. I say I have here a test which I desire to bring under

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

your notice as a test that can be applied by anyone at all times, which enables you to satisfy yourself whether there is vapour given off or not.

16,040. (*Chairman.*) You see, the difficulty the Committee are in is this: that you, an eminent authority, have made certain experiments, and you have obtained a certain result; but we bring forward evidence from the French, who have also made experiments by eminent men, in a different way, and they have got a different result. What are we to do?—May I be allowed to see that description to refresh my memory. Have you it here?

16,041. (*Dr. Collis.*) Here is a translation, and here is the original (*handing some papers to the witness*)?—I do not think that that test is in any way a test for lead alone. That would be given by many other substances, and especially by a substance which is undoubtedly produced whenever oxidation takes place by the oxidising agent, peroxide of hydrogen.

16,042. Have you used the test?—Yes, I know the test. It is one of the most sensitive materials known for testing oxidation. You get this coloured matter produced from the colourless material. It is very sensitive, but in no way is it a test for lead. It does not distinguish lead from many other things, more particularly from the thing which is there most undoubtedly whenever oxidation takes place.

16,043. But you see our present position as regards the evidence. The evidence you are giving us to-day, and the beautiful method of demonstration you have shown us for vapour, do not indicate to us, for certain, that there is no lead in the vapour. In the French work published some years ago, on authority, it is definitely stated that there is lead in the vapour, and, failing the repetition of those tests by yourself, so far your evidence has not carried us any further than we were before?—I should get the same result as they did with the vapour, but it is not a test for lead. Their test is not a test for lead.

16,044. (*Chairman.*) That is rather an important point. Would you mind explaining that a little more fully. You say you would get the same results as they did?—I should get the same results as they did if I used their test.

16,045. (*Dr. Collis.*) May I read further from their report? They say: "We have, moreover, varied our arrangement by making the air pass up and down over a white lead paint surface in a large glass bulb, and we have been able to establish in this manner the evolution of lead by using simply the ordinary re-agents, sulphuretted hydrogen or sodium sulphide."—That is a very different statement.

16,046. It is all in the same work?—But that is a very different statement. This is a test for lead; the other is not a test for lead.

16,047. (*Chairman.*) That is only one of their tests. It is not the only one. What do you think of that method of procedure?—That method of procedure is one which is the one recognised test for lead—getting precipitate with sulphuretted hydrogen.

16,048. They assert that, with that experiment, they found lead?—Yes, according to that statement. Then we have to consider whether that might be mechanical or not.

16,049. (*Dr. Collis.*) As they were only drawing air over it, and they give us the rate at which the air was drawn over, which is no greater practically than may occur in any room, we come to the question whether ordinary drying paint may not be carried off in that same mechanical manner—the same small particles (they are looked upon as such) containing lead?—Yes; if that test is properly applied, no doubt that would be so.

16,050. M. Trillat is a chemist of some eminence, is he not?—I cannot say exactly; I do not know.

16,051. He is a professor of the Pasteur Institute; I therefore ask whether he is not a man of some eminence?—Anyone attached to the Pasteur Institute, of course, may be so described, but I do not know him at all. I know nothing of his work apart from having heard of it here.

16,052. You see our position—that, before throwing aside this work that was done in France, for the

Government, with considerable care apparently, and by men of considerable reputation, we want that work to be repeated and refuted?—Yes.

16,053. It stands until it is disproved; and no one who has come before us, up to the present, has attempted to disprove this work, although they tell us they are acquainted with it. They give us their methods of inquiry, which carry us no further than we were before?—I quite agree with you there. That work ought to be repeated very carefully. I have not repeated it at present, and I am not prepared to —

16,054. Any attack on the subject, it seems to me, should take that line, as far as we are concerned. This work seems to me sound (I am speaking for myself) until it is controverted?—I cannot get the result myself, using the method that I have used. That is the only point on which I can speak, of course.

16,055. The report definitely states that these experiments were attacked and repeated time after time in France. Speaking for myself, I should not dream of asking for them to be repeated again; but, for those who are taking the opposite point, I think it necessary for them first to repeat those experiments, and to obtain or not to obtain the results, before asking us to consider that they are not authentic. The report on this point is really a very complete one?—Of course, in all this kind of work there is no doubt that very much depends on the way in which you work. You may have the same result over and over again, and yet the result may be due to some accidental circumstance. I, in the beginning, got lead carried over time after time, and I had a great deal of difficulty in separating out the accidental circumstances, so to speak, and showing myself that there was no lead volatilised that I could detect. In this sort of work, you see, we are dealing with small quantities at the best, and it is very difficult, as I say, to be sure that you are working under conditions which would not give rise to mechanical distribution of the material—very difficult.

16,056. Of course the points on which you differ from Professor Baly I must leave entirely to Professor Baly. It is not for me to take up the cudgels on behalf of anyone else, especially when he himself only professes to be in the middle of the work and has suggested that he be allowed to give further evidence; so that I must leave all those points to him. But there is a further question. On the matter of turpentine, I am rather astonished to hear your expression of opinion that turpentine as a vapour is not a dangerous thing. We consider it to be so, and have done for a long time. Work has been done abroad on the subject as well as at home, and we know that turpentine poisoning is a very serious thing. It does not pass through the body without injuring it?—It depends entirely on the amount. It is just like the case of chloroform. You may give quantities of chloroform which produce very little effect, and of course you may give quantities which produce death. It is all a question of quantity. That is true in the case of any volatile body.

16,057. Do you, as the result of your experiments, think that, if you have paint made with lead, oil and turpentine, and, let us suggest, zinc white, oil and turpentine, the evaporation from the lead paint will be slower or more rapid, or about the same as will occur from the paint made up with zinc?—Evaporation of the turpentine, do you mean?

16,058. Evaporation of anything; evaporation from the paint as a whole?—So far as the turpentine is concerned, I take it the effect would be very nearly the same.

16,059. Is it as the result of experiment that you make that statement?—You cannot make the experiment easily.

16,060. I thought you could, with the leaves?—That does not give you the measure of the quantity.

16,061. It gives the measure of the rapidity with which the leaves change?—Whatever paint you put into those, if it contains turpentine, you will find that it will act very rapidly. It is not so rapid that one cannot distinguish between them, so long as turpentine is present. The remainder of the process, the drying

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

of the oil, takes place more rapidly in the presence of lead.

16,062. Could not you retard the action by cooling?—Of course. It is all a question of temperature.

16,063. Would not you then have the opportunity, by retarding the action, of seeing whether there was any difference?—That might be done, if you cooled considerably.

16,064. The point is one, I think, of some importance?—You mean the relative rates of evaporation of turpentine from different paints?

16,065. It would suggest itself to me that, since lead has such a profound action upon linseed oil, and promotes the emanation of vapour when mixed with the oil, that emanation coming off from the surface would assist in carrying off any other volatile substance that is mixed with it, such as turpentine?—That is correct, if the emanation took place at a really measurable rate. The quantities concerned, in my tests with leads, are so small that that does not mean very much in point of quantity. Theoretically you are right, of course; but practically the difference, I take it, would be so slight as to be barely appreciable, if appreciable at all.

16,066. But in practice, it is appreciable. It is the whole question that makes lead paint dry quicker than zinc paint, is it not?—No. It is the thickening and the setting of the oil which makes the difference. It is not the disappearance of the turpentine, which is there merely for thinning.

16,067. But this action that we see demonstrated in your leaf tests, demonstrates the action of the lead upon oil which promotes what is known as "drying," by which I mean oxidation of the oil and the drying of the paint?—But the drying mainly involves the absorption of oxygen and the formation of a solid compound. It does not involve, so far as we know, the emission of much vapour. It is practically impossible to get that. You find a big increase in weight due to oxidation, and you know that something goes off.

16,068. But knowing that something goes off and that oxidation is taking place, is it not reasonable to conclude that the two things have an intimate relation one to the other, and that the chemical change shown in the oxidation is an indication of the emanation of the vapour? Knowing that vapour is given off, the two interchanges, one being the taking up of oxygen, are associated with the evolution of the vapour?—But the amount of vapour given off is probably very small, I contend.

16,069. My point is: have they a direct relation?—The more rapid the oxidation, the more rapid must be the evolution of vapour; if there is vapour given off; but the quantity of vapour, I should say, is so small that it will not materially affect the rate at which the turpentine goes off, which was your point.

16,070. That is my point?—I quite agree with the point theoretically.

16,071. Accepting the point that the amount of emanation given off is too small to hasten the evaporation of the turpentine to any extent, we yet have the point that lead paint does dry over quicker than zinc paint?—Yes, owing to the influence that the lead has on the oil.

16,072. Do you think that there is any indication there that the turpentine may have come off more rapidly or not—either one way or the other?—No, I do not think so, one way or the other.

16,073. Your only suggestion with regard to the method of guarding the worker from the fumes of turpentine when they come off, should they get too much in the air, is a mere question of opening the window?—Yes.

16,074. But that cannot be done where good paint work is being done, because of the dust?—It usually is done; is it not, whenever possible.

16,075. I must leave that to the practical painters, but they assure us to the contrary, and that they are afraid of opening the windows too much, because the dust which comes in settles on the paint and spoils the work?—It appears that you must have some

diluent to thin the paint. Now what will you use in place of turpentine?

16,076. That is not the point, at the moment. I am on the point of its being easily guarded against?—I quite agree, but I want to point out that you must use a substitute, and the substitute will probably have the same effect. All these coal tar oils which are used are more volatile, and, if anything, they have a worse effect.

16,077. (Chairman.) We want to establish whether turpentine is dangerous, and, if we establish that, we must seek for some way to protect the workmen, if possible?—Turpentine being so dear, they would have been glad to substitute something for it if they could.

16,078. (Dr. Collis.) At any rate, the less turpentine in the air, probably, the better for those working in the room?—Yes, it is a question of temperature, of course. You cannot get a very large quantity.

16,079. The paints which contain less turpentine, from the turpentine point of view, are likely to be less troublesome to the workmen than those that contain more?—I do not think that the quantity matters much. It is a question of the time during which the man is exposed to it. If there is turpentine there, it will not make much difference whether you put 10 or 20 parts of turpentine into the paint. The rate at which it was given off would be practically the same. I do not think that the amount of turpentine would make much difference. Using practical quantities—minimum practical quantities—I doubt if it would make much difference what amount of turpentine you had there. It is a question of temperature, just as it does not matter how much water you have present. It is a question of the pressure which the water vapour has, and that depends on the temperature. The quantity of evaporation is independent of the quantity of water.

16,080. But a wall which contains a small amount of moisture, compared with one which is covered with it, will, under similar conditions of warmth and pressure, give off the less amount of vapour?—I think not. If there is beyond a certain amount there which is not held back by the wall—I mean if the wall is really wetted.—

16,081. We come to the point of the amount that is held back. A certain amount of turpentine will be held back by the paint, you agree?—No, I do not think there will be much. I think you will find that the vapour pressure over paint would be practically independent of the amount of turpentine, so long as there is a reasonable proportion there. If I were to put five grammes or ten grammes into two cylinders, it would make no difference to the amount of vapour.

16,082. I quite follow that point when you once get the vapour saturated, but when your vapour is not saturated surely the wall will continue to give up its turpentine to the air, and as long as there is turpentine in the wall it will continue to give it up until the air is saturated, and if there is not enough turpentine in the one paint to saturate the vapour, and there is in the other, you will get more off from one than the other?—You never get that condition in a room, I think. The conditions are very different. It depends on the temperature and on the air current. Turpentine vapour flows very slowly. The amount you would get off would vary very much in practice according to the conditions of temperature and otherwise.

16,083. I quite agree?—I do not think that, as long as the wall is wet with turpentine, as it would be if you applied paint, it would make very much difference—not a practical difference—I agree with you that, theoretically, there might be a small difference, but in practice, I think, if you had turpentine in the paint it would not very much matter. Of course it would be given off over a longer period if you used more.

16,084. That is what I mean. That is obviously the point?—But the painter is subjected to it only during a certain period.

16,085. If a painter is painting that part of this wall, and slowly works round the room, by the time he gets to this side of the room, which may take a practical

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

painter a day, it will be a material point to him whether that has ceased to give off any turpentine, because it did not contain much to commence with, or whether, having contained twice as much, it is still giving off turpentine, and the whole room is giving it off instead of half the room?—It would be a question of ventilation. Suppose it were a shut-up room.

16,086. It is not a question of ventilation, surely. You are getting away from my point. I ask whether the amount of turpentine is not a material question in the amount that comes off, given similar conditions?—You are putting the question of increasing the surface, which is a very different thing from increasing the amount of turpentine in the surface.

16,087. I am taking the conditions of practical painting. That wall is painted with paint which contains more or less turpentine. First let us take a small amount of turpentine. That turpentine ceases to be given off, roughly, in half a day or four hours' work. By the time the man comes to this side of the room, which will take him a day, it has ceased to be given off for several hours, the room being closed to keep out the dust. In the second case, with twice the amount of turpentine, the paint is continuing to give off turpentine at the time the man comes round here?—The more turpentine there is the more it comes off.

16,088. It seems an obvious point, does it not?—My point was that if you had two mixtures it would not make much difference to the condition at the moment whether you had twice as much in the one case as in the other. If you accumulate it all in the room, the more you accumulate the more must be there.

16,089. That is the obvious point, but your first answer hardly seemed to agree with that?—I did not think you were putting the obvious point. I thought your question was the immediate influence on the painter of a mixture, according as it contains five or ten parts of turpentine. That was my understanding of your question.

(Dr. Collis.) I am sorry I did not make myself more clear.

16,090. (Mr. Sutherland.) I suppose that laboratory tests deal with small quantities; do they not?—Yes, as a rule.

16,091. And the French tests would be on the same scale in respect of quantity as yours?—You mean they would have made their experiments in the kind of way that we should make ours—yes.

16,092. What do you wish to prove to the Committee from these leaves?—Merely to illustrate the relative rates at which changes takes place with these various paint mixtures.

16,093. Would the rate have been accelerated if the stoppers had been off? Were they off?—No; they were just as they are now, so as to expose the leaves to the vapour that comes off. I do not think that that would make much difference.

16,094. Would it not?—If you had a current of air going over a surface, the change would be more rapid.

16,095. But would not the air go in and out of those?—There is such an excess there that I do not think it makes much difference. Those are not airtight; the air would get in.

16,096. What do you deduce from that, as applied to a painted surface?—That the rate of change would be greater with the lead mixture than with the zinc mixture, if there were no driers used. By adding driers, the zinc is brought up to the same point, about, as the other.

16,097. There is no drier in either of these?—No.

16,098. Merely the pure lead in the oil, and the zinc in the oil?—Yes.

16,099. Do you think that the smells you find in a newly painted room arise from the action of the oxidation of the paint on the air, and do not proceed from the lead?—The first impression you get, I think, is mainly from the turpentine. You get a very strong smell when you go into a newly painted room, if the painting is going on. The more permanent effect is given by the boiled oil and lead, and that is, I think, simply due to the volatile substances, whatever they

are, which come off from the oil during the process of oxidation.

16,100. The most nauseous smell (I think Mr. Parsonage and the other gentlemen will confirm me) is from boiled oil and lead paint that has been locked up in a workshop on a job. When you go in there first thing in the morning, the effect of that is very offensive and sickening?—There has been an accumulation of product, I take it, in that case.

16,101. Yes. Does the fact that all paint gathers weight when it is applied to a surface in the first period, and some paint loses weight in the second period, and sometimes regains it in the third period, prove that, in the first instance, at all events, the paint is absorbing rather than emitting?—Both may be going on, you see, simultaneously. It is a question of difference. You have something given off, and you have more absorbed, and therefore you get increase of weight.

16,102. You know Professor Baly's lecture that he delivered at Liverpool?—Yes, so far as it is in the "Oil and Colour Trade Journal."

16,103. It practically covered the ground, I think, of his evidence here.

16,104. When he was here he expressly guarded himself from definite conclusions on the subject; so we cannot really deduce anything serious from either the lecture or his evidence in relation to the emanation of lead?—His evidence is rather definite, is it not, in concluding that lead is given off? His statement in the lecture is conclusive, is it not?

16,105. Yes, but he guarded himself here by saying that he would not stake his reputation on it. It is your definite opinion, professor, that lead paint does not give off an emanation of lead?—So far as I am able to detect it at present.

16,106. (Chairman.) You mean as far as your experiments have gone at present?—Yes; I cannot go beyond that.

16,107. (Mr. Sutherland.) So far as your own tests are concerned?—So far as my own tests and so far as my knowledge of lead compounds go. It is a new thing for us to be told that there are volatile lead compounds producible under conditions of this kind, apart from other statements that we have had. It is in connection with this whole paint inquiry that the suggestion of volatile lead compounds has been brought forward.

16,108. (Mr. Parsonage.) Have you tried turpentine and lead in a jar with leaves?—You cannot distinguish the difference.

16,109. It has the same effect as turpentine only?—But it would make no difference whether you had turpentine and lead or turpentine alone. You get the effect of turpentine, and one cannot distinguish by this test any difference between turpentine alone and turpentine plus lead.

16,110. You have not tried turpentine and lead?—Yes; I have made mixtures of the two. You get the same turpentine effect.

16,111. No effect from the lead?—One cannot say. The test does not enable you to draw any distinction.

16,112. Have the turpentine and the lead mixed together not had any effect on the leaf at all?—Yes. Whenever turpentine is present, whatever it is mixed with, it is always a volatile substance which comes off and affects the leaf.

16,113. But the effect of turpentine and lead mixed is no more than the effect of turpentine by itself?—So far as that test enables you to distinguish, it is not, but I do not contend that that test would enable one to distinguish in such a case as that.

16,114. (Mr. Sutherland.) Lead and turpentine in combination do not produce the conditions that lead and oil do?—No. Taking the materials alone, oil alone produces no effect, lead alone produces no effect, turpentine alone produces a big effect and a still bigger effect when mixed with something else, whatever it is mixed with: and you cannot say that what it is mixed with influences it.

16,115. Oil itself has no effect on the leaf?—No.

16,116. The oil mixed with the lead has a great effect?—Yes.

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

16,117. Would not that mean that the oil was setting the lead compound free, and that was the reason of the discolouration of the leaf, not the oil, but something in the lead that was set free by the mixture of the oil with it?—It might be, of course, assuming that lead did volatilise, but that experiment simply shows that there is a production of vapour from the mixture. It does not show you what it is from, except that it is from the mixture. Neither alone gives the result. The mixture gives it.

16,118. You would not assume that the discolouration was caused by anything that came from the oil?—I do assume that, because I have no evidence of lead being there.

16,119. Is it not more reasonable to assume that it arises from the mixture of oil with the lead, and that it was the setting free of volatile compounds in the lead, rather than that the action of the lead on the oil was causing it?—No; it is quite the other way. Driers and oil give just the effect without any lead.

16,120. What driers?—Manganese driers.

16,121. Containing no lead whatever?—No lead whatever.

16,122. Would that have exactly the same effect on the leaf?—Yes, plus the oil. The oil changes and dries. You do not need the lead to get the oil to dry if you have the driers there. You may have a neutral substance, sand or chalk.

16,123. (Mr. Sutherland.) Does not that prove that it is the oxidation that is taking place that affects the change on the leaf?—It is the products of the oxidation of the oil which produce the change.

16,124. (Mr. Parsonage.) Linseed oil mixed with whiting, say, would have the same effect on the leaf that the lead and oil would have?—Yes, with driers. Without driers you can get the action from the oil alone if you wait long enough. The oil will oxidise even when left to itself, but very slowly. All these things hasten the rate of oxidation very much.

16,125. (Mr. Sutherland.) Even the zinc, as I understand you, slowly oxidises?—Zinc sometimes, in one or two cases, acts almost as rapidly as lead. I have known that. It may be a matter of a small difference in the oil. You do not know what it is. Something promotes the oxidation. It may be a little manganese. Anything that promotes the oxidation of the oil produces the effect.

16,126. (Mr. Parsonage.) Would that lead and oil, and the zinc and oil, be mixed in exactly the same way?—Yes; they were just rubbed up together.

16,127. The oil in these jars is separated from the lead, but it is not separated from the zinc?—There is known to be that difference, of course. Lead is a very heavy substance. There is too much oil there. The oil was adjusted to give a paste with the zinc, and the same quantity was taken with the same weight of lead.

16,128. The oil mixes more readily with the zinc than it does with the lead?—It takes a larger quantity of oil to get your paste.

16,129. But does the oil mix more readily with zinc than with lead?—I do not think so. It is held in suspension better in the case of the zinc. In that sense it mixes more readily.

16,130. It is held in suspension better?—Yes.

16,131. The two substances really keep together better?—Yes, that is the expression; they keep together better.

16,132. Now you know that boiled oil is very little used for interior work?—Yes.

16,133. In fact, the main constituent is turpentine more than oil?—You use a very thin paint for interior work as compared with the other, of course.

16,134. With regard to working in rooms, painting, you could not reasonably work in a room and have the windows open to admit currents of air?—I have seen it done often in my own house.

16,135. But it is not generally done, and in many cases it would not answer on the work. For instance, if you painted that wall, and had that window open, and were flattening that wall, you would spoil the whole thing because of the air from the window?—Yes.

16,136. In your evidence you said that the windows should be open?—I know perfectly well that for flattening you have to avoid currents of air. I know that it is a very delicate business to flat a large surface properly.

16,137. My point was this: in flattening, it is turpentine, and practically all turpentine, that is used. I want to know whether the air has an effect on the turpentine. Would the air blowing on to the wall bring the turpentine more out into the room?—It would hasten the evaporation of the turpentine.

16,138. (Mr. Sutherland.) The opening of the window, do you mean?—Any air current that passed it would have that effect.

16,139. (Mr. Parsonage.) That would mean that there would be more vapour set free?—Yes, if there were a current of air.

16,140. That would make it worse for the painter?—It would depend where it was carried. If you had a current of air, you would probably carry the vapour somewhere.

16,141. If it passed the painter it would be better if you were lucky enough to get it carried past him. It would have to be carried past him to be any good. The effect of air being admitted would not make it any better for the painter if the air only set more vapour free?—No, but as a matter of practical experience one knows that that does not amount to much. I have been in rooms over and over again with painting going on, and I know that it does not amount to anything serious on the average.

(Mr. Parsonage.) It would have a marked effect on the surface in some way or another, and if the result of that is that it sets the vapour free it is worse for the painter.

16,142. (Mr. Gardner.) In your conclusions you say that turpentine undoubtedly produces a marked effect. As there are a great many substitutes, petrol and naphtha, used in the trade, would not these produce much more marked effects?—Some may. I do not think that there will be very much difference, because you would probably select material of about the same degree of volatility, whatever is used. I take it that it would not differ very much from turpentine in its physical properties, and there would not be very much difference. Some few of the benzine things are distinctly likely to be more dangerous, and some would be less dangerous, than the turpentine. I should think that, on the average, it would make very little difference.

16,143. Naphtha, for instance?—Naphtha is not good, it does not mix well, petroleum naphtha does not. Coal tar naphtha mixes well, and that would certainly be about as bad as the turpentine. If you could use petroleum naphtha it would not be quite so bad, but practically you cannot use much of it.

16,144. I did not quite understand your answer to Dr. Collis with regard to the amount of turpentine vapour which would be set free in a room. Am I to take it that you mean, no matter the quantity of turpentine in the paint, only the same amount of vapour will be given off in a certain period of time? If I took a paint made up with three parts oil and one part turpentine, and another paint with no oil but four parts turpentine, would there be much more vapour given off from the second paint than from the first?—There would be more. I think that that was made clear by Dr. Collis. On the other hand, there being more in the room to come off, you will get more off.

16,145. There would be much more, at any rate?—I do not think, if you compare the rates of evaporation from two equal surfaces under equal conditions, the amount originally present would make much difference; but if you have more in that paint and apply more to the wall there must be more coming into the room.

16,146. (Mr. Fell.) I want to know whether, if you had two surfaces painted, one with lead and the other with zinc, with those mixtures, and you made the zinc dry as quickly as the lead, you would get the same effect of vapour given off?—I imagine that the change would be very much of the same order, but those are

14 December 1911.]

Prof. HENRY EDWARD ARMSTRONG, F.R.S.

[Continued.]

matters we can only give an opinion about, because they are so very complicated. We do not know what the changes are in the least.

16,147. Do you think that it would be possible to practically reproduce these experiments with actual painted surfaces, so that you could tell what the effect was?—In what sense reproduce them?

16,148. I mean a board painted with lead and with zinc, endeavouring to get the effect under actual working conditions?—Tested by what means do you mean?

16,149. Tested in a confined place like you are testing them in the jars?—Yes, you could do that. It would be possible to build a box, say a foot square, and paint the bottom foot of it and test. You could do that.

16,150. We want to demonstrate whether there is any difference really if you use zinc white instead of white lead?—That can be done in that sort of way. It is all a question of the character of the mixture that is made; but I imagine that the quantities given off in these extreme cases, after all, are so small that, apart from the turpentine effect, the effect is not considerable.

16,151. Would the temperature of the room affect the rate of the giving off of this gas?—Yes; the higher the temperature the more rapid the action.

16,152. (*Mr. Mason.*) I did not understand your answer, professor, to Mr. Fell's first question. I understood from what you had previously said that, if you made a paint composed of zinc and manganese with oil, and a paint with lead and oil which would dry equally rapidly, it would have the same effect upon the leaf. Is not that so?—Yes.

16,153. Could that not easily be proved by your apparatus?—You have of course to adjust, first of all, so that you get equal rates of drying. If you do that, I have no doubt that you could do it quite easily.

16,154. I understood you to say that it was simply a matter of opinion as to whether it would affect the leaf?—No.

16,155. Then I misunderstood your answer?—I said it was a matter of opinion as to the changes that went on in the oil. All we know is that the oil changes, that it oxidises, and that volatile things are given off, but what happens to it we do not know.

16,156. Are we to understand that the action on the leaf shows that a similar action would occur on the human system, or a noxious action?—Suppose you take, for instance, blood corpuscles, one knows that they respond in the same kind of way. The things which affect the leaf affect the blood corpuscles, and, therefore, one assumes that. This is an effect on a living material. It is nervous.

16,157. I notice from your evidence that you have made an extensive study, from a chemical point of view, of the noxious vapours from turpentine. Mr. Goadby, in telling us of his experiment, mentioned that fresh turpentine was very much more noxious than turpentine which has stood for some time, and it was suggested that aged turpentine, if I may call it so, would be equally useful to a painter, but less noxious?—I am afraid that that depends entirely on the age, and what you have done with it—what change you have allowed it to undergo. If you allowed it to get oxidised much, it would not be fit for use in paint any longer. But I do not quite know what Mr. Goadby has done. There are certain small quantities of very volatile substances in turpentine which are not turpentine, and those come off quickly, perhaps, and I

expect that that is what he has observed. I expect if we gave him purified turpentine, the pure material, he would not get those differences. I think it is some small quantity of very volatile material there, more volatile than the ordinary turpentine, that he is dealing with.

16,158. Can you suggest what the turpentine might be?—It depends on the kind of tree. Turpentine is a complex mixture. It is not a single substance. It varies according as it is Russian, French, or American. It varies with each. Each oil is different slightly. He has been applying, I think, a very quick delicate test, has he not, which enables him to make a distinction of that kind; but I do not think that it is a distinction to be made with turpentine as used in practice.

16,159. (*Mr. Kinggate.*) With regard to the vapour given off by lead painting, and also by zinc painting, in the drying of lead paint, which dries quicker, would not a larger volume of vapour be given off than there would be in painting with zinc?—Yes, in a given time, if it dried quicker.

16,160. A larger volume?—If it dried quicker.

16,161. Assuming that both vapours were harmful to the worker, would it not be much more harmful to the worker where lead was used than it would where zinc was used?—If there were a practical difference, yes, but it would all depend on the kind of difference.

16,162. In the coach-making trade frequently there is a very high temperature in the shops, and no ventilation, because varnishing is going on in the same shop as the other work, and there is fear of getting dust on it. I take it that drying quickly with lead would have a very injurious effect on the workmen?—I doubt it. It is mainly the volatile turpentine which is given off there, is it not?

16,163. But as it is quicker with lead, and there is a larger amount of turpentine loss with lead than with zinc, would it not necessarily be more harmful to the worker?—There is no doubt, if the change takes place more rapidly, and is given off, then, in so far as the vapours are harmful, it will be more harmful. That is the common-sense conclusion. There is no question about it.

16,164. Seeing that there is more volatile matter in new turpentine, is that one of the essential properties?—In no way.

16,165. (*Mr. Sutherland.*) Are the changes produced on the leaf due to deterioration of the air produced by the oxidation, and not to any emissions?—They are due to volatile substances given off during the drying of the oil and lead mixture.

16,166. Not to withdrawing from the air of certain properties?—No; that has nothing to do with it. It is quite independent of the air. If you put a drop of chloroform in it produces an effect.

16,167. (*Chairman.*) Do you think that it might be easy to remove the most highly volatile portions of the turpentine which, it seems, may possibly also be the most poisonous?—I do not think that that would make any practical difference from what I know of commercial turpentine. I do not think that you could do anything to it which would really essentially modify its properties. You will allow me to report later on on with regard to these experiments which have been referred to?

16,168-9. If you would, we should be very grateful?—I ought to have done it before, but my time has been taken up a good deal with the experiments I have made, and I have not directed myself particularly to that.

The witness withdrew.

## TWENTY-SIXTH DAY.

Wednesday, 17th January 1912.

PRESENT:

LORD HENRY BENTINCK, M.P. (*Acting Chairman*);

Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GAEDNER.  
Mr. J. PARSONAGE.  
Mr. A. L. C. FELL.

Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WEBNER (*Acting Secretary*).

Mr. E. L. COLLIS, M.B. (*in the Chair*).

Mr. A. VILLEMOT.

Evidence to 16,186 handed in and taken as read; witness then called and examined (through an interpreter).

16,170. I am the President of the Colour and Varnish Manufacturers' Association, and I have carried on business in Paris for 40 years. In both my personal and representative capacity I have taken great interest in the questions of the prohibition of the use of white lead, and twice appeared before the French Commission and gave evidence on behalf of my Society.

16,171. As a grinder of colours and colour manufacturer it is immaterial to me whether I make paints with a basis of white lead or of zinc white; in fact, owing to the greater durability of white lead, it is more to my interest to support the use of zinc white. As a practical man, however, I am strongly of opinion that there is at present no effective substitute for white lead paint where the surface to be covered is exposed either to atmospheric variations, to moisture, or to strong sun. I am not an enemy of zinc white. It has its place beside white lead, but cannot replace it. Impartially comparing the two products, I say, as an expert, as follows:—

16,172. White lead is a hydro-carbonate of lead. Its chemical composition varies with the process by which it is manufactured. It is always a neutral body, neither acid nor basic.

16,173. Zinc white is a protoxide of zinc. It is a weak acid, and produces salts with certain metals, e.g., zincate of sodium, or barium, or potassium, &c.

16,174. The two articles are employed in painting as oil pastes, which pastes are delivered to the consumer at about the same consistency.

16,175. White lead paint contains about 10 kilogrammes of oil per 100 kilogrammes. Zinc white paste contains 18 to 22 kilogrammes of oil per 100 kilogrammes of powder.

16,176. In order to use these substances the painter dilutes the paste with linseed oil and essence of turpentine sufficiently to make it run freely from the brush. Both products are easy to use, and a competent workman can obtain with each of them a very good finished surface.

16,177. There is, however, a great difference in the result. First as to covering power, one coat of white lead completely hides the painted surface, but the zinc white allows it to be seen; and to arrive at the same result it is necessary to add a second coat of zinc white. The quantity employed to cover the same surface with a single coat is about equal in weight, but since twice as much zinc white is required to arrive at the same result, one may say that white lead has a covering power of nearly double that of zinc white. This term has been very much misunderstood by those who are not actually acquainted with the products and the trade. I define the meaning of the term as follows:—The covering power of a paint is the capacity, more or less, which that paint has of causing to disappear the surface which is painted and the differences of colour and faults which are found upon the object to be painted. The covering power of an oil paint is measured by the volume of solid matter deposited on the surface. My experience is that in order to cover a black surface I have to employ

75 grammes of dry white lead and 75 grammes of liquid, 65 grammes of zinc white and 35 grammes of liquid, so that there is 10 per cent. less solid matter and 10 per cent. more liquid matter in zinc white, and consequently its capacity is less.

16,178. The difference in covering power is not the only instance of inferiority of zinc white. Oil paints, in drying, transform their components in the following manner:—First, the spirit of turpentine evaporates, leaving a very small deposit of resin, of which the action is secondary. The oil oxidises rapidly and is partially transformed by the white lead or zinc white to linoleate of lead or zinc. These products serve as intermediaries for the oxidation of the oil, oxidising on contact with the air and contracting on contact with the oil, and so on until the complete transformation of the oil into linoline. This linoline is an almost elastic product insoluble in water, turpentine, or benzine.

16,179. The dry paint is then composed of an excess of white lead or zinc white, of linoline and linoleate of lead or zinc, but the linoleate of lead is elastic even though of old manufacture, and the linoleate of zinc is brittle and flakey.

16,180. The excess of zinc white being acid, attacks the linoline little by little and transforms it into powder, which falls and leaves bare the painted surface. The excess of the white lead being neutral has no action, and does not produce the same inconvenience.

16,181. This action of zinc white on the other constituents of the paint is also a grave inconvenience in the preparation of a number of the colours; in fact, the colours prepared with zinc white change very rapidly under the action of the sun, which assists the reactions. Hence the practical impossibility of matching up any portion of the painted surface which may be damaged. This inconvenience does not exist with white lead, and for that reason zinc white should never be employed for painting carriages, naval constructions, or any article where it is absolutely necessary to obtain a durable surface.

16,182. White lead furnishes, with minium, a steam-tight joint, very stable and very easy to use, and this is of considerable importance for contractors, railway companies, &c.

16,183. Zinc white (which has been on the market for upwards of 60 years) is well known to all painters. A very powerful company supplies the greater part of this material, and they have never ceased to make great efforts to increase their clientele. They have neglected no method of pushing their product, and if the consumer persists in using white lead it is because he recognises its qualities; and that it is impossible to employ any substitute for it in many cases.

16,184. While zinc white is said not to be dangerous, white lead is accused of great crimes; but since it has been delivered mixed with oil, it no longer gives off dust or smell, and under ordinary working conditions it offers no danger either to the workman who uses it or to the occupier of the houses where the work is done. The paste, mixed with oil, is now obtained in the factories by the harmless process of grinding the white

17 January 1912.]

Mr. A. VILLEMOT.

[Continued.]

lead whilst wet and mixing with oil. By this process the lead is never dried, but the water is driven out by the assimilation of the oil. Mixed with oil and spirit it cannot have any deleterious action, and in the accusations against white lead I have never found any serious charges which do not apply equally to all paints. The rubbing-down of old paint is very injurious, but since the introduction of potash and caustic soda solution, which completely removes the old painting without dust, one can see that in all paint work, if the workman does not neglect ordinary care, he runs no danger.

16,185. I will go further, and say that the danger presented by metal colours with bases of lead, zinc, or antimony has been very much lessened by the use of white lead in oil, and becomes negligible as soon as they are perfectly dry.

16,186. Finally, I do not think that white lead is so dangerous that its use ought to be prohibited, and my view is that proper regulations strictly enforced are sufficient to protect house painters. Without proper care there is always danger in the manipulation of industrial products, even the most innocent.

16,187. (*Dr. Collis.*) In paragraph 16,170 you state that you gave evidence twice before the French White Lead Commission?—Yes.

16,188. Notwithstanding your evidence, the French Government resolved to prohibit the use of lead. Is that so?—Yes. The law was voted, but it does not come into force until 1915.

16,189. Is it not a proper inference to draw, then, that the French Government had much stronger evidence on the other side?—No, it is not a necessary inference to draw, because the whole of the French agitation was based upon the desirability of suppressing the use of white lead, and not on the existence of another pigment which might take its place—a thing which was never proved.

16,190. We have had another witness from France, who spoke very strongly about the findings of the Commission, but he produced no new evidence. Unless you can lay before us some new facts, it will be impossible to give your personal opinion preference over the decision of the French Government?—As I have already said, the Government decided upon the suppression of the use of white lead, but a delay of five years was given in order that the scientists might during that period find a pigment which might adequately take the place of white lead. Up to the present time nothing has been found.

16,191. We are bound to assume that the French Government was serious in passing the law of 1909 in the form in which it was accepted by both Houses of Parliament. We cannot therefore allow the views of one gentleman, however eminent, to weigh much with us, when he is in opposition to the settled decision of the French Government?—The opinion that I am expressing is not entirely my own. It is also the opinion of all my colleagues in the trade, and also of the *Chambre Syndicale*, of which I am the President.

16,192. You will understand that if we are to go into all the circumstances on which the French Government arrived at their decision, it would be necessary for us to hear the whole of the evidence which was presented to them?—The agitation in France lasted some 10 years, and the interests were considerable, and of an opposing nature. At first it was a personal question; subsequently it became a political question, and then it transformed itself into a question of competition between the various interests. I cannot, of course, go into all the details of the agitation; the hard fact is that lead was suppressed, but nothing was created in its place—no pigment and no factories for the manufacture of a substitute, and so on, and this I can affirm as being the opinion, not only of myself, but of all my colleagues in the trade in France.

16,193. Of course, we are acquainted with the evidence that was presented to the French Government, and the replies that were made on both sides. In the evidence which you have presented to us, which will be printed, you have not introduced, as far as we can see, any new facts, since the closing of the dis-

cussion which finally resulted in the French Government passing the law. If you have any new facts to bring to our notice, we shall be very pleased, and thank you very much for the information which you can give to us, but we cannot open the whole discussion that took place anterior to the passing of the Act?—I would point out that, whilst there are perhaps no new facts, at the time of the agitation the question of the suppression of white lead was taken up by a number of politicians. At the present time there is no longer any question whatever of the suppression of white lead in political circles, or indeed in the trade. Everything is going on exactly as if the law had never been passed.

16,194. Then am I right in understanding that you are attending to-day not to present to us new facts, but to present to us the position of those who were in opposition to the French Government when the law of 1909 was passed?—The principal fact in the actual situation is that at the present time, as I have already said, nothing whatever has been done in order to make ready for the enforcement of the law at the beginning of 1915, which means that the Government will not be able to put it into operation when that time comes.

16,195. Then, except for the fact that in your opinion nothing further has been done to enable the carrying out of the law which comes into force in 1915, no new facts have transpired to your knowledge on the white-lead question?—No, there are no new facts. I simply repeat what I have already said.

16,196. (*Mr. Sutherland.*) You speak, from a long personal knowledge, both of lead and zinc?—Yes, from an experience of 50 years.

16,197. It is immaterial to you as a colour grinder whether you grind lead or zinc?—Yes; I am indifferent. We can prepare either the one or the other without inconvenience to ourselves or our customers.

16,198. Your judgment is not affected by the decision of the French Government to prohibit white lead?—No. It is based entirely on practice.

16,199. The decision of the French Government was arrived at, not on the merits of zinc as compared with white lead, but on purely humanitarian grounds?—It was principally based upon the question of the health of the workmen.

16,200. That is on humanitarian grounds?—Yes.

16,201. Your opinion as a manufacturer is sustained by most of the colour manufacturers and the master painters in France, is it not?—Yes. White lead is not only cheaper, but is more easy to apply, and the same amount of work can be done with it in a shorter time. In addition, work with white lead lasts much longer, and the workman who applies it need not necessarily be a specially clever workman; he need not have any special knowledge; whereas with zinc oxide a workman of the same calibre would do poor work.

16,202-3. Do you mean to imply that to use zinc oxide successfully, special knowledge is required in the ordinary painter?—What is necessary is more practice, a longer experience of it. All cannot do it.

16,204-5. The Chairman asked you if you had any new fact to bring before us since the decision of the Government to prohibit white lead. Now is there any new fact? Is it possible for any new fact to transpire in reference to a substitute for white lead?—Besides zinc oxide, lithopone has come, and also pure sulphide of zinc.

16,206. That is not since the prohibition?—No. Possibly some compound of zinc might in future be found, which would take the place of carbonate of lead, but I cannot say. But one of the unfortunate sides to the question, as decided by the French Government, is to be found in the fact that it brought about a number of trials on the part of manufacturers to manufacture substitutes. Three factories, for instance, were established for the manufacture of lithopone, with a capital of three million francs, and three factories were also established for the manufacture of oxide of zinc; and all these institutions have gone into liquidation.

16,207. That is since the report of the Government, is it not?—Yes, since the adoption of the law.

16,208. Is it true that white lead is still largely used by the Government departments in France?—

17 January 1912.]

Mr. A. VILLEMOT.

[Continued.]

The Government has forbidden the use of white lead in the Marine Department and other departments, and in addition has recommended the railways to give up its use; but all have been obliged to come back to the use of white lead and red lead—not generally, but in certain cases—just as in ordinary painting in France at the present day, white lead is used generally, and zinc oxide for certain special work.

16,209. May we take it that the latter part of your statement qualifies the first part. You said that the Government were not using it generally, whereas you say that the trade are using it generally in domestic work, qualified by the special use of zinc white for interior work?—That is so. I would point out as an illustration that in the painting of ships of war, the engineers have the custom of using white lead and red lead in all parts which are difficult of access, whilst using zinc oxide and oxide of iron for those parts which can be easily got at, and consequently can be re-done more easily.

16,210. That points, does it not, to this: that where they want permanency and stability, they use lead; but where they have good access, and the painting can be easily renewed, they use zinc oxide or oxide of iron?—Yes, and red lead.

16,211. Do you know the practice of the Maison le Claire?—Yes, the Le Claire firm uses probably only zinc oxide.

16,212. How is it that they have solved the question? If they have succeeded in using zinc oxide only, how is it that other firms have not been able to do so?—The Maison le Claire has a clientèle quite special. It only does work of the very highest class, which, of course, is well paid. Their workmen are selected workmen who only use zinc oxide, and therefore are well qualified to apply it. But this could not be done in the general mass of work which is paid at lower rates—the ordinary competitive rates.

16,213. The Maison le Claire still use red lead, do they not?—Yes, but only in small quantities, because they do principally work on buildings, whereas red lead is chiefly used for iron.

16,214. Then may we take it that their experience, being special, does not justify the use of zinc for general painting?—No, and much less, because the quantity of zinc which would be necessary does not exist. If England suppressed the use of white lead, it must be remembered that, whereas in France the consumption of white lead is something like 20,000 tons, in England it would be about 100,000 tons: that is including export; and there are no factories, and there are not sufficient men with the actual knowledge to produce the quantity of zinc oxide that would be necessary to replace it.

16,215. (*Dr. Collins.*) Do you mean import into England, or export of white lead out?—Imports into England from other countries. The price has already gone up very considerably. It has gone up by 10 per cent., and in the presence of any diminution of its use, it would go up 20, 30, or 40 per cent.

16,216. I gather from your statement that there is no visible source of supply of the manufactured zinc sufficient to meet the demands even of France, if white lead was prohibited?—Up to the present, no. We are at the present time dependent on the New Jersey Company, which scarcely suffices, even at the present time, when the demand for zinc oxide is relatively restricted. We have the Veille Montagne Company in France and the Rocour firm in Holland, but these firms only produce a relatively minimum quantity, which under present conditions could not be sufficiently expanded to meet an entire-replacing of white lead.

16,217. Is it your opinion that the law will not be enforced at the end of 1914 in France?—In order that it may be put into operation it is necessary by a fairy enchantment or some such method, for a number of factories to suddenly spring up. I ought perhaps to say that there are at present two small shops for the manufacture of zinc oxide, one in France and one in Tunis, but they have been in existence for some considerable time, and their output is much too small to affect the market in any way.

16,218. (*Mr. Gardner.*) When you speak in paragraph 16,171 of being a practical man, I presume you mean practical as a manufacturer, not as a house painter?—As a merchant, a commercial man who has relations both with the producers of the various materials and the actual users. I might perhaps take this opportunity to mention that I myself manufacture white lead to a small extent, and certain colours, but I am principally a merchant.

16,219. Your practice is as a maker, not as a user?—I am a merchant, something between the two.

16,220. When you say that the experience of the Maison le Claire with regard to the use of zinc cannot be applied to the general trade of France, you are really giving a personal opinion based on no real practice?—I am not a painter.

16,221. Why did the politicians take up the question of the suppression of white lead in France?—That is an exceedingly difficult thing to reply to, because there are a good many things that everyone knows and that one sees, but which naturally one cannot talk about. It commenced by two political men taking up the question.

16,222. May we not put it that it was because of the evil effects of white lead upon the health of the workmen?—I think that at the commencement of the campaign, the question of the health of the workmen had absolutely nothing to do with it.

16,223. Does it not seem rather strange that politicians should attack a certain material without any tangible reason?—There is a reason, but it is precisely that reason that we cannot say. We can know many things without saying them.

16,224. It is rather singular. Do you think that white lead exerts injurious effects upon the health of the workmen?—Yes. White lead is a poison, but it is not necessary for everybody who uses a poison to poison himself. There is certainly need of precaution, and regulations already exist in France at the present time; such, for instance, as the prohibition of the transport of dry white lead, and the prohibition of dry rubbing down. In addition, every day the workmen use utensils which could be improved, and the various ways in which the workmen can be dangerously affected could be obviated by special precautions. When the regulation is properly enforced lead will be able to be used without inconvenience.

16,225. Then are we to understand that the French Government took action with regard to the use of white lead without having had serious complaints from the workpeople?—The question arose entirely from private initiative, and the condition of the workmen, the number of accidents, and so on, has actually very much improved during a number of years; that is to say, cases of illness.

16,226. (*Mr. Parsonage.*) Did not the French Government have expert evidence that five years would be a reasonable time for a substitute to be found when they fixed the period of five years for the abolition?—The Government had two motives in giving a delay of five years. The first was to give a certain time in which to replace white lead, to transform the factories and so on as might be necessary without having any special point in view. The second was in order to give something in the nature of an indemnity to the manufacturers of white lead. I would repeat what I said before about the six attempts that have been made to manufacture zinc oxide.

16,227. You ascribe the origin of the inquiry into the use of white lead in France to personal motives. How would you explain the fact that the same inquiry has taken place on the continent, in Germany, Austria, and Holland?—The inquiries in the other countries followed, and were originated by the inquiry in France. Owing to the press agitation and the enormous prominence that was given to the whole question during the agitation in France, other countries began to look into the question. Of course a good deal of what was said was very much exaggerated. I would point out that in Belgium the result of the inquiry is regulation; in Germany the result of the inquiry is regulation, and even a recommendation in certain instances of the use

17. January 1912.]

Mr. A. VILLEMOT.

[Continued.]

of white lead. In Austria the use of white lead for interiors only has been forbidden, and so on.

16,228. It is a wonderful thing that the political activities of two men should have led to such great results. There must have been some good ground to go upon before this was started. It seems to have been a fine selection?—Great things have small beginnings, and stupid things very often lead to great results. The manufacturers of white lead at the commencement of the agitation did not thoroughly realise the largeness of the question, and consequently they, without having looked into the matter seriously, thought in general that it did not matter to them much one way or the other, that they could manufacture white lead, or they could manufacture something which should take its place. In general they did not give sufficient thought to the whole question.

16,229. (Mr. Sutherland.) Do you mean the corroders?—The manufacturers. They are not all corroders.

16,230. Are you speaking of manufacturers of paint?—Manufacturers of white lead; I, for instance, am not a corroder; I am a manufacturer. I make a small quantity—say 500 tons a year—of white lead by the chamber process.

16,231. (Mr. Fell.) You stated just now that the French railways had been recommended to give up white lead, but had had to return to it. Can you tell us whether there are any railway carriages at the present time painted with any substitute for lead—zinc white or anything else?—I do not think so. The first coat, the filling is a base of white lead and the other colours, the future colours, so to speak, are also lead colours, that is to say, they contain white lead. My principal reason for saying that I do not think so is that very little railway work is white, and the only reason for using zinc oxide is to get a really good white finish. The filling is done with a base of white lead, because it is necessary to have something with a very good body in order to properly prepare the surface.

16,232. But did the railways never test zinc white in place of lead?—No, as filling, never.

16,233. Are not some of the railways owned by the Government?—Yes. There is one system.

16,234. Can you say why they do not carry out their own recommendations?—In order to comply with the recommendation, they ceased to buy white lead for the purpose of jointing, but not for painting, in which it plays a very unimportant part, because it is mixed with a number of other materials. But I would point out that the law does not affect carriage painting and coach painting at all.

16,235. (Mr. Sutherland.) It is only applicable to buildings?—Yes, it is only applicable to buildings. Coach painting was not brought under the law.

16,236. (Mr. Kinggate.) With regard to the firms that you mentioned that went into liquidation, I understood you to say that three firms were established for the purpose of making zinc oxide, and all went into liquidation. I presume that was not for want of material, but for want of customers?—They only succeeded in producing a very small quantity of zinc oxide of very poor quality. Speaking generally one might say that they went into liquidation before they got to the stage of producing on a reasonable scale a reasonable article.

16,237. But was there any shortage of ore?—No; I do not wish to say by any means that there is a lack of ore. That is not the reason. But take, for instance, the manufacturer in Tunis whom I have already mentioned. The principal interest of the firm being in zinc ore, the manufacture of zinc oxide being a supplementary branch, so to speak, of the firm, and having every facility from the point of view of ore, they only succeeded after a number of years of experiment in producing a small annual quantity of 150 tons, which is grey or black, and they are still continuing to make experiments with a view to the production of a good zinc oxide. The point is, that they are not inconvenienced in any way by the lack of ore.

16,238. But it is impossible, according to that, to produce zinc oxide of a good quality?—No. I mean that it is a question of knowing how to manufacture.

16,239. (Mr. Sutherland.) There is a great difference in ores?—Yes.

16,240. (Mr. Kinggate.) You conveyed that the reason of these companies going into liquidation was the want of material?—No.

16,241. You say that the consumer persists in using white lead because he recognises its qualities, and it is impossible to employ a substitute that will suit many of the house painters in France. Does the old conservative idea exist with many old firms that no substitute can be found, and, therefore, they never attempt to find one or rise one?—Trials have, of course, been made. A large house in Paris, which I do not recollect the name of, went in very heavily for zinc oxide, but found that at the end of four years its lasting properties were over, so far as its protective qualities were concerned. In France the exterior of a house has to be re-done every ten years. It must be done. In this particular case which I was mentioning, the results were negative, because, whilst white lead lasts for ten years, it becomes dirty, and so on. So far as a damp-proof coat is concerned, it keeps to the end of the ten years its preserving property with regard to the wood, or whatever is underneath it, in spite of the fact that it becomes dirty, and so on. But with regard to zinc oxide, they found after four or five years that the work had to be done again.

16,242. Presuming that zinc oxide had a good coat of varnish on it, would it last as well?—The varnish would last for one year, and consequently it would prolong the lasting properties of the zinc oxide for something approaching that time. In other words, the zinc would not be open to the effects of the atmosphere until the varnish had been destroyed; that is to say, as I have said, in about a year's time. From the moment that the varnish began to disintegrate, it would contribute to the disintegration of the zinc oxide paint, and the effect from the point of view of decoration would be very poor.

16,243. We have had before us a master painter from Vienna, who, in reply to questions with regard to painting exterior doors, said that he should never think of using white lead; that zinc white was far preferable, and made a better job on account of its being varnished. Do you agree with that?—No, it is not my opinion at all. The painting of doors—I am speaking of large doors—is a special work, and is of the same nature as carriage work. They are very rarely painted white which is the only case in which I should use zinc oxide, but the filling, the under-coats, would be of white lead. It might be that the finish would be of some such enamel as Ripolin.

16,244. I am not speaking of enamels. There are a number of doors that are painted white, especially in Belgium. If a practical painter makes the statement which I have put to you with regard to using zinc white in place of white lead, what do you say? Suppose that the doors are varnished?—You could, of course, use zinc oxide where work is to be finished with varnish, but the work would not last for more than two or three years.

16,245. With regard to the law of 1909, does that also apply to shipbuilding as well as to house painting?—Only to buildings, not to shipbuilding. Ships use zinc oxide for interiors, and that is indeed the principal employment of zinc oxide in France; but for exteriors they use lead.

16,246. (Mr. Robins.) You, not being a painter, laid great stress upon the fact that there was great difficulty with regard to using zinc white, whereas it is easy to use lead. What ground have you for saying that, you not being a painter?—I have already stated that I have been in constant relations with painters and master painters for half a century. I have heard them discuss these questions; I have seen the work, and I am quite certain that they all have special men for applying zinc oxide.

16,247. Seeing that that is so, and that five years elapse from 1909 to when the law comes into operation, are special classes being held to educate the painters to

H h 4

17 January 1912.]

Mr. A. VILLEMOT.

[Continued.]

use zinc white when that law comes into force, if it is so difficult?—No, there is nothing of the kind. There is even a great lack of apprentices.

16,248. Knowing the difficulties that exist, or are supposed to exist, with regard to the use of zinc white instead of white lead, no preparation is being made in France for a change?—No. There is great difficulty in France at the present day in obtaining workmen, and master painters have to employ in the season a number of men who know more or less about their work. If only really expert workmen were employed, then the large majority of the work could not be done, because the number would be nothing like sufficient.

16,249. You would not imply by that that the majority of the work done in France is of a shoddy nature, and that there is only a small proportion of expert workmen to do the first-class work, would you?—No, that would not be the case, because in everybody of workmen there are a few really good workmen who finish the work. In regard to the De Claire firm, of which I was speaking a little time back, and in regard to which I said that their workmen were of a very high class, they have a scheme of profit sharing, by which a workman who has been in the employment of the firm for at least five years obtains a certain percentage of the profits every year, and consequently they have, if one might so call it, the *élite* of the workmen in Paris.

16,250. Seeing that no action is taken to educate the workmen, we may take it that this difficulty is not such a great difficulty after all?—I do not follow.

16,251. Seeing that no technical education has been applied to training the painter up to the future use of zinc white, which he will have to use under the new Act, then the difficulty is not so great as has been made out?—In view of the great lack of apprentices, the change from white lead to zinc oxide would have very little effect. The good workman of the present day knows how to apply anything, speaking generally, but the good workman is not in a majority. The majority do not know how to apply a finish to first-class work, and if the law were put into force the work done would be done presumably less well. I may add that if the law is put into force, and zinc oxide only is used after 1915, where 100 workmen are employed at present it would be necessary to employ 125 for the application of zinc.

16,252. (Dr. Collis.) Do you yourself use all the white lead which you manufacture?—I am a merchant.

16,253. Yes, but I understood that you said that you make a certain amount of white lead?—Yes, I manufacture it and sell it to the master painters. I manufacture paint.

16,254. That was not brought out quite plainly. Do you use up in the manufacture of paint all the white lead that you manufacture, or do you sell it as such?—We sell white lead as ground white lead, and we also use a certain part of it for the manufacture of colours.

16,255. Do you sell all your white lead in France?—A small amount we export to the French colonies.

16,256. Has the price of white lead risen at all recently?—Yes; there has recently been a rise equivalent to the rise in the price of lead, which would be about six francs per 100 kilos. The price follows the price of lead.

16,257. In the case of zinc white, has the increase of price followed the increase in the price of zinc?—Not as much as lead, because although a certain amount of it is made from the metal, and that would

follow the price; a good deal is made from the result of galvanising works—bye-products, and so on—and that is obtained much cheaper than the actual metal would be.

16,258. You have suggested that the price of zinc has risen, apparently due to the demand, but you have also said that there has been no alteration whatever in France in the use of white lead and zinc; therefore, it must be due, surely, to the increase of trade, and not the increase of demand?—I might say, to be as brief as possible, that the price of zinc itself has increased from 24*l.* to 28*l.*, but no doubt the increase in the price of zinc oxide has also something to do with an increased demand.

16,259. But you have assured us that there has been no increased demand in France. It cannot be both ways?—Yes, I think it has increased. The consumption of zinc oxide has certainly increased during the last few years, but the consumption of paint, in general, and white lead, has also increased. In other words, the consumption, generally speaking, has increased all round.

16,260. You have not placed before us any figures to show that the increase in the consumption of zinc white is less than the proportionate increase in the consumption of white lead?—It is impossible to give figures, because it is impossible, from my point of view, to say how much of the increased consumption of zinc oxide goes to painting, and how much of it goes to other industries, such as rubber, and so on.

16,261. A certain amount of white lead goes to rubber. Then you have not proved your point when you say that there has been no effort at all, as far as the manufacture of zinc oxide goes, to prepare for the carrying out of the Act of 1909?—In taking the manufacturers of oxide of zinc one by one, you would find that the increase in output is insignificant.

16,262. Figures should be given to support a statement like that. I want to place before you the value of the evidence which you have given to us to-day. It practically is that since the passing of the law nothing has been done in France, and consequently the law will not be able to be carried out. To substantiate that evidence you should place before us figures showing the exact amount of consumption of white lead and white zinc to-day in France. A personal opinion cannot be depended on in such a case?—There are no figures.

16,263. I want to give you the opportunity of substantiating the evidence which you have given us to-day, that is all?—I cannot give figures, but I refer to the fact that in 1910 and 1911, during the painting season, there was an utter lack of zinc oxide, and then also I refer again to attempts which have been made to manufacture zinc oxide, and I mention particularly the firm of Rocour that I mentioned before, saying that they are actually in communication with the Government. They are afraid to put in a large capital, and to make further endeavours to manufacture zinc oxide until they know actually whether the law will be put into force. I cannot bring figures.

16,264. With regard to the value of your evidence on that point, your statements are rather vague. You have nothing further to say?—No.

16,265. (Mr. Parsonage.) You said that there was an utter lack of zinc oxide during the busy painting season?—Yes, a shortage of supply.

16,266. Then there was a greater demand than the supply could meet?—Yes.

The witness withdrew.

Mr. EMIL NIEDERHAÜSER.

Evidence to 16,277 handed in and taken as read; witness then called and examined (through an interpreter).

16,267. I am a master painter of Cologne employing about 100 hands. As a young man, soon after my apprenticeship to the trade, I had to grind all my lead colours by hand. This would be between the years 1868 and 1872, when the white lead was supplied to us in cakes and we had to grind it down on the stone. A considerable amount of dust was caused in this process,

some of which we no doubt breathed into our lungs, but I was careful always to scrupulously wash, and it was our practice to take a spoonful of sweet oil prior to eating our midday meal.

16,268. I have come across very little lead poisoning among workmen in my long experience. Some years ago, before the new rules came into operation, a work-

17 January 1912.]

Mr. EMIL NIEDERHAUSE.

[Continued.]

man would occasionally come and say that he was being treated for colic, but even when the dry white lead was used the cases were few, and nearly always it was the careless workmen who suffered. I personally have never had any lead illness, notwithstanding the very large amount of lead which I have handled.

16,269. The regulations now in force in Germany amply protect the workmen, who are quite well acquainted with all the new requirements. We have to hand each new man a copy of the enclosed book, and the half-yearly medical inspection brings home to them the care which is requisite. We also supply the nail-brushes and towels to workmen who are working at private houses. I think that the printed instructions to the workpeople might be made more simple.

16,270. It is a matter of common knowledge in Germany that since the regulations there has been a notable decrease in lead poisoning, and the figures for lead poisoning among painters collected by Dr. Kaup show more exactly this marked decrease both in the number of cases of lead poisoning and in the days of sickness in respect thereof. In my opinion the decrease is principally due to the prohibition of the dust-producing process of dry rubbing down and to the improved personal cleanliness of the painters.

16,271. No additional factory inspectors have been appointed to superintend the carrying out of the new regulations in this district.

16,272. There is nothing so good as white lead for exterior use. Also, in the interior of a house, where the paint is exposed to moisture or much wear, white lead gives the best results. Even in the highest class of house painting we usually give the first two coats of white lead to rooms, and finish with a coat of zinc white where a pure white colour is required. White lead is liable to go yellow inside, but it has a far greater covering power, and our workmen prefer to use it for the priming coats. In exposed situations, or where durability is of the first importance, zinc white and lithopone require far oftener to be renewed than white lead. Indeed, where the sun has dried out the large quantity of oil in the zinc white, the colour can easily be rubbed off by hand, or is washed off by the rain.

16,273. The inquiries addressed to all users of paint when legislation was in contemplation in Germany in 1903—i.e., to shipbuilders, railway carriage factories, and to master painters—which are published in two volumes of *Gutacliten*, showed a universal opinion that for exterior painting white lead could not be replaced by any other material, and also that it was necessary as a ground colour for interior painting, and that uncleanness was the chief cause of lead poisoning.

16,274. I regard white lead mixed with oil as practically innocuous as a paint. In the preparation of the old surface, however, the rubbing down (whether with pumice or glass paper) should be done wet, and the products removed before they are dry.

16,275. The *Königliche Preussische Eisenbahnverwaltung* issued a circular in September, 1907, prohibiting the use of zinc white, lithopone, &c. for exterior use in consequence of tests which showed that white lead alone was satisfactory for this purpose.

16,276. I agree with the article in the "*Kölnische Zeitung*," of 7th October 1903, written at the time of the regulations for white lead factories, that whilst the easiest course is to prohibit the use of an article which causes industrial poisoning, carried to a logical conclusion this method would affect very many industries besides white lead painting. Taking lead alone, its uses are manifold, and thousands of workers would be breadless if its use was entirely prohibited. There are very many trades, such as printing, electrical accumulator making, &c., where the workmen are liable to lead poisoning, but it has not been suggested that the use of lead should be interdicted in them.

16,277. To summarise my views, I am of opinion that there is no efficient substitute for white lead where the durability of the paint is important, and that so long as it is supplied mixed with oil, and the old paint is rubbed down wet, there is no more danger to the workmen in this industry than there is in many other trades.

16,278. (*Chairman*.) You say in your proof that the new regulations in Germany are amply sufficient for the protection of the workmen?—I think that these regulations are quite sufficient to protect the worker.

16,279. Have you any statistics to bear out this statement?—I have no statistics.

16,280. Dr. Kaup supplied certain statistics of lead poisoning for Berlin and Prussia, based on hospital records. These are necessarily incomplete statistics, but, for what they are worth, they show a very slow rate of improvement; for instance, in the case of Berlin, only 5.5 per cent. per annum, and for the whole of Prussia even less, namely, 3.8 per cent. per annum?—Yes.

16,281. Other tables based on records of sickness insurance fund show a similar improvement?—Yes.

16,282. Under these circumstances, do you still consider the new regulations in Germany amply sufficient for the protection of the worker?—I still think that they are sufficient protection for the workers.

16,283. Do you not consider that lead poisoning need be considered?—Would you make your question more clear? In what way do you mean "need be considered"?

16,284. There was a certain amount of lead poisoning before the regulations. The utmost up to the present that the regulations have done is to reduce that total amount of 5.5 per cent. per annum?—I think that all lead poisoning is due to lack of cleanliness on the part of the workers, apart from regulations.

16,285. Then why do you state that you think that the regulations are sufficient for the protection of the workmen, if they do not protect the workmen?—Personally I do not know of a single case of lead poisoning, and I do not quite see the connection between the lack of cleanliness and the regulations. Since these regulations have been in force, cleanliness amongst painters has very much improved.

16,286. Yes, but Dr. Kaup's figures shows us that 94.5 per cent. of the lead evil still remains after each year of the regulations?—I think that a good many of these cases of lead poisoning may be explained in this way: that the painter feels unwell, goes to the medical man, and says that he has a pain; the medical man inquires, "What is your profession?" and the painter says that he is a painter. Thereupon his pain is pronounced as lead poisoning. I myself have worked in the trade for upwards of 35 years, have handled great quantities of white lead and other paints, and I have never myself suffered, nor have I known of any serious or genuine cases of lead poisoning.

16,287. We have had Dr. Kaup before us, and he has told us how the statistics are biased from a medical point of view?—I have no opinion either way concerning the statistics. I have simply wished to quote my own personal experience.

16,288. How are the German regulations enforced?—By control and by police regulations and industrial inspectors also.

16,289. Do you think that there is necessity for preventing dust, and, if so, how can you do this in house painting?—Does your question refer to inside painting or outside painting, or house painting generally?

16,290. To house painting generally?—I think that the question should necessarily only apply to inside painting, because for outside work no grinding or polishing is ever done—no rubbing-down.

16,291. Do you consider that there is any necessity for preventing dry rubbing down?—I think it very desirable.

16,292. It is prohibited in Germany, is it not?—Yes.

16,293. How is this regulation enforced?—It is contained in the regulations of every business.

16,294. Yes, but what happens if the painter rubs down dry? Who stops him?—There is an organisation amongst the men. They always inform each other of everything that is going on which may be against the regulations.

16,295. Do you know whether anyone has ever been prosecuted for dry rubbing down since the regulations came into force?—No, I do not know of any such case.

17 January 1912.]

Mr. EMIL NIEDERHAUSER.

[Continued.]

16,296. Does not that suggest that the regulation only exists on paper?—I think that the law is still young, but it is to be carried out very strictly. It has been in force for five years, and during these five years my work has been inspected twice, once by an industrial inspector and once by a police inspector.

16,297. Does that mean that two pieces of work have been inspected in five years?—No, my own private workshop, my central workshop.

16,298. How many times has the work been inspected on the spot, at the houses where it has been done?—It has never been inspected in that way.

16,299. So that as far as you are concerned, the regulations are not enforced, although they be carried out?—It has never been controlled so far, but the men in carrying out the work act as controllers by informing the trade unions in cases of irregularity.

16,300. Is there no danger of a man by so informing his trade union possibly losing his place?—Yes, that is the usual course. The man gives information to the trade union; the trade union informs the authorities, that is the police or the industrial inspector; the employer is fined and the man is dismissed.

16,301. Is that the only way in which the regulations are enforced?—I know of no other method of controlling the enforcement of the regulations.

16,302. Perhaps you cannot speak for others, but as far as you are aware is this the experience of other master painters in Germany?—You could not say that generally. If a man were a very capable worker he might not be dismissed.

16,303. Might not. We have been told by many witnesses that some dry rubbing down is indispensable. Do you agree with that?—I think that it is possible to dispense with dry rubbing down.

16,304. In all cases?—In all cases you can dispense with it.

16,305. After the application of the first coat, how long do you consider it should be left to dry before wet rubbing down is done?—It depends on the composition of the colour, but it may be anything from 12 to 15 hours.

16,306. After the paint has been put on, in from 12 to 15 hours, it can be wet rubbed down with pumice?—Yes.

16,307. The first coat?—With sand-paper, not with pumice. It can be done by sponging down the surface, and then rubbing down with sand-paper. Doing it with pumice is a totally different method.

16,308. If you rub down a sponged surface with sand-paper, is not that something like dry rubbing down? The surface will not keep damp?—No; the surface is continually kept wet. You sponge down a small piece, rub that with sand-paper, and then another small piece, and so on, always sponging down small pieces.

16,309. Is that the way in which it is done, or the way in which you think it should be done?—That is the way in which it is done in the work that I carry out. It is generally known to be carried out everywhere in that way.

16,310. Can you ensure adequate lavatory accommodation being available at every piece of painting work?—Every man on entering the employment is supplied with a basin, towel, nail-brush, and a piece of soap. He is compelled to carry those always with him to any painting work that he does.

16,311. Is hot water always provided?—No; hot water is not provided at all.

16,312. Do you think it practicable that it should be?—I think it impossible.

16,313. Is it always possible in buildings in course of construction to obtain water?—Yes, it is always possible to obtain water, because finished houses are compelled to have water laid on, whilst houses in course of construction are bound to have water present for the work of the masons.

16,314. How do you ensure that the men use their basin, towel and sponge, when they have got the water?—It is the duty of the foreman to look after that.

16,315. Do you ever dismiss the men if they do not use them?—No, they are not dismissed for that. We

simply give them a warning. In cases of disregarding cleanliness, men are dismissed.

16,316. Have you ever had any of your own men dismissed, because they did not wash?—No, I have never, myself, dismissed men for that.

16,317. How many men do you employ?—Between 80 and 100; at present only 80.

16,318. So that during five years, employing 100 men, you have never found the necessity for dismissing any of them for uncleanness?—No, I have never had occasion to dismiss for that.

16,319. In regard to overalls, are these worn regularly?—They must wear special blouses and trousers for the work.

16,320. Do they always wear clean ones?—Yes they are always as clean as possible.

16,321. How often are they washed?—That depends on the nature of the work.

16,322. Who provides them?—The men themselves.

16,323. Do the men have to undertake the washing?—Yes, the men themselves again.

16,324. Has a man ever been dismissed, because he has not carried out the regulation in regard to keeping his overalls clean?—No one has ever been dismissed on that score.

16,325. Do you think that it is possible to enforce regulations of this sort?—I do not think that the regulations can be enforced, but the welfare of the men is considered as far as possible.

16,326. Are not the regulations drawn up in the interests of the welfare of the men?—They are not always observed, but I quite acknowledge that they are drawn up for the welfare of the men.

16,327. And you do not consider that the regulations can be enforced by inspection?—It is impossible to control it by inspection.

16,328. (Dr. Collis.) You understand that if in England it was decided to establish regulations for painting operations, we should make an effort to have the regulations enforced?—I wish to impress upon you that although there is very little control as to the regulations in Germany, as a rule, the regulations are very well carried out, particularly because the men are very keen on their being carried out well, and the trade unions do their best to control it.

16,329. Notwithstanding the fact that the men who give information are dismissed?—I think that this control by the trade unions is carried out very strictly, because the trade unions are very fond of worrying the employers as much as possible, as the larger trade unions are controlled by the Socialist party.

16,330. If a large number of employers of labour in England themselves prefer prohibition of the use of lead to a cumbersome and irksome code of regulations properly enforced, would that cause you to modify your views as to the practicability of establishing such regulations?—I think it impossible to prohibit the use of white lead.

16,331. And you think it also impossible to enforce regulations?—I do not know the English conditions. I think it might be possible in England.

16,332. Are you aware that all the precautions which you advocate are strictly enforced in our Government dockyards, say at Portsmouth?—I do not know anything concerning dockyards, but I think it is essential that the regulations should be carried out.

16,333. Notwithstanding the carrying out of these precautions, the reduction in the number of cases of lead poisoning amongst painters employed in the Government dockyards has been very slow, and the necessity for restricting the use of lead has been recognised?—I think that the reason of the slow reduction of cases of lead poisoning does not lie in the white lead, but in the cleanliness of the workers.

16,334. Is it likely that we should find the workers more cleanly outside the Government dockyards?—I think that it would be very much the same outside the dockyards. They might be, perhaps, a little laxer outside, but the whole result might be the same.

16,335. If it is your contention that cleanliness is the main point, and the men cannot be made cleanly, is not that an additional reason for greatly restricting the

17 January, 1912.]

Mr. EMIL NIEDERHAUSER.

[Continued.]

use of lead, rather than putting on regulations which are not effective?—I think it impossible to do without white lead in my trade, and I think that in time it will be possible to educate the workers up to the necessity of keeping clean, but you cannot force them to do so.

16,336. If it is impossible to use anything but white lead with satisfactory results, how is it that paints which do not contain lead have been successfully used for six or seven years by the Midland Railway Company in England for all their carriages and wagons, and for various shorter periods by other railway companies?—I think it quite possible that they have used it for six or seven years, but I think it unlikely that the paint can have lasted for any length of time, and I would like to know how often the paint has been renewed.

16,337. It is the custom to go over the coaches and carriages for the purpose of re-varnishing and touching up once every year so that they have had ample opportunity of getting experience of how the paint wears?—I think that this proves my contention, because the Midland railway carriages have to be varnished every year, whilst with white lead that would not be necessary.

16,338. It is the custom, whether white lead or any other paint is used?—If there is a varnish coating, it is quite a matter of indifference what material is used below the varnish.

16,339. That would also explain why the Bradford Corporation has been able for several years to use similar paints on their trams, and the Daimler Motor Company and other motor car firms for the whole of the paint work on their cars, and also one of the leading firms of perambulator makers for their body work, and so on?—Yes, that would be the only explanation. I want to point out that even in that case it would be essential to have a ground of white lead, even if there is a lead-free paint used on top.

16,340. That is not usual in the places which I have mentioned?—I use white lead invariably for filling out crevices (for puttying as they call it) and I do not know how it is possible to do without it.

16,341. If lead has such marked advantages as you suggest, for exposed positions, how is it that leadless painting has been successful in the following cases: the Savings Bank buildings in London—painted in 1906, inside and outside with zinc paints, and reported as in excellent condition in 1910, when they became due for repainting; a large number of Post Offices and Sorting Offices in the London district, similarly painted with zinc paints; the top structures of the Orient Steamship Company's liners; the Royal Yacht "Victoria and Albert"; the "Medina," the P. and O. liner, on which their Majesties are at present settling out on their return from the East—these are all painted with zinc white—various gasometers and other ironwork painted with zinc and iron oxide paints; the exterior of the Stock Exchange painted with leadless paints, which are reported by the official architect as very satisfactory?—Firstly, I think that lead would be durable for a much longer period than four years, as given for the Savings Bank from 1906 to 1910.

16,342. But it is the regular custom always to repaint at the end of that period?—In the case of the other instances quoted, I think it highly probable that varnish was used on top of the zinc white paint, and I would like information on the point, whether or not varnish was used in addition to the zinc paint. Also it may be possible that they have not been exposed much to the weather, and I would like to be informed in what way these paints were exposed.

16,343. In the case of the yacht they have been exposed to the weather?—Then they must have been coated with varnish. Have you any information on that point?

16,344. Some were varnished and some were not. I suppose the reply is that it is contrary to your experience?—I cannot very well judge the point without seeing the paint in question. I think it rather peculiar that paint should be covered with varnish in some cases and not be covered in other cases. In my own experience I have never known zinc white to be as durable as white lead. For interior work I frequently

give a grounding of white lead, and then put on a top coat of zinc white.

16,345. Have you ever done it by giving a grounding of zinc white?—I have carried out some experiments with zinc white, using a zinc white grounding and a zinc white top coat. In those cases the paint was spoiled by rain and wind and was washed away by the rain.

16,346. But for interiors?—For exteriors. I am referring to windows. I have carried out experiments with zinc white exclusively for inside painting, but I find that an exclusively zinc white paint cannot be washed. If it is washed, the paint is ruined. Particularly I would mention the case of kitchens, which have to be washed frequently. There I found zinc white quite unsatisfactory.

16,347. But has the zinc white been used with a varnish coating?—In some cases varnish was used.

16,348. Could they not wash that?—If it was varnished you could wash it, and it would stand washing, provided that good varnish was used.

Lord Henry Bentinck (*in the Chair*).

16,349. (*Mr. Sutherland*.) Is there much outside painting done in Cologne?—Large quantities of outside painting are done in Cologne.

16,350. How often do you paint the outside?—Extremely frequently.

16,351. But they have no specified time?—About every five or six years.

16,352. Have you had any experience of zinc oxide for outside painting?—I have tried to use zinc oxide paint for outside work, but it did not last.

16,353. Can you tell us what is the average duration of zinc paint outside, compared with lead?—The zinc white will become bad in appearance very quickly, and must be renewed at the latest within two years, whilst white lead paint will last perfectly well for from five to six years. It is difficult to give average figures, because a great deal depends upon the nature of the atmosphere.

16,354. I am speaking of Cologne?—These figures relate to Cologne.

16,355. In your opinion is there any substitute for white lead which would give as good results, and at the same cost?—No, I think it quite impossible to obtain a substitute of equal efficiency and at an equally low price.

16,356. In your opinion, should not regulations be tried before resorting to prohibition?—I think it desirable first to try to stop lead poisoning by regulations before going to prohibition.

16,357. You would not place railway carriage work, which is highly varnished, and frequently washed and varnished, with ordinary painting on buildings?—No. I think that the two types of painting cannot be compared in any way, firstly, because the paints on railway wagons are renewed so frequently by varnishing, and, secondly, railway wagons are exposed to heat, steam and sulphurous gases from the engines and smoke, and all sorts of exposure, increased draught, and all sorts of weather, and the two cases are quite incomparable.

16,358. You have heard of the Bradford Corporation, but they have only had two years' experience with zinc paint, and the trams are constantly being washed and touched up. That does not compare with ordinary house-painting work?—No; I think that that cannot be compared with house painting in any way.

16,359. Do you know that the Admiralty is the largest consumer of white lead in this country, and that since March of last year their contracts have exceeded 1,700 tons of white lead?—I am not aware of the fact.

16,360. That being the case, do you think that if the Admiralty knew of anything better than lead they would not use it?—I am quite certain that the Admiralty would not use white lead if they knew of any efficient substitute.

16,361. And is not that a very strong argument in favour of white lead?—Most certainly.

16,362. Do you have to guarantee your paint to last a specified time outside?—I am always compelled to guarantee that the paint will last some five or six

17 January 1912.]

Mr. EMIL NIEDERHAÜSER.

[Continued.]

years. Generally, if it is not treated at all during that time, at the end of the six years it will have to be renewed entirely, but the general practice is to leave the paint on for four years, wash it down, and then give it only one coat of fresh paint.

16,363. Would you undertake to guarantee work done with zinc oxide?—No, I would not be prepared to guarantee that.

16,364. (Mr. Parsonage.) You say that the men are very keen in carrying out the regulations, and at the same time you say that all lead poisoning is due to the men's uncleanness. How do you reconcile those two points?—The men are particularly keen on carrying out the regulations with the intention of annoying their employer.

16,365. Are we to take it then that the men and the employers are always in antagonism to each other in Germany?—The relations between employer and employed are extremely bad. All the workers are Socialists, and whenever they can do any harm to the employers they do so.

16,366. In carrying out the regulations the workman would be allowed time to wash his hands, and it would be to his interests to study his own health before it would be the employer's interest to see the regulations carried out in any other way?—He is given time to wash, but the washing time is outside his working time, and he is not paid for the time spent on washing himself.

16,367. It is in his own time?—It is in his own time, after working.

16,368. The employer then does not allow time for washing?—No; strictly speaking, there is no time for washing during the working hours. The time used for washing is outside the working hours, and the man receives no pay for that time.

16,369. And that is the reason why he does not trouble to wash?—That may be so.

16,370. You have used zinc oxide for interior work. Do you find any difficulty in working with it?—The only difficulty in using zinc white is that the covering power of zinc white is less, and that generally an additional coat of paint is required.

16,371. I am speaking of the ability of the workman to use the white lead paint or the zinc white. Does it require any special training on the part of the workman to use zinc white?—No; there is no special skill required for applying zinc white.

16,372. The man who can apply white lead paint can apply zinc white equally well?—Certainly.

16,373. I entirely agree with that. With regard to rubbing down wet with glass-paper, you wet the work

with a sponge, and then apply the glass-paper to it. Do you put anything in the water when you put it on the paint?—Nothing whatever.

16,374. You know that water will not take a grip on fresh paint, unless you put something in it to make it grip. On the oily surface of fresh paint the water will not spread; it will lie on it in beads?—You must wait until the first coat of paint is dry and that will not take place. Then you wet it with a sponge, and rub it down with glass-paper.

16,375. But even when the paint is dry it may be dried hard, and water of itself will not apply to the fresh paint. There must be something put in the water before the water will take to the oil in the paint?—No; I think it is unnecessary to add anything to the water. The mechanical action is quite sufficient to spread out the water over the entire surface.

16,376. It would be a very easy matter to give a practical illustration of that. I believe even on the paint here on that wall water would not apply, and that has been done perhaps for years?—I am quite prepared to give you a practical demonstration if you desire it.

16,377. It is not my experience that water will spread on fresh paint?—It is only necessary to damp the surface, and the mechanical action is quite sufficient to spread out the water so that the entire surface is sufficiently moist.

16,378. Is it not the sponge that spreads the water; it is the glass-paper afterwards that spreads the water which stands in beads over the surface?—Certainly.

16,379. Then it does not differ much from dry rubbing?—I think that there is a very essential difference, because if carried out by this method, rubbing down first with a sponge, and then with glass-paper, does not cause any dust whatsoever, and a surface polished in this way is much smoother than one polished without water. I think that, generally, surfaces painted in Cologne are very smooth and very excellent in general condition.

16,380. You say that all lead poisoning is due to the uncleanly habits of the workmen. I would like to know if you give them sweet oil before they take their meals, or what is the reason that you put it down only to the dirty habits of the workmen?—Olive oil.

16,381. Yes?—No. Olive oil is not taken at all now. That was only necessary in the days of dry white.

16,382. There is no necessity for it now?—There is no necessity for it now, because there is no more dry white, and dry white is now unobtainable in Germany.

The witness withdrew.

Mr. HANS LEYENDECKER.

Evidence to 16,398 handed in and taken as read; witness then called and examined.

16,383. I am President of the German White Lead Manufacturers' Association. I was for many years a commercial judge.

16,384. I and my family have devoted great attention to the question of lead poisoning. As long ago as 1876, W. Leyendecker, who was my father, published a brochure entitled, "Treatise on the Injurious Influences of Lead upon the Health of Workers occupied in White Lead Factories, and upon the Most Effective Means of Remedying this Evil," which was presented to the First International Exhibition of Hygiene held in Brussels in that year. That publication dealt with the causes of white lead poisoning among workers in white-lead factories and the means of prevention, and was founded upon his experience and the method of prevention adopted by him in his factory. Again, in 1892, the same work was published by the firm of W. Leyendecker & Co. for the Exhibition of Hygiene in Berlin in an extended form, comprising the results of further experiments and preventive means adopted by the firm since 1876. These works advocated the general adoption of means of preventing dust; of ensuring cleanliness by providing lavatories and overalls, and encouraging a good nourishment.

16,385. In 1903, elaborate regulations for the white lead factories were passed by the Bundesrath, in the drawing up of which I and a number of other white lead manufacturers and workmen were consulted by the Government. These rules provide for the prevention of dust, for the cleanliness of the workrooms and the workers, separate washing rooms and meal rooms, periodical medical inspection.

16,386. The white lead manufacturers have in many cases gone beyond the requirements of the regulations, and have adopted special arrangements for making the workrooms healthy and dustless; have provided milk, coffee, &c., for the workers, and cheap dinners of fatty foods, special medical preparations, and in some cases light baths, &c.

16,387. The result of these methods of prevention has been a marked diminution in the case of lead poisoning in white lead factories. The figures published by Kaup in the "Archiv für Soziale Hygiene" (September 1910) show a large decrease.

16,388. In 1905, the Department of Commerce and Industry caused extensive inquiries to be made of the master painters and users of white lead with a view of extending the white lead regulations to the painters, and

17 January 1912.]

Mr. HANS LEYENDECKER.

[Continued.]

the white lead manufacturers were frequently in communication with the Minister in charge of the matter. We also caused independent inquiries to be made. A set of questions was addressed to the Guilds of Painters (Malerinnungen) in 60 cities and towns throughout the German Empire, and to the chief shipbuilders and railway carriage works.

16,389. The answers to these questions were published under the title of "Gutachten," which I now produce. From a perusal of it there will be seen to be an almost complete unanimity upon the following answers by the Guilds of Painters:—

1.—Q. What material is the best for a good and durable paint for the outside of buildings and other objects?—A. White lead.

2.—Q. Can white lead be replaced by any other material of equal efficiency for outside painting; if so, by what?—A. None, especially for durability and covering power.

3.—Q. Is the use of white lead to be recommended to obtain a good cover for the first and second coat of woodwork and walls for interior work?—A. Yes; zinc white can only be used for the last coat.

4.—Q. What experience have you of the use of zinc white with lithopone for outside painting, and are these materials to be considered for outside painting?—A. Various unfortunate experiences of zinc white and lithopone were given, as to durability, &c., neither being fit for outside use.

5.—Q. What is the position of these two materials (zinc white and lithopone) for inside painting, and which of them is to be preferred, and on what ground?—A. Zinc white was preferable to lithopone for durability, good colour, &c.

6.—Q. What experience have the masters of your guild in respect of lead poisoning among workmen, and what means are to be recommended in order, if possible, to prevent lead poisoning in painting?—A. Varying experiences were given. Cleanliness was the best means of preventing lead poisoning.

16,390. The shipbuilders stated that they preferred lead pigments for use whether above or below water.

16,391. The railway carriage works also emphasised the necessity of the use of lead pigments, especially for iron, and their great superiority over zinc white and lithopone.

16,392. Prohibition was not seriously contemplated, as all the evidence showed that the principal danger was in the use of dry white lead and in dry rubbing down.

16,393. Finally, in June 1905, regulations\* were made.

16,394. The inspection is carried out by the ordinary sanitary or factory inspectors in the usual course of their duty, and no additional inspectors have been appointed for this special work. The carrying out of the regulations is facilitated by the fact of their having to be communicated to every workman, and displayed at the shops, and the trade unions and Social Democrats also keep a keen watch for any infractions.

16,395. The regulations provide that the employer shall hand to a new workman a copy of instructions as to the danger and the way of avoiding lead poisoning. It is generally felt that the effects of the regulations might be even better than they have been if these instructions were made somewhat simpler.

16,396. Since the introduction of the 1905 Regulations, practically all the painters in Germany buy their white lead mixed in oil, and very little of it is supplied to them in the dry state. In order to obviate the objection that when white lead is mixed with oil it is more difficult to detect any adulteration, our association has introduced the system of certifying as to the quality of each package of white lead. In addition to the manufacturers' marks, we put on each cask or box the association's trade mark, with description of the goods. White lead pure is marked "genuine white lead." If intermixed, the percentage of admixture is denoted—e.g., 20 per cent, or 40 per cent.—as the case may be. The painters are quite satisfied with this, and when they order through their colour merchant,

they specify exactly what they want, and see that the delivery is in accordance with their order.

16,397. My firm supply white lead to the railway department, and I annex a copy of a circular addressed by the central office in Berlin to the provincial offices in September 1907, prohibiting the use of mineral white, zinc white, lithopone, &c., for exterior use, as after practical tests extending over two years they found that white lead gave the only satisfactory results. The provincial offices were given the option of buying the white lead (dry or mixed in oil), and during the last three years they have been buying chiefly the paint mixed with oil. The circular is as follows:—

"After lengthy experiments, it has been established that no satisfactory substitute for white lead can be found in non-poisonous pigments, in particular, lithopone and mineral white. We, therefore, request you to discontinue for the future the use of these pigments for the painting of wood and the other parts of railway carriages. The remaining stocks of lithopone and mineral white may be used up."

16,398. I have only recently heard of the theory that noxious emanations arise from newly painted surfaces where white lead is used, but as a practical man, I cannot understand how under ordinary working conditions the white lead can be volatilised, any more than I can see how the burning off process can produce emanations except of the oil. It is true that the lead saponifies when mixed, but the ordinary painters' lamp would not, in my judgment, develop sufficient heat to set free the lead compounds in the form of lead fumes.

16,399. (Chairman.) You are a white lead manufacturer?—Yes.

16,400. As your business depends on the use of white lead, your natural desire is to protect the industry in which you are engaged, is it not?—Of course.

16,401. You tell us that the elaborate regulations in force for white lead factories in Germany have been effective. This has also been the case in England. In the course of 10 years the number of cases in English white lead works has fallen from 358 in 1900 to 34 in 1910, and 41 in 1911. Can you give statistics for German white lead manufactories?—The practical statistics I have not with me, but I think I have given quite a lot of single data; I have put in my evidence all our experience as manufacturers in the course of 10 years.

16,402. It is possible in the manufacture of white lead to have such regulations and enforce them. Do you think the same is possible in the case of house painters?—From the experience we have had in Germany since our new regulations in 1906, I think it possible.

16,403. For example, in paragraph 16,384 you refer to the necessity of preventing dust. How can you do this in house painting?—In Germany in house painting it is strictly forbidden to use the system of rubbing the walls.

16,404. Dry rubbing down?—Dry rubbing down.

16,405. How is this regulation enforced?—It is put under certain punishments. It is under the control of the police or inspectors of factories.

16,406. We have been told by many witnesses that some dry rubbing down is indispensable. If they are right, how would you protect the worker from the danger of inhaling dust containing lead?—I think there will be no other means than respirators or wet sponges, just as we have in our white lead works. We have some points where dust cannot be entirely avoided, and in these places our people must wear wet sponges or respirators, but I must mention the fact that in Germany all rubbing down is done with water and pumice stone, and I think what is possible in Germany cannot be impossible in England on this practical point.

16,407. Are respirators used in Germany in house painting?—I cannot exactly tell.

16,408. The next precaution you mentioned is the provision of lavatories. Can you ensure adequate lavatory accommodation being available at every

\* See Appendix VI.

17 January 1912.]

Mr. HANS LEYENDECKER.

[Continued.]

painting job?—I think it possible. I cannot exactly judge these questions from the practical point, because I am only a manufacturer, and I have not a very great insight into the regulations or the manner in which the painters do their business. Those who have a dozen people to employ, and more, I think, might do it very easily; but if only two people are employed it would not be so easy.

16,409. Is hot water always provided in Germany?—Yes, it is.

16,410. How can the lavatory regulations be enforced?—By the same means, by control.

16,411. And overalls—how can the wearing of these be enforced?—All these places are under the control of the police in the first instance, and, besides, the best control are the painters themselves.

16,412. You also allude to a very interesting and important point, namely, the need for “encouraging a good nourishment.” How can you apply this to house painters? You mention that the white lead manufacturers have in many cases provided milk for the workers, cheap dinners of fatty foods, and so on. Do you recommend that this should be introduced for house painters also?—I think it would be very good for these people, but I think it is very difficult to enforce it.

16,413. With regard to the questions given in paragraph 16,389, the answers to these were all *ex parte* statements, were they not?—Yes.

16,414. Were the witnesses whose evidence was taken in this manner and which you quote in your evidence, cross-examined in any way?—No, there was no cross-examination.

16,415. We have precisely similar statements made by English master house painters, but many of these witnesses admitted that they had not thought out fully the details of the necessary regulations and the inspection requisite to enforce them. After these points had been put to them, many said they would prefer prohibition to these strict regulations. Are you aware of that?—It may only be difficult for these people to carry these regulations out at the beginning, as it was in our country, but very soon they became accustomed to them.

16,416. You mean in Germany it is difficult to carry them out?—Not difficult. Our people carry them out, but of course they found difficulties at the beginning in the first one or two years.

16,417. Can you produce any statistics as to the decrease in lead poisoning consequent on the introduction of regulations for house-painters in Germany?—I think in Dr. Kaup's evidence the statistics are given, and he has collected them from official sources.

16,418. Yes, he has. They are necessarily incomplete, but for what they are worth they show a very slow rate of improvement. Are you aware of that?—Yes.

16,419. In the case of Berlin, only 5·5 per cent. per annum; for the whole of Prussia even less, namely, 3·8 per cent. per annum. That is a slow decrease, is it not?—That is a slow decrease, but it is only relatively slow, when you remember that from year to year the painting work, especially in Berlin, is increasing rapidly. That must be considered.

16,420. The tables based on records of the sickness insurance fund show a similar slow improvement?—I am not aware of that.

16,421. If regulations are to be adopted and enforced it will obviously necessitate a body of inspectors to see that the rules are observed. Such inspectors would have to enter every place where painting operations were carried on, even private houses?—No, that would not be possible, but in the case of new buildings, for instance, it would, and the best and most effective control is exercised by the painters, who know the regulations and who can go to the police if they are not observed.

16,422. Not other places when painting is renewed?—No.

16,423. If a large number of employers of labour themselves prefer prohibition of the use of lead to a cumbersome and irksome code of regulations, would

that not cause you to modify the views you have expressed?—No, it would not alter my views.

16,424. In paragraph 16,397 you quote a circular of the German Railway Department which implies that white lead is the best pigment for vehicles?—Yes.

16,425. If it is impossible to use anything but white lead with satisfactory results, how is it that exclusively leadless paints have been used successfully for six or seven years by the Midland Railway for all their carriages and wagons?—I cannot understand this, and think there must be particular reasons. At least thousands of practical experiments in Germany are in perfect contradiction with this.

16,426. And by other railway companies also for shorter periods, and by the Bradford Corporation for their tramway cars, for four or five years by the Daimler Motor Car Company and other motor car firms, for the whole of the painting on their cars?—I am not aware of that.

16,427. Leadless paints have been used by all these firms?—I did not know that.

16,428. And by one of the leading firms of perambulator makers for body work, and so on. Now, if lead has such marked advantages as you suggest for exposed positions, how is it that leadless painting has been successful in the following cases for outside work: the Savings Bank buildings in London—painted in 1906, inside and outside, with zinc paint, and reported in excellent condition in 1910, when they became due for repainting; a large number of post offices and sorting offices in the London district, similarly painted with zinc paint; the top structures of the Orient Steamship Company's liners; the royal yacht “Victoria and Albert”; the “Medina,” on which their Majesties are at present returning from the East—all painted with zinc white; various gasometers, and other work, painted with zinc and iron oxide paint; the exterior of the Stock Exchange, painted with leadless paints, which are reported by the official architect as very satisfactory?—With regard to those points, I may say that we have made many painting experiments in Germany, dozens and dozens, hundreds I might even say, and always with the same result—that lead colours are the best to protect iron, wood, and brick work against atmospheric influences.

16,429. (*Dr. Collis.*) How many men do you employ in your own factory in the manufacture of white lead?—250.

16,430. Have you had any cases of lead illness and sickness among those men?—Certainly, but relatively few.

16,431. Do you know at all how many?—It differs. You have one year only four or five, and another year eight or nine. It depends in many instances on the condition of the people themselves. A weak person becomes ill sooner than a strong person.

16,432. You have in your factory all the regulations in strict force?—Yes.

16,433. And yet you get a percentage of about four?—Not a percentage. It is four people among 250.

16,434. You get 13 over two years, and 6·5 on 250 is very close to 2½ per cent.?—I do not know if you understood what I said.

16,435. They vary in different years, but taking one year with another you get 6½ cases among 250, which is about 2½ per cent., working it out?—Yes.

16,436. So that with all the regulations in full force within factory walls, where you can look after the men very carefully, there still remain 2½ per cent. of cases?—Yes, 2½ per cent. of cases, but the 250 is the average number we employ, and during the year they change.

16,437. This is the work of 250 men, and I understand that this is the way in which your statistics are taken in Germany; so I use it in that way. So that regulations, even though strictly enforced, do not get rid of lead sickness?—Not perfectly.

16,438. You say that you think the regulations in the house painting trade are well enforced?—Yes.

16,439. How many visits do the inspectors make to places where work is being carried on? I do not mean paint-shops?—I cannot tell you.

16,440. It is rather necessary to know that, is it not?—Yes, but I am not acquainted with the painting

17 January 1912.]

MR. HANS LEYENDECKER.

[Continued.]

business. That is a question you should put to the master painters.

16,441. But I am bound to put it to you, because you have made the statement that the regulations are properly enforced?—I am not acquainted with this line of business.

16,442. Then you should withdraw your statement that the regulations are properly enforced, because you have no information as to whether they are?—What I have told you is simply what I have from the master painters themselves, but I refer to my former remarks of the control exercised by the painters.

16,443. German master painters have told us that the inspectors never visit these work places. In five years one has never had a visit to the work place, but only to the paint shop. He has never known such a thing as a visit. You follow my point, that there seems to be a discrepancy?—Yes.

16,444. In your white lead works the men wear respirators, I suppose, in the white lead beds?—We have no white lead beds; it is the chamber process.

16,445. Taking the corrosions out of the chamber, then?—They wear wet sponges.

16,446. Do you find any difficulty in getting them to wear them?—None at all.

16,447. They always wear them quite regularly?—Yes.

16,448. In Germany do the men chew tobacco?—Sometimes.

16,449. Do you have prohibition of that?—We have it in our works.

16,450. Do you ever discover a man chewing?—We find no difficulty.

16,451. Have you ever looked in their mouths to see?—If I see a man chewing, I tell him that if I see it a second time he will be punished or dismissed.

16,452. We have exactly the same regulation in our English white lead factories, and I have found the men not wearing respirators, or if they have seen me coming in, the respirator has been put up very quickly, and on looking inside to see their teeth, I have found chewed tobacco in their mouth. Is it the same in Germany?—Sometimes, but very seldom, because they risk their position.

16,453. That being so within factory walls, how is it possible to enforce regulations in the painting of houses if you cannot control the men when they are actually under your personal supervision. If they are 20 miles off painting a house, could you enforce regulations?—It would be impossible. You would require thousands of persons to control them, but such control is not necessary.

16,454. That is our feeling. I presume the same condition of things obtains in Germany?—Yes.

16,455. In Germany you probably have better possibilities of carrying out regulations, because your men have all been through the army, and have learned to do what they are told, perhaps better than here, where we have not got conscription. You cannot enforce regulations?—Not to the point which would be necessary to prevent this lead poisoning entirely. I think that is really impossible, but you can improve the situation considerably.

16,456. That probably will account for the fact that the regulations you now have in Germany have not had a greater effect in reducing cases of sickness and illness?—There is an improvement from year to year.

16,457. The improvement is not accelerating. The employment has been more considerable, I agree, but the improvement has become stationary, and in years when trade has been slack, and there has been no increase in trade going on, we have had a similar reduction as shown by Dr. Kaup's figures of lead poisoning in England in the same years; but when trade has increased, as it did last year, lead poisoning increased with it. The big fall occurred simultaneously with slackness of trade, and I drew his attention to the fact that slackness of trade was simultaneous with the coming into force of the regulations, and he agreed that it would be necessary to wait to see what was the effect of the increase of trade before he could really say that the regulations had had a marked effect. You

follow my point?—Yes. I think it is always in some way dependent on the condition of trade. If you have very much to do, and you change your people many times, it has always a bad influence. If we can keep our people, we have much more influence than if we are changing them, but in the years of Dr. Kaup's statistics the white-lead business in Germany was rather regular and without much fluctuation.

16,458. That is our experience too; I quite agree with you. So that the evidence with regard to regulations in Germany is not very strong. First, they cannot be enforced, and secondly, such enforcement as you have obtained of those regulations has not brought the lead poisoning cases yet as low as we have got in England to start with. You see our difficulty in taking Germany as a help to us?—Of course I cannot judge of English conditions on this point.

16,459. Of course not?—I can only say what we have in Germany. We are comparing our former figures with what we have reached in consequence of regulation, and we think we are in such a position now that they will improve much more in future. With regard to painters, it is awfully difficult from the beginning to force them to be clean, and they must be forced to cleanliness.

16,460. Personally, as a medical man, I do not think that is the main thing that causes lead poisoning. We know that it is in the opinion of the occupiers, but I think from your own experience you will agree that cleanliness does not produce so much good as making the men wear respirators and so on, so that they cannot inhale the dust. The washing of the hands is a minor point, is it not?—I thought that both measures must come into effect.

16,461. I do not wish to ignore cleanliness, but would not you agree, from your experience as a manufacturer, that the dust question is very much more important?—Certainly, but cleanliness is nevertheless important and necessary.

16,462. So that the point which has been so frequently raised as to the cleanliness of the painter is not the most important we have to consider, and therefore the enforcement of the regulations as regards removal of dust and such like must come first?—Yes.

16,463. And those regulations, where they have been tried, seem to fail with regard to enforcement?—Yes.

16,464. So far as we can get the conditions in Germany to help us, that seems to be the difficulty we have to face. I do not know whether you can throw a different light upon it. That is why I am presenting the case to you just now?—No.

16,465. (*Mr. Sutherland.*) In your opinion, apart from your interests as a lead manufacturer, is there any basic material that, for white and like paints, can take the place of lead?—I think it is possible, like all things may be possible, but up to now we have not yet found anything.

16,466. You have no knowledge of anything?—No.

16,467. How long did the Prussian State railways give to their experiments?—As far as I know, three or four years.

16,468. Do you know the nature of the materials they employed?—They have employed all these different colours which are considered substitutes for white lead: zinc white, lithopone, brilliant white, and many others. I have seen at least 20 different whites.

16,469. Do you know what vehicles they mix them with?—Linseed oil and varnishes.

16,470. The experiment would be very carefully conducted, and the question would only be determined by the merits of the paint?—Yes.

16,471. There is no desire to keep lead if they could get anything equally good?—Certainly not.

16,472. And you think there are no alternatives to the use of white lead?—Not at the present time.

16,473. Is it possible, unless at enormous cost to the public, to substitute any other white for white lead for outside painting?—I do not think so.

16,474. How do the white paints have to be strengthened to make them last like white lead lusts

17 January 1912.]

Mr. HANS LEYENDECKER.

[Continued.]

with ordinary linseed oil?—I think the reason why white lead lasts better than any other colour is just that it combines chemically with the linseed oil.

16,475. Yes, but that is not quite my question: I am asking you, how would substitutes for white lead have to be strengthened to make them approximate to white lead in durability, with what material?—I know no material.

16,476. The general opinion amongst master painters in the trade in Germany is that white lead is the best base for oil paint?—Yes.

16,477. Do you know that the general opinion of the trade in England is exactly the same?—Well, I have heard it many times,

16,478. It is so: Now, does not this point to the fact that white lead is the best base for light paints?—Yes, I think so.

16,479. The trade have not supported white lead because of a love of white lead, but because they cannot get anything to equal it?—Yes.

16,480. Do not you think that a strong argument for its maintenance?—I think so.

The witness withdrew.

## TWENTY-SEVENTH DAY.

Thursday, 18th January 1912.

### PRESENT:

LORD HENRY BENTINCK, M.P. (*Acting Chairman*).

Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. DE MORSIER.

Evidence to 16,549 handed in and taken as read; witness then called and examined (through an interpreter).

16,481. I am editor of "Le Signal de Genève," and was formerly a *Deputé* to the Grand Conseil of the Republic and Canton of Geneva.

16,482. In the month of February, 1904, the question of the prohibition of white lead in the work of painting was first raised in our Chamber by Dr. Wyss. After consideration by that Chamber, a draft of a law was prepared by the Conseil d'Etat, which was referred to a Commission to examine thoroughly and report.

16,483. I was appointed a member of and reporter to that Commission, who set themselves the following questions:—

1. Does the use of white lead in Geneva create a danger of lead poisoning to house painters?
2. If yes, what is the comparative importance of that danger in the Canton of Geneva?
3. If that danger is found to be a social danger, what measures are necessary to avoid it? and
4. Lastly, is the use of white lead necessary, and, if so, to what extent in the work of house painting?

16,484. The Commission decided to examine the whole question, and studied it scientifically, in order to ascertain the facts and to draw accurate conclusions.

16,485. We could not, however, altogether lose sight of the fact that the war against white lead was more particularly of French origin, and also that the question seemed to have been specially studied in that country. We felt that we must examine what had been done in France with the utmost care. Accordingly, I read word for word, and examined in detail the French proceedings, which form a book of some 2,300 pages, and I have had interviews in Paris with various persons interested in the subject.

16,486. The Commission decided to publish a resumé of their enquiries, which were conducted under the following conditions:—We took the evidence of 31 persons, including a number of employers and workmen (the majority of the employers being, or having been themselves painters), and two doctors, a chemist, and members of the Trade Union of Painters and Plasterers. We also made enquiries by circular, of the benefit societies, the doctors of the Canton, from building contractors, and master painters, and from architects, and altogether received about 125 replies.

16,487. The fundamental question being to find out whether prohibition ought or ought not to be recom-

mended, I divided the replies into two classes—those who asked for prohibition, and those who did not.

16,488. The following are the figures resulting from our enquiries:—The Commission heard 28 persons of special knowledge—that is to say, workmen, employers either having themselves been workmen, or, in fact, working with their workmen, and one manufacturer.

16,489. Of these there were—

In favour of prohibition by law—

8 trade union workmen.

2 employers.

16,490. Against—

8 workmen.

9 employers.

1 manufacturer.

16,491. Of the 8 workmen in favour of prohibition, 2 recognised that the danger is much lessened by hygiene, and 1 recognised that white lead was necessary.

16,492. Five employers and 1 workman approved of zinc for the interior.

16,493. Two trades union workmen recognised that zinc had less covering power.

16,494. As a result of the inquiry by letter, there were 5 employers in favour of prohibition, making, with the 2 heard, a total of 7; and there were 46 against prohibition, making, with the 9 heard, a total of 55.

16,495. One architect was in favour of total prohibition, and 1 in favour of prohibition for the interior; 9 architects were against prohibition.

16,496. Of the 43 replies from doctors, 2 only asked for prohibition, the remainder pointing out that regulations appeared, in their judgment, to be sufficient to meet the danger.

16,497. With the exception of the workmen representing the trade union, and those whose names were supplied by the trade union, all the witnesses declared that the use of white lead in the form of paste for painting would reduce the danger of lead poisoning to little or nothing at all.

16,498. The following were the general conclusions arrived at by the Commission:—

- (1) The employment of white lead in Geneva does not create a danger of lead poisoning for house painters. White lead is a poison when absorbed in certain quantities and in certain doses, but the inquiry shows that the use of the product for house painting in Geneva

18 January 1912.]

Mr. DE MORSIER.

[Continued.]

- does not constitute a social peril necessitating a measure so radical as the prohibition by law.
- (2) Oxide of zinc is capable of replacing carbonate of lead in a large number of cases. The use of zinc white is already practised, but white lead remains a product of which the trade has need, and which cannot be replaced completely by zinc. This is the general opinion of the trade, and results from experience.
  - (3) White lead is not dangerous when applied by the brush in painting, provided that the painter does not absorb it by the mouth. Consequently, the operation of painting with white lead does not constitute a real danger when simple precautions are taken.
  - (4) White lead dust is dangerous when taken in with the breath for a long time or in too large quantities.
  - (5) The use of white lead in the form of paste does away with the production of dust in ordinary painting, and the mixing with oil does not offer great danger.
  - (6) The dry scraping off of old lead paint produces a large quantity of dust, which it is difficult, if not impossible, to avoid breathing. Burning off is equally bad.
  - (7) The dry rubbing down of old paints, or those which have been recently made, is not dangerous unless it is prolonged in rooms without proper ventilation, or if the workman does not take elementary precautions, such as keeping his face a certain distance from the paint to be rubbed. The rubbing down in Geneva does not form an important part of the work of the house-painter. In certain ordinary work it is indeed insignificant. When it is necessary to make a good job, or for especially fine work, precautions ought to be taken against prolonged or intensive rubbing down, which is otherwise not used amongst us.
  - (8) The trade fear an increase in the price of zinc, and the general increase in the cost of painting work which would necessarily follow upon a complete prohibition of white lead.
  - (9) In the absence of regulations, precautionary measures of cleanliness and general hygiene do not at present seem to be carried out with sufficient thoroughness in all workshops.
  - (10) In general, lead poisoning is an illness uncommon in Geneva. The proportion of sufferers reported to the Commission is very small, and these cases are not generally dangerous, and it seems probable that certain precautions of elementary cleanliness have not always been taken by the sufferers.
- 1) There does not exist in Geneva among the workmen any special demand for the total suppression of white lead. That measure would, we are convinced, cause very great surprise among the great majority of working painters.

16,499. Our report proceeded to discuss the matter from various points of view, viz. :—(A) *Medical*: Upon this part of our inquiry we had the advantage of the learned and exhaustive report of Dr. Roch, presented to the Société Médicale, of Geneva, and of his conclusions, which were unanimously approved at a meeting of that society. We found that white lead was absorbed by (a) the digestive system—from eating with dirty hands, &c.; (b) the respiratory—from breathing dust, especially in dry scraping off and rubbing down; (c) perhaps by the skin—although this is doubtful except in the case of wounds. The poisonous action arises from the gradual accumulation within the system of small quantities. The quantity requisite to cause damage varies with the individual, some show a predisposition to lead poisoning, especially alcoholics. The causes are chiefly uncleanness and the dust from dry rubbing down, &c.

x 7790

16,500. As to the question of poisonous emanations from surfaces painted with white lead, the results of the experiments conducted by Prof. Trillat, of the Pasteur Institute, and by M. M. Heim and Hébert showed us that at ordinary temperatures these are infinitesimal, the discomfort caused by fresh paint being mainly due to turpentine.

16,501. By reason of the special interest of the French investigations for Geneva we determined to examine carefully the multitudinous statistics and medical opinions contained in the French reports. We found that the French statistics had in many respects no application to Genevan circumstances. In the first place the practice of painting is very different in France, because of the large amount of dry scraping off of old paint, and also the custom much more frequent there of mixing the dry paint in the workshops. In the next place the Commission found that a great number of the French statistics related to conditions of work which have passed away. The cases of grave lead-poisoning were largely to be attributed to workmen working before the introduction of modern methods of grinding white lead by the wet process and painters working before the introduction of white lead in the form of paste, and others who performed the operation of *enduisage* (putty filling in) by hand and the use of essences which have now been abandoned.

16,502. The Reporter of the Commission was surprised and astonished at the gross inaccuracy and recklessness displayed in a large number of the statements appearing in the French reports. Such statements as the following appeared to be far apart from the truth: that "white lead sends hundreds of painters to death yearly and cripples thousands"—that "for Paris with 30,000 house painters there must be reckoned about 1,500 more or less infirm and professionally incapable, and a rate of mortality of 150" (the true figures being, according to the careful figures of Prof. Gautier for 1902-1905, about 137 annual hospital cases of lead poisoning among 30,000 workers in lead (not merely house painters), with 13 deaths; or, again, the calculation that as the number of lead-poisoning cases on one day in the Paris hospitals was 43, therefore the number of cases for the year was 365 times 43, or 15,000; nor was there anything to corroborate Dr. Laborde's statement that "there were 3,000 permanent victims of white lead in France." I found that many statistical calculations on fine problems of science and medicine became distorted and falsified as they passed from citation to citation, from pamphlets to lectures, and so into the Press, a process which is natural where polemics take the place of the objective discussion of facts. It is to such causes that we attributed statements such as that "from the moment when an individual is poisoned by the lead the whole of his physical organisation is attacked, his liver, his kidneys, heart, and arteries," or that "when a workman feels the first attacks of the trouble he is already terribly affected by the disease," or the statement of Dr. Labbé, that "an individual who works at painting becomes poisoned by small doses after four or five years, and ends by acquiring the terrible malady of lead poisoning and dying of it," or, lastly, the declaration that "there is not a painter who is not poisoned more or less seriously;" and that of Dr. Layet, "Every member of this body is a sufferer from lead poisoning, either patently or latently, and will die sooner or later of disease of the brain, of the kidney, the heart, or the arteries," and that "the poison takes the mask of every disease." We answer that if these were facts they were not to be verified in Geneva, unless it were from the point of view that we were all more or less suffering from latent lead poisoning, inasmuch as we are all daily exposed to lead and are all exposed to death by disease of the brain or the kidneys, the heart or the arteries.

16,503. It became clear to us from the report of Dr. Roch and from the works of first-rate authorities, such as Dr. Gautier and Meillère, that the diagnosis of lead poisoning, apart from cases shown by colic, is often of great difficulty, as there is no symptom which is characteristic of lead poisoning and nothing else. We were also impressed by the statements by each of

I i

18 January 1912.]

MR. DE MOESIER.

[Continued.]

these authorities that in the genesis and development of all the diseases attributable to lead poisoning a very important part is played by alcoholism, and the Commission quoted in its Report from Prof. Gautier: "Again, is not a great part of the misery due to the alcoholism and tuberculosis, which carry off these unfortunate workmen, the larger part of whom are badly housed, badly nourished, badly advised, careless of the rules of hygiene, as little economical of their health as they are of their purse, which chiefly goes to enrich the wine merchant. It is a deplorable state of things. Ignorance and alcoholism are two causes which are responsible for much more sickness than lead poisoning."

16,504. So far as we felt it necessary to come to any conclusion upon the French statistics, the Commission considered as proved the figures of Prof. Gautier and of M. Treille. According to Prof. Gautier, of 28,000 to 30,000 workers in lead in Paris (of whom 15,000 were reckoned as house painters), the figures for the annual average in the hospitals and the average of days in hospital for each case were:—

| —          | 1876-1881. | 1882-1901. | 1902-1905. |
|------------|------------|------------|------------|
| Cases - -  | 557        | 275        | 137        |
| Days - -   | 126        | 166        | 165        |
| Deaths - - | 5          | *16        | *13·2      |

\* Hospitals and City.

the cases having dropped from about 600 to 400 in 1882 after the French regulations of 1881.

16,505. The figures of Dr. Treille were on a different basis and were slightly higher, showing 10 deaths per annum for the whole of France for lead poisoning, or 1 for every 7,000 or 8,000 painters, and an annual average of 160 hospital cases of lead poisoning for the 15,000 painters of Paris. In quoting these figures the Commission stated that, in their view, lead poisoning is an evil which diminishes in quantity and importance with measures of precaution and hygiene; that the introduction of white lead in the form of paste has considerably changed the situation, and that the fall in the number of cases after the regulations of 1881 made it probable that if these regulations had been perfected and better enforced the condition of things would have continued to have improved.

16,506. In regard to the whole of the French evidence the Commission remarked the fact that the controversy about white lead became somewhat of a political question, and was conducted on both sides with all the strategy of an impassioned warfare, a state of things which explains the journalistic incidents to which it gave rise. The Reporter also had to ask himself whether the campaign was not stimulated by undertakings interested in fighting competitors in this way.

16,507. (B) *Can zinc replace lead for all purposes in painting?* This is the fundamental question. A great majority of the trade in Geneva reply, No!

16,508. They informed the Commission that, given the same conditions, precisely those works which are exposed to variations of temperature, alternations of sunshine and shade, to moisture, to wind, &c., are unquestionably better when painted with lead than with zinc paint, and that is the conclusion arrived at by the Commission. Upon consideration we did not feel that the assurances of a minority of master painters that they could dispense entirely with white lead would justify us in depriving a majority of a product which they state to be indispensable. For this reason the Commission abandoned the idea which they at first entertained of conducting difficult experiments with surfaces painted with zinc white. Our studies led us to the conclusion that (when there is no question of price) either zinc white or oxide of zinc can replace white lead in a great number of cases, particularly where a pure white colour is desired, which will not be affected by sulphuretted hydrogen

or ammoniacal vapours, and will not go yellow with age. Pure zinc white is preferred for the highest class work for the interior, and it forms a last coat of such works, but is rarely used for the first coats.

16,509. Two points of great importance had to be examined on this question, first the solidity of the paint and then its covering power. As to the constitution of white lead, it was demonstrated to us that the oil mixing with the powder of lead carbonate gives at the end of a certain time, after drying, an homogeneous paint very stable and resistant. It may be an oleate of lead, or it may be something else, and this can be discussed interminably; but practice proves that the powder of zinc oxide and the oil never form an homogeneous paint. It is a chemical problem not completely demonstrated, perhaps, in theory, but which seemed to us to be absolutely demonstrated in practice. White lead and oil form together a sort of varnish, hard and impermeable. The formation of this varnish is complex. White lead is an hydrated oxide of lead, and is a combination of hydrate of lead and carbonate of lead. When a fatty body is mixed with a metallic oxide they produce what is called a saponification such as the soaps of potash or of soda, for example, and the same phenomenon seems to be produced by the mixing of linseed oil and white lead. The hydrate of lead and oil form a soap (salts of lead), solid, insoluble, hard and elastic, which one may compare with a varnish offering great resistance to external changes. The other part of white lead, viz., the carbonate of lead, plays no part in forming this varnish, but communicates to the varnish its covering power. There is thus a combination between the white lead and the oil under the form of a lead salt, which being oxidised is formed into a hard varnish which can be applied in very thin and solid coats. This theory was first propounded by the great Belgian chemist, Stas, in 1855, and has since been confirmed by Professor Thibaut, of the School of Industrial Arts and Sciences at Lyons.

16,510. Zinc white absorbs more oil than white lead, that is to say, in order to obtain a paste sufficiently fluid it is necessary to use more oil. Painters estimate, in order to obtain the desired fluidity, 40 per cent. of oil for white lead as against 85 per cent. with zinc. The zinc and the oil do not seem to constitute a varnish as do the white lead and the oil. It is this essential difference between the two products which determines the comparative lasting power of the paint. The zinc white thinned with oil dries less quickly and requires a drier, which is usually litharge mixed with the oil or sometimes manganese salts. Some colours, for example, vermilion, would be better employed with zinc than with white lead. Zinc does not blacken when affected by sulphuretted hydrogen and ammonia. It remains indisputable that in the present state of science a stable chemical composition cannot be obtained between the oxide of zinc and the oil.

16,511. The question of covering power is very complex. It is a problem of physics and molecular chemistry in which one has to consider the density of the powders employed, the quantity of oil incorporated (both for manufacture and thinning), the quantity of spirit, the degree of fluidity, &c. The question of the thickness of the coats is equally important, because a painting composed of a number of thin coats is much more lasting than one composed of less coats applied thicker. Without going into all the dissertations upon the comparative covering power of zinc and lead, the Commission pointed out that by "covering power" is meant the capacity which a paint possesses with a coat of a given thickness to render opaque the surface to which it is applied. The problem presents itself thus:—In order to make a given surface, how many grammes of zinc white or of white lead it is necessary to mix with how many grammes of oil, spirit and drier? The Commission were much struck with the opinion of Professor Thibaut upon this subject, and accepted his statement that the covering power of oxide of zinc is inferior to that of white lead, when considering its capacity for masking or rendering opaque a given surface. It is true that oxide of zinc covers a greater surface than white lead, because with

18 January 1912.]

Mr. DE MORSIER.

[Continued.]

the same weight of powder there is in effect more zinc powder than white-lead powder, the specific gravity being about 5.40 for zinc and 6.57 for lead, so that zinc is less dense than white lead. For the same weight there is more in bulk of the zinc white, so that it can be spread over a larger surface, and the more so, because, before it is thin enough to be spread, it takes up a larger quantity of oil than does white lead. But the true covering power is the power to render opaque. Given an equal fluidity, zinc white is in this respect inferior to an equal weight of white lead, because the opaque matter is absorbed in a larger quantity of oil. As is indicated by theory, and above all by the actual practice, in order to obtain the same opacity with an equal fluidity it is necessary to paint one coat more of zinc to obtain the same opacity as with white lead, that is to say, the same opacity is obtained by two coats of white lead as from three coats of zinc white.

16,512. Another product, however, is used in the painting industry, viz., minium or red lead. Its manufacture is dangerous as is its use, seeing that it is nearly always employed in the form of powder and not as an oil paste. According to expert and medical advice minium is more dangerous than white lead, but this product cannot be replaced in all places by oxide of iron any more than white lead by zinc. Minium is especially used for painting iron. Like white lead, it is also employed in numerous other industries as in the colouring of paper and in the manufacture of flint glass and crystal. It appeared to the Commission that the same methods of cleanliness and dust prevention would sufficiently protect workers with minium as workers with white lead.

16,513. Litharge is used principally in small quantities as a drier, particularly with zinc white. The other driers which have been tried with zinc do not give equally satisfactory results, such as the peroxides, sulphates, nitrates, borates, acetates, and oxalates of manganese which have been tried by the trade. The best of them appears to be the oxalate of manganese. Boiled oils and varnish also contain litharge, and it is difficult to suppose that their use could be prohibited.

16,514. Minium and litharge are not the only toxic lead products which are used in house painting. There are also sulphate of lead, orange lead (oxide of lead), French red (bichromate of lead), mineral yellow (chlorure of lead), English green (arsenate of copper), vermilion (oxide of mercury), chrome red, Prussian blue (ferro-cyanide of potassium), and the various mercurial colours, zinc greens, and other dangerous colours.

16,515. In the course of the Commission's enquiry, we learned that cases of poisoning occurred in other trades than that of house painting, and found that the question of white lead is only a very small part of the industrial use of lead.

16,516. The Commission also considered various other proposed substitutes for white lead, such as sulphate of lead, lithopone, but found that none of these was so satisfactory even as zinc white.

16,517. In conclusion, the Commission recommended to the Conseil d'Etat a law to regulate the use of white lead, which was passed on 26th October, 1907.\*

16,518. Further, in pursuance of the recommendation of the Committee, regulations were issued on 21st December 1907.†

16,519. The following is a chronological paper from the Protocol of the Swiss Federal Council for 5th January 1904, and 30th June 1908, in order to show what has taken place in Switzerland generally apart from the Canton of Geneva, with which I am identified with reference to this subject, from which it would appear that although the Federal Council prohibited the use of white lead in all Government departments for four years from the 1st January 1904, with a view to general prohibition, at the expiration of that period, on the evidence of the Factory Inspectors and Dr. Roth, the prohibition was removed except for inside work.

\* See Appendix XIX.

† See Appendix XX.

*Proceedings of the Swiss Federal Council,  
5th January 1904.*

16,520. 1st October 1902.—Memorial by Council of Central Union of Painters, Plasterers, and allied workers:

That the Master Painters avoided their responsibility for lead poisoning by not employing workmen who had been once attacked by it; that the proved dangers to health of white lead made it a duty to effect the removal of this stuff from use—especially as there were no technical difficulties in the way. They wished that the use of white lead and its preparations in painting might be prohibited, but recognised the difficulty of immediately effecting such a prohibition, and petitioned that as a first step towards such a measure the Federal Government should exclude the use of white lead and its preparations in the specifications for its works.

16,521. 6th October 1902.—Swiss Labour Department requests opinion of Union of Swiss Master Painters.

16,522. 15th June 1903.—Answer of Union of Swiss Master Painters.

16,523. Statistics of German Swiss (the Union does not include French) showed that for a period of 40 years in 318 businesses, accounting altogether for 5,207 years, and an annual employment of 2,236 there had been 188 cases of lead colic with 5,451 days of illness and only four deaths.

16,524. The amount of sickness, which was now small, had formerly been much more. Uncleanliness and improper food were often the causes.

16,525. The Union had no objection to prohibition of white lead for Government works. Apart from cost and durability, zinc white, lithopone and others can be substituted where there is no exposure to severe weather. For outside exposed work white lead is the most durable.

16,526. The Union were against a general prohibition of the use of white lead.

16,527. 7th January 1903.—Two white lead manufacturers protested against injury to trade, stating that the present means of preparing and using white lead wet are dangerless.

16,528. 12th November 1903.—Report of the Federal Factory Inspectors and Dr. O. Roth (Professor of Hygiene, Zurich).

16,529. The statistics of both the painters and the master painters were unreliable.

16,530. Foreign experience, especially France, showed that there were substitutes, especially zinc white; but it was doubtful whether zinc white is sufficiently durable in exposure to weather.

16,531. Regulations for the prevention of lead-poisoning would not be effective owing to lack of effective control.

16,532. They recommend exclusion of white lead in specification for Government contracts for three years, and recommendation by Federal Council to Cantonal Governments of similar action.

The decision of the Federal Council was as follows:—

16,533. General agreement was expressed with the report and recommendations of the Inspectors.

16,534. They were not prepared to prohibit all use of white lead and compounds, because—

- (1) On the basis of the existing law it would only affect a limited number of businesses.
- (2) In other industries than painting, the use of white lead is indispensable, e.g., potters, printing, electric accumulators, and
- (3) The protection of home industries must be considered.

16,535. No State had pronounced a general prohibition, but there were precedents for various kinds of legislative interference both in Switzerland and abroad.

16,536. As a check upon the discrepant estimates of the amount of lead-poisoning given by the painters and the master painters, they took the factory in-

18 January 1912.]

Mr. DE MORSIER.

[Continued.]

spectors' statistics for factories and employers' liability for five years' illnesses, which were:—

| —          | Painters. | Others. | Total. |
|------------|-----------|---------|--------|
| 1898 - - - | 9         | 16      | 25     |
| 1899 - - - | 24        | 15      | 39     |
| 1900 - - - | 12        | 17      | 29     |
| 1901 - - - | 5         | 13      | 18     |
| 1902 - - - | 7         | 13      | 20     |
|            | 57        | 74      | 131    |

16,537. The figures were not comprehensive, as many small businesses were not included.

16,538. Finally, the Federal Council considered that the best course would be to prohibit use of white lead in Government works for a trial period of four years.

16,539. The question of further and general prohibition to be considered upon experiences gained.

It was therefore resolved that—

16,540. In all Federal departments for four years from 1st January 1904, only leadless materials to be used for painting, and a condition for leadless materials to be inserted in all contracts.

16,541. During the trial period materials to be collected by the Department of Labour useful for consideration of general prohibition.

*Extract from Protocol of Federal Council,  
30th June 1908.*

16,542. 5th June 1908.—Report of Factory Inspectors and Dr. Roth:—

- (a) For outside work white lead is indispensable—at least at present.
- (b) In accordance with the general opinion of the trade there was nothing to prevent prohibition for inside work. Cost of a substitute would be higher.
- (c) For moving materials (e.g., railway rolling stock) and iron constructions in the open, leadless materials give unsatisfactory results.
- (d) Red lead especially cannot be prohibited—its use for painting iron (grounding) and other purposes is indispensable.
- (e) Generally, a considerable increase of the use of lead is indicated.

16,543. The Federal Council therefore considers that:—

16,544. The discussion of the question in all its bearings is not yet possible, because there is no effective substitute for lead—apart from inside work.

16,545. In any case any enquiry would extend over many years and have to be on strictly scientific lines, and would have to take into account the general industrial circumstances. Such a commission was not recommended, as there had been unfortunate experiences in foreign countries.

16,546. Further practical developments would give further information.

16,547. They did not consider feasible the legislative prohibition of the inside use, as in the present state of the law it would only affect a limited number of businesses, and it would not be expedient to make a special prohibition for inside work.

16,548. The only effective step to be taken was the restriction of the use of white lead in Government works.

It was therefore Resolved that:—

16,549. The use of white lead for inside work be prohibited in all the works executed by or contracted for by the Federal Governmental Departments.

16,550. (Chairman.) Can you tell us if there are any statistics showing the amount of lead poisoning among painters in Switzerland?—There are no very exact statistics, because the painters in Switzerland mostly consist of a floating population, chiefly Italians, who come and go, irregularly, and have no fixed abode for any length of time.

16,551. Are there any statistics for Geneva?—The same holds good for Geneva with regard to the majority of painters in Geneva. There are only some 300 painters who work continually in Geneva.

16,552. Do the Italian workmen come in in the summer time?—They generally come in in the summer, and stay, as a rule, only two or three months. They go as soon as there is no more work.

16,553. If these Italian workmen suffered from lead poisoning, they would not come under the cognisance of the Geneva doctors and the authorities?—They do not really come into the statistics, because, although they are treated at the hospitals in Geneva, they have travelled about such a great deal that it is impossible to ascertain the origin of their illness.

16,554. If there are no reliable statistics showing extensive ill-effects of lead, this fact may account for half the workers consulted being against prohibition of lead?—The chief reason is that there was in Geneva at the time of our inquiry no properly-constituted trade union of painters. There is a trade union, but it consists chiefly of foreigners, and it is impossible to obtain an accurate account of all the painters working in Geneva, and the trade union cannot obtain a proper vote of all its members.

16,555. The general conclusions arrived at by the Commission, as quoted by you in paragraph 16,498, are doubtless based, to a large extent, on the fact that you have extremely little evidence of lead poisoning in Geneva?—They have never found in Geneva a real danger in the case of proper or clean painters. There are a number of painters who have been in the trade for some 50 years who have grown up in the trade, and who have worked originally with white lead in the form of dry powder, and they have all said that as far as they themselves were concerned they have never known of a serious case of lead poisoning.

16,556. If the Commission in question had had to consider the question of house painting in a country where large numbers of cases of lead poisoning occurred every year, their conclusions might have been modified, I suppose?—It is not at all certain that they would have arrived at the conclusion of prohibition if they had found a large number of cases, because they carefully went into the causes of lead poisoning. If they had found a large number of cases of poisoning, they would have found as the principal reasons the lack of cleanliness, and the danger of dust from dry rubbing down and scraping, and they would have introduced regulations, but they would not have come to prohibition.

16,557. In paragraph 16,501, you refer to a difference between painting in France and painting in Geneva. In what respect are the circumstances different? You draw attention to the great difference there is between the Geneva conditions and the French conditions?—The chief reason is that Geneva is a small place, and there is only a comparatively small number of master painters, who are all known to each other, and they exercise on each other a sort of mutual control. Further, the Geneva painter is much more advanced than the French painter, and is generally more prudent in his work, and takes more precaution in regard to his health.

16,558. (Mr. Sutherland.) More advanced in what way?—In his education as a worker.

16,559. Do you mean technically in his trade, or general education?—Technically, the French painter is quite as efficient as the Geneva painter, but the Geneva painter seems to be more careful in regard to the effect of his trade upon his health. For instance, a thing never known in Geneva is for a painter after work to go straight away to the bar without washing or changing his clothes, whilst the French painter no doubt does not take the same precautions.

16,560. (Chairman.) There may be different conditions in England, which account for a large number of cases of lead poisoning among house painters, as compared with a very small number in Geneva?—That is very probable, but I do not know anything of English conditions.

16,561. In your proof you have gone somewhat into detail regarding *ex parte* statements bearing on the

18 January 1912.]

Mr. DE MORSIER.

[Continued.]

French reports. We cannot discuss individual French witnesses unless we are going to hear the whole of the evidence which was placed at the disposal of the French Commission?—Can you give an instance of my having quoted a French witness?

16,562. Yes, there are a great many here: "The reporter of the Commission was surprised and astonished at the gross inaccuracy and recklessness displayed in a large number of the statements appearing in the French reports." You will understand that unless we can sift all these statements thoroughly, it is very little use considering these sorts of statements?—I am quite prepared to give you a supplementary report proving all the self-contradictions contained in the French inquiry. That, of course, will be a very lengthy piece of work.

16,563. We have, however, before us the fact that France has resolved to prohibit the use of lead after sifting all the evidence on both sides?—The fact that the French Government has decided on prohibition does not prove anything, either for or against white lead. The conclusion of the report of the French inquiry was that part of the witnesses were in favour of white lead and part of them against; and it was simply debated in the Chamber of Deputies, and the majority voted for the witnesses against white lead, but I think that this does not prove anything either way.

16,564. But why did the majority vote in favour of prohibition? You have not explained that yet?—My chief point is, that the French Chamber of Deputies arrived at conclusions on a divided report, and not on the report of a finally settled result.

16,565. Do you maintain that the French Deputies were incapable of sifting the evidence and arriving at a conclusion themselves?—The majority of the French Deputies do not seem to me to have considered the question from a scientific point of view, and they would be unable to sift the evidence given by technical men. Thus have rather decided in accordance with a wave of opinion and on principle.

16,566. But how do you suggest that the general current of opinion arose on this subject?—The point is, that there are two currents of opinion, the opinion of the workers, which is in favour of prohibition, and the industrial and employers' opinion, which is against prohibition. The point is simply this: if you accept the report of Mr. Treille, you are bound to be against prohibition. If you accept the report of Mr. Breton, you are bound to be in favour of prohibition.

16,567. (Mr. Sutherland.) Were there two reports?—Yes, the report of Mr. Treille, and the report of Mr. Breton.

16,568. (Chairman.) This is the report of two doctors, is it not?—It is expert evidence by two doctors. They were two members of the Committees of Inquiry. Mr. Treille was a Senator, and drew up the Senate Report; Mr. Breton was a deputy, and drew up the Chamber of Deputies' Report.

16,569. The reporter of the Chamber of Deputies was Mr. Breton?—Yes.

16,570. As a result of the Swiss Commission a law was passed in October 1907, and regulations applying to the use of lead were issued in December 1907. It is clear, then, that the necessity for some action, either prohibition or regulation, has been recognised in Switzerland?—That law applies only to the Canton of Geneva, not to Switzerland.

16,571. Are you speaking also of the regulations of 1907?—Yes. The regulations of 1907 apply only to Geneva.

16,572. Then it is clear that the necessity for some action, either prohibition or regulation, has been recognised in Geneva?—It has been added here, that the Geneva inquiry had a report before it, which made it impossible to decide on prohibition. There was the report of the minority, but that report did not disprove anything contained in the other report.

16,573. If the Geneva workmen have been so free from lead poisoning, why was it that the necessity for regulation was generally recognised?—Though there were very few cases of lead poisoning, one recognised that there were certain methods of working that might

give rise to danger to the workmen, such as dry rubbing down and scraping, and also lack of cleanliness amongst workers. There is in Geneva a considerable number of apprentices, unskilled workers, and they might be poisoned; but on the other hand, there are very few cases of poisoning, because the majority of the workers were careful.

16,574. These regulations prohibit the use of white lead in powder, they prohibit dry pumice-stoning, dry scraping off and burning off of paint; they prohibit the direct use of fillings with the hand; and they require the provision of washing accommodation, overalls, and places for clothing put off during work. How are these regulations enforced?—Firstly, all men have to be informed of the regulations by means of a poster (*producing a specimen*). The remaining part of the regulations applying to the provision of overalls and places for clothing is put on a similar poster, and the police are charged with the enforcement of the regulations. Also the Works Department or the Police Department are entitled to receive complaints from workers, if there are any.

16,575. Do the police enter houses where jobs are being done?—The sanitary police generally try to obtain their information from the contractor, or from the person owning the house, but they very rarely actually enter a house, unless they receive a complaint. They enter a house directly without notice only as the last step, if it becomes absolutely necessary, if they find that they cannot otherwise obtain the information they want.

16,576. From whom do they receive complaints?—It may be either from one of the workers or some person interested in the proper enforcement of the regulations.

16,577. Do the workmen often complain?—Since the coming into force of these regulations, there has not been a single complaint from the workers.

16,578. How can dust be prevented in house painting?—First, all dust-raising operations have to be carried out in the wet way, that is sweeping, pumicing and scraping off have to be done in the wet way. In the case of scraping off, the paint is moistened with a solution of soda and then scraped off. The paint comes off in the form of a length of scraping, somewhat like rubber. In the case of rubbing down, it is simply moistened with a sponge, and then rubbed down. Exceptions are allowed in regard to dry rubbing in certain special cases. In the case of white new surfaces freshly painted, it is permitted to rub them down dry, and in the case of luxury work, dry rubbing down is permitted, but in that case the worker may not spend more than half of his whole time on this class of work.

16,579. Are these regulations made by the police?—Regulations have been drafted by the head of the police, but he had sanction from the Government, as the head of the police cannot set out regulations which apply to the whole of the Republic, that is to say, the executive authority.

16,580. Are the regulations in Geneva made by the police always faithfully obeyed?—It is very hard to say whether regulations are always obeyed, because the people of Geneva are very individualistic, and they are very like the English in their respect for their own liberty. There is always a certain struggle between the authorities and other parts of the community to enforce respect for the police.

16,581. We have been told by many witnesses that some dry rubbing down is indispensable. If they are right, how would you protect the worker from the danger of inhaling dust containing lead?—There is never any necessity for dry rubbing down, because dry rubbing down is only required for very fine work, and in the case of very fine work, for interior painting; what is generally done is that the first two layers of paint are of white lead, but the last layer of paint is of zinc white, which is much whiter and smoother than white lead, and keeps its whiteness better than the other, and the final coat, which consists of zinc white, is rubbed down.

16,582. But in Geneva do they never rub down on the first two coats?—If the plaster on which the paint is applied is absolutely smooth, it is unnecessary to

18 January 1912.]

Mr. DE MOESIER.

[Continued.]

do any rubbing down of the first and second coats, and masons generally take great care to obtain a very smooth plaster to work on. In the case of painting on wood it is always possible to obtain a smooth surface to paint on, and it has constantly been found that one can quite well dispense with dry rubbing down entirely. The regulations which have come into force for Geneva were made by the police only after consulting a number of master painters.

16,583. Your regulations lay down that adequate lavatory accommodation should be available. How can these lavatory regulations, and the provision of hot water, be enforced?—There is no mention of hot water in the regulations.

16,584. The provision of hot water is not laid down, but lavatory accommodation is, is it not?—It is not necessary to provide actual lavatory accommodation. It is only necessary to have a continuous supply of water for the men.

16,585. Next with regard to overalls. How is the wearing of these enforced?—This is controlled by the sanitary police. They frequently inspect work on new buildings, and they would always see at once if the workmen were wearing their blouses. The chief point concerning overalls is that the master painters are compelled to see to the washing of the overalls, because the men themselves do not have them washed sufficiently frequently.

16,586. (*Mr. Sutherland.*) Do the master painters wash them?—Yes; it is the duty of the master painters.

16,587. (*Chairman.*) If regulations are to be adopted and enforced, it will obviously necessitate a body of inspectors to see that the rules are observed?—That is perfectly true, but if you come to prohibition you will have to appoint a still greater number of inspectors to see that prohibition is carried out.

16,588. Inspectors to enforce regulations would have to enter every place where painting operations were carried on, even private houses?—These new inspectors would certainly have to have the right to enter any house they thought fit to inspect, but at present there are no special inspectors for this work in Geneva. The inspection is carried out by the police authorities. However, Geneva hopes to have soon a new organisation of inspectors, and in that case the police will be relieved of that work.

16,589. The duty would also have to be laid on the employer of notifying every place in which painting operations are carried on?—In Geneva it is not permitted to carry out any type of work on buildings without informing the authorities previously.

16,590. Even painting work?—It applies to all.

16,591. Repainting of private houses?—Yes, because all painters come under the heading of contractors, and all contractors are compelled to have a general licence for working, and consequently can be controlled with regard to where their workers are.

16,592. Does the fact of having a licence compel the employer to notify every job of repainting a private house?—The licensed contractor is compelled to keep a list of where all his workers are, and he is compelled to show that list on demand. It is necessary to have that list in order to carry out the federal law of labour and also that of insurance.

16,593. (*Mr. Sutherland.*) Has the master painter in Geneva to be licensed?—All professions have to be declared.

16,594. But have they to take out a licence before they can undertake work?—It is not exactly a special licence, but a general licence for working. It is an information given to the local authorities of his having set up in a certain undertaking. It does not necessarily imply any definite skill.

16,595. (*Chairman.*) You say that the employer has to declare where his men are working, on demand. Will you tell the Committee on whose demand? Whose duty is it?—The Board of Trade authorities if the employer is subject to the laws just mentioned.

16,596-7. The Board of Trade authorities are not the inspectors under the regulations? Have the police authority to demand where the workmen are working?

—No, they have no authority apart from the authority of the Board of Trade.

16,598. If a large number of the employers of labour themselves prefer prohibition of the use of lead, to a cumbersome and irksome code of regulations, would not that cause you to modify the views you have expressed?—Is the supposition that they have a preference?

16,599. The supposition is that the majority of employers who have hitherto appeared here, prefer prohibition rather than cumbersome and irksome regulations?—In Geneva the majority of master painters were in favour of regulations rather than prohibition, because they all decided that it was impossible to dispense with white lead for most of their work.

16,600. Have these regulations been successful? Has there been any improvement in the number of cases of lead poisoning since they have been enforced?—Before the coming into force of the regulations there were extremely few cases of lead poisoning, and at present there are still very few, or possibly a less number of cases of lead poisoning, because these statistics only deal with the workers fixed in Geneva.

16,601. Then if there never have been any complete statistics, how is it possible to say whether these regulations have any value at all?—It would be possible to prepare statistics of nomad workers, but in such case I think it unfair to apply these figures obtained for nomad workers to estimate the result of these regulations, because these regulations are in force only in Geneva, and therefore one should count only the cases of lead poisoning which have been caused in Geneva, and since the coming into force of these regulations there has been only a single case of lead poisoning amongst Geneva workers—a case of dry rubbing down in spite of the prohibition.

16,602. But we understood, at the opening of your evidence, that in Geneva there were no reliable statistics, and that it was not possible to say how much lead poisoning did occur in Geneva?—Even if there were statistics for the nomad workers they are not very valuable, because they only register the number of cases and the duration of the illness when they have been in hospital. They do not take cognisance of the origin of the illness. It is never possible to ascertain whether the man fell ill from lead poisoning as the result of dry rubbing down or painting, or bad working, or any such thing, and that is also difficult enough in the case of permanent Geneva painters.

16,603. Can you give the Committee the statistics as to nomad workers?—No, but Dr. Rochi, who will be before the Committee later to-day, will be able to give these figures.

16,604. If it is impossible to use anything but white lead with satisfactory results, how is it that leadless paints have been successfully used for six or seven years by the Midland Railway for all their carriages and waggons?—I cannot judge the conditions holding good for the Midland Railway, and I have no opinion on that point, but in France they decided to do away with white lead, and decided to do iron work free of lead paint. It was done in this way: they gave the iron first a coating of red lead; and then afterwards zinc white on top. This was called leadless paint. In the case of the Metropolitan Railway of Paris it has been used considerably, but they always used a thick layer of red lead and zinc white on top of that. I do not know of any case where zinc white has been put directly on iron where the paint has lasted. In France minium (red lead) has not been prohibited.

16,605. (*Dr. Collis.*) Other paints can be used, without lead, which are not zinc white. Graphite paints, for instance?—It is possible.

16,606. (*Chairman.*) Leadless paint has also been used for a shorter period by other railway companies; for several years by the Bradford Corporation for their tramway cars; for four or five years by the Daimler Motor Car Company and other motor-car firms, for the whole of the paint-work on their cars?—It is quite possible to obtain good results with leadless paint, but then you have to put on one or two or several more coats of paint to obtain a satisfactory result. That

18 January 1912.]

Mr. DE MOÏSIEU.

[Continued.]

has been admitted by a number of painters before the Geneva Inquiry. They do not wish to put on these extra coats of paint.

16,607. (*Mr. Sutherland.*) It costs more?—Yes.

16,608. (*Chairman.*) The Savings Bank buildings in London were painted in 1906 inside and outside with zinc paints, and reported in excellent condition in 1910, when they became due for re-painting?—I quite agree that it is possible to obtain satisfactory results with zinc white, but only under certain special conditions, provided that you put on a certain number of extra coats of paint. They had the same question before them in Geneva, and they had to decide between the right to use white lead or not, and they came to the conclusion that they should permit the use of white lead, because it was possible to reduce the danger of painting to a minimum, provided that the painting took place under certain conditions. They felt they had no right to interfere with an industry which might be put under such conditions that the danger would be sufficiently reduced.

16,609. Are you aware that the Office of Works has stated that it is not necessary to put on extra coats of paint, and that painting with zinc white paint does not entail any extra cost?—In Geneva they did not obtain the same result, but they obtained a different result.

16,610. Are you aware that the top structures of the Orient Steamship Company's liners and of the Royal yacht "Victoria and Albert" and of the "Medina" are all painted with zinc white?—I was not aware of it.

16,611. Are you aware that various gasometers and other iron work have been painted with certain proprietary paints—zinc and iron oxide paints?—I am strongly in favour of the use of zinc white instead of white lead, and I hope that it will be possible to replace the use of white lead entirely by zinc white in a few years, when we have more experience on the subject. But I speak as a legislator. My colleagues felt that they had no right to suppress the use of white lead, as they were convinced that white lead could be used without any danger to the individual.

16,612. (*Dr. Collis.*) Do I understand that in connection with the inquiry in Geneva there was a minority report?—There was a report of the minority, and it is affixed to the other report. The report of the minority does not refute any of the statements made by the report of the majority. There is no single point dealt with scientifically. It simply makes general statements. The report is appended. This report was made by a single member on the Committee of Inquiry, and it was that member who had started that inquiry and who had moved for a law of prohibition of white lead in the Chamber, and, in my opinion, this report was very feeble in all its arguments.

16,613. It was the report of one member only?—It was the report of one member only, the member who had originally moved the prohibition.

16,614. (*Chairman.*) Was Dr. Wyas in a minority of one?—Yes, he was the only person in the minority.

16,615. (*Dr. Collis.*) How many were there on the committee?—At the beginning of the book the constitution of the committee is given.

16,616. What number were there?—I believe that there were eleven, but I cannot say for certain without referring. I think I can furnish you with the exact number, and also the names of the members on the Commission.

16,617. Have the police kept any list of the number of private houses which they have inspected with regard to the question of house painting since the law for the Canton of Geneva was passed?—There is a list of all the works carried out in the hands of the police, and I was informed by the chief of the police before I departed for England that they had never been able to find a single case of contravention of the regulations.

16,618. The factory inspectors in Switzerland publish the number of visits they make every year, do they not, not necessarily inspection of house-painting, but factory inspection?—There are three kinds of inspectors; first, Federal inspectors—those inspectors who are in the pay of the Federal Government, and

who do one kind of inspection. They have the right to control the Cantonal inspectors (the inspectors of the counties, so to speak) to inspect, and those Cantonal inspectors further have the right to instruct the police to go on an inspecting visit. The Federal inspectors make a report of all inspections every two years, and I have here the reports of 1908 and 1909.

16,619. Will this report include the work done by the police on behalf of the Federal inspectors, in house painting?—This does not contain the report of police inspection, but it contains the report of inspections done by the Cantonal inspectors, who hand in their reports to the Federal inspectors. The chief reason for this is that the majority of painters do not come under the inspection of the Federal inspectors, because they do not come under the Federal factory law.

16,620. It appears to me that the regulations laid down require a certain amount of skill to enforce. The individual must have a knowledge of the trade. Have the police in Switzerland the skill, and have they the knowledge of the painting trade to enable them in their ordinary work to enforce these regulations?—No. I think that the police do not have any such knowledge, which I think extremely necessary, and I therefore think it desirable that the inspection of painting should be placed entirely in the hands of the Cantonal inspector, who always is a technically trained man.

16,621. You say that the Cantonal inspectors have power to give instructions to the police to make certain inspections. I presume that is only to places which are under the Factory Act, and does not include house painting?—No. The police have the right and the duty to inspect those painters who do not come under the Factory Act, but I desire that it should be taken from the police and placed exclusively in the hands of a technically trained man, the Cantonal inspector.

16,622. You do not think it satisfactory to leave the inspection in the hands of the local authorities, such as the police?—I think it most undesirable that it should be in the hands of the police, because I think it is likely to scare the painter if he is visited all of a sudden by a policeman, and I think it much better that it should be in the hands of a technically trained man. You cannot possibly obtain good results of control by control through the police.

16,623. Do you know how lockers and places sufficient to keep free from poisonous dust clothing which the workers take off during their work, can be supplied on work in private houses done away from the factory?—In the country wooden boxes can be used.

16,624. Who provides the wooden boxes?—It is the duty of the master painter to supply such a box. The master painter has done his duty if he provides a special room where the clothes are kept, and that room must be closed, of course.

16,625. Yes, but in the case of boxes, are these boxes never used for anything else?—If there are boxes they should not be used for anything else, but I have no proof that they are not.

16,626. (*Mr. Sutherland.*) You said that the report presented to the French Chamber was a divided report. What do you mean by that?—There were two reports handed in, one by the senator, Monsieur Treille; it was against the prohibition of white lead; and there was another report handed in by Monsieur Breton, a deputy, which was strongly in favour of prohibition. There was an additional report, supplemental to the first report, by Mr. Pédebidou.

16,627. These gentlemen were all members of the same profession, were they not?—There were certain alterations in the composition of the committee during the inquiry.

16,628. But one of these did not report to the Chamber, and one to the Senate?—Monsieur Treille was a member of the Senate, and Monsieur Breton a member of the Chamber of Deputies.

16,629. There was a conflict of opinion, was there not, between the two bodies on the question?—Yes. The report for the Senate was by Monsieur Treille, and the Senate appears to have decided against pro-

I i d

18 January 1912.]

Mr. DE MOESIER.

[Continued.]

hibition, whilst the report for the Chamber of Deputies was the one by Monsieur Breton.

16,630. Your complaint of the inaccuracies of the report is sustained, is it not, by Professor Gautier's figures as given?—Dr. Armand Gautier is the medical man whose duty it is to make an annual report on lead poisoning. There is also a statistician, Bertillon, and both their figures bear out my opinion that the figures given in the French report are not in agreement. I am of the opinion that the French inquiry was not held in a scientific or in an impartial spirit. Some of the statistics given are quite meaningless. For instance, Armand Gautier quotes all the cases of death from lead poisoning amongst painters, and compares them with the total number of deaths occurring in France amongst all classes of people, whilst Mr. Bertillon compares the number of deaths from lead poisoning with the total population, and I think it a most absurd comparison. I think the only way you can obtain comparative figures is to compare the death rate per 100 of painters with the death rate per 100 in other professions. I could quote a number of other instances in which the figures compiled in the French inquiry are incorrect or useless.

16,631. Did the French Government make any practical tests of different paints?—The French Government did not carry out experiments, but all these experiments were carried out under different conditions, and consequently they do not prove anything, and have no right to be called scientific experiments.

16,632. Would you be surprised to hear that a witness in this room stated that there were hundreds of painters suffering from lead poisoning walking the streets of a certain English town, and yet a certifying surgeon in the same town, giving evidence to this Committee, stated that they had only had 15 cases in two years?—I am not in the least surprised, because before French inquiries I have frequently found similar discrepancies. Dr. Roch, who will be before this Committee this afternoon, states that it is frequently very difficult to identify a case of lead poisoning, and it may be confused with alcohol poisoning, and altogether the cases of poisoning which have been put into statistics have frequently been badly observed or not properly classified.

16,633. In paragraph 16,511 you state, "The question of the thickness of the coats is equally important, because a painting composed of a number of thin coats is much more lasting than one composed of less coats applied thicker." Is not that a very strong argument in favour of white lead? Will you tell the Committee why you can spread white lead into a thin serviceable coat, and why you cannot do the same with zinc?—The chief point is that the durability of paint depends not on the number of layers of paint, but on the thinness. The maximum durability of paint is obtained if you have a great number of extremely thin layers, and it is possible to obtain much thinner layers with white lead, because the white lead itself forms a more solid coat than zinc white; the reason for this being that lead carbonate forms with the linseed oil a soap, whilst zinc white does not do so.

16,634. Your evidence confirms the evidence of master painters whom we have had before this Committee?—That is the opinion of all the master painters in Geneva.

16,635. The National Association of Master Painters of England and Wales have passed a resolution which they have sent to this Committee that they prefer that a trial should be given to regulations before resorting to the prohibition of white lead. Do not you think that a more reasonable attitude?—I think it is extremely difficult to judge the conditions in a country which I do not know; but, generally speaking, I think that regulation is a far more reasonable course to take than prohibition, because first, I am convinced that by means of proper regulation you can reduce the danger to painters to the same degree of danger occurring in any other trade, such as, for instance, roof builders or

railway employees, or any other profession. The only point necessary is to stop the creation of dust in painting, and the absorption of white lead by the mouth. I think it not just to try prohibition, and I think it also impracticable. I think it will be much easier to control the enforcement of the regulations than to control the enforcement of prohibition. It is very rare that you obtain zinc white which is absolutely free of lead, and it will be very difficult to control all the time how much lead is to be allowed in the zinc white. Then you would have to decide whether you are to bar a paint containing  $\frac{1}{2}$  per cent., or 1 per cent., or a higher percentage of lead. I would very much like to see the way in which England proposes to carry out the enforcement of complete prohibition.

16,636. So that prohibition would not release the Government from instituting a staff of inspectors. They would have to have a staff of inspectors to see that prohibition is carried out?—Exactly.

16,637. The Savings Bank and other buildings named by the Chairman were all painted with proprietary paints; that is paints in which there is a large element of varnish to strengthen the zinc and other ingredients. Now can we compare paint made in this way, at a largely increased cost, with ordinary white lead paint in the ordinary operations of building?—I think it unfair to make a comparison of varnish paint with a pure oil paint.

16,638. Are not experiments made by the Federal Council extending over four years and leading up to the conclusion that they can only dispense with white lead for inside work, a very strong argument for permitting the use of white lead?—The prohibition of the use of white lead on inside painting is not a law in Switzerland. It is simply a decision of the Administrative Council or Federal Council to use zinc white for the present on interior work, and they may return at any time to the use of white lead.

16,639. But is it not the law so far as the Federal Government is concerned?—It is not a law which has been passed by the Government, but it is purely an edict of a department, something corresponding to an edict, say, of the British Office of Works.

16,640. The Admiralty and the War Office of this country are the largest consumers of white lead in this country. They use thousands of tons a year. Now is not that an argument as to the value of white lead, because if they could get any efficient substitute they would be anxious to remove the dangers arising from its use, but they still use it?—Zinc white was discovered some 50 years ago; for fifty years they have tried to substitute zinc white everywhere for white lead, and for fifty years it has been found impossible to replace white lead efficiently by zinc white. I think that the British Admiralty must have come to the same conclusion. I think it impossible, and an error of judgment, to try the prohibition of white lead, because it will not be practicable. There are always certain purposes for which lead must be used, and prohibition will have to contain numerous clauses of exemption in which they will be permitted to use white lead, and the control of these exempted cases will be far more difficult than regulation. You will also have to permit possibly paints containing certain maximum limits of lead, and these will be extremely difficult to control.

16,641. (Mr. Gardner.) As the house painting industry in Switzerland does not come under the Factory Act, the figures which have been given in paragraph 16,536 are of no service?—Those figures given in paragraph 16,536 are certainly outside the scope of the federal inspectors of factories, but the cantonal inspectors, who have the right to inspect painters, have given these figures for the purpose of statistics to the Federal inspectors.

16,642. Then they apply to house painters, and not to factories under the Act?—The latest publication by the Federal inspectors contains this statement: "We have sent round an inquiry to the departments of cantonal inspections and have from them obtained figures concerning painters", and the figures for painters are published. These figures are later figures than those given in my evidence above.

18 January 1912.]

Mr. DE MORSE.

[Continued.]

16,643. Can you tell us if the Swiss workmen are better nourished than the French workmen?—It is impossible to say. It is a question of locality.

16,644. If the workmen in Switzerland said in 1902 that the proved dangers to health of white lead made it a duty to effect its removal from use, and that there were no technical difficulties in the way of removing it from use, should not a great deal of weight be given to the opinion of the men who are always using the material, as opposed to the opinion of those who merely go into it from a scientific point of view?—I think that you have to take into account also the opinion of the master painters, as most of the master painters are former workers themselves.

16,645. The factory inspector's report that regulations would not be effective owing to lack of control. If that is the case, of what use are regulations?—I have never stated that it was impossible to control. What I said was that it would be far more difficult to control prohibition than to control the enforcement of regulations.

16,646. Do you agree that an unskilled man may be able to apply white-lead paint much more easily than a zinc paint?—It is generally the custom, for interior work in houses where zinc white is used, to have painters who do nothing but painting with zinc white. If you get a new man on this kind of job, you have to explain to him the necessary conditions very thoroughly, and with white lead a new man requires very much less training than with zinc white.

16,647. But that is scarcely an answer to the question. I will put it in this form. A man who is not a painter can apply a white-lead paint when he could not apply a zinc paint?—I think that in both cases, whether he uses white lead or zinc white, if he has not learnt the trade he is quite certain to commit great errors.

16,648. Possibly why the Admiralty use so much white-lead paint is that they have unskilled men applying it, viz., the ordinary sailors. Probably the ordinary sailor could not apply zinc paint. That is the point I want to make?—The only difference is that with zinc white it is more difficult to obtain a thin layer of paint.

16,649. Then you will agree with me that when work is finished with a leadless paint it has to be applied just as thinly as a lead paint?—I certainly think that it is far more difficult to apply a finer coat of zinc white, because zinc white is generally mixed with a very much larger proportion of oil than white lead, and when a paint contains a less solid base than another, it will show far more marks of the brush than a thicker paint, and consequently it requires far more work and skill to obtain a thin smooth layer of zinc.

16,650. I suppose you are aware that a man may be suffering from lead poisoning, and yet not be so disabled as to be able to claim compensation from his employer?—I have no definite view on that point. I would prefer that you should put that question to Dr. Roch. But, generally, I think that the first symptom of lead poisoning is invariably colic, which would not necessarily prevent a man from continuing his work, and would not necessarily enable him to obtain compensation.

16,651. (Mr. Parsonage.) Do they pay compensation for lead poisoning in Switzerland?—Lead poisoning is considered a professional accident. In all cases of professional accidents the employer has to pay compensation, whether his employees come under the Factory Act or not.

16,652. If an employee suffered from lead poisoning, the employer would not give him work again after he had once paid him compensation?—He would certainly find a second job with the same employer.

16,653. He would certainly find one?—Yes.

16,654. With regard to the enforcing of regulations, we were told that it is left to the workmen to complain, but the workmen never make any complaints. If a workman made a complaint, would he be discharged?—Very frequently the man giving information against his master will be dismissed, but that depends on the mental attitude of his employer.

16,655. The same thing applies all round. With reference to the number of cases of lead poisoning, would you be surprised to hear that a surgeon who examines candidates for admission into the trade union, stated, that if he had to reject all candidates who showed traces of lead poisoning, he would have to reject over 50 per cent. of those who applied to him for admission into the trade union?—That question never occurs in Switzerland. Whenever a workman is ill, his trade union will show the greatest possible interest in him, and they will always be ready to admit a workman in need of support.

16,656. But they will not admit a workman and pay him sick benefits if, at the time he is applying for admission, he is suffering from a disease, will they?—It is impossible to give a general reply to that question, because a number of Swiss trade unions have different regulations applying to the admission of sick workers in particular cases of illness. Some of them admit workers who are in a bad state of health, and others do not.

16,657. With reference to its being easier to enforce regulations than to prohibit the use of lead, do not you think it would be much easier to pass a law to prohibit the sale of white lead to employers, than to carry out regulations where they have to enter private houses and make inspections?—If you prohibit and prevent the production and sale of white lead, then, of course, the white lead question is settled.

16,658. But the question is, would it be easier to do that than to enforce the many regulations that would be required?—Certainly. I acknowledge that it would be easier to do it in that way.

16,659. That disposes of the previous answer, that it would be easier to impose regulations?—Of course, that would be very much simpler if you could do it in that way, but you would have to make certain that no white lead was imported, and that other paints, which really are white lead were not sold under some other name.

16,660. Yes, that would be the position, and we could easily do that?—The French law does not deal at all with the production of white lead. It simply deals with the use of white lead, because the French law has assumed that there will always be cases where it is absolutely necessary to have lead carbonate.

16,661. (Mr. Kinggate.) Have you any practical knowledge of painting, either as a workman or as an employer in the painting industry?—I have no practical experience whatever of painting. I am a newspaper editor, and the only way in which I came into contact with lead poisoning is that I formerly heard of lead poisoning amongst printers; but now that they are cleanly and have to obey certain regulations, lead poisoning amongst printers has been entirely stamped out.

16,662. I take it, then, that all your information comes from the fact that you were secretary or reporter to the Commission that sat to inquire into the question of lead poisoning?—I gained all my experience by being secretary and reporter, but whilst I was secretary and reporter I felt that it was my duty to inspect personally some of the buildings where painting was being carried on, and I personally studied the craft in a practical way.

16,663. You have no practical knowledge of painting at all? We have to take it that your information is taken from the facts placed before you on the Commission and your own figures?—I beg your pardon. I myself went to new buildings and tried my hand at painting work.

16,664. We will take that for what it is worth. With regard to the evidence given before the Commission, there is rather a remarkable feature connected with it. Sixteen workmen altogether gave evidence. Eight trade union representatives are unanimous in favour of prohibition; but the others, who are not trade unionists, are in favour of the retention of the use of lead. May we take it from that that the organised workers of Geneva are unanimously in favour of the prohibition of the use of lead?—One cannot assume that the whole of the trade union is in favour of prohibition. First, at the time of the inquiry the

18 January 1912.]

Mr. DE MOSSIÈRE.

[Continued.]

trade union of painters was quite a small union, not registered and not properly organised, and the workmen who appeared before the Commission were asked to inquire from other workers whether they were in favour or against prohibition, and they all of them were unable to point out any large number of painters who were in favour of prohibition. It was also found that some of the members of the trade union who had appeared before the Commission were not resident workers, but were nomad workers, and consequently their opinion is not representative of the workers of Geneva.

16,665. Is it not rather a remarkable fact that eight of the workmen, the trade union workmen, are in favour of prohibition, and the other eight workmen are not? Does it not also point to the fact that the workmen might have been used by the employers for a certain purpose?—One cannot assume that these eight painters, who were not members of the trade union, were under the influence of the master painters in giving their evidence. On the contrary, one must assume that all the witnesses before the Commission were in every way uninfluenced. They were all of them well-known workers, who had lived there for some time—that is, the non-trade union men. They were fathers of families, and were men of long standing in the place; whilst the members of the trade union, who were in favour of prohibition, took that attitude simply because the painters' trade unions of all countries have always been in favour of suppressing white lead, without going at all into the scientific reasons why it should be suppressed.

16,666. It is very evident, then, that they know the danger attached to it. Would you be surprised to know that there are hundreds of cases of painters in England suffering from lead poisoning which are never reported. They are only reported to obtain the benefit of compensation generally, and the workmen often fear to apply for compensation because of the risk of losing their employment. We have had before us an employer witness who definitely stated that, if he knew a man was suffering from lead poisoning he would not employ him?—That may be the case in England, but it is not the case in Switzerland.

16,667. Mr. Sutherland put his point, so I thought the point should be put on the other side. That only shows that the statistics that are given in England do not in any way convey the evil of lead poisoning, and, further, insurance companies also as far as possible get employers not to employ men who have been suffering from lead poisoning?—That is totally different from the case in Switzerland. There is a compensation Act there which compels the master painters to pay compensation. That is always done quite independent of all insurance companies.

16,668. Seeing that there is great danger attached to this, as we know in England, if a substitute can be found to take the place of lead, do not you think that lead should be prohibited?—I think that, as soon as you find a paint which can efficiently take the place of white lead, white lead should be prohibited straight away, but that day has not yet arrived.

16,669. (Mr. Fell.) Do you know of any process in connection with carriage painting that could not be carried out with leadless paints?—The coach-painters who have given evidence before the Geneva Inquiry have all stated that they would refuse to guarantee the paint on a carriage painted without lead,

but they also asked to be permitted to do the rubbing down of the paint without water, provided that the paint was fresh, and for that reason an exception has been put in permitting the dry rubbing down of quite fresh paint.

16,670. What was their objection—weather conditions?—Because they considered that carriage paint is more exposed to bad weather than the outside paint of houses.

16,671. Yes; but the paint on carriages and on motor cars and railway carriages is thickly covered with varnish, and therefore is not so much exposed?—It may be a question of the contact between the varnish and the paint, but generally the coach-painters before the Geneva inquiry said it was impossible to do without white lead.

16,672. Do the coach-painters come under the same regulations as the other painters in Geneva?—The regulations apply only to public work, and to work on private buildings. The only regulation which also applies to coach-painters is that they are prevented from using white lead in the form of dry powder.

16,673. Is not dry rubbing down prohibited?—Only within the limit of Article 4, saying that the coach paint must be quite fresh. I would like to make another statement: These remarks, I wish to be understood, are purely confined to Geneva and Switzerland. I do not attempt to make statements concerning England. Generally, the question between lead and zinc is based on this: lead will form with the oil a soap that is a compound which is perfectly durable and stable, while zinc does not form such a compound with oil. Further, zinc is far more difficult to apply in thin layers, and zinc has very much less covering power than lead. When the inquiry was started in Geneva at first, Dr. Wyss moved in the House that white lead should be either prohibited, or its use should be saddled with certain regulations. Before this could be put into law or could be voted on, it was necessary to institute a public inquiry. Before this inquiry was instituted, I was strongly in favour of prohibition, because I thought there was a danger, and that it would be possible to do without white lead. I was elected to report on the doings of this Commission, and while on that Commission I gathered a good deal of information concerning white lead. I found out firstly, that it was impossible to replace white lead by any other article; secondly, that it was perfectly possible to suppress the danger by regulations, and I considered that to suppress white lead simply by prohibition would be an abuse of legislation. I had the instances of a good many old painters, who had been in the profession for a great many years, who knew how to carry out their work, and who had never suffered from lead poisoning, and I felt consequently that it would not be right to go to prohibition. Finally, the statistics of M. Bertillon have clearly proved that there are five professions in which lead is used, and in which there is greater danger of lead poisoning than in painting, but because in these professions lead cannot possibly be replaced by anything else, they have never been attacked. The five professions are accumulator making, printing, pottery, glazing, and polishing. In all these five professions lead is used, and the danger of lead poisoning is greater than in painting; but, because one cannot do without lead there, one has never attempted to legislate.

The witness withdrew.

Dr. MAURICE ROCH.

Evidence to 16,705 handed in and taken as read; witness then called and examined (through an interpreter).

16,674. I am Chef de Clinique at the Cantonal Hospital at Geneva.

16,675. In February 1906, a Bill for the prohibition of the use of lead compounds for painting having been presented to the Grand Conseil of the Canton of Geneva, a Commission was appointed by the Conseil to prepare a report upon the subject, and in the course of their inquiry that Commission requested the opinion

of the Société Médicale of Geneva. I was requested by the College of Medicine to prepare a report for discussion at the special meeting held on the 16th of January 1907, and in order to enable me to prepare that report I made a very exhaustive study of the subject from the purely medical side.

16,676. I desire to explain, in the first instance, that the Canton of Geneva being situated on the

18 January 1912.]

Dr. MAURICE ROCH.

[Continued.]

French frontier, a large number of French and foreign workmen migrate to Geneva during the spring and summer months in order to work at their trade, and among these are included a large number of house painters. The hospital serves a resident population of more than 130,000, without taking into account the surrounding district; the average annual number of patients treated being 2,200. Additional provision is made for treatment of the sick poor by a dispensary, or Polyclinique, which gives advice to some six or seven thousand patients annually.

16,677. I took out the statistics of cases of lead poisoning treated during the seven years preceding 1906 at the Cantonal Hospital of Geneva, and I found their total was 44, of whom 24 were house painters and 20 followed other trades. Upon inquiry of Professor Mayor, of the Polyclinique, I ascertained that not more than three cases of lead poisoning had been treated at the dispensary per annum during that period, and among these all the patients who were seriously ill had been sent to the hospital, and consequently had been included in their statistics. I went carefully through the medical history of each of the cases treated, and embodied the results in my report to the College of Medicine published in "la Revue Médicale de la Suisse romande," 20th February 1907, and in a review which I wrote with Dr. Edouard Long for the "Bulletin Médical of France" on the 27th of April 1907.

16,678. I ought, perhaps, to premise that I entered upon this study without any preconceived idea other than that of the great danger which since my early youth I had attached to the use of white lead, which I had been taught to consider a terrible poison. I need hardly add that I side neither with the workmen nor with the employers, and that neither the alleged action of the Vieille-Montagne zinc mine in Belgium, nor the contra efforts of the white lead manufacturers has been allowed to affect my judgment. I arrived, however, at a very definite opinion at the end of my studies.

16,679. I made a careful study of the medical literature on the subject and also of the then recent enquiries in France, Belgium and Germany before writing my report, which I sub-divided into headings as follows:—

16,680. (a) *The fight against white lead* (in which I set out the short history of the movement).

16,681. (b) *The comparative importance of lead poisoning*.—All poisonings are there classed under the one title of "Intoxicants." In going through the records, I was struck by the very large number of patients treated for alcoholism (which, of course, falls under the heading), and the small number of those who suffered from lead poisoning. For 20 cases of alcoholism, I came across scarcely one of lead poisoning. When there is taken into consideration the number of those suffering from alcoholism who refused to enter a hospital so as not to be deprived of their favourite poison, and when there are also considered all those alcoholics whose cases are classed under the titles of tuberculosis, pneumonia, gastritis, neuritis, &c., it becomes apparent that this proportion is still far from corresponding with the brutal facts. I found, however, that the registers of the Polyclinique appeared, even more strongly than those of the hospital, to support the relative insignificance of lead poisoning.

16,682. (c) *Lead poisoning and its gravity*.—My studies soon led me to the conclusion that so far as concerns the chronic lead poisoning which appears to me to alone merit the French name of "saturnisme," there can be no doubt as to its reality. Lead is a poison for which there is no immunity derived from habitual use—that is to say, all those who absorb appreciable quantities of lead become poisoned. It would appear, however, that various individuals are more susceptible than others.

16,683. It is rare that a case of saturnism escapes the attention of the doctor; in fact, one may say that the diagnosis is often of saturnism when in reality it is something else, for it is often sufficient for a house painter to have stomach trouble for his doctor to immediately diagnose lead poisoning.

16,684. Of the 24 house painters treated at the Cantonal Hospital in the seven years preceding 1906, 17 were simple cases of colic, and the others were more serious. Of the cases whose history was traced, six were engaged on rubbing off old paint, four cases were from neglect of elementary cleanliness, in three cases the man prepared the white lead in powder; himself, in three cases there was alcoholism, and one was of weak intellect.

16,685. (d) *Trades liable to Lead Poisoning*.—My investigation showed that everybody is exposed to lead poisoning, and that the ordinary person absorbs a milligramme of lead per diem. The number of workers exposed to lead poisoning in their trade is enormous. One list that I read showed 138 trades; and it grows with the progress of civilisation.

16,686. (e) *Prophylaxis of Lead Poisoning*.—Lead poisoning is brought about by the absorption each day of small quantities of lead, which accumulate in the body and eventually produce sickness. The greatest danger arises from dust and dirty hands; and undoubtedly from a medical point of view the most certain course would be to simply prohibit the employment of lead and all lead salts in all industries. Very little reflection shows that such a prohibition would affect the whole civilised world, and if this metal were prohibited there would appear to be no logical reason why a similar restriction should not be made against the use of petrol, benzine, and alcohol, which cause many more accidents and deaths than lead.

16,687. (f) *Etiology of Lead Poisoning among House Painters*.—I next ascertained which of the products of lead were used by house painters, and found that the following were used:—

- (1) Litharge, which acts as a drier by oxidizing the oils;
- (2) Minium, which is used for the first coats to iron work; and
- (3) Chromates, yellow and red, which are toxic, but relatively little used.
- (4) Sulphate of lead, which is claimed to be a substitute for white lead.
- (5) White lead or hydrocarbonate of lead.

16,688. Absorption takes place through: (a) the digestive organs; or (b) the respiratory organs, or (c) possibly through the skin, but the absorption by a healthy skin may be disregarded; the absorption by the respiratory organs is either by means of gases or dust. Upon the question of emanations at the ordinary temperature, it seems to me that having regard to the small volatility of lead compared with that of mercury, for example, the emanations arising under ordinary working conditions are negligible. The dust undoubtedly is a very great danger, whether the absorption be by way of the respiratory or the digestive organs.

16,689. The influence of alcohol upon poisoning is, I believe, very great, although indirect. It is the case that neuritis may be due to lead or to alcohol; and so also with sclerosis and cerebral troubles; alcoholism is one form of intoxicant and lead poisoning another. Nevertheless, I cannot say with Professor Treille that lead poisoning is only a branch of alcohol poisoning. The predisposing and aggravating influence of alcoholism appears to me to be exercised upon a house painter who is addicted to drink (amongst other ways) through his often stopping work to quench his thirst, without washing his hands or rinsing his mouth. As such a man is usually a rolling stone, he travels from town to town, often being put to the most dangerous tasks of rubbing down and flatting by different employers, in order to spare their good workmen.

16,690. (g) *Prophylaxis of Lead Poisoning among House Painters*.—All the authorities agree that lead poisoning is often a very serious intoxication and that it is necessary to take measures to limit it as much as possible. Different opinions prevail as to the best means of dealing with it, some being for regulation and others for abolition. Personally I advocate regulation, for the reasons I will indicate.

16,691. According to Professor Armand Gautier, the most toxic products of lead utilised in painting are first the chromates, secondly minium, and thirdly white lead.

18 January 1912.]

Dr. MAURICE ROCH.

[Continued.]

16,692. Although I am not competent to give any opinion upon the industrial side of the matter, it appears to me that salts of lead, white lead in particular, form with the acids of the oil metallic soaps, which cannot be produced either with zinc-white or barium, and that it is to this chemical property that white lead painting obtains those special qualities of solidity and durability which result from its use for exterior work.

16,693. I observe that the Belgian Government, who prohibited the use of carbonate of lead for their railways, have recently reversed that decision, and that the originators of zinc-white in France, the Leclair Company, also employ some 15,000 kilograms of white lead. These facts seem to show that white lead is indispensable for the exterior work, and that it is therefore also a great advantage for interior work.

16,694. Before prohibiting it, therefore, it is necessary to ascertain whether it is possible to do away with its toxic effects, and to ascertain whether it is really so terrible as one is led to believe. My own view is, and I think everyone else will agree, that the life and health of the workman is far more important than the question of the durability of painting. It appears to me, however, that not only is it possible, but at the same time it is easy, to prevent the poisoning, and I see no reason for a prohibition which would be regrettable from an industrial point of view.

16,695. Litharge, which is employed by reason of its oxidising properties, can, I believe, be replaced by oxide of manganese, but minium appears, for the moment at least, indispensable for the first coating of iron work.

16,696. To summarise, it seems industrially very difficult to prohibit all lead colours. Prohibition could only be partial, and partial prohibition is always difficult to supervise. It seems to me that proper regulations carried thoroughly into effect would be sufficient. In my view those regulations should include:—

- (a) Prohibition of dry-grinding and mixing.
- (b) Prohibition of the importation and supply of lead colours not already mixed with oil and ready for use.
- (c) Prohibition of the handling of white lead by the workmen when filling or making fillings.
- (d) Dry rubbing down with glass-paper which produces dust should also be prohibited, as should the burning off with a spirit lamp of old paint which is likely to produce toxic emanations.
- (e) The cleaning down of old paint should be done wet and with a liquid solvent.
- (f) Workmen should be prohibited whilst at work from smoking (especially cigarettes). They should be compelled to wear working clothes whilst at work, to take them off immediately they have finished and before eating their food, and the working clothes should be regularly washed.
- (g) A strict regulation should be made for the washing of the workmen's hands with soap, and the use of nail brush and clean towel before they partake of food. Perhaps, also, it would be advisable to have a medical examination of all painters once or twice a year.

16,697. If these precautions were carried out my opinion is that they would be very efficacious, and it seems to me before considering the question of prohibition, which would only be partial, and therefore hygienically insufficient, and might also give a false sense of security to the workmen, a lengthened trial should be given to the regulations which I have indicated.

16,698. I am told that workmen become so accustomed to the dangers that they neglect the precautions which they took in their early career, but because of that alone it does not seem to me that sufficient ground is made out for a complete prohibition.

16,699. The above is a resumé of the report which I submitted to the Extraordinary Meeting of the College of Medicine on the 16th January 1907, at which there were 48 members present. A considerable discussion ensued, in the course of which my colleague,

Dr. Long, pointed out that in his professional experience in Paris lead poisoning was more frequent and grave in France than in Switzerland, partly because of the practice in France of dry scraping of old paint, and partly because of the mixing of paint in the form of powder in the course of work. Dr. Mayor, the Chief of the Policlinique, also pointed out that none of the three workmen who had been treated at his dispensary had been in the habit of washing their hands before eating, and he opposed prohibitive measures and favoured regulations. Mr. E. Ador, a well-known chemist, also informed the meeting that workmen using zinc white were also subject to lead poisoning, because they used driers containing lead.

16,700. I submitted the following propositions or theses to the meeting, which were carried:—

1. In comparison with other causes of illness and mortality, such as alcoholism and insanitary dwellings, against which it is urgent to take energetic legislative measures, white lead poisoning is only of small importance in this country.
2. White lead poisoning shows itself frequently in the first instance by symptoms which are very alarming but not really dangerous in themselves. The dangerous complications nearly always ensue where people have not, owing to the force of circumstances, or their own negligence, taken notice of these first warnings.
3. There are a great number of trades and circumstances in which workmen are exposed to lead poisoning, and even if a law could completely suppress lead poisoning among house painters, this would not diminish by more than one-half the number of persons suffering from lead poisoning.
4. In a large number of trades in which workmen use lead and its compounds, and in which there is no possibility of replacing these products by others less dangerous, it is necessary to take simple but strict hygienic measures in order to diminish if not entirely prevent the poisoning of which they can be the cause.
5. The trade of a house painter, which permanently exposes the operator to the danger of lead poisoning, can be made one of little danger by minute attention to cleanliness, particularly before meals, and by the prohibition of the handling of the colours in a dusty state and of dry rubbing down.
6. It is desirable to suppress as much as possible the industrial employment of lead substances. So long as this prohibition can only be partial, it is necessary to take steps to protect workmen called upon to handle these products, and not only house painters, but also plumbers, enamellers and typefounders, &c.

16,701. The Commission having made their report, regulations were made on the 21st December, 1907, largely on the lines suggested by the College of Medicine, and I have been very interested in studying the effect of those regulations in the *interim*. In March, 1910, I wrote a further paper on the subject of "Lead Poisoning as an Avoidable Sickness" *appropos* of the cases treated at the Cantonal Hospital, Geneva, 1907, 1908, and 1909; published in "la Revue Suisse des Accidents du Travail" (March, 1910).

16,702. In this paper I set out that during those three years 20 cases of lead poisoning had been dealt with in that hospital, of which 10 were patients who were employed as house painters. 16 of the patients had slight attacks of colic, and, in fact, 18 of the patients had merely preliminary symptoms which although not really in themselves dangerous to the patients, were indications to him that he ought, if possible, to either change his trade, or take extra precautions in exercising it. During those three years, I was particularly careful to question each of the patients as to the steps he had taken to protect himself from the dangers of his trade. I found that in nearly every

18 January 1912.]

Dr. MAURICE ROCH.

[Continued.]

instance the sickness was due to some want of care on the part of the sufferer. The lack of precaution is almost incredible.

16,703. The experience I have had during the last three years entirely confirms the propositions which I put forward in 1907, especially having regard to the small number of cases of lead poisoning in my country, compared with those of tuberculosis and alcoholism.

16,704. Further, I am influenced by the fact that, from a medical point of view, the first attack, which is a sort of warning that the sufferer should take care, and the fact that house painters only constitute a portion of the patients affected by lead poisoning through their trade, and, lastly, that many of the trades subject to lead poisoning can be carried on without danger, so long as elementary and simple rules of hygiene are carried into effect.

16,705. As corroboration of the statement, that if ordinary care is taken in the matter of personal cleanliness, there is no real danger, I may mention that I have under my care at the present time a patient 70 years of age, who has been exercising the trade of a house painter since he was 15 years old, and has used little else than white lead, but who has never had any illness from lead. Everywhere one meets many of these old workmen, respectable, orderly, and cleanly, who have handled white lead all their lives without ever having any trouble.

16,706. (Chairman.) You state that you have found that all who absorb appreciable quantities of lead become poisoned. What authority have you for that statement?—I think that, in all civilised countries, all men absorb continually certain minute quantities of lead, but only if they absorb considerable quantities of lead will it lead to poisoning. This is a common opinion amongst medical men.

16,707. That everyone in a civilised state absorbs lead?—Yes, and that all those who absorb considerable quantities of it are poisoned.

16,708. (Mr. Sutherland.) Does that mean every inhabitant?—Yes, every inhabitant.

16,709. (Chairman.) Can you produce reliable statistics of lead poisoning in Switzerland?—Only for the Canton of Geneva.

16,710. Will you give them?—Yes.

16,711. If you hand them in that will be sufficient. Can you summarise them?—During seven years, that is from 1900 until 1906, in a population of 130,000, there occurred 44 cases of lead poisoning. Of these 44 cases of lead poisoning, 24 cases were painters. For 1907, 1908 and 1909, there were the following cases of lead poisoning: ten house painters, two coach painters, two plumbers, two enamel workers, a gas fitter, one stone worker, one colour maker, and one picture restorer.

16,712. Could you give the figures for the last two years since the regulations came into force?—In 1910 there were three painters, and one enamel worker; in 1911 there were two house painters, one enamel worker, one plumber, one tinsmith, and one baker.

16,713. (Dr. Collis.) Could you give us the figures for 1908 and 1909?—I can send the figures, but I have not got them here.\*

\* The witness has since forwarded the following table:—

Cases of Lead Poisoning treated at the Geneva Hospital.

| Country or Canton. | Age. | Profession.  | Illness.        | Remarks.                                 |
|--------------------|------|--------------|-----------------|--|
| In 1908:—          |      |              |                 |  |
| Italy              | 28   | Housepainter | Colic           | Does rubbing down.                       |
| Geneva             | 31   | "            | "               | Does rubbing down and bites his nails.   |
| France             | 32   | "            | Enteritis       | Works in Paris.                          |
| Tessin             | 44   | "            | Colic           | Works in France and rubs down and dusts. |
| Schwytz            | 45   | "            | " gout          | Very alcoholic.                          |
| Italy              | 21   | Coachpainter | "               | Rubs down dry, eats while working.       |
| France             | 46   | Lapidary     | Gastritis       | Cuts diamonds.                           |
| Italy              | 52   | Tinner       | Colic           | Does not wash his hands before eating.   |
| In 1909:—          |      |              |                 |  |
| Switzerland        | 33   | Coachpainter | "               | Alcoholic.                               |
| France             | 50   | Housepainter | Entero-neurosis | Neuropathic.                             |
| Italy              | 29   | Labourer     | Colic           | Uses red lead.                           |

18 January 1912.]

Dr. MAURICE ROCH.

[Continued.]

painting is done?—One would have to consider in this not only white lead but all the other lead colours such as red lead, litharge, and any other lead colours.

16,727. Would it not be more easy to supervise the mixing of those paints than to carry out regulations which would refer to every job in every single house?—It will be only easier if you make absolute prohibition of all the compounds.

16,728. Not, for instance, if a percentage of 5 per cent. of lead was allowed?—I do not think that it would be more easy in that case, because then one would not only have to superintend the manufacturer but also the workers, the painters.

16,729. Have you considered the possibility of restricting the use of lead to not more than 5 per cent. of lead compound soluble in dilute hydrochloric acid, a limit which has been found to give immunity from lead poisoning in the pottery industry?—I consider that a man who uses a paint containing 5 per cent. of lead would be more exposed to the danger of lead poisoning than a man who uses pure white lead with proper precautions.

16,730. What reason have you for thinking so?—In all cases where I have visited a painter suffering from lead poisoning, I have found invariably that the reason of the lead poisoning was the lack of the necessary precautions.

16,731. You are aware that in the pottery industry 5 per cent. is allowed without the full precautions, and that no cases of lead poisoning have been found traceable to the use of those glazes?—In those cases did they take any precautions against the creation of dust?

16,732. The provision requiring the use of fans in ware cleaning was set aside in that case. The use of 5 per cent. of lead in paints would allow a very wide range of colours, because, first, many lead colours such as chromates are not very freely soluble, and, secondly, in a mixed paint ready for use, a comparatively small proportion of lead colour is added?—I cannot answer that question from an industrial point of view; but I think, as long as you have any soluble lead whatever present, it will be necessary to take precautions as though you had lead alone present.

16,733. But if it could be demonstrated to you that 5 per cent. of soluble lead is allowed in pottery work, and allowed with immunity, would you be inclined to modify your opinion?—I am not prepared to admit that, as I do not know the conditions of work in a pottery.

16,734. In paragraph 16,696 you state what provisions should be included in regulations. The first of these (a) is the prohibition of dry grinding and mixing. Are you aware that the dry grinding and mixing by painters in England is practically unknown?—I am quite aware that dry grinding and mixing has almost died out, because generally white lead is now sold in the form of paste, but in 1911 I had two cases of lead poisoning among painters. One of them was due to the use of white lead in the form of dry powder. That was an Italian painter.

16,735. This provision, then, would not lead to any material alteration in the incidence of lead poisoning?—No.

16,736. Then (c). The prohibition of the handling of white lead in making fillings. Do you consider that this could be enforced?—I have no practical experience on that point. I simply conclude this from experience I gathered in France. In Geneva the handling of white lead for that purpose is practically unknown. It is generally done by a process, "enduisage," which is filling in with a pallet knife.

16,737. But how do you know that it is an almost universal custom to fill in by that process?—I have obtained my information by enquiring from sick workers.

16,738. Another provision is (d). Prohibition of dry rubbing down and rubbing off. You have stated in paragraph 16,686 you consider the danger from dust one of the most serious. Is it possible to prohibit all dry rubbing down?—That is a technical question, not a medical question, but I am quite convinced that all forms of dust of lead are particularly dangerous.

16,739. You draw up certain suggested regulations but you do not suggest how they should be carried out. Is that so?—I think that I, as a medical man, have done my share of the business if I have proposed the regulations necessary to protect the worker. The enforcing of these regulations is not my business.

16,740. But if the regulations cannot be enforced, what is the use of them? If they are so difficult to enforce, would it not be better to prohibit the use of white lead altogether?—If it is impossible to prevent the formation of dust, then prohibition would be better; but, from the information which I have received, I think it quite possible to prevent the formation of dust in painting work.

16,741. We have been told by many witnesses that some dry rubbing down is indispensable. If they are right, how would you protect the worker from the danger of inhaling dust containing lead?—One could have the work carried out by different workmen, so that one man should not always be kept at the work, and also one could insist on his wearing a wet mask or respirator.

16,742. Now, you say that old paint should be cleaned down with a liquid solvent. How would you enforce this regulation?—The only possible way of controlling is to punish or fine every painter who does dry breaking off of paint.

16,743. You say that smoking should be prohibited, and overalls insisted upon. How could this be enforced?—Simply by inspectors.

16,744. Lastly, you advocate strict regulations for the washing of the hands with soap, and the use of nail-brushes and clean towels before partaking of food, with possibly also medical examination of all painters once or twice a year. How can you ensure adequate lavatory accommodation being available on every painting job?—I think it advisable that the working men should be allowed five minutes before the closing of the working time to wash their hands, and this five minutes' washing time should be included in the working time, and they should receive payment for the five minutes as working time.

16,745. Is that the regulation in Geneva now?—I do not know.

16,746. If regulations are to be adopted and enforced, it will obviously necessitate a body of inspectors to see that the rules are observed?—Yes, that would be necessary.

16,747. Such inspectors would have to enter every place where painting operations were carried on, even private houses?—Yes, that would be necessary.

16,748. Is there a body of inspectors in Geneva?—The inspection is in the hands of the police, but it is practically inoperative. There is very little inspection carried out.

16,749. Are the workmen content that the inspection should be inoperative?—I think that the workmen are indifferent on that point.

16,750. The duty would also have to be laid on the employer of notifying every place in which painting operations are carried on. Do you agree?—Yes, I agree.

16,751. And if a large number of employers of labour themselves prefer prohibition of the use of lead to a cumbrous and irksome code of regulations, would not that cause you to modify the views you have expressed?—Yes, I quite agree; but for me the question of white lead is only a small part of the question, because there are so many other lead compounds which are used and which are dangerous.

16,752. You allow that lead is dangerous?—Yes.

16,753. Would you not agree that, if it is possible to prohibit the use of lead in paint, it would be a very desirable thing?—Yes. But even if in Geneva the use of lead paints were prohibited and that prohibition were strictly carried out, the total number of cases of lead poisoning would be only half.

16,754. Surely it would be much easier to supervise the mixing of paints than it would to follow every job in every house, as I said before. Do not you agree?—Even then it would be difficult to control the observance of these regulations, because it would be

18 January 1912.]

Dr. MAURICE ROCH.

[Continued.]

necessary to take samples of paint everywhere where painting is carried out, and have these samples analysed.

16,755. (*Dr. Collis.*) How many house-painters are there in Geneva?—It is a very varying figure, and I do not know whether you will find the figure given accurately in the depositions of M. de Morsier.

16,756. No?—(*After referring*) 300 to 400.

16,757. You say that the 24 cases of lead illness among painters were hospital cases and therefore severe cases?—Generally they were more or less grave cases.

16,758. In England we know that a proportion of lead cases die without ever having been admitted to any hospital. Is not this also possible in Switzerland?—It is possible. I think that it may be possible, but I think that there have been no such cases during the last ten years, because a movement against white lead was started by the workers and by the trades unions, and also all the medical men in small villages were influenced by these trades unions, and whenever they came across a case of lead poisoning they informed the other medical men of their medical society, and those cases were generally handed over to the hospital.

16,759. Is there any law calling upon a medical man to notify the authorities of cases of lead poisoning under their care?—No.

16,760. We have such a law in England for the factories?—That applies only to factories.

16,761. And all cases which die of lead poisoning are the subject of an inquiry by a coroner, that is to say an inquest is held, and information of all such cases is sent to us at the Home Office. We know that, over ten years, in the factories only 28 per cent. of the cases were severe. If we apply the same argument to the cases in your hospital in Switzerland, we should obtain for seven years not 24 cases, but at least three times 24 cases, namely 72 cases of lead illness among 300 to 400 men, which gives us an attack rate per year of 3 per cent.?—How can you decide in cases which are not lead? How can you identify cases as lead poisoning?

16,762. In all factory cases which are notified to us, we have a report from a certifying surgeon to us on the severity of the case. In England we consider an attack rate of 3 per cent. as very high?—I have difficulty in accepting your figure of 3 per cent. incidence amongst Swiss painters, because according to my experience the incidence is only 1 per cent.

16,763. M. de Morsier gives 3 per cent. in his report?—The figure of 3 given is the result of personal enquiries by M. de Morsier. My figures do not agree with his. According to my experience, the incidence is only 1 per cent. I have found an average of 1 per cent. of incidence amongst the four hospitals which I visited in Geneva. I do not know under what heading these 8 or ten painters mentioned there come.

16,764. I have asked you about the percentage in the hospitals. They are severe cases. We find that the severe cases are only 28 per cent.; therefore you must multiply by three, and you have still to make allowance for cases which do not go into hospital and which we know from experience in England die without ever going into hospital; therefore it is a low estimate to multiply by three?—I am quite willing to acknowledge

that your method of arriving at the total number of lead cases is quite correct.

16,765. It would appear, then, that the number of lead poisoning cases in their total in Switzerland, viewed as case incidence, is high?—I think that the incidence may be rather high compared with other professions, but there are certainly a good many other professions a great deal more dangerous than painting. I consider the danger of accumulator work much greater.

16,766. But have you exact figures? Our case incidence in regard to electric accumulators is not high?—I have not those figures.

16,767. Three per cent. case incidence is, in our experience, very high for any occupation in which lead is used in factories. The regulations which were brought into force were brought into force, I believe, at the end of 1907. So that there are now four years' experience, and there has not been, according to your figures, any reduction, so that we are hardly, from your experience, justified in trying to use the same method in England?—I hope that if you have regulations in England, these regulations will be a great deal better observed than they are in Switzerland. In Switzerland there is hardly any control to enforce these regulations, and they exist only by the good will of the master painters and of the workers.

16,768. We foresee similar difficulties in trying to get them enforced in England. Do you not think that any law which prevents so much lead being used in paint will affect others besides the painters, such as the manufacturers of lead paint, the manufacturers of white lead, the smelters of lead from the ore, and the getters of the ore from the mines?—The industries which you refer to do not exist in Switzerland, but it is, of course, self-evident that all these industries would be affected by the diminution of the use of lead.

16,769. Now you have drawn attention in your evidence to the fact that you have known individuals of 70 years and over who have been exercising their trade all their lives, and who have never had any illness from lead. Is not this a usual experience—that lead poisoning is more frequent among those who are first employed and first exposed to the influence of lead than among those who have been for a long time employed and who have escaped illness in the early years?—Yes.

16,770. Do you not think that there is some evidence to show that the worker can become to a certain extent immune against the influence of lead by long employment?—My experience is that generally these old men who have been referred to have not suffered from lead poisoning, and they do not show the blue line in the gums.

16,771. (*Mr. Robins.*) As a medical man, seeing that the use of white lead in painting is a dangerous occupation, do you consider that the hours of work should be restricted to a certain number of hours per day?—It is chiefly important in dangerous work that the painter should not have to finish his work as quickly as possible. Therefore I think it is desirable that painters should not be paid by piece-work. It is quite certain that the less a painter works the less he will be exposed to poisoning.

16,772. Then I take it that excessive hours, over the ordinary day, are dangerous?—Yes, I quite agree.

The witness withdrew.

**TWENTY-EIGHTH DAY.**

Thursday, 22nd February 1912.

## PRESENT:

LORD HENRY BENTINCK, M.P. (*in the Chair*).

Sir GODFREY BARING, Bart., M.P.

Mr. E. L. COLLIS, M.B.

Mr. W. G. SUTHERLAND.

Mr. F. G. RICE.

Mr. A. GARDNER.

Mr. J. PARSONAGE.

Mr. A. L. C. FELL.

Mr. C. L. MASON.

Mr. C. KINGGATE.

Mr. W. ROBINS.

E. A. R. WEBNER (*Acting Secretary*).

Mr. CARL ADOLPHE KLEIN.

Evidence to 16,842 handed in and taken as read; witness then called and examined.

16,773. I am a technical chemist, and was educated in the Honours School of Chemistry, Victoria University, and was afterwards demonstrator in chemistry at Sheffield University College. Since that time I have had eight years' experience as technical chemist.

16,774. At the request of the Chemists' Committee of the White Lead Corroders' Section of the London Chamber of Commerce, I have conducted certain

experiments, the details of which are as follows. I may premise that, in order that the conditions should be free from the possibility of interference from external surroundings, a private house was taken at Enfield Highway, and this was fitted up as a laboratory and no redecoration of the house was permitted; all the apparatus used was new and was carefully examined for lead before being used.

## EXPERIMENT No. 1.

Volatile Products obtained from Paint.

An apparatus as per sketch was used.

**APPARATUS USED IN SMALL ASPIRATION EXPTS****@ 40° OR 100° C.**

16,775. Certain experiments had shown that when air, which had been aspirated through white lead and linseed oil, was bubbled through nitric acid, the acid became yellow, and sometimes red in colour. It was, therefore, decided to use this method to ascertain whether other paints produced the same effect.

16,776. The paints to be examined were contained in a 200 c.c. distillation flask, provided with a tube

dipping into the liquid, through which air was aspirated, thence through concentrated nitric acid contained in a wash bottle. Precautions were taken to guard against the possibility of solid matter being carried over, by bending the tube leading from the flask, also by introducing a trap before the nitric acid wash bottle.

16,777. A series of experiments were carried out at

22 February 1912.]

MR. CARL ADOLPHE KLEIN.

[Continued.]

40° c., but it was found that after 27 hours' aspiration (intermittent) the changes were slow—consequently a 5 hours' continuous aspiration at 100° C. was made.

16,778. *Results.*

| <i>Substances in flask.</i>   | <i>Appearance of HNO<sub>3</sub> at end of trial.</i>              |
|---|--|
| White lead and linseed oil<br>5 gr.            50 cc.                 | } Coloured yellow in 80 mins. Small amount of red tar on tube.     |
| Ground native and linseed barytes and oil<br>5 gr.            50 c.c. |  |
| Lead acetate and linseed oil<br>5 gr.            50 cc.               | } Coloured yellow in 70 mins. Small amount of reddish tar on tube. |
| Linseed oil<br>50 c.c.  |  |
|   | } Coloured pale yellow in 70-mins.                                 |

*Order of Intensity of colour.*

|              |         |                     |
|--------------|---------|---------------------|
| Lead acetate | - - - - | } Yellow.           |
| White lead   | - - - - |                     |
| Linseed oil  | - - - - |                     |
| Barytes      | - - - - |                     |
|              |         | } Pale yellow.      |
|              |         | } Very pale yellow. |

16,779. These experiments showed that at 100° C. in five hours all the samples yield volatile products which produce a change in the nitric acid, although the amount of change varies with different pigments. A series of experiments was then carried out, using the foregoing bases, but adding manganese borate as drier to those of poor drying properties, and under these conditions they were found to behave more nearly alike, thus confirming the conclusion that the vapour is a drying product, and that when drying is hastened, this vapour is given off more rapidly whether lead is present or not.

16,780. The comparative rates of drying of different paints have been determined, and are shown on the curve below, in which the increase in weight is taken as an indication of rate of drying. The spectroscopic experiments of Baly were carried out, using a tube entirely coated with pigment; therefore the effect of light was absent. It has long been established that light is of great assistance in the process of drying, but in order to be exactly comparable, I carried out these experiments in a dimly lighted-box. In order, however, to illustrate the influence of light on rate of drying, I also show comparison curves. The experiments were made by painting out equal weights of oil and pigment in each case.

EXPERIMENT No. 2.

*Nature of Volatile Products formed when Linseed Oil is dried.*

16,781. The process of drying is a complicated one, and its exact nature is by no means clear. The oil increases in weight owing to saturation with oxygen,

x 7790

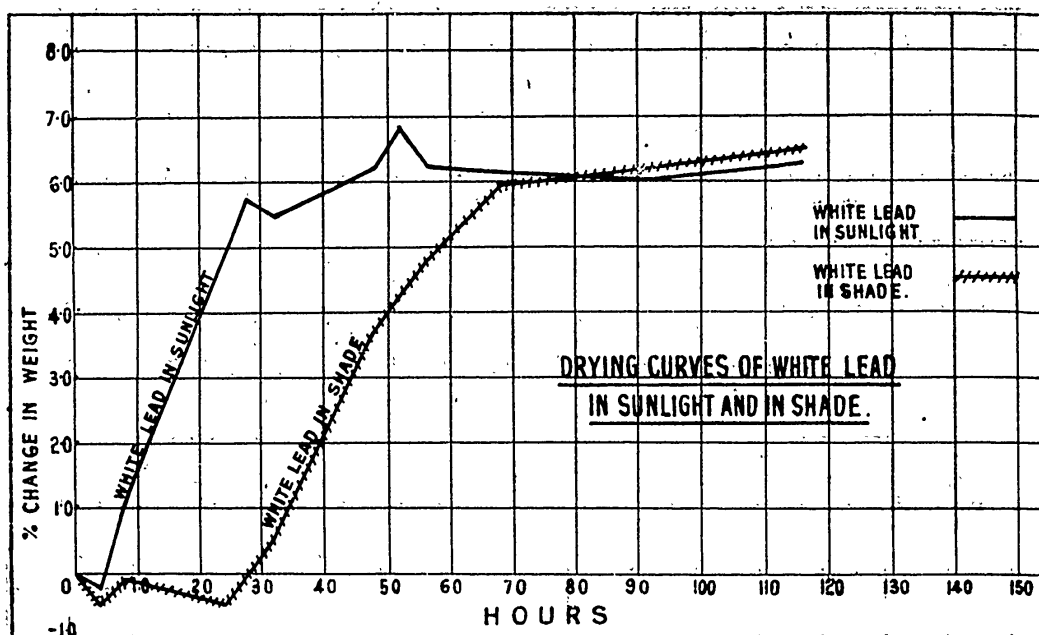

and the ultimate oxidation to linoleyn, but although an absorption of about 25 per cent. of oxygen takes place, the increased weight obtained in linoleum work is only about 10 per cent., the difference being due to 15 per cent. loss of volatile products. The volatile products are complicated in character, and contain principally the volatile lower fatty acids formed by the

K k

22. February 1912.]

MR. CARL ADOLPHE KLEIN.

[Continued.]

oxidation of the glyceryl radicle in the oil. The volatile fatty acids are of considerable importance, as these unquestionably contain formic acid, and the

mixture of oil and lead salt to be steam distilled were put in the 800 c.c. flask, the steam being blown through a tube dipping below the surface. The steam was

influence of such products in mould or bacteriological experiments must be borne in mind when considering results so obtained.

16,782. Experiments, using an apparatus as per sketch, by bubbling the air through ferric chloride, silver nitrate, mercuric chloride, gave definite reactions for acetic and formic acids.

### EXPERIMENT No. 3.

#### Distillation Experiments.

16783-4. Although chemically the existence of a volatile compound of lead composed of lead and the linseed oil fatty acids appeared improbable, I suggested that a small amount of lead acetate present in white lead might give rise to lead in the distillate, and I therefore carried out a number of steam distillation experiments, and as a result of these, stated that I considered lead acetate to be slightly volatile when steam distilled with linseed oil, as traces of lead were always found in the distillate. The amount of lead found was quite minute, yet its presence demanded the strictest inquiry. Professor Armstrong suspected that priming was the source of the trouble, and has since proved this to be the case. A large number of experiments were necessary to establish this, but at last definite proof was obtained that such was the cause. Professor Armstrong has also established this point by using an entirely different apparatus. The apparatus finally employed by me is shown in the sketch. The

then passed through a trap, two distillation flasks, a tower and another trap—then condensed. Experiments were made using.

- (1) White lead,
- (2) Litharge,

linseed oil and lead acetate being added in each experiment. No lead was found in the final distillate, but the contents of the first distillation flask contained lead, whilst the second distillation flask and the tower were quite free from lead.

The presence of lead in the first distillation flask could be due to one or both of two causes:—

- (1) Volatile lead compound, soluble in water, volatile in steam, but not volatile at the temperature of No. 1 flask.
- (2) Spraying over of lead compound.

16,785. In order to decide the cause, the experiment with litharge was repeated with the following alterations:—

- (1) Flask No. 1 was heated by boiling water bath so as to drive off any volatile lead compound in solution, it being obvious from the previous experiment that if a volatile compound was formed, it was volatile at this temperature.
- (2) Flask No. 2 and tower exposed to the air.

16,786. Distillation was continued for half an hour, and the flask contents examined. Lead was found in the first flask, but no traces in the second flask, tower, or distillate, showing that lead had been carried from

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

Distillation Experiments.

the distillation flask mechanically into Flask No. 1, but although this was maintained at the boil, the lead compound travelled no further, showing that the lead compound was sprayed over from the distillation flask.

## CONTROL EXPERIMENT No. 3.

16,787. A confirmation of this conclusion was obtained by steam distilling the condensate from Flask No. 1. No lead was present in the distillate, showing that the concentration of lead in the distilling flask was so low that the priming did not carry over sufficient amount of lead to give an indication.

16,788. The significance of these experiments lies in the fact that the priming is a serious source of trouble in distillations or in aspirations, and that the greatest caution must be observed in interpreting results so obtained. In this connection it must be noted that white lead on heating gives rise to carbon dioxide and water vapour, whereas none of the other substances examined give rise to gaseous decomposition products. The disengagement of such gaseous products in the form of bursting bubbles would assist priming to a large extent, and in vacuum distillations this effect is exaggerated.

## EFFECT OF AGE ON WHITE LEAD GROUND IN OIL.

## EXPERIMENT No. 4.

16,789. It has been suggested that the formation of volatile lead compounds in white lead and oil takes place during the period of nine months. This suggestion was based on a comparison of the results of vacuum distillation experiments with the observed freedom from lead poisoning amongst those engaged in grinding white lead in oil. In order to experimentally investigate this suggestion, I have examined a sample of white lead paste ground in September, 1907, which means a period of 51 months between time of grinding and examination. The white lead was broken down with pure linseed oil to a liquid paint and then steam distilled exactly as in Experiment No. 3 and Control No. 3. The results obtained were exactly the same as those obtained from new white lead and linseed oil, showing that it is impossible to detect any volatile lead compound in white lead paste which has been stored for 51 months.

## EXPERIMENT No. 5.

## Painting Experiments.

16,790. None of the experiments so far described, or, indeed, few other reported experiments, can be said to be exactly comparable with the practice of painting, therefore the following experiments were made to

ascertain whether under ordinary painting conditions, using an ordinary white lead paint, a volatile lead compound could be isolated. It must be pointed out that these experiments are quite comparable with the conditions under which the painter works, and I submit are of value in consequence.

The apparatus used is shown in sketch (p. 516).

16,791. "A" is an air-tight box, 10 ft. long by 9 in. broad by 2 in. deep, arranged so that the air which was aspirated through should travel over the surface of the box by means of channels, the air thus travelling the length of the box four times, as shown. The box was fitted with a glass top, in order that the paint should dry under normal conditions as regards light. The joints between the top of the channels and the glass were made by laying rubber tubing on the top side of the partitions, and tightly screwing down the glass cover, so as to render air-tight, and thereby compelling the air to travel 40 ft. of channel. The box was painted, using an ordinary linseed oil and turpentine paint, at once closed, and aspiration commenced, the air passing through the various devices shown in order to obtain, if possible, any compound which might be formed. The outlet tube was fitted through a cork into the box, and arranged so that the tube was above the painted surface. Where possible, all joints were fused glass, otherwise they consisted of paraffined cork.

## 16,792. Details of Apparatus :

- (1) Condensers at approximately 20° C.
- (2) Bulbs at 0° C. (ice and water).
- (3) Traps at -12° C. (ice and salt).
- (4) Washer containing water.
- (5) Wash bottles containing KOH  
HNO<sub>3</sub>  
H<sub>2</sub>SO<sub>4</sub>.

Area of painted surface, 20·89 sq. ft. = 1·94 sq. metres.

Weight of paint used for each coat, 190 grs. approx. = 67 grammes per square metre.

Time of aspiration :

|          |   |   |           |
|----------|---|---|-----------|
| 1st coat | - | - | 48 hours  |
| 2nd coat | - | - | 12 hours  |
| 3rd coat | - | - | 18 hours  |
|          |   |   | 78 hours. |

Rate of aspiration, approximately 300 c.c. per minute.

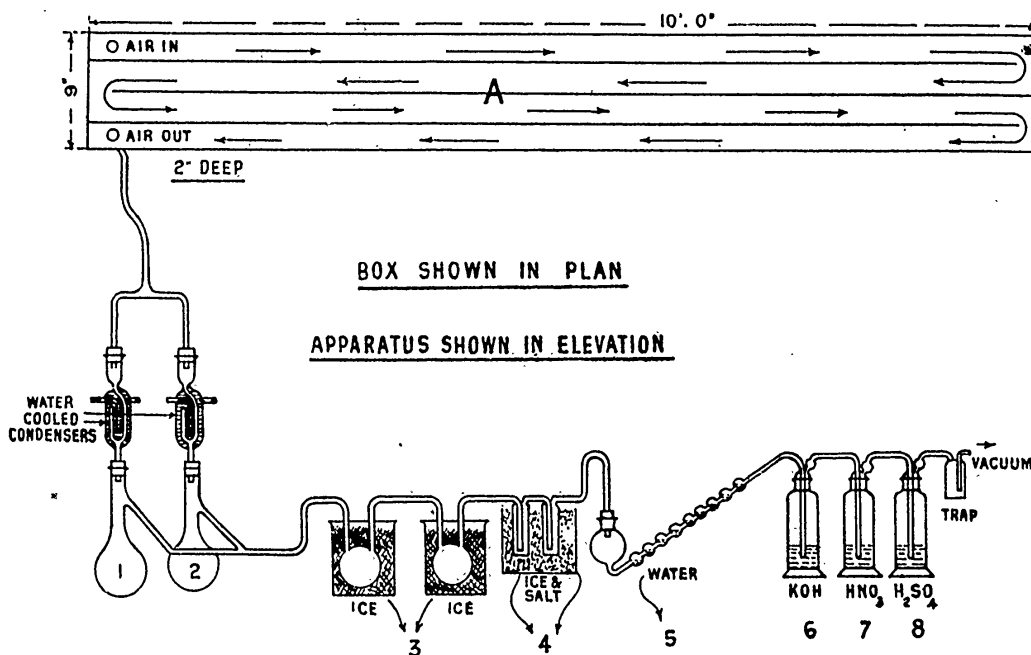

Volume of air aspirated through, at least 1,406 litres.

K k 2

MR. CARL ADOLPHE KLEIN.

[Continued.]

APPARATUS USED IN PAINT DRYING EXPERIMENT.

16,793. Three successive coats of paint were applied before the apparatus was disconnected, and contents of washers examined. Therefore the apparatus had received the paint fumes from 390 grammes of paint and total single-coated area of 62.5 square feet.

16,794. *Flasks 1 and 2*: Empty—odour of paint.

16,795. *Bulb 3*: Contained 5 c.c. of colourless liquid, smelling of turpentine. Boiled with  $\text{HNO}_3$ , yellow colour; added  $\text{AmHO}$ , no change; added  $\text{AcH}$ , no change; colourless when cold; added  $\text{H}_2\text{S}$ , very slight straw discoloration.

16,796. *Trap 4*: 3 c.c. colourless liquid, smelling of turps. Tested as above, very slight straw discoloration; quantity, if any, is too small to be positive.

16,797. *Washer 5*: Colourless liquid. Pb absent.

16,798. *KOH Wash Bottle 6*: Yellow liquid. Crystals on bottom; soluble in water. Sweet ester-like smell. Pb absent.

16,799.  *$\text{HNO}_3$  Wash Bottle 7*: Brownish-yellow liquid. Evaporated to dryness and ignited. Left a large quantity of carbon residue. Extracted with  $\text{HNO}_3$ . Pb absent.

16,800.  *$\text{H}_2\text{SO}_4$  Wash Bottle 8*: Very pale yellow. Pb absent.

16,801. *Conclusion*: Volatile lead compounds are not produced in detectable quantity when a freshly painted surface is dried under normal conditions.

*A repeat experiment gave exactly similar results.*

#### EXPERIMENT No. 6.

*Attempts to Prepare a Volatile Organic Lead Compound from Linseed Oil and Various Lead Compounds.*

16,802. The following experiments were made for the purpose of discovering whether any volatile lead compound could be prepared as above, but all efforts failed to give any indication of such a compound, though there was very clear proof that linseed oil gives rise to volatile organic compounds when air is aspirated through mixtures of oil and lead compounds.

The apparatus used is shown in sketch (p. 517).

16,803. The method of experiment was to aspirate air through mixtures of white lead and linseed oil at  $20^\circ$  and  $100^\circ$  C., and of litharge and linseed oil at  $100^\circ$  C.

(100 c.c. linseed oil and 100 grammes lead compound). Three sets of experiments were carried out, of 6, 12, and 48 hours' duration respectively. The air was aspirated through the mixtures of lead compound and linseed oil, and then passed through

(a) A bulb surrounded by ice.

(b) A bulb surrounded by a freezing mixture.

In the 48-hour experiment, a wash bottle containing strong nitric acid was added to each apparatus.

16,804. *Method of testing contents of bulbs, &c.*—The bulb contents were rinsed out with distilled water, and boiled with nitric acid, neutralised by  $\text{AmOH}$ , acidified with acetic acid, and  $\text{H}_2\text{S}$  water added. The contents of the nitric acid wash bottles were evaporated to dryness, ignited carefully, extracted with  $\text{HNO}_3$ , neutralised with  $\text{AmOH}$ , acidified with acetic acid, and  $\text{H}_2\text{S}$  water added.

16,805. The latter method was adopted for any liquids containing oil, since many of these contained a substance which was turned red or deep yellow on adding  $\text{HNO}_3$ , the colour disappearing on boiling. When made alkaline the colour was increased, acetic acid reduced the colour, and in some cases made the solution almost colourless, but still yellow enough to prevent the detection of small traces of lead.

#### SUMMARY OF RESULTS.

16,806. *White Lead and Linseed Oil.*—Experiments at  $20^\circ$  for 6, 12, and 48 hours showed no visible change in appearance of aspiration flask contents. Bulbs 1 and 2 contained from 0.5 to 2.0 c.c. of a colourless liquid, which, on evaporation with nitric acid and subsequent examination for lead, gave no reaction.

16,807. In the 48-hour experiment, a nitric acid washer was introduced after the condensation bulbs, this became yellow in colour at the end of the experiment but no lead could be detected in the liquid.

16,808. Experiments at  $100^\circ$  C. for 6 and 12 hours showed considerable change in the aspiration flask, the contents smelling strongly of boiled oil. The colour of the oil was dark, and its viscosity was considerably increased. Bulbs 1 and 2 contained 5.0 to 7.0 c.c. of yellow liquid, in which no lead was found, whilst the nitric acid washer became yellow, then red, and finally deposited a brown coating on bottle.

22 February 1912.]

MR. CARL ADOLPHE KLEIN.

[Continued.]

Apparatus used. (6, 12 &amp; 48 hours 20° &amp; 100° C.)

- A.—Flask containing lead compound and linseed oil, through which air is aspirated. Heated to 100° C. on water bath, or not, according to conditions of experiment.  
 B.—Flask to collect volatile products; liquid at 20° C. (approximate temperature of condenser water).  
 C.—Bulb cooled in ice to collect volatile products; liquid at 0° C.  
 D.—Bulb cooled in ice and salt to collect volatile products; liquid at -12° C. approximately.  
 E.—Wash bottle containing HNO<sub>3</sub>, to absorb volatile products uncondensed in B, C, or D.  
 F.—Safety trap for pump.

16,809. *Litharge and Linseed Oil*.—Similar experiments were carried out at 100° C. for 6, 12 and 48 hours. The changes in the aspiration flask were more marked, the oil becoming brown, and in the case of the 48 hours the oil was almost solid. The volatile organic products were increased, and in the 48-hour trial, red nitrated clots floated about in the nitric acid. No lead was present.

16,810. I have therefore found it impossible to prepare a volatile lead compound as above, and under conditions much more favourable than those obtaining in painting practice.

16,811. It appeared to me that a possible source for these emanations might be found in the process of pugging white lead with oil, as much water vapour is given off, and one might expect to find volatile lead compounds present if any were formed. In conjunction with the Home Office officials, I have condensed the vapours from Fug Mills, and the liquid has been tested by them and found to be free of lead.

#### VAPOURS OF THINNERS.

16,812. In view of the animal experiments of Dr. Goadby, I considered it advisable to make experiments with a view of determining the rate of volatilization of turpentine from a paint film. The following diagram represents change in weight of films of paint applied on glass (p. 513).

16,813. The immediate decrease in weight owing to the evaporation of turpentine is apparent, and the induced drying effect is also shown in some of the curves.

16,814. The paints were made up so as to contain an exactly equal quantity of turpentine, though the same decrease is not observed. This, I am of opinion, is due to the volatilization of the turpentine producing

oxidation of the oil, thereby reducing the induction period during which organic auto-catalysers are produced, and thus assisting oxidation, thereby decreasing the apparent loss in weight. This is most apparent in the case of white lead, which by slight interaction with the oil forms a ready acceptor or drier. In short, turpentine by volatilization and consequent oxidation hastens the formation of an organic drier in the oil, and when this takes place oxidation proceeds alongside volatilization, so that loss in weight is to some extent compensated by the increase accompanying oxidation.

16,815. After a period of one hour it appears that practically the whole of the turpentine is removed, and there is little difference in the behaviour of any paint, whatever its base. So that the effect of turpentine remains the same, whether white lead, zinc white, or lithopone is used.

#### SUBSTITUTES FOR WHITE LEAD.

16,816. The use of white lead as a pigment is of great antiquity, and for many years past numberless attempts have been made to replace it. The files at the Patent Office show an enormous number of processes, but so far as I have been able to ascertain substantially the only substitutes which are at present on the market in active competition with white lead are the following:—

1. Lead oxysulphate.
2. Zinc oxide.
3. Lithopone.

16,817. Their chief characteristics are briefly:—

1. *Lead Oxysulphate*.—A basic sulphate of lead (of variable composition) introduced by Bartlett in 1866. It has had extensive use in the United States of America for some years. Lead oxysulphate is

22 February 1912.]

MR. CARL ADOLPHE KLEIN.

[Continued.]

blackened by sulphuretted hydrogen gas, and, further, being a soluble lead compound, is poisonous, and must be considered as a dangerous product of exactly the same nature as white lead. My authorities for these statements are:—

Experiments of Dr. Goadby detailed before the Departmental Committee on the Dangers attendant on the use of Lead, &c., in the manufacture of Earthenware and China, 1910, and reported page 49 (Appendix XXIV.) of the Volume II. (Appendices) of their Report.

16,818. I produce:—

- (a) Specimen of wood painted with lead oxysulphate which has been exposed to sulphuretted hydrogen gas.
- (b) Photomicrographs showing a section of such paint films after exposure to sulphuretted hydrogen gas.
- (c) Analytical figures showing that oxysulphate can be completely decomposed by  $H_2S$ , giving rise to free sulphuric acid.

16,819. 2. *Zinc Oxide*.—Zinc oxide is a pigment the use of which was first suggested by Courtois in 1780. Its commercial introduction dates from 1846, when Leclaire established it practically, and since then many improvements have been made, both as regards its method of manufacture and its quality, with the result that it now occupies a definite position as a pigment. There are two types of zinc oxide on the market, one known as "indirect" viz., almost pure zinc oxide prepared from spelter, and a somewhat impure product prepared direct from the ore, termed "direct."

16,820. The latter product usually contains lead in the form of basic sulphate in varying proportions. The lead is not intentionally added, but is consequent on its presence in the ore treated.

16,821. Certain continental specifications admit of 4 per cent. of lead in zinc oxide. There would appear to be no generally-accepted opinion as to the superiority of one type over the other, though it is claimed by the makers of the direct product that the presence of a small amount of lead increases the stability of the resulting paint film. In America, products known as leaded zincs are sold these contain between 20 and 30 per cent. of lead sulphate, together with 70 to 80 per cent. of zinc oxide.

16,822. The merits of zinc oxide can be said to lie in its lesser poisonous effects, its good colour, and further, it is not discoloured by sulphuretted hydrogen, though the latter has only decorative value. Its real

value as a pigment considering its cost, cost of application and wearing properties, is much less than that of white lead; by such a value I mean a comprehensive value, taking into consideration all the factors which go to make up the provision of a well-protected painted surface.

16,823. 3. *Lithopone*.—This is a generic name applied to white pigments of somewhat varying composition, but generally approximating to an average composition of 75 per cent. barium sulphate and 25 per cent. zinc sulphide. The pigment is prepared by mutual precipitation so as to obtain a homogeneous product; subsequent furnacing operations which are necessary in order to improve the physical conditions often oxidise some of the zinc sulphide to oxide, and frequently a little is found to be present in the finished product.

16,824. Lithopone has not generally a good reputation, and is not extensively used alone as a white pigment for oil paints for decorative work. The curious effect of light on the paint is an objection, as also is the vulcanisation which sometimes occurs.

#### READY-MIXED PAINTS.

16,825. The above covers practically all white pigments in use as bases for oil paints. Many additions are made when ready-mixed paints are prepared, but, generally speaking, the principal base consists of one or more of the above.

16,826. The purchase of ready-mixed paints by the painter is established on a very large scale in the United States of America, and many of the products are composite, being often admixtures of two or more of the following components:—Zinc sulphide, white lead, zinc oxide, lead zinc, lithopone, gypsum, talc, silica, alumina, barium carbonate, barytes (natural and artificial), calcium carbonate, magnesite, china clay, French chalk, asbestos. The direct sale of ready-mixed paints is increasing in England, though the bulk of the white pigments are as yet sold in paste form. It has been found necessary in certain States of America to introduce legislation with regard to the labelling of such paints, whereby the chemical composition of a paint is stated on every package so as to guard against fraud. In England a number of white bases are stained by means of aniline colours being developed on same. This applies to fairly cheap products.

16,827. I have personally examined a large number of suggested substitutes covering all ranges of white substances which the ingenuity of man could suggest,

22. February 1912.]

Mr. CARL ADOLPHE KLEIN

[Continued.]

but none so far have been worthy of recognition when viewed from any standpoint other than that of the inventor.

16,828. It then appears that there are at the moment four reasonably practical materials available for use as white paints, and I am of opinion that no pigment is ideal; further, that a well organised and carefully carried out enquiry would be necessary before any definite ruling could fairly be enforced in connection therewith.

16,829. State trials have been carried out in countries other than Britain, and the results have possibly been of value to the particular countries concerned, but the results are not exactly applicable to any other country. In North Dakota trials are being made, and results will doubtless be obtained which will be of value in indicating the respective merits of different pigments or mixtures for different purposes. These results are of little or no value to Britain, owing to different climatic conditions, *e.g.*, wide ranges of temperature and humidity.

16,830. The merits or demerits of any paint can only be determined by practical trial in combination with organised observation. It is futile to examine the subject from any one standpoint whilst so many factors are necessary to arrive at any definite conclusion.

16,831. The value of a paint is not the result of any one factor, either chemical or physical, but is necessarily a combination. In dealing with pigments, the nature of the vehicle is of great importance, and the fact that pigments other than lead require an increased quantity of oil, is of fundamental significance in view of the well-known porosity and shrinkage of linseed oil films.

16,832. If one considers the chemical aspect of the question, the real merits of white lead are more prominently brought to light. The charge is frequently made against white lead that exposure to sulphuretted hydrogen gas produces discolouration, a statement which, of course, is obviously true, yet it is seldom recorded that an exactly similar change takes place when zinc oxide is submitted to like conditions, though, of course, this is not so apparent, owing to the absence of colour change. I produce photo-micrographs in support of this statement. I submit that the chemical changes are of great importance because of atmospheric influences—air, water, heat; and further, the oxidation products of the two sulphides are vastly different. In the case of lead sulphide there is produced lead sulphite and sulphate, both practically insoluble in water; whilst with zinc sulphide a water soluble sulphite and sulphate is formed which crystallises and is fatal to the painted surface. It is therefore obvious, so far as sulphuretted hydrogen is concerned, that zinc oxide is inferior to white lead when the whole of the interactions are examined:

16,833. In spite of the foregoing, zinc oxide is better than white lead from a decorative standpoint, when applied in places where sulphuretted hydrogen is present, as, for instance, in chemical laboratories; but this raises another point, which is not frequently realised when discussing the merits and demerits of the two pigments. It is generally considered that sulphuretted hydrogen is the destructive agent to which painted surfaces are exposed, yet this is entirely untrue. Sulphuretted hydrogen is a minor evil except under special conditions, such as in the vicinity of chemical works, where it is the product of chemical operations. Sulphur dioxide is by far the most important agent, and it is the action of this gas which must be considered.

16,834. The effect of sulphur dioxide is apparent on historic buildings in London, and Sir A. H. Church\* in discussing the "conservation of historic buildings and frescoes" (Royal Institution, April 12th, 1907) states that the amount of sulphuric acid poured yearly into the London atmosphere is estimated by Rideal as being between one half and one million tons.† This, there-

fore, is the factor of great importance, and its effects can shortly be stated to be the production of a water soluble compound with zinc oxide as against the production of an insoluble compound in the case of lead. I must also point out that the same holds to no small extent for internal painting, in consequence of the sulphur dioxide produced by the combustion of the coal gas; water and sulphur dioxide are produced and effect the changes previously outlined. The relaxation of the sulphur rule has made the position worse, inasmuch as the sulphur contents of the London illuminating gas has increased, according to official figures, to three or four times the previous figure. Lithopone contains zinc sulphide, and is affected by these gases.

16,835. The superiority of the spreading power of white lead is explained by the changes which take place between the oil and white lead. During the time of its storage as paste, chemical reaction takes place to a small extent, resulting in the solution of some lead in the oil, which materially assists in the subsequent drying operations. With zinc or allied pigments, little or no change takes place whilst the mixture is in a paint form. When applied as a paint in both cases the drying takes place by oxidation, although physically the products obtained differ considerably between the two pigments. In the case of lead, there is obtained a film having considerable elastic powers, so that the contraction and expansion produced by climatic conditions do not result in fracture of the film, whereas with zinc the oxidation product has a hard brittle surface, having no elasticity, and consequently does not change in unison with the surface on which the paint is applied. The ultimate product is hard and finally blisters and cracks, or becomes translucent and peels off. The final result is a surface which is not so suitable for repainting as is obtained when lead is used.

16,836. The physical condition of a pigment must also be considered in relation to its powers of lasting. White lead is not a powder of uniform size, it being invariably graded to some extent, as is apparent when the product is elutriated. This gives the film mechanical stability, and the condition is imitated to some extent in what are termed "reinforced" paints which consist of the previously named white lead substitutes ground together with asbestos or other inert materials of larger size, in order to as closely as possible obtain the condition naturally obtaining in white lead. The substitutes of white lead are invariably in an extremely fine state of division and regular in size; therefore, the reinforced effect cannot be obtained with these pigments *per se*. A practical result of this is the defect observed when the mouldings on doors are painted with the substitutes of white lead. It is quite useless to attempt to determine the painting value of any pigment on what might be termed straight painting. The intricacies of moulding and similar effects are the most conclusive test.

16,837. I am, therefore, convinced that on chemical and physical grounds white lead is, for most purposes, the best pigment of to-day. I do not claim that it is the only pigment of value, because I know that there are purposes for which some of the substitutes are equally valuable. The ideal pigment would be an absolutely inert pigment possessing otherwise the properties of white lead.

#### Lead Poisoning Amongst Painters.

16,838. At the outset I must point out that my observations have been quite general in character, and not confined to the manufacture of lead products, though I submit that experience in a lead works proper is of value when considering the use of its products. In a lead works, although the operations are carried out inside four walls, it should be realised that the risk of danger is immeasurably greater when a man is handling tons instead of pounds, and this is particularly important when it is stated that in eight years handling an aggregate of probably 50,000 tons, no single case of poisoning could be attributed to white lead in the form of oil paste, in spite of the fact that the paint grinder is exposed for 10½ hours per diem to white lead at a temperature of 50° to 60° C.

Mr. CARL ADOLPHE KLEIN.

[Continued.]

conditions which are obviously more severe than those to which the painter is subjected.

16,839. Lead works experience clearly indicates that dust is the source of practically all their trouble; and efforts have been, and are still, concentrated towards dust prevention. It is impossible to emphasize this too strongly. Dry rubbing should be prohibited as far as possible amongst painters, not only because of the lead effect, but because of the effect of dust *per se*, and this feature is present when any paint is rubbed down. I understand that wet rubbing down is already considerably practised. If dry rubbing is ever carried on, the painter ought to be compelled to wear a respirator or hood.

16,840. The other principal source of danger is the handling of dry lead colours, and this point is one of supreme importance; many colours containing lead, e.g., Persian red, chromes, vermilionettes, Brunswick green, &c., are handled by the painter in a dry state.

16,841. The danger of such bodies is dealt with (as regards the precautions necessary in their handling by the manufacturer) in the report of the Chief Inspector of Factories for 1910, where Mr. Shaxby (East London) states that it was shown in the 1909 report that the handling of these dry products by the manufacturers resulted in as many cases of poisoning as could be ascribed to both the oxides and carbonate of lead, and that the dust removal plant insisted on and erected during the following year had reduced the total number of lead poisoning cases to one-fifth, proving therefore the dangerous nature of the products.

16,842. Such sources of danger could be avoided by means of regulations prohibiting their use except in the form of an oil paste, and there appears to be no practical difficulty in this.

16,843. (*Lord Henry Bentinck*.) You state in your proof that you are a technical chemist. Will you give the shorthand writer a note of your degrees?—I have no degrees. I am a member of several societies, but I do not carry any degrees.

16,844. You say that since leaving the Sheffield University College you have had eight years' experience as a technical chemist. Would you please say exactly in what capacity?—As chief chemist of the Brimsdown Lead Company, who are manufacturers of white lead.

16,845. In paragraph 16,810 you state that you found it impossible to prepare a volatile lead compound?—May I read the whole of the expression? "I have therefore found it impossible to prepare a volatile lead compound as above and under conditions much more favourable than those obtaining in painting practice." In order to explain that, I must refer you to paragraph 16,802, where the method is described. "The following experiments were made for the purpose of discovering whether any volatile lead compound could be prepared as above,"—namely from linseed oil and various lead compounds. That statement merely outlines that I am quite unable to prepare any volatile lead compounds, using linseed oil and any of the lead compounds stated there. There are volatile lead compounds, but not produced from linseed oil or any of these compounds described in my proof, and these compounds are those used in painting. I know of lead compounds which are volatile at extremely high temperatures, but those do not enter into the question under consideration.

16,846. Do I also understand that you hold that there is no mechanical carrying off of lead particles from a newly painted surface?—May I describe the experiments that I have made?

16,847. Yes?—You will find details in paragraphs 16,790-1. All the experiments which I have read of, or had carried out myself prior to this experiment, could not be compared with painting conditions, because in many cases they were carried out in the dark. In many cases a bell jar made of glass was painted with a paint. In many cases turpentine was left out, which, of course, renders the thing at once not comparable with ordinary painting conditions. Therefore I took a box. That is a twelfth the size of the box (*producing a box*). It was divided up into four partitions. The exact size of the box was 10 ft. long by 9 ins. across; and 2 ins. deep. Everything was got ready so

that a painter could paint it. I myself was not the painter. A man who was a professional painter was called in. He was given white lead of the normal composition; he was given turpentine, he was given linseed oil, and he was given a drier in some cases; in others not. He was told to paint the large box exactly as it was. Immediately it was painted a joiner was in readiness, who sealed the box by means of screws running along the edge. It was provided with india-rubber tubing, so that a rubber joint was made between the two surfaces. That was accomplished within five minutes of the box having been painted. The whole apparatus was put on a shelf over a bench, and air was aspirated through one hole and drawn along all the channels. (*See illustration of apparatus, paragraph 16,790.*) The air which had passed over the white lead was then passed through a series of condensers, the first one an ordinary water condenser, the second ice and water, the third ice and salt. It was afterwards bubbled through water. It was afterwards put through caustic potash, nitric acid, and sulphuric acid, and a trap was inserted to see whether anything came over. I wanted to give the thing a chance and I think that anybody will agree with me that I have tried to be fair towards it. Aspiration was continued on the whole of this apparatus. In the first experiment you will find I took a long time, because I wanted to make quite sure that the paint was dry. After the first coat the top was taken off, and another coat put on. This was repeated, and a third coat was applied and allowed to dry before I dismantled the apparatus. I want to point out that the whole of the joints in the apparatus were either fused glass or, where that was not possible, they were made of paraffin cork. Before use, the apparatus was tested to see if it would stand a considerable amount of pressure. I felt that one must make perfectly sure that none of the products of drying could follow any path other than that I desired, namely through my apparatus. You will find a description in paragraphs 16,794-801 of what I found on dismantling the apparatus. The total amount of paint applied to the box in the three coats was 390 grammes, rather more than  $\frac{3}{4}$  lb. A single coated area of 62½ square feet was painted, and that I consider to be the most important feature of the whole experiment. In this experiment I have not painted little squares. I have done away with test tube experiments. I have tried to cover a surface which at least might be compared to actual working conditions. And furthermore, in order that nothing abnormal should obtain with regard to the action of light on it, the box was fitted with a glass top. Too many experiments have been carried out where the effect of light has been ignored. I feel very strongly about that, because in certain experiments which have been made, not only in this country but on the continent, that effect has been totally left out of sight. In paragraph 16,780 you will find two curves which I have drawn out, showing the difference which is observed between white lead when it dries in sunlight and when it dries in shade. Those who have actually handled paints on a large scale know very well that it is quite impossible with ordinary paints to get them to dry within a reasonable time in the dark, and therefore I submit that all experiments, which have been made where the effect of light has been ignored, are rendered invalid. This has been brought home to me not by laboratory experiments but from a study of painting conditions generally. Like all white lead makers one is called on at times to advise with regard to paints, and on several occasions I have been called in. Where the paint has been wet for some days the explanation is that there was no light getting to the paint in the process of drying. I can quote you a less exaggerated instance than that from a house in Park Lane, where it was almost impossible to dry the paint under ordinary conditions, at the ordinary rate, because of the lighting of the room. Therefore I think that I have made out my case that this box was treated fairly.

16,848. Yes?—With regard to the contents of the bulbs, the whole of the method of examination is detailed, and if there are any chemical questions on it I shall be very glad to answer them. I think they are

22 February 1912.]

MR. CARL ADOLPHE KLEIN.

[Continued.]

quite the usual methods, and I think I might mention here that during the whole of my work the apparatus I used was perfectly new, and in order that I should have no interfering influences from a lead works laboratory, we took a private house. That house was half a mile from the works, and during the whole of the experiments there, or before the experiments, I would allow no redecoration, so that I should not get any interference from outside conditions, and if I found lead then I would know that the lead had come from the paint.

16,849 In paragraph 16,811 you refer to certain tests of vapours from white lead pug mills. Would you please state the names of the Home Office officials to whom you refer as having tested the condensed vapour?—The Home Office official who took the sample was the Factory Inspector for the district, and the sample was divided with me. One half was examined by myself, and the other half was taken away by the official to the Government chemist. Afterwards, on enquiry, I was given the information stated.

16,850. Are you acquainted with the published reports of Professor Baly's work on this subject?—The only published reports that I am acquainted with are two reports, one of which appeared in the "Chemical Trade Journal," and the other in the "Oil and Color Trades Journal." There have been no official publications to my knowledge of any work of Professor Baly. Professor Baly originally read his paper before the Society of Chemical Industry (Liverpool Section), but up to to-day it has never yet appeared in their official journal. Therefore anything I may say with regard to that would be only what I heard at the lecture myself, because I attended the lecture. Professor Baly has a perfect right to repudiate any reports taken by a reporter, because his official paper has not appeared. I should like that point clear.

16,851. Do you wish us to understand that you dissent entirely from those conclusions?—I could not reply to you in one word. If you will allow me to qualify I should be glad. Professor Baly's first experiments were carried out, as you know, by using tubes of glass, which were coated on the inside with white lead and other paints. Light from a cadmium, or iron arc (I am not certain which), was sent through the tubes, and photographs were taken after the light had traversed the whole length of the tubes. He found by the photographs that some absorption took place in the passage of the light through these tubes. His conclusion was that certain volatile compounds were given off. I submit, gentlemen, that I have shown, and that everyone else will be able to show, that volatile compounds are given off, but Professor Baly's spectroscopic experiments prove nothing more than that volatile compounds are given off, and they do not, and cannot be presumed to indicate the presence of lead in such compounds. He has carried out certain distillation experiments under vacuum. From those experiments I absolutely dissent. I have tried more severe conditions than Professor Baly, and I am unable to find lead in my distillates, provided that I take some care to avoid what is known as mechanical priming.

16,852. Are you aware that results entirely similar to those which Professor Baly claimed to have obtained were published by various observers in France?—I am not aware that any results at all similar to those of Professor Baly have ever yet been published in France.

16,853. Do you know that those French experiments were repeated again and again by M. Heim, M. Hébert, and Dr. A. Marie?—I am aware of the work of Heim and Hébert and of Marie and of Trillat. I would like to point out that the experiments of Professor Baly have never yet been reproduced in detail in this country or any other except by Professor Armstrong and myself, who have tried to repeat them. The experiments of Heim and Hébert were carried out under conditions quite different. There was no vacuum work at all in Heim's experiments. The experiments of Trillat, which you have not mentioned, were carried out, using his own indicator, and he failed to confirm the work reported by Breton. The reference for those experiments is the Comptes Rendus, 1903, page 1215, where he says that although he was able by means of

his reagent to detect very small quantities of lead, he was quite unable to detect any volatile lead compounds coming off from white lead painted on the inside of a cloche.

16,854. Do you wish it to be taken as your definite conclusion that those observers and their observations were wrong? I would not make a statement so slashing as that, but I would like to discuss in detail, if you will allow me, the results which have been obtained, and I think that I shall be able to show you that the results which have been obtained by Trillat in his growth experiments, and by Marie, in his typhosus experiments, are quite capable of explanation, when the thing is viewed from an aspect in which lead does not enter, because, in the case of Marie's experiments with zinc white and linseed oil, he found a distinct retardation of growth. The evidence is here if you wish to have it. With regard to the Heim and Hébert experiments, I am prepared to discuss those to the slightest detail, because I maintain that the whole of those experiments are based on a presumption with which I cannot agree, and with which Duckering in the appendix to the Pottery Report also could not agree. The whole of the experiments of Heim and Hébert depend on the efficiency of a certain filter. Duckering\* himself has stated that it is impossible to prevent the passage of air between glass and cotton wool. I have a full discussion of Heim and Hébert's results here. I might point out to you that some of the figures, some of his final figures, differ to the extent of 66½ per cent. in their accuracy. With regard to the reagent they used, I can discuss that in detail with any of you, because I have made it and I have carried out a good deal of work here. It will be quite a big business to discuss the whole lot, but I am very willing to do it. It will be quite necessary for Heim and Hébert to be able to substantiate, in any statement they made, that their materials were quite free. In the first place, experiments of this delicate nature would depend on their being able to prove by photographs or other things that the laboratory itself was free from lead compounds lying about. Furthermore, the rate of volatilisation given by Heim and Hébert does not differ between 0° and 100°, a feature which it is quite impossible to reconcile with scientific observations on any other substance.

16,855. Can you give any reason for believing that all these observations were wrong, other than the fact that your experiments did not produce similar results? Yes, if you will allow me. It will take a long time. I will go into detail and show you how this can be explained.

16,856. You stated that you did not consider the Trillat test reliable?—Yes. I do not want to go into detail, but I will give you one or two statements which support that.

16,857. Do please?—In the first place the Trillat reagent is not a test for lead. It depends entirely on what is known as an oxidising reaction, and before you can get that oxidising action you must convert your lead into one of its oxides, which will produce that effect. Therefore that reaction is not peculiar to lead. Moreover, chlorine, water, bromine, iodine, and many other oxidising reagents will give you that result. I will try to avoid technical detail as much as I can. I have carried out Heim's test in exactly the method described by him in his report, and he states that it is necessary to oxidise his lead to lead peroxide, and for that purpose he uses sodium hypochlorite. He then states freely that it is necessary to remove that before the test is carried out. He gives, as a method of testing, heating. I have not found it possible in ten experiments to remove it by heating. If you have sodium hypochlorite *per se* and heat it and then apply the Trillat test to find lead present it will indicate that. But there is nothing of the sort; it is simply an oxidising phenomenon.

16,858. In paragraph 16,842 you state that the dangers arising from dusty operations should be

\* Departmental Committee Report re Potteries, Cd. 5278, Vol. II., Appendix XLIX., page 93.

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

avoided by regulations. Among these regulations you would include the prohibition of dry rubbing down?—Yes; dry rubbing down should be prohibited as far as possible amongst painters, not only because of the lead effect but because of the effect of the dust *per se*, and this feature is present when any paint is rubbed down. I understand that wet rubbing down is already considerably practised. If dry rubbing down is ever carried on, the painter ought to be compelled to wear a respirator or hood.

16,859. Can you tell us how such regulations could possibly be enforced?—I think by quite straightforward application. My own experience of the painter is that he is not aware of his sources of trouble. I think that regulations have been applied with excellent results in white lead works.

16,860. That is different from painting?—Yes exactly. I would like to go on with my answer.

16,861. Certainly?—Seven or eight years' experience of the application of these regulations has brought them down to practically a fine art. The conditions in white lead works are very intense; they are much more intense than those to which any painter is ever submitted.

16,862. You have told us that you are acquainted with the regulations which have been found necessary in other lead industries, such as the manufacture of white lead, to reduce the incidence of lead poisoning to its present figure?—Yes.

16,863. To effect a similar reduction in the attack rate and death rate from lead poisoning amongst painters, similar regulations would be necessary?—Regulations would necessarily have to be framed to meet the particular conditions of a painter.

16,864. Have you thought how it would be possible to apply and enforce any such regulations in the scattered house-painting jobs?—By one method only, and that is by first a study, if possible (you may have the figures—I have not), of the rate of attack amongst painters. It is quite necessary. Further analysis would be necessary in order to see whether casual employees suffer at a much higher rate than regular employees. Dr. Legge has shown very conclusively, in the 1893 report, that that holds with regard to white lead works, but my own experience is that that is true in all cases. In the painting industry in the last few years my own experience is that a lot of jerry men have come in, a lot of men who are not skilled painters, and they are the men who will suffer. They are the men who, unless you can get their sympathy and educate them to a sense of their danger, I think, you will find will suffer. It seems to me a perfectly reasonable thing that regulations should not be too harsh, because I know exactly the feeling of the British workman towards regulations, and no one knows that better than those who are engaged in white lead works. Would the Home Office go so far as to send out a very carefully-worded, plain, blunt English, statement of the sources of danger? There is one, but I have never seen it amongst painters. The average painter whom I have struck is not aware of his sources of danger. I have carefully cross-examined them for the last three years, and they have given some very weird and wonderful channels of lead poisoning.

16,865. Can you explain to the Committee how it is possible to educate a man who is perhaps only taken on for a fortnight in the summer?—I think that such men are few and far between. The man who only works for a fortnight in summer is quite the exception.

16,866. There were plenty of them during last summer?—But a fortnight is rather a short time.

16,867. I will say a month then. There is undoubtedly a great deal of casual work in the painting trade. Perhaps I exaggerate when I say a fortnight, but it was a short time. The painter is unfortunately affected by seasons; there is no question about that?—In summer he works long hours, and that usually means that he has more money to handle. He is not always the most abstemious man in the summer.

16,868. You will allow that it is more difficult to educate the casual man than the regular worker?—

But if those men are painters, whether they are casual or not, the education would hardly be wasted on them.

16,869. If a considerable number of employers of painters state that they prefer restriction of the use of lead to the irksome system of regulations, would that weigh with you?—I should like the position with regard to my evidence here to be perfectly clear. I am a chemist in a white lead works, but my living does not depend on white lead, and therefore I have attempted to come before you as a perfectly impartial witness. I can certainly say that I am not consciously biased. If bias has been shown in any of my evidence it has been unwittingly on my part. The question is one for you to consider. You know whether the painter would rather be restricted. That I am afraid I could not express any opinion upon.

16,870. (Sir Godfrey Baring.) I understand that you are the Chief Chemist of the Brimsdown Lead Company?—Yes.

16,871. They are engaged in the manufacture of white lead?—White lead and litharge.

16,872. Chiefly for the purposes of the painting trade?—Yes.

16,873. Therefore the prohibition of the use of white lead in painting would have a serious effect on the company's business?—It would simply close the doors.

16,874. (Dr. Collis.) In paragraph 16,783 of your proofs you use the word "priming." By "priming" do you mean drawing-over?—Mechanical spray.

16,875. The word has a technical meaning, has it not?—Yes.

16,876. Perhaps all the members of the Committee would not be acquainted with its technical meaning. I only want to bring that out. We have had it used as meaning a first coat on wood?—I am sorry that I used the word in that connection. It means the priming which is often observed in boilers where steam carries up spray with it. It does not mean the first coat on wood. I have driven steam through liquids, and in consequence a small spray has come up, which I have called "priming." It does not mean the priming of paint.

16,877. Referring to tests carried out upon bulbs and traps, with regard to bulb 3 (paragraph 16,795) you used certain tests, but you do not definitely state that no lead is present?—I summarise in paragraph 16,801:—"Conclusion: Volatile lead compounds are not produced in detectable quantity when a freshly painted surface is dried under normal conditions." I use the words "bulb 3, very slight straw discoloration." "Trap 4, very slight straw discoloration." I recorded that because I observed it. I am strongly of opinion that it was not lead, but as I observed it I recorded it. The efficiency of the test is quite well known. If you calculate out the amount of lead that that might show, I think it would be less than one part per million.

16,878. If it was lead, would you put it down to the priming?—No not here. You are talking of experiment 5, the box experiment.

16,879. Is there any possibility that in the process of the drying of ordinary lead paint some very small bubbles may burst on the surface—infinitesimally small?—Unless I made an experiment I would not like to pass any opinion on that. I might say that I have attempted for some time past to contrive an experiment which would show that, but if you will think it over you will find it an extremely difficult thing to do.

16,880. It is extraordinarily difficult I imagine, but theoretically it suggests itself that fluids pass into the air by some such method?—That is a thing I can say nothing on. I have not tried the experiment, and therefore any answer I gave you would be only an opinion of my own. I have not come here to give opinions; I have come here to give you the results of experiments which can be repeated or refuted.

16,881. You consider that there is very clear proof that linseed oil gives rise to volatile organic compounds when the air is aspirated through mixtures of oil and lead compounds?—Yes. My experiment gives tangible proof of it.

16,882. You do not suggest that if zinc, or one of the non-lead bases which are used for paints, like oxide of iron, was substituted for the lead compound, you

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

would get these volatile organic compounds coming off?—Whatever you substitute, if you have linseed oil in any form in which it will dry, you will get a volatile organic compound over.

16,883. Without adding the drier. I am dealing with it in that way for the moment?—Yes, without adding the drier. You have your question answered by the experiment described in paragraph 16,783, where I have examined the nature of the volatile compounds given off where no drier was added.

16,884. But is this volatile compound precisely the same when lead is present and when lead is not present?—As far as my experiments go they appear to be the same. It is impossible to carry out a detailed analysis; it is too complicated.

16,885. Does this compound come off more rapidly in the presence of lead than in the presence of the other bases?—It does, because lead paints dry quicker than ordinary paints, but if you have zinc paint and add to it any drier—

16,886. I want you to deal with it without the drier at present. It comes off more rapidly in proportion to the rapidity of the drying of the paint?—Yes.

16,887. It is purely the rapidity of the drying of the oil, or the paint; of which it is a part, which determines the coming off of the volatile compounds?—Exactly.

16,888. You used turpentine in your experiment with fully made lead paint?—Yes.

16,889. Have you determined whether the same is true in the presence of turpentine and oil and any base pigment. Does the statement hold true that the evaporation of the turpentine and oil bears the same relation?—You will find that experiment described.

16,890. I should like to follow it?—It is described in paragraphs 16,812-5, "Vapour of thinners." It appeared to be of very considerable importance in view of the animal experiments which had been carried out, showing that some of the symptoms in animals were comparable to those obtaining in lead poisoning. I carried out that experiment to see whether white lead, lithopone, zinc oxide, and barytes lost their turpentine at the same rate when they were applied, and I found very clearly that that took place. Exactly the same thing took place. There is an immediate drop, and within an hour 90 per cent. of the turpentine has gone. The white lead is the most prominent of the lot. It does not lose so much, but that is because where the turpentine dries you get compounds produced, which arise in the drying of the oil. I have pointed that out. It conditions the formation of an organic peroxide, which hastens the rate of drying.

16,891. I follow the point as regards the drying of the turpentine, but I rather wanted to get at this: does the turpentine have any effect as regards the rapidity of the drying of the oil in the presence of lead as a base or of other bases?—That is a question I cannot answer.

16,892. You cannot say whether if more or less turpentine is present in the paint it will make any difference to the rapidity with which these volatile compounds are given off. That is the point?—No, I am not able to say.

16,893. Referring to the test which you speak of in paragraph 16,811, on the condensed vapours from the pug mills. You remember, I daresay, why these were carried out?—No, I really do not. Perhaps you have information as to why they were carried out.

16,894. I happened to be present at an investigation. A number of cases of lead poisoning occurred in the Brimsdown works. In that department all the lead was damped in filter presses, and we tried to find out how the lead poisoning occurred. We found no lead in the air or in the vapours that were aspirated. That did not help us; it remained a mystery how these cases of lead poisoning had occurred when all the lead was damped?—Have you details here as to the number of cases?

16,895. I regret that I have not the actual details, but between five and seven occurred within a short period in that department, I think. I am speaking from memory, but I think that that is not far wrong?

—I could not discuss it at the moment, because I have no books with me at the present time.

16,896. It is a minor point?—If it is a point of any importance I would like to deal with it. What is the year?

16,897. 1905 I think?—Unless you could give me more detail I could not discuss it. I thought that possibly I might have the detail with me but I have not.

16,897a. It remains a mystery after all?—I think you were fairly satisfied from your own tests that that was not a source of trouble; at least you never asked us to do anything, so I presume that was so.

16,898. Now have you questioned some of the French work?—Yes.

16,899. I do not wish to enter into a long discussion of all that hangs on that. Perhaps it is hardly fair to ask your opinion upon Marie's work on retardation of growth. That is rather for bacteriologists to answer?—I happen to have studied bacteriology, so I am on familiar ground with regard to that.

16,900. He got a retardation of growth with the zinc oxide, but it was not so marked as the one he got with the carbonate of lead?—His exact expression is: "less retardation than with lead, but distinct."

16,901. Yes. So that some compound apparently comes off from the lead mixture which does not come off from the zinc oxide, or not so rapidly?—It is exactly compatible with the explanation tendered—that an organic compound not necessarily containing lead comes off more rapidly from white lead than from zinc oxide in the absence of added driers.

16,902. After all, what we have to consider is not so much whether this compound contains lead or does not contain lead, as whether there comes off from lead paints a compound which is inimical to life, and which does not come off so rapidly from zinc paints, so that the people who are using lead paints may possibly be thereby harmed. It becomes a question of entirely theoretical and scientific interest to say whether the compound contains lead or does not contain lead?—My reply to that is that you do not apply zinc and white lead to dry at different rates.

16,903. What do you mean by that?—You would make your zinc dry as nearly as you could in the same time as your lead paint. That being the case, the same amount of objectionable vapour would be given off—if it is objectionable. We have shown this. The Committee, I take it, as you say, are not considering the scientific aspect of the case anything like so much as the practical side, and therefore my reply to you is, that to have the thing from a practical standpoint you must take paints which dry in the same time. Therefore, I say, there is not a pin to choose between them with regard to these organic volatile compounds. Moreover, I think it is rather a stretch of imagination on the part of Marie or the other French people. The organisms treated were particularly susceptible, and you cannot compare them with the human system.

16,904. I do not think that they intend to?—But I think it is put rather in that way. When you come to practical conditions and leave the laboratory, then you have two paints which will behave in the same way.

16,905. Do you explain in the same way their experiments with the guinea pigs?—They are physiological experiments, and I would rather that some physiologist dealt with them, because English physiologists do not agree.

16,906. You stated, with regard to rubbing down, that, even in the absence of lead, it should not be done dry, because you consider all dust *per se* to be dangerous?—Yes.

16,907. Why?—That feature presented itself largely in the Pottery Inquiry. In the Pottery Report issued by the Home Office dealing with lead compounds it is shown that the rate of mortality per 1,000 workers is between seven and eight times higher than that amongst lead workers, and I think it is fairly stated there that the rate of poisoning is increased by dust *per se*.

16,908. I think not. I think it is pointed out there that the dust to which pottery workers are exposed renders them liable to chest diseases, but it does not say that all dust does?—It says that pottery dust does.

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

16,909. The dust to which those pottery people are exposed?—Exactly.

16,910. It does not say that the dust which is rubbed down from the zinc paint is the same dust that the pottery worker is exposed to?—No, I quite agree, but I cannot follow you into medicine.

16,911. But I cannot let your statement in your evidence in chief pass, that all dust *per se* is dangerous; not only so, but there is the kind and the amount of dust to be taken into consideration. Are you aware that no chest diseases have been found associated with men working at plaster of Paris burning, and that is extremely dusty work. I do not want to put you to trouble on the point, but simply to ask whether you have any reason for thinking that dust coming off from paints which do not contain lead is sufficient in amount, or of such a nature with regard to chemical composition, as to be likely to cause disease?—I ought to have mentioned in dealing with dust *per se* that I am thinking of those zincs which contain lead.

16,912. We come back to lead and we have to deal with the lead problem. Now with regard to the regulation of the trade, I tried to follow closely the suggestions, which you made, and I have come to the conclusion that you do not advocate any special regulations, but instructions and education, which are very different things?—If I led you to that opinion I am afraid I gave you a wrong impression. It was hardly what I intended to say.

16,913. The whole trend of your observations was that the worker should be instructed and educated?—And that education should take the form of regulations.

16,914. But you cannot educate a man by regulation?—Pardon me, I differ from you there.

16,915. You may send him to school, but you cannot make him learn?—I do not know. I am certain that the experience in white lead works is that you can educate a man by regulation and very very much so.

16,916. You can only make him do certain things by regulation?—That is education.

16,917. Excuse me. You can compel him to do certain things under penalty, but that is a very different thing from appealing to his reason, so that he in the future shall not always take risks if he is not watched?—But my own experience in white lead works (and I cannot go outside my own experience, and I do not presume to) is that you can educate him. May I roughly describe what we do? You know it probably, but other members of the Committee do not. We have a foreman who instructs and initiates new workers as to the dangers to which they are likely to be exposed, and for about a week, sometimes more, he goes along and gives them little tips as to how to avoid dust here and how to avoid getting dirty there. That is what I call education combined with regulation. This foreman has the power of dismissal, which is rather an important feature when you have a works manager and staff. The fact that the power of dismissal should be vested in a foreman (not solely) because of breaches of Home Office rules is an important one. That foreman we look to as being responsible for the health of the place, because he is in and about. He goes to the mess room, and when washing is carried out, if he finds a man dirty he turns him back. That is the education I mean, combined with regulation.

16,918. But surely the regulations are at the back of it all, because if these things are not done and the factory inspector finds the regulations broken, the employer is liable to penalty. And, moreover, he is bound under the regulations to use due diligence in seeing that those regulations are carried out?—Exactly. I would not like you to think that I am posing as a philanthropist; I am not.

16,919. My point is that there is a *vis et ergo* at the back. The *vis et ergo* is the presence of the factory inspector at odd times?—I quite agree, but you will also agree that manufacturers have gone beyond the Home Office regulations in their own interests.

16,920. Yes, but what we find difficulty in understanding is how we can get that same *vis et ergo* behind any regulations we establish for the house painting

trade?—I think you will find that you can, but do not make them too irksome.

16,921. In Austria, where they have regulations for external painting, they are practically a dead letter, we have been informed?—You have had Austrian and Prussian witnesses I cannot enter into that. It would not be right for me to discuss it because you have had their evidence.

16,922. Exactly; but you suggested in your evidence-in-chief that you are prepared to stand by the value of education, so that I am bound to ask you about some points to see whether you have any regulations to suggest, or any way of cutting the gordian knot, which has certainly not been done abroad, where they have already tried the line which you are at present advocating?—I can only express an opinion. I am confident from the success which has attended the application of regulations in white lead works, that the same success would attend their application amongst painters. If you ask me for a method of application; then we shall have to go into much more detail, and it will be necessary for me to outline some regulations in giving my opinion.

16,923. We should require that, if we are to consider your opinion as one that should stand. We have had nothing placed before us which seems practicable, as regards regulations which it is suggested should be established, differing from those which have been tried abroad. Now you have mentioned the point of casual employees, and their tendency to lead poisoning: Do you think it is due to the fact that they are casual men, and, as you, I think, rather suggested, more careless, that they get lead poisoning. Is it not due to the fact that it is fresh exposure to the influence of lead. Our experience is not as you have suggested, that it is the casual type of the person employed, but the fact that he is more likely to take lead poisoning when first exposed than after more prolonged exposure, which is a very different way of looking at it?—I am afraid I do not quite follow you there, because my own opinion in regard to casual labour is that you have a man coming to you who is a casual worker, and who has been probably out of work for quite an indefinite period, and his resistance is thereby reduced. You do not know how long he has been out of work.

16,924. Yes, but let me instance your own trade, when the employment of women was stopped. Women as a whole in that labour were worse paid and worse fed than the men who replaced them, but you know as a matter of history that the lead poisoning which occurred on that substitution was enormous?—Such substitution necessarily having the effect of introducing a large number of new workers to work which they had never yet been engaged in. You will agree with that.

16,925. To a certain extent, yes, but looking at it medically (and Dr. Goadby, I think you will find, entirely agrees, if you speak to him) it would appear that the chief cause in the case—I will not say the only one—is the fresh exposure, and that men by long exposure become salted and less likely to get poisoning?—Then would you suggest that the so-called "salted" men have initially or within a short time of their first employment undergone lead poisoning. It more or less follows, I think.

16,926. No, it certainly does not. If they have lead poisoning, they get more prone to have it again and again?—Yes, I quite agree. Perhaps I have misunderstood your argument, but I take it that what you just said was this: that fresh exposure, or first exposure, might I say, to lead is the dangerous feature. There must have been a first exposure for the older workers. The older people may be viewed as people who have passed through the ordeal of first exposure. Now this is only my understanding of what you mean: do you consider that you have found them by experiment resistant? That I take to be more or less roughly what you say. Can you work out a ratio between the people who fall and the people who do not fall? That you may know but I do not know it.

16,927. That is the curve of exposure (*handing a paper to the witness*). I put it to you that the number of cases which occur within the first two years of

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

employment is nearly equal to the number of cases which occur during the next 48 years?—I follow.

16,928. The number of cases which occur in the first six months is double those which occur in the next twelve months?—I follow, but it is hardly applicable to painting conditions.

16,929. I do not say painting conditions. I am talking of lead poisoning now?—Those men have had prior exposure to lead in a number of cases.

16,930. You see the influence with regard to intermittent employment, like house-painting, where for many months of the year they are away, and may lose some of their immunity by—?—Ill nourishment?

16,931. By pure absence from the exposure, to which when they return they are more liable. Now have you any evidence that the house painter is not abstemious?—Well, if you want statistics, I cannot give you those, but my own experience of painters who have been engaged in and about houses which I have occupied and works in which I have been engaged is that they are not.

16,932. You think that they are not abstemious?—I do not think they are.

16,933. Do you think that any regulations would make them abstemious?—Regulation combined with education. Do they know themselves how serious the question of lead poisoning is amongst them? I submit to you that they do not. The average painter that you come across is proud, as you will find if you discuss it with him, of what he considers to be his own power of resistance to lead.

16,934. One is fully acquainted with the British working man and his pride in his own health, but can you suggest any way in which we can make these men more abstemious, as you maintain that they are not abstemious?—Yes, by issuing Home Office Regulations showing them how excess is deleterious to their health.

16,935. You agree that if they do take alcohol, it adds to the risk of lead poisoning?—Certainly I agree. I do not know whether you think so, but I certainly do.

16,936. You are not prepared to give us a regulation by which you can stop their taking alcohol?—No, I do not see how you can; I should like to know how.

16,936a. (Mr. Parsonage.) Or cigarettes?—No.

16,937. (Sir Godfrey Baring.) Would you issue temperance pamphlets to them?—No, I am not a temperance man. I hope I am temperate, but I am not a blue-ribbon man.

16,938. But would you issue that sort of recommendation to workmen?—Yes, I think so—not of the type of the German regulations, because they are far too complicated. They suggest all sorts of diseases, and after the men have read them they think they have got them.

16,939. (Mr. Sutherland.) I have the diagrams here of the Dutch Commission. I do not know whether they confirm your experiments as to evaporation (*handing some diagrams to the witness*). It would be interesting to get your evidence on this point. They seem to have taken great pains upon the point, which is an interesting one; and I thought that I would take the opportunity of getting your opinion upon it?—I think that these are of substantially the same type as my results. I had not seen them before, but I think they agree quite well.

16,940. Do you think that the absence of any intimation to the workman as to the danger of the material he is using has made him indifferent to it?—I certainly do.

16,941. Do you think that insistence by the employer on the observance of certain rules would of itself put the men on guard against the danger, and tend to mitigate the danger?—It could only have a salutary effect. From start to finish it could only be for good.

16,942. That is, I take it, what you mean by the educating effect of regulations?—Yes; it could only be for the good of the painter.

16,943. Would not the abolition of dry rubbing down enormously reduce the danger?—I think so, from my own experience, I may say that I have known of no case where lead poisoning in white lead works has been caused by anything other than dust. In my

own cases it was an accident. I am certain that if dry rubbing down were stopped, and washing appliances provided, you would see an immediate decrease in lead poisoning.

16,944. I think that the Home Office admit that other causes are very slight compared with the danger from dry rubbing down?—That seems to me to point very distinctly to the salvation of the painter if he requires salvation.

16,945. Can you give me any explanation of this very important fact: that the two large centres of lead poisoning cases in England are London and Manchester, and in Scotland the Glasgow area; but outside these areas the effects are very slight, taking the country over. Generally in Scotland, where the proportion of white lead used per man, so far as my knowledge goes, would be more than in England, the number of cases, including the Glasgow area, is very small?—I could not explain that.

16,946. Does that indicate that the attacks are conditioned by other things than lead?—It certainly has that look, because if you view the painter as being rendered easily attacked by outside conditions (which I think is the case) stretching one's imagination so far as to apply that to paint itself, I think you will find that the rate of decay of paint itself when atmospheric conditions are bad, agrees fairly well with what you have stated.

16,947. Does it not point also to the fact that bad housing conditions make the painter much more susceptible in the large congested areas than in the open country?—I would not like to express an opinion on that. It is rather beyond my depth as a chemist.

16,948. But speaking as a layman, it points that way, does it not?—Yes. I would like to say that I have meant to state from start to finish of my evidence that good home conditions are the key to the whole situation. Take a man whose conditions at home are good, and who is careful in his habits. You will know whether he will be likely to be lead poisoned or not if you examine the food he brings to the works.

16,949. Dr. Leggo admits the comparative immunity of Scotland, and he ascribes it to the prevalence of stone buildings. Do you think that that has any effect?—No. I am afraid that one would have rather to consider a painted area.

16,950. Are you quite of opinion that there is no poisonous emanation from a lead painted surface?—I am, distinctly.

16,951. Have you considered the question of fumes arising from burning off?—I have considered it. Under ordinary conditions I can see no possibility of that taking place.

16,952. No lead fumes?—No, not at the temperature which is ordinarily used for the burning off of paint.

16,953. What is the ordinary temperature of a blow-lamp?—The temperature of the flame is very high, but it is not in contact with the paint long enough to produce the same temperature in the paint. All you require to do is to melt the oil, and a painter will not hold it too long against the paint, because he will burn the door.

16,954. It cracks the paint?—It shrivels it and he takes it off with a tool.

16,955. One witness told us that before he got any fumes from lead he had to get to a degree of 760 Centigrade?—Yes.

16,956. Would the blow-lamp approach that?—Not on a door. You would have the door charred a very, very long time before that.

16,957. So you think that that disposes of the question of the fumes of burning off?—I do think so.

16,958. (Mr. Parsonage.) You speak of a paint not drying in the dark. Do you say that it will not dry in the dark?—No, but I say that the rate of drying is very much slower.

16,959. You said that in a house in Park Lane it took some weeks for the paint to dry?—Yes, that is the case. I can refer you to the whole of the scientific literature on it if you like; but it is an experiment you can very easily try.

22 February 1912.]

Mr. CARL ADOLPHE KLEIN.

[Continued.]

16,960. (Mr. Sutherland.) Was the drying of that paint accelerated by a drier?—No, it had no drier.

16,961. (Mr. Parsonage.) It was simply an experiment, not the ordinary house paint?—No; it was an experiment.

16,962. That is a different matter altogether. You say you have questioned painters with regard to what they thought caused lead poisoning?—Yes.

16,963. What reasons have they given to you?—The reason in 90 per cent. of the cases, when I have asked a painter, is that when he washes his hands with turpentine the lead goes into his hands.

16,964. Are painters in the habit of washing their hands with turpentine?—Yes; to get the paint off.

16,965. Several painters have been called before this Committee, and there have been employers, and medical witnesses, and I think I can safely say that their evidence has assigned dry rubbing down as the principal cause of lead poisoning. That has been put forward by every operative painter who has given evidence before this Committee?—I will try to describe to you my last interview with a painter. It took place a week ago. It was a painter in my own district. I said to him: "Look here, have you ever had lead poisoning?" "No." I said, "Well, how do you chaps get lead poisoning?" "Oh," he said, "I do not know; it is the stuff we get on our hands." I said, "What about dry rubbing down?" and he said, "A lot of dry rubbing down there is in this district. I do not think I have rubbed down more than three jobs this last year." And that it a typical district. It is just outside London. The cottage property in the district will not stand rubbing down. They have to hold the house up with the paint.

16,966. (Lord Henry Bentinck.) I understood you to say that if dry rubbing down were forbidden it would be a very good thing?—I think so. I submit that where there is no dry rubbing down you can hardly prohibit it.

16,967. (Mr. Parsonage.) How would you account for the fact that the largest number of lead poisoning cases are in London and Lancashire, as Mr. Sutherland says. I will take Lancashire. That is a district where the apprenticeship system is more strictly enforced than in any other part of the country, and where there are technical schools, where the painter is taught the danger of the trade when he is an apprentice, and educated to the dangers?—As a Lancashire man myself, although I bear a foreign name, I could not answer that question unless you would be at the same time prepared to give me the ratio of apprentices to students.

16,968. The arrangement with regard to all apprentices is fixed by rules, and I can give you the rules of a score of towns in Lancashire where the apprenticeship rules are fixed between the employer and the workman?—Could you give the percentage of actual students at the technical schools and those that are under indenture, or are ordinary apprentices?

16,969. On an average the percentage would be one apprentice to five men?—But what is the percentage of apprentices to students.

16,970. I could not give you the percentage of apprentices to students at the technical classes?—But that is rather the key to the situation.

16,971. But it is not necessary for an apprentice to go to a technical school to learn the danger of the material he is using every day of his life, and that he intends to use for the rest of his life, to earn his living. It is more important to him to know the danger he is working in, than to anyone else. He knows that he has to look after his own health and that his health stands before anything else. Now you decline to express an opinion on the question whether bad housing conditions have anything to do with the health of the painter?—Yes.

16,972. But I suppose you have made a special study of lead poisoning, and you are quite ready to put down the drinking habits of the painter as a cause. Have you studied one more than the other?—I have not frequented the houses of painters and I know nothing about the houses of painters, therefore I cannot express an opinion; but with regard to the other question,

that is a matter of my own observation combined with observation in lead works, where it is quite obvious that men who take alcohol to excess are easily attacked. The housing condition has not come within my own purview, but the other condition has.
