## MINUTES OF EVIDENCE

TAKEN BEFORE THE

## DEPARTMENTAL COMMITTEES

On the use of Lead Compounds in the Painting of Buildings  
and in the Painting of Coaches, &c.

Home Office, Whitehall, S.W.

### FIRST DAY.

Wednesday, 22nd February 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. F. G. RICE.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER } (*Acting Secretaries*).  
R. U. SHAXBY }

Mr. T. M. LEGGE, M.D., examined.

1. (*Chairman*.) You are a doctor of medicine and a diplomat in public health, are you not?—Yes; and have been Medical Inspector of Factories since 1898.

2. Have you, in your capacity as Medical Inspector, devoted a large part of your time to the study of industrial lead poisoning?—Yes. Section 73 of the Factory and Workshop Act, 1901, requires every medical practitioner attending on or called in to visit a patient whom he believes to be suffering from lead poisoning to report the case to the Chief Inspector of Factories. All those notifications come before me, and I have to see to their proper following up by the certifying surgeon and the Factory Inspector, and tabulate in the Labour Gazette every month the figures for lead poisoning and other diseases.

3. Are you prepared to give evidence to-day with regard to the occurrence of lead-poisoning cases among both coach-painters and house-painters?—Yes.

4. Which of these two classes do you wish to deal with first?—The coach-painting, because house-painting proper does not come under the Factory and Workshop Act.

5. Are reliable statistics of plumbism among coach-painters available?—Yes, following on the section that I quoted, and I have tabulated since 1899 cases occurring in that industry.

6. With regard to coach-painting cases, how long have such notifications been collected?—Might I say that, in addition to the notification from the medical practitioner, an arrangement was made as long ago as 1898 with the registrars of deaths that they should send to the Chief Inspector of Factories a copy of every death certificate on which lead poisoning was entered as directly or indirectly a cause, and in that way we have had full particulars of deaths amongst coach-painters and house-painters.

7. Then with regard to non-fatal cases, how long have such notifications been collected?—Since the Act came into force in 1896; but personally I should prefer only to deal with the figures that I have myself prepared since 1899. In the earlier years notification was not properly recognised perhaps.

8. Up to 1899 or 1900 is that?—Up to 1899, but perhaps 1900 is a good date at which to commence with the figures.

9. Do you think the notifications since 1900 have been complete and reliable?—As far as any statistics on lead poisoning can be complete and reliable. There is always a difficulty with regard to them, because there is no definition of what constitutes lead poisoning, and every medical practitioner has to form his own judgment of what is lead poisoning, and cases that one medical practitioner would report another would consider to be premonitory symptoms, and consequently there is some doubt arising from that fact.

10. Can you put in a table to show the number of cases of lead poisoning reported from the coach-building industry since 1900?—Yes; I have prepared those figures regularly since 1900, and I hand in a table\* giving that list; and further Mr. Shaxby has been preparing in graphic form diagrams showing at a glance the extent of the prevalence of lead poisoning.

11. What is the general conclusion that you draw from this table?—This table shows the reported cases of lead poisoning grouped under 18 industries, of which coach-building is No. 15, and it shows that there is a considerable occurrence of plumbism in that industry.

12. Is there a tendency for the number of lead-poisoning cases in factories and workshops generally to decrease from year to year?—Yes, since 1900 the total has decreased by about half.

13. Does this apply to the coach-building industry taken by itself?—No, and I attribute that to the fact that the same remedial measures which have brought about the reduction in the other industries are not applicable in coach-building; in particular I refer to the removal of dust at the point at which it is produced by means of fans and locally-applied exhaust ventilation, and also periodical medical examination.

\* See Appendix I.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

14. Will you please tell us what industries are included under heading No. 17 of the table?—No. 17 is "Paint used in other industries."

15. Are the conditions of work in factories of that class similar to those in coach-building?—They are precisely the same in that, and it has been very difficult to separate the two classes, and indeed I think for one or two years such industries as perambulators were included under "Paint used in other industries," but latterly I have included them under "coach building." The use of paint in the manufacture of safes, bicycles, bedsteads, gas meters, metallic enamelling of baths, and the use of lead in engineering and machine-making works, in cabinet-making and in French polishing, in the painting of bridges, girders, and signal posts, and the making of tape measures, would all come under "Paint used in other industries."

16. Most of these trades appear to be outside the scope of the terms of reference to the present Committee on coach painting, which are worded as follows:—"The use of lead compounds in the painting, enamelling, or varnishing of coaches and carriages"?—Yes; but I should hope that the terms of reference would include the manufacture of perambulators. It is a very small industry and the incidence of poisoning is considerable, and there seems to be no reason at all why the poisoning should arise from the use of lead paint there. There does not seem to me to be the exposure to weather conditions for a perambulator that there is in the case of house-painting. I might say that the recommendations that your Committee eventually makes in reference to coach-building would have a very direct application to industries like the painting of safes and bicycles and bedsteads and gas meters, which cause a good deal of lead poisoning, and it would give us a remedy, no doubt, for those trades also.

17. Do you include agricultural machines in the statement that you have just made?—Yes, I include them under coach-painting. I should like to regard under the heading of "Coach-building" anything that is on wheels.

18. That would rule out safes, would it not?—Yes, quite so. You would want the terms of reference widened to include safes, but it would include perambulators and agricultural machines.

19. But not bedsteads?—I do not think that it would include bedsteads.

20. Have you prepared a further table showing the severity of the attacks in the 18 classified industries of Table I.?—Yes; that I have done for a number of years past, and I put in this table\* showing an analysis of reports on lead poisoning by certifying surgeons, distributed according to the severity of the symptoms, the number of the attacks, and the main symptoms.

21. Will you explain the method of tabulation by severity?—The personal element enters into the character of the reports somewhat. I mean the personal element of the reporting surgeon and symptoms which one surgeon might describe as slight, another might regard as moderate or severe. In general, however, "slight" includes cases of colic without complication and of comparatively short duration, anæmia, and either of those with a tendency to weakness of the wrists. "Moderate" would include a combination of colic with anæmia, profound anæmia, and partial paralysis of the wrist, and cases in which there was constitutional undermining of the health. And "severe" would include marked paralysis, drop wrist, and brain symptoms, such as convulsions and blindness.

22. Is any account taken of the possible after effects of an attack of lead poisoning?—No. The reports are made during the attack, and information of the ultimate result we do not obtain unless the man returns to work, and is again attacked by lead poisoning. Then he is reported again, and we follow up the same procedure.

23. In what way is the number of the attack arrived at?—Transient attacks which have preceded the disabling condition are usually disregarded. I call

a second attack an attack where a man has been definitely reported, say a couple of years ago for colic, and then returns to work, and two years after has a fresh attack perhaps more severe. And I call it a chronic attack where that is repeated for a third time.

24. To which of the columns headed "Symptoms" do you attach the most importance?—I think the headings "Gastric," "Paretic," and "Encephalopathic," which are the brain symptoms, represent fairly accurately the relative incidence of these symptoms; and of those the paralysis and the brain symptoms are the most important. The headings "Anæmia" and "Headache" are useful in comparing the relative incidence on men and women, as headache is much more prevalent as a symptom of lead poisoning in women and anæmia also, whereas paralysis is commoner in men. Under "other symptoms" I have included sequelæ such as gout, chronic nephritis, and cerebral hæmorrhage, which indicate chronic rather than mild lead poisoning.

25. What general conclusions do you draw from this table?—In regard to coach-painting, that the symptoms in general are colic rather than paralysis or other very serious injury arising from plumbism. Comparing it with other non-regulated industries the severity of the attacks among coach-painters is rather below the average.

26. With regard to the 697 lead poisoning cases reported from the coach-building industry, can you tell us in what classes of work the greatest numbers originated?—352 of those were reported from railway carriage and wagon works, 297 from ordinary carriage works and wheelwrights' shops, and 46 from motor-car manufactories, but it is only since 1905 that these last have been classed separately from the others. So that those 46 cases in motor-car works occurred within the last five years.

27. What is the total number of railway carriage and wagon works, of ordinary carriage works, and of motor-car works respectively?—I am afraid I have not those figures. I do not think that one can say. It is not accurately known.

28. Do you mean that the totals have not been tabulated?—They have been tabulated, but not in such a way as to account for a considerable number.

29. Can you tell us the number of lead workers employed in the coach-building industry as a whole?—The total number employed, as given in returns from occupiers in 1904-1907, was 106,434, of whom I estimate that 10,000 or 11,000 use lead paint. I base this estimate on the fact that, from the inquiry that was made by the Factory Department in 1902, 9,605 persons were found who used lead paint in 603 factories and workshops.

30. Is it impossible at the present moment to say what is the precise number of men among whom the 697 lead poisoning cases originated?—Yes; but in 58 of the factories visited in 1902, principally large works, including several railway carriage works, it has been found that 354 cases of lead poisoning have occurred in the 10 years 1901 to 1910, and those 354 cases occurred amongst 5,469 men exposed to lead, using lead paint, out of a total of 59,700 men employed. This corresponds to an attack rate of 6.5 per 1,000 annually. In the china and earthenware industry last year the attack rate worked out at 8 per 1,000, and in previous years nearly 15 per 1,000. It was exceptionally low last year.

31. Is it not essential that statistics should be collected on all these points in order that the Committee may be in possession of the attack rates among lead workers in each section of the industry?—It would be useful no doubt, but I think that you can get at the facts in other ways. If an examination, for instance, of 1,000 lead workers was made, and you knew how many of them were showing signs of lead absorption, you would get a better criterion of the actual effects of the industry on the men employed, I think, than by a single statement of so many reports per 1,000 employed. You would know how many were being affected who were not being reported, and

\* See Appendix II.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

you want to get that as well as the figures for actual reported plumbism.

32. You suggest that as a very valuable addition to the general statistics?—Yes; we must have statistics to base conclusions on.

33. Can you give us a table showing the reported cases classified according to the description of works in which they originated?—I have tables here showing the cases during those 10 years for railway carriage and wagon works, for tramcar works, for perambulator works, and for the principal other carriage works in which poisoning occurred, distributed according to the factory where the actual poisoning occurred, with the name of the factory and the number of cases which occurred in each year.

34. Do you hand in that paper?—Yes. I suppose that the names of the particular factories will not be published. That would be contrary to our practice.

35. No. Names will not be published?—I have classified these cases for each year, and under three heads: those that are included in the return, which of course are much the largest; then a certain number which were excluded because the diagnosis was wrong, or in my opinion I felt that it would be unfair to put it down against the industry; and others which were excluded because they had been previously reported within a year, and one imagined that that was really the same attack the effects of which had not passed off.

36. Have you distinguished cases from perambulator works throughout the years 1900 and 1909 inclusive?—The number of perambulator works is quite small, and I do not suppose that in any of them there would be more than ten persons employed exposed to lead, and yet the incidence is considerable.

37. Have the Home Office conducted any systematic inquiry into the dangers attendant on the use of lead in this industry prior to the appointment of the present Committee?—Yes, in consequence of the fact that no diminution was taking place in coach-painting factories, inquiry was made in 603 factories and workshops in 1902 by the staff of inspectors, and forms were supplied stating the information that they were requested to give. I can hand in one of those forms.

38. In what manner were those 603 factories and workshops selected for the inquiry of 1902?—In view of the large number of such factories and workshops generally (something like 4,000), district inspectors were asked to take the opportunity of visiting as many as possible of the coach, carriage, wagon, and locomotive factories, especially the more important of them. They could not be expected to visit them all.

39. How many other coach-building factories and workshops were there, which were not included in that inquiry?—Rather over 3,000 I think, judging from the fact that there were 1984 factories in the 1907 returns from occupiers and 1825 workshops in the 1904 returns.

40. Why were so many coach-building works omitted from the scope of that inquiry?—The Inspectors were asked to visit the more important ones only.

41. What were the points dealt with in this inquiry?—On that form information had to be given as to the number of persons employed in painting with lead paint, the total number employed, a description of the method adopted in rubbing down, whether it was done by a wet method, that is with use of pumice stone and water, or whether it was done dry by means of sand-paper, or by what other method, and whether substitutes had been tried for white lead paint, and with what success, and also they were asked to state the number of cases of lead poisoning that had occurred within, I think it was, five years.

42. Did this inquiry embrace every class of coach works?—I think pretty well every class.

43. What was the result of the inquiry as to the number of persons using lead paints?—The number of persons found to be employed in painting with lead paints was 9,608 in the 603 works.

44. How many lead cases have been reported from those 603 works?—Well, during the last 10 years, 1901 to 1910, there have been at least 354.

45. With regard to the other coach-building works, you have told us that you have no means of knowing

the number of workers exposed to contact with lead?—I have already explained, in an answer, that I have given the approximate number whom I believe to be working in contact with lead, which is based on this very considerable number that was found in the 1902 inquiry.

46. What method of smoothing the coats of paint was found to be most generally adopted?—Certainly the wet method; but in 52 works smoothing of coats of paint was not practised at all; in the remaining 551 it was affirmed that a wet method alone was used in 178, a dry method of sand-papering alone in 39, and both wet and dry methods at some stage or other of the work in 334.

47. Where a wet method took the place, either wholly or partially, of the dry sand-papering, what materials were used?—Generally pumice stone and water.

48. Of what class were the 52 works wherein all smoothing was dispensed with?—Those 52 places were nearly all premises for the repair or manufacture of railway trucks requiring no special finish.

49. In which classes of works did it appear that dry sand-papering alone was done?—The 39 factories coming under this head were premises in which rough, cheap, or common vehicles, such as carts, were made.

50. Why is the dry process used in such works?—Because sand-papering is a quicker and less expensive method than the use of pumice stone and water, and where there are any iron surfaces wet methods cannot very well be used.

51. Will you describe to us the processes carried on in the better class coach-building establishments?—In ordinary coach and carriage building the first two coats, known as the priming coats, are sand-papered, and after that six or seven coats of filling are applied, each of which is rubbed down wet with pumice stone and water. The body is then ready for the application of the final coats of colour.

52. What is the nature of the material which you speak of as filling?—Usually it consists of ground slate mixed with gold size and turpentine.

53. Are there any subsidiary processes in which lead is used in ordinary coach work?—All joints and interstices and irregularities in wooden surfaces and iron surfaces are filled in with a stopping or paste of white lead, in the smoothing of which sand-paper is often used.

54. Are the processes the same in the manufacture of motor-car bodies?—Not entirely. The motor-car body is made from terns plates, that is sheets of iron or steel coated with lead, and these plates are generally first sand-papered, after which two coats of a lead paint are applied. These are either lightly sand-papered or flatted with pumice and water. Three coats of a non-poisonous filling next follow. These are flatted with pumice stone and water or with German brick and water, and after that the body passes to a skilled workman who applies the final coats of paint.

55. Are those final coats of paint treated dry or not?—They are not sand-papered, I believe.

56. There is, then, a considerable amount of dry sand-papering in motor-car body work?—Yes, and, moreover, for facing mouldings and corners, throughout all stages of the work, dry sand-papering would take the place of pumice stone and water. All stopping on the chassis, the first coat—a lead coat—on the bonnet, and all coats of paint on the wheels are sand-papered dry. For wheels and rounded surfaces pumice stone and water cannot be used.

57. What can you tell us with regard to the wet process?—The figure given—178—as the number of places where the wet method alone is used is probably much too high; it doubtless means that pumice and water alone are used for the flat surfaces which constitute the bulk of the work; but dry sand-papering of the two priming coats and of the final finishing coats (when white cream or yellow is the colour) of the under parts of carriages, of the iron chassis of motor-cars, and of curved surfaces such as spokes of wheels, is almost universal. The reason for thus

22 February 1911.]

Mr. T. M. LEGGIE, M.D.

[Continued.]

treating the priming coat dry, I am always told, is that a wet process would raise the grain of the wood.

58. What information did you gain in regard to the use or trial of substitutes for white lead?—Substitutes are mentioned as having been tried at one time or another in 94 instances, but this was almost exclusively for the filling and jointing processes, and not for the priming and finishing coats if of a white colour.

59. Has any detailed information been collected in respect of these substitutes?—Yes; 28 of these substitutes which were said to be free from lead were forwarded by the Inspectors and were analysed in the Government Laboratory, and we have particulars of the samples as forwarded and particulars of the analyses that were made. They were nearly all free from lead or with very little lead in them.

60. Which of the operations, which you have referred to, do you consider to be the most dangerous?—The dry sand-papering. Rubbing down the wheels probably causes more poisoning than any other operation.

61. Would it be possible to determine by experiment the amount of lead dust in the atmosphere of rooms where sand-papering or other specially dangerous work is being done?—I think it would be extremely useful to have exact analyses made of the amount of lead in the air at the level where the workman is breathing. It could be done by aspirating a volume of air and weighing the amount of dust, and of lead in the dust in the same way as was done in the inquiry by Mr. Duckering in china and earthenware factories.

62. Is the wet process entirely free from danger?—The actual operation would be, but what is rubbed off falls on the floor and dries there and gets trodden upon, and there must inevitably be a certain amount of lead dust in the air, I think.

63. What means do you advocate for mitigating the dangers which you have described?—In the absence of the possibility of replacing white lead by some substitute, I do not see any complete remedy. There are the usual precautions of washing accommodation, which, of course, would not affect the poisoning from lead dust at all, but would be a safeguard for the men whose hands are smeared with lead paint. Then the wearing of overalls is essential where there is the possibility of splashing from paint, and there should be meal rooms.

64. And exhaust ventilation?—Exhaust ventilation is practicable for the rubbing down of wheels, and if it were installed, as I know it is installed in some works in Coventry, it would improve the conditions very much, and possibly when locally applied exhaust ventilation is impracticable it would be possible to arrange a respirator through which compressed air was delivered.

65. Is that something new?—I have seen an arrangement that the Vacuum Cleaning Company have devised with that object in view. It would give complete protection.

66. Is it comfortable?—I think it might be made quite comfortable.

67. I have never heard of a respirator that is comfortable yet, and I think you will agree with that?—The ordinary respirator which simply covers the nose and mouth, owing to the fact that the man has to re-breathe his expired air and consequently has to take deeper breaths, he cannot be expected to wear for the whole day; he can only do it for half an hour at a time.

68. Is the respirator you have seen of the Vacuum Cleaning Company a new invention?—It is. It is a new application.

69. In your view is it a success?—It has not been tried on any scale, and I would reserve my judgment, but the principle seems to me quite sound.

70. In cases where it is not found practicable to apply local exhaust ventilation, what would you suggest?—I have mentioned the usual requirements of washing accommodation, meal room, cloak room, overalls, and principally the substitution of wet methods for dry.

71. Is personal cleanliness of very great importance?—While I think that in all painting operations inhalation of dust is the most potent cause of lead poisoning, I do think that the eating of food with

unwashed hands is a more prevalent source of plumbism in the coach-painting and house-painting industries than in any of the other industries involving the handling of lead or lead colours.

72. Would you then advocate the provision of lavatory accommodation similar to that recommended by the Committee which recently reported on regulations for the earthenware and china industry?—Yes, but at the same time I would rather see substitution of leadless paint than the requirement of lavatories.

73. That would be the ideal solution. You would extend to this trade the requirement of the provision of hot and cold water?—Certainly. In fact I do not think a painter with hands smeared with paint could really remove the paint very well in cold water alone.

74. Also nail-brushes and soap and an adequate supply of clean towels?—Quite so, and preferably a trough with jets of warm water so that they can wash under running water and not in basins.

75. Similar, in fact, to that which we recommended in the recent report on earthenware and china?—Yes.

76. Would you advocate also the provision of mess rooms, to be kept clean and healthy, and to be properly warmed in winter?—I should.

77. You offer these suggestions, of course, only as an alternative if the substitution of non-poisonous materials for white lead is found to be impracticable?—Yes.

78. How far have you found that the use of lead has been discontinued?—The progress, so far, in this direction has been limited. A few firms manufacturing motor cars use no lead colours at all. One important railway company in England, which, however, does not paint its carriages white, and another railway in Ireland, and a few perambulator makers have dispensed with the use of white lead altogether, I believe, and in some other industries, as, for example, the making of cornice poles, where there used to be incidence of lead poisoning, the substitution of lithopone has been entirely successful. Those are the principal cases.

79. (Mr. Fell.) Have you found that there is a very great difference between actual contact with paint and inhalation? Is there a great distinction between them?—Do you mean in the symptoms?

80. Yes?—I should say not; but my view is that what you might perhaps consider poisoning produced by the paint I would attribute to the dust. What I mean is that a man is breathing 17 times a minute, and in that time the exchange of air that is going on, setting up currents in the air and wafting particles of dust into his lungs from which lead is absorbed, is a far more rapid method of getting lead into the system than getting lead on the fingers. It will not go through the skin. There is no lead poisoning caused through the skin unless you have absolutely soluble salts like acetate of lead. White lead will not go through the skin, nor do I think it will go through a cut.

81. Is there not any case where a man is poisoned through lead getting through a cut?—I do not believe so. I think that the amount of lead that is transferred to food through the hands is very very small compared with the amount that he gets in ordinary breathing.

82. Is not the trouble in the air got over to a great extent by constantly pumping fresh air into a paint shop?—No, because that pumping in, although it would be extremely useful in improving the air breathed, would only tend rather to keep the dust in motion in the air. Unless you can get the air at the point where the dust is produced, and remove it, it is still floating about.

83. Can you do anything by altering the temperature in the shop and the arrangement of heating, so as to keep the lead floating at a height that is not dangerous?—No, I do not think you can.

84. You think that that would not alter it?—I do not think it would. I agree that pumping in air for purposes of ventilation is a good procedure.

85. (Mr. Mason.) I would like to ask whether it is not very difficult to diagnose these cases of lead poisoning, especially in their early stages, not when they get to the drop-wrist stage?—The symptoms set

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

up by lead in the early stages, anæmia, headache, indigestion, constipation, are, of course, the same symptoms as are commonly met with apart from lead, and there may be difficulty. Undoubtedly a number of cases are reported in which other causes ultimately are found, but still they do not interfere with the general statement as to the numbers. I have made out a list of the deaths in regard to house-painters, but perhaps that had better come later.

(Chairman.) I will question you on that later.

(Witness.) I might say that about 7 or 8 per cent. of cases that pass through my hands I exclude, because I do not think it would be fair to include them. There is so much doubt about the case that I do not include it.

86. (Mr. Mason.) Have these cases increased since lead poisoning came under the Factory Act?—Before that one had no means of telling the state of affairs. It was on the 1st January 1896 that the section requiring notification of lead poisoning came into force. I do not think that in the coach-building industry it has increased. It keeps stationary. It just keeps about the same as it was 10 years ago. The table shows that. You see that in 1900 it was 70, in 1909 it was 95, and in 1910 it was 70. Do you mean that the Workmen's Compensation Act may have increased the number of cases brought to light?

87. That is what I was thinking of?—I think that the Workmen's Compensation Act operates in bringing to light old-standing cases that have not been notified, and it will lead a man, I think, to consult a doctor more readily for symptoms due to lead now that he knows that he can claim compensation if he gets a certificate from the certifying surgeon that it is lead poisoning. You see the ordinary practitioner's notification does not enable the man at all to claim compensation. He can only get compensation for lead poisoning on the certificate of the certifying factory surgeon, who must be satisfied that it is lead poisoning.

88. Then the certifying surgeon does not see him for some days after?—No.

89. That would render a diagnosis still more difficult?—Yes. It is best, of course, to see the case as soon as one can.

90. They would not go against the other doctor if there was any doubt?—I do not know. They do form an independent judgment.

91. Perhaps we misunderstand each other. I meant to say in doubtful cases, and many of these are very doubtful cases in the early stages?—Yes.

92. He would certainly give it as a case of lead poisoning, would he not, if he had any doubt?—Really I do not think he would. My feeling after having examined thousands of persons for lead poisoning is this—my inclination would be to consider, as lead is so subtle in its manifestations, that in a doubtful case, lead had had a share.

93. You were speaking some time ago about dry and wet rubbing. I take it that that refers to filling only and not to the coat of paint after the filling?—No. The dry rubbing refers to the priming coats, the first coats.

94. Do I understand that a large number of people use wet rubbing in coach-building?—That is where I expressed the doubt. I think that that is not the case. The information the inspectors got on that point was wrong, I think.

95. It would seem from your figures that they were referring more to the filling coats? I think they were.

96. There is not very much lead in the filling coats? They were misled, I think, on that point.

97. (Lord Henry Bentinck.) Do I understand that there is no wet rubbing in the priming coats?—I think there may be; I think that that is possible.

98. (Mr. Mason.) Do you think that there is any danger from the fumes of wet paint?—No. I think there may be danger from the fumes of burning off, but not from wet paint. I do not understand the reported cases to show that.

99. I have had cases of men who have never touched lead at all, and who never go near paint at all, who have suffered from lead poisoning, and I cannot understand how they got it?—There is an

inclination to assume that the illness is associated with the work. If men have the symptoms of anæmia and dyspepsia and constipation and are asked, "Where do you work?"—"We work in a lead works," naturally it will be assumed that the illness is associated with their work unless an inquiry follows as to whether they come into contact with lead or not. I told you that I excluded about 8 per cent., and it would be for such reasons as that that I would exclude them—because there is no possible contact with lead.

100. You would know that from the report?—Yes, I would know that from the report.

101. Taking a case of a man working in a paint shop but not working with lead, would you know then?—There I can quite conceive that the symptoms would be lead poisoning from the dust that has been floating about in the air. Take the case of a man in a paint and colour works grinding colours in the same room where white lead has been ground. If the exhaust ventilation is imperfect he may get poisoned, even although he is 5 or 6 yards away, through the dust floating in the air.

102. I take it that the effects of lead are different according to a man's state of health?—Yes.

103. It is more likely to affect him if he is not in good health? If he is an alcoholic subject he is undoubtedly more likely to get lead poisoning. If he is run down in health I think he is more susceptible; and many certifying surgeons lay great stress on the necessity of men commencing work with food in their stomachs, because an empty stomach predisposes to absorption. But mind you, unless there is lead dust floating about I do not think that those cases come in. If you can keep the dust away then those points do not signify.

104. (Chairman.) Would you say from your observation that a large number of people are more susceptible to lead poisoning than others?—I suppose that that is so. Women are more susceptible to lead poisoning than men.

105. You get cases of lead poisoning in some works, and, under precisely the same conditions, no lead poisoning at all in others?—Yes, but I would not like to push that too far. If you had half a dozen men each one exposed to the same amount of lead dust, I should be surprised if any of them escaped. One might get colic, another might get brain symptoms, another might get anæmia; but I think they would all show something. I think that susceptibility is brought in too much to explain the effects of lead dust.

106. (Mr. Mason.) Following on that in times of bad trade, when the men would not be perhaps getting so much to eat, and would not be so well fed, would they be more liable to lead poisoning in such cases?—I suppose that might be so. I know one big railway carriage works, for instance, where they tried to explain a rather heavy incidence in that way; but I would not lay too much stress on it.

107. (Mr. Kinggate.) I desire to ask whether any distinction is made in returning the cases of white lead, as to whether they are painters or any other branch of the coach-making industry?—Do you mean whether they are coach bodymakers or actually painting?

108. Yes?—Very often that distinction would be made, but I have not classified them separately.

109. What was the instruction to the inspectors when they examined these various works; was it only in the painting departments they were supposed to examine?—No, I think they were to include the coach bodymaking too. But by coach bodymaking do you mean the woodwork solely?

110. Yes?—Where they use red lead paste or white lead paste in jointing.

111. They use white lead in jointing and in fixing ironwork. In the carriage making industry they use a great deal more white lead than painters use, and in proportion to the number employed a very much heavier percentage suffer from white lead poisoning. Take those that make the undercarriage for instance?—For broughams, &c.

112. Landau or Victoria or Brougham—the body is hung on—you understand that?—Yes.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

113. The underpart is of wood and iron, and it is all put together with white lead; every bolt is put in with white lead under the head. A man putting his work together is practically covered with white lead the whole of the day. He cannot get it from his hands. My experience is that the large proportion of carriage makers have always suffered very much from gout brought on by that. I am a carriage maker myself. With regard to the number examined you said 11,900 out of 106,434 that were employed were painters, as I understood, coming into contact with white lead in bodymaking, or in painting?—I should take it that the terms of reference of the Committee cover bodymaking just as much as painting.

114. Yes. I have noticed that the factory inspectors seem to neglect that branch very much. No accommodation has been given for washing with regard to bodymakers or coachmakers such as has been carried out in the painting department?—I should think myself that the risk was very much greater in the painting department, where they are putting on the priming coats, than in coach body-making where only a little of the lead paste is used to fix spokes in.

115. But the spokes are not fixed in with lead at all in an ordinary wheel?—Then I stand corrected; but surely they use white lead paste. Do you mean for the iron part—the chassis only?

116. With regard to chassis, that is engineers' work, and they do not use lead; and they somewhat ridicule us with regard to using lead so much for putting on ironwork; but every bit of iron has to be covered with white lead?—And has it to be sand-papered?

117. No, putting them together. With regard to the bodymaker or the coachmaker it is the practice generally, as soon as a body is finished, to take it away from the bodymakers' bench, and take it to where another man works at it. The priming coats are put on there, and the sand-papering and filling are done. So, apparently, they suffer more than the painters do, because they are always breathing it?—I do not think that my figures would bear out the fact that the bodymaker suffers more than the painter.

118. They are not very frequently reported as cases of lead poisoning. There is also this to be considered; we know that men ask not to be reported as suffering from lead poisoning for fear of losing their jobs?—But do you think that that is so much so now?

119. I think that it is more so now?—Since the Workmen's Compensation Act?

120. Yes. It is a fact that men ask not to be stated as suffering from white lead on account of fear of losing their employment. With regard to using water for priming, I have never known that to be done, and my colleague, I think, would say the same as a practical painter—that he never saw water used for two coats of priming. It is all sand-papering. The most fruitful cause, undoubtedly, is the dust. We had a case in the Manchester Corporation of a man not using lead at all who died from lead poisoning. We had three cases in the Manchester Corporation in two years, of deaths from lead poisoning in the Tramways Department?—Three cases of lead poisoning?

121. (Mr. Robins.) I speak as a practical painter. I commenced at thirteen, so I have some knowledge of the trade. With regard to the perambulator industry which you touched upon, the great prevalence of lead poisoning there is in connection with the sand-papering, and not the rubbing down. My experience of eight years goes to prove that no wet rubbing down is done, or very little, in perambulators, at all. I have unfortunately suffered from lead poisoning, and ever since that time I have been troubled with lumbago; in fact I can feel a little of it this morning. I was glad to hear your testimony with regard to the after effects of lead poisoning, that, although it did not attack a man a second time, yet it may attack him in other forms, such as gout or lumbago. My medical adviser told me after I had been attacked a time or two with lumbago, that it was nothing more nor less than having lead poisoning that was running its course. Do you believe that these after effects follow lead

poisoning?—Undoubtedly there are sequelæ of lead poisoning. I do believe in the association of gout with lead poisoning and of chronic Bright's disease.

122. With regard to the inspection that was made of factories some years ago, you said, I believe, that the larger of the factories were visited with regard to lead poisoning, but the smaller ones were not visited?—Wheelwrights' shops in villages would have been omitted from that inspection I dare say. They would have gone to places where the largest number of men were employed.

123. Do you find among your figures that there is any great prevalence of lead poisoning in these little shops?—No. I take it that that is because the work is done intermittently, and there is not the rush and hurry that there is in big shops. I believe that the speed at which lead work has to be produced profoundly influences the incidence of the poisoning. Where there is pressure of work and piecework, there you get lead poisoning, but you do not get it in leisurely work.

124. Do you believe that within the last two years the large increase of lead poisoning has been due to the large amount of overtime and Sunday work that has had to be put in in the motor and coach-building trades of the country?—You are referring to coach-painting?

125. Yes?—I should think that is undoubtedly the cause—the rush to get the cars out. There has been a diminution in lead poisoning generally throughout the country.

126. There has been a boom during the last two or three years; that I know from my own knowledge. Taking one firm where I was employed, I was at work no less than eight Sundays. I have had to work with my men, and late at night too, and that high pressure that men have to work at, certainly, in my humble opinion, must be detrimental. I should like your opinion on the matter?—Most certainly. I think any overtime work in lead work is certain to have an effect on the incidence of lead poisoning.

127. You made some remarks with regard to the substitutes for lead. Do I understand that nearly all the samples were free from lead?—For the filling I might say that they were nearly all free from lead and the jointing pastes. There were very few analyses of priming coats.

128. Were there any analyses of zinc whites and other substitutes for white lead?—Yes.

129. Those you found to be practically free from lead?—Yes.

130. Do you think that they were non-poisonous?—Yes.

131. With regard to factory inspectors, I am afraid that the inspectors do not come into paint shops at the proper time. It may be a charge, but still it is a friendly one. I contend, myself, that factory inspectors should come more at night. Would you consider, with regard to the increase of lead poisoning from inhaling, that men would be more susceptible to it at night when you have to have gas, and the fumes of the gas?—I do not think that that would influence it much. It would all depend on the amount of dust floating in the air.

132. And then at night you find a greater amount of dust. It is at its height then?—Do you refer to working overtime or do you mean the night shift?

133. I mean the last hour, between five and six?—I do not see why men should be getting more lead poisoning between five and six than they would between nine and ten in the morning, if they are making the same amount of dust.

134. (Dr. Collis.) It has been suggested that lead has to bear a burden which is not always its due. A number of cases are put down to lead which may perhaps be doubtful. That being so, I wish to ask you a few questions. Could not a man absorb small amounts of lead and yet never have any definite attack of lead poisoning?—Undoubtedly.

135. Do you consider that these small amounts may have some influence, never diagnosed as plumbism, and that we see this influence in the high mortality from Bright's disease and gout, which undoubtedly occur among lead workers?—Yes.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

136. (*Lord Henry Bentinck*.) How far is it possible to apply exhaust ventilation to a whole shop?—What is meant by "locally-applied exhaust ventilation" is the arrangement of a duct, say a foot in diameter, or six inches in diameter, with small branch ducts coming to the actual point where sand-paper is applied, and sucking the dust away. There is a fan at the end.

137. It is not possible to apply that ventilation to a large area?—No.

138. It would not carry away the dust arising in a whole shop?—No, and if you applied it to a large area you would perhaps be drawing the dust across the faces of the people before it got to the exhaust. It must be below the level of the person's mouth. It is owing to the exhaust ventilation that the reduction in lead poisoning has been possible in industries where it can be applied, such as the large china and earthenware industry.

139. It could not be applied to coachbody building?—I thought it might be possible to get an exhaust apparatus fixed to the back of a man's hand, so that when he was sand-papering, this arrangement fixed to the back of his hand would take away the dust. The Vacuum Cleaning Company kindly experimented in that direction when the suggestion was made, but apparently they found it was not practicable.

140. Can you tell me something about the extra cost of respirators with compressed air?—I believe that a large shop with, say, 20 men, could be supplied with a compressor—the engine for compressing air—and all the apparatus for 50*l*.

141. That would be the initial cost?—Yes, and the cost of running it would be 1½*d*. an hour, perhaps.

142. Have you had any experience with regard to the working of it?—I have tried it myself.

143. Is it possible to wear it for long?—It is like breathing fresh air. It is a perfectly different idea from the respirator covering the nose and mouth. The idea rather is to have a collar round the neck, and from this collar to have jets of air coming up across the man's face, exerting a pressure, and preventing any of the dusty atmosphere coming through.

144. Is it used in any other trades?—I believe that something similar is used for sand blasting. I believe it is being used in the London streets for cleaning the tram lines, and it is used for sand blasting certainly; but it is a much clumsier apparatus, quite an impossible apparatus to expect men to wear constantly.

145. Is it?—The sand-blasting apparatus is; this would be very different.

146. Not so clumsy?—No, not so clumsy. It requires of course a flexible half-inch pipe attached to the collar from which the stream of air is being delivered. In several of the big railway carriage works now they are using the vacuum cleaning arrangement for taking the dust out of cushions.

147. Would this be any use as regards burning-off or cleaning?—I think that it would be an entire protection in regard to burning-off.

148. (*Chairman*.) Now I will put a few questions to you in connection with house-painting; and then ask gentlemen to cross-examine on that section. Will you now give us your evidence on the incidence of plumbism amongst house-painters? Are such cases also notified to you?—There is no legal requirement for the notification of cases of lead poisoning occurring outside a factory or workshop. The object of notification is to obtain a clue to unsatisfactory conditions over which the inspector can exercise control; and, consequently, these cases, although they are notified are not followed up.

149. Are men not frequently employed as house-painters working part of their time in a workshop and part of their time on jobs outside?—Yes. Where a painter is employed part of his time at the mixing of paints in a workshop, the question may legitimately be raised as to whether plumbism may not be due to mixing the paint in the workshop. But I classify all those cases as house-painters. I do not consider them as coming under the Factory Act.

150. Do you then get a number of notifications of cases of lead poisoning among house-painters?—

A large number of cases are notified although there is no obligation on the medical practitioner to notify; and the practice of the department is to accept and pay the medical practitioner for his notification, but not to follow it up by detailed inquiry, for the reason I stated—that the inspector cannot do any good. In the painting of a house he cannot require the installation of washing accommodation for the house-painter. At first a number were followed up, but it involved such difficulties in administration to the staff, that what is done now is to send a leaflet on the dangers of lead poisoning to the decorating firm employing the workman, and also a leaflet explaining section 73 of the Factory Act, and asking them, if the man contracted it really in a workshop, to report it. I should like to hand in those two leaflets that are used in following up these cases.\*

151. This state of affairs results in the notification to the Home Office of many cases, then?—Yes. The number exceeds that of any lead industry in the kingdom.

152. What was the number of cases of lead poisoning among house-painters and plumbers notified to the Home Office in the years 1900 to 1909 inclusive?—1,973 among house-painters and plumbers. Of the 232 cases in 1910, 197 were house-painters and 35 were plumbers. That is about the relation of house-painters to plumbers.

153. Where did these cases chiefly occur?—I have a table† here showing the distribution of these cases for five years. The largest number occurred in South London, in West London, in East London, and in North London. Then comes Birmingham with 71 and Manchester with 59, Bristol with 44, and Leeds with 32. In the whole of Scotland there are only about 20 cases—12 in Glasgow. I attribute that not to what might be thought to be the reason—practitioners not notifying cases there—but to the fact that it is a stone country and consequent absence of outside painting. Certainly in Edinburgh lead poisoning is practically unknown. Those are figures for the five years 1906 to 1910.

154. These figures, for the reasons you have given, represent probably only a fraction of the whole?—That is undoubtedly the case.

155. Have you any means of estimating the number of fatal cases with any certainty?—Yes, by arrangement with the Registrar-General whereby the District Registrars in England, Wales, and Scotland notify the Chief Inspector of Factories, sending copies of death certificates in which lead poisoning is directly or indirectly the cause.

156. What is the number of deaths from lead poisoning among house-painters and plumbers ascertained by this means?—In the 10 years 1900 to 1909, 387 deaths.

157. What means have we of estimating the proportion of house-painters who are attacked by plumbism, or who die of lead poisoning?—There are no means of calculating that, as there are no exact statistics as to the numbers employed in house-painting.

158. If the Trade Unions and Friendly Societies would give the number of house-painters in their memberships, and would state also the number compensated for lead poisoning each year, do you not think we could deduce valuable percentages from that information?—Well, you would get a number of house-painters, but I do not think that the number who get compensation or who apply for compensation for lead poisoning now is sufficiently large to be a fair criterion of the amount of lead poisoning occurring amongst them.

159. At the present moment we have merely the total deaths in 10 years, namely 387, as a reliable figure. Have you made any estimate of the total amount of lead poisoning existing in this trade, based on the number of fatal cases ascertained through the registrars?—I think it would be fair to assume that the proportion of deaths to attacks would be about the same amongst house-painters as amongst

\* See Appendices III. and IV.

† See Appendix V.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

other lead workers; and a calculation based on that assumption gives the total attacks in the 10 years amongst house-painters and plumbers as 9,516.

160. Should the medical practitioner not be expected to report to the Home Office all lead cases arising among house-painters and plumbers?—It would be useful for the statistical information which it gave, but it would throw a great burden on the Factory Department if we were asked to follow them up. We cannot do any good, and I do not think it would be right to expect the factory staff, with its present powers, to spend their time in the futile inquiry which would be involved.

161. Have you observed anything noteworthy as regards the severity of the cases notified?—I am impressed with the prevalence of severe symptoms such as paralysis and brain symptoms and chronic plumbism amongst many of those reported.

162. What, in your opinion, are the main sources of lead poisoning among house-painters?—I think that the chief causes, in the order of their importance, are: first, dust from mixing dry white lead with oil; secondly, dust arising from paint which has dried on overalls; thirdly, dust from sand-papering one coat of paint before applying another; fourthly, contamination of food by unwashed hands; and fifthly, possibly the fumes from burning off old paint.

163. Would it be possible to determine, by experiment, the amount of lead dust in the atmosphere of rooms where sand-papering or other specially dangerous work is being done?—Yes, in the same way as was suggested for coach-painting. It is more difficult perhaps in house-painting, and if it were limited to the coach-painting industry you would get all the information you wanted.

164. To what extent have you found in your experience that leadless paints have been introduced?—I believe that zinc oxide or zinc sulphide or mixtures of the two have been tried.

165. Are they efficient substitutes for white lead?—There is some divergence of opinion on that point notwithstanding the numerous experiments and investigations made by different foreign Governments; but I think that there is a general consensus of opinion that for internal painting in a house, and for all surfaces that are not exposed to the weather, zinc paints have advantages, apart from their non-poisonous quality, over white-lead paint, as they do not change in colour so much.

166. Can zinc-oxide paints be applied in precisely the same manner as white-lead paints?—So far as I have been able to gather, the technique for applying zinc-oxide and zinc-sulphide paints differs materially from that for white-lead paints. As the zinc oxide is much less dense and much more bulky it requires to be ground with a much greater proportion of oil, and the driers and vehicles necessary for thinning the stiff paste are different from those ordinarily used for thinning and mixing white lead.

167. Does this involve difficulties for a painter who is accustomed to the use of lead paints?—It would mean that he had to learn a new trade practically. The coats of zinc oxide should be applied as thin as possible, and consequently three coats of white lead might suffice where five coats of zinc oxide were necessary, unless they were skilfully applied.

168. Can you tell us anything about the vehicle?—I understand that linseed oil should be the vehicle for zinc oxide, with a minimum of turpentine.

169. To what extent can zinc sulphide be used in the place of white lead?—Zinc sulphide is usually mixed with zinc oxide and barytes because it has defects in colour which are concealed in that manner. It adds to the paint an important property known to the painter as "body."

170. Is zinc sulphide widely used?—Yes, for internal decoration.

171. Under what names?—Under the names of lithopone (which is a mixture of zinc sulphide with zinc oxide) patent zinc white, enamel white, and so on.

172. Are there any regulations in force in Great Britain dealing with the work of house-painters at the present time?—No.

173. Why is this? Because the Home Office has no powers to deal with the painting carried on in places outside the Factory and Workshop Act.

174. Then it would be necessary to apply to Parliament for powers to enforce any of the recommendations of this Committee?—Yes.

175. In your view, are the dangers of plumbism to which the house-painter is exposed as great as those in other employments for which regulations have been made?—Quite as great.

176. Would you say greater? Yes, I think they would be greater, perhaps.

177. Then should not similar precautions be adopted?—Well, here again the exhaust ventilation cannot be applied, and precautions short of exhaust ventilation do not seem to me to have the desired effect.

178. What are the difficulties?—You could not apply exhaust ventilation to house-painting. Also, as I said before, we have no control over house-painting operations. Then again, the trade is a seasonal one. House-painters are a migratory class of people, who change their employment a good deal. It would be a very difficult trade to control.

179. Would it not be possible to overcome these difficulties by requiring every painter to have a certificate from the certifying surgeon in a portable register, as has been done for the last eight years for casual lead workers in the pottery industry? There are administrative difficulties that I see in such a recommendation. If you are going to make a man submit to a periodical medical examination, if it is going to be of any service, the certifying surgeon who examines the man would need to have the power to suspend him from his work; but if power of suspension is contemplated, I do not approve of suspending a man from his work if the conditions cannot be improved. I would say that the man should be left alone.

180. What conditions do you mean?—The conditions that produce the ill-health. If you cannot remedy them, it is unfair to the workman to make him submit to a medical examination, I think.

181. The two ought to go together, you think?—Yes.

182. If no one was allowed to work in house-painting without a certificate, we should very soon know from the certifying surgeon the exact number of men so employed?—Yes, but still that presupposes that it could be easily carried out, with which I am afraid I am not in accord.

183. Are there any regulations for house-painters in Germany? There are regulations in Germany. The work of house-painters and decorators is controlled by special rules, dated 27th June 1905,\* prescribing, firstly, the prohibition of actual contact with the material (that is with white lead) in crushing and mixing, and adequate protection from the dust so created; secondly, the mechanical incorporation of the white lead with oil and varnish. That means no handling and prevention of the escape of dust into the workroom. That would apply to the workshop where the mixing is done.

184. (*Mr. Sutherland.*) Does that refer to house-painters and decorators?—Yes.

(*Mr. Rice.*) In Germany, much more than we do here, they mix their paints in the paint shop.

185. (*Chairman.*) Any further regulations?—(*Witness.*) Thirdly, scraping or chipping off dry oil colours shall be done only after preliminary moistening. The fourth and fifth regulations require provision of overalls and washing accommodation, including soap, nail-brushes and towels, and they say in connection with the erection of new buildings, that provision must be made so that the workers can wash in a place free from frost.

186. Free from frost?—So heated, I suppose, as to prevent the pipes freezing. Seventhly, the employer must instruct the workman as to the risk attaching to the work by supplying him with a copy of these regulations, and with a cautionary notice. That is a leaflet such as we have drawn up, and which

\* See Appendix VI

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

we send also to the house-painters. Then it deals with places where painting operations are carried on in factories or workshops as subsidiary to other processes—in coach-building, for instance. The washing accommodation must be in a special room capable of being heated, and provision must be made for keeping clothing, and for periodical medical examination of the workmen at half-yearly intervals. Then there is prohibition of smoking in the factory.

187. Are similar regulations in force in other countries?—In Belgium they have a somewhat similar law dating from the 20th August 1909. I can hand in a translation of that.\*

188. What are the requirements in Belgium?—The sale, transport, and use of white lead are forbidden in the form of powder, small pieces or lumps, when intended for paint work. The sale, transport, and use of white lead in the form of powder, small pieces, or lumps intended for other uses—I suppose that would be, for instance, for glazing pottery—are only permitted under such conditions and such limitations as are fixed by Royal decree. Secondly, white lead intended for paintwork shall not be sold, carried, or used except in the form of a paste combined with oil. Thirdly, the partial or total prohibition of the sale, transport, and use of other products, of which lead is the basis, in the form of powder, small pieces, or lumps, and intended for paintwork, can be determined by ministerial decree. Fourthly, dry scraping or dry rubbing of surfaces covered with white lead is forbidden. The rest refers to administration and penalties.

189. Do you know if these regulations are found to work satisfactorily?—I cannot express an opinion on that. I know that in Belgium the periodical examination of house-painters has been found a difficult matter. The trouble of finding them by the surgeon, and so on, leads to difficulty.

190. How could that regulation be improved, in regard to the medical examination?—I am not prepared with a suggestion on that point.

191. Can you tell us anything further with regard to regulations dealing with house-painting in foreign countries?—Regulations have been made, I believe, in France and in Austria.

192. Can you give us the details of the French regulations?—I cannot quote the details, but the text of the law has been published in the "Journal Officiel."†

193. Can you give us the details of the Austrian regulations?—The Austrian‡ are very similar to those that I have read from Belgium. I rather fancy that in France there is a definite prohibition of the use of white lead for painting.

(Mr. Parsonage.) In five years' time.

194. (Chairman.) Will you let us have the original documents so that we can have them translated and circulated?—Yes, I will.

195. (Mr. Sutherland.) With regard to the point that you stated as to the German practice, is it not necessitated by the practice of painters grinding their paint very much more than we do here? Our men buy paint ready ground. In Germany, and generally on the Continent, the master painter has in his workshop the machine that he grinds the dry powder with, and mixes it with the oil?—That I did not know, but I can quite believe it is so, because so much dry white lead is manufactured in Germany.

196. The terms of restriction point to it, do they not?—Yes. We have similar regulations for paint and colour factories requiring exhaust ventilation, and so on, where grinding of white lead is done.

197. Practically every painter is a small mixer really; he grinds for himself?—Yes; a small paint factory.

198. In reference to the question the Chairman asked about applying exhausts to house painting, you quite recognise the difficulty of that? It is impossible, I think.

199. Do you think that, even if it were possible, it would be desirable or necessary? It is so fraught with difficulty that I have never given it consideration.

200. Do you think that the danger of inhalation is as great with the house-painter as with the coach-painter?—No, I should not think it was quite so much, but I am not so familiar with the work of the house-painter.

201. Take a room like this. There would not be a great deal of rubbing down here. It would probably be all confined to the doors, and that would probably be done by the wet process, so that the air could not get charged with the dust?—But I have seen house-painters sweep their hands over wall surfaces with sand-paper. Is it not a fact that they get a matt surface on the wall sometimes?

202. Not with sand-paper?—On which to put another coat of paint.

203. They always rub it down, but very lightly. They do not break the surface? But from my point of view, to do it very lightly is just as hurtful as to do it heavily.

204. Do you think they get it from the surface which is charged with oil? The lead rubs on to the sand-paper, and ultimately makes the sand-papered surface smooth. Do you think that that would get into the atmosphere?—I think it would.

205. I am not with you there. You give a medical opinion, not an expert opinion. Years ago the trade used to fill up with a white lead filling, and then they would sandpaper it down?—Yes.

206. The rubbing would distribute the dust?—Yes.

207. In answer to a question on coach-painting you said you did not think that there is danger from the fumes of paint, you said?—I was thinking of the fumes from burning off.

208. You do not think that there is any danger of actual contact with lead?—Do you mean with the hands?

209. Yes?—Only by subsequent contact with food or smoking, or putting the hand near to the mouth, and so on.

210. What is the danger from smoking?—The danger from smoking would be the contamination of the pipe stem.

211. (Chairman.) You think that the actual smoking would not harm the worker?—No, the actual smoking would not harm him.

212. (Mr. Sutherland.) He gets the lead on the pipe and gets it into his mouth?—Yes, or he may take a cigarette out with paint covered fingers.

213. Are not many people sufferers from the fumes from paint?—Yes, but I do not think that they would get lead poisoning, they would get headache perhaps. There are some cases of lead poisoning, I am bound to say, where the only explanation seems to be fumes given off from the paint; but those are to my mind inexplicable. From my knowledge of thousands of cases of lead poisoning, I have no experience of such cases. They are curiosities.

214. The custom of the trade has changed a good bit in recent years. 20, 30, or 40 years back there was a good deal of what is known as flutting, where a number of men would lock themselves up in a room. They would use turpentine in the paint; the fumes would rise and I know would produce headache?—Yes.

215. Would that produce lead poisoning?—No, I do not think it would. The lead poisoning that the house-painter gets is not from smell, certainly not.

216. And not from actual handling of paint?—That contributes materially.

217. Except when it gets into his system?—That contributes materially, I think, in house-painting.

218. You have no absolute data to go on as to substitutes for white lead, have you, in this country?—General reading, and the discussion of the subject.

219. And the statements of proprietors, which are very picturesque?—I believe you will get evidence from the Office of Works on the subject.

220. There are plenty of substitutes, but we have no absolute proof as to their physical or wearing

\* See Appendix VII.

† See Appendix VIII. ‡ See Appendix IX.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

qualities?—No, the evidence is very contradictory indeed.

221. If we could solve the difficulty we should achieve a very great task?—You would.

222. (*Mr. Rice.*) You make no distinction between men working as mixers and men working as painters in your returns?—Do you mean in coach-painting?

223. No, house-painting. I know it is the custom for men in some cases to mix paint and use it, but my experience is that men are set apart mostly for mixing paint?—Yes.

224. That is on account of the migratory state of the trade. Men work in other businesses in the slack season, and a good colourman is rare. I wanted to get from you, if I could, whether the returns show the colourman or mixer to be more liable to lead poisoning than the ordinary painter who uses the paint?—I cannot speak of that with regard to house-painting, but I can with regard to coach-painting, where also there is a special mixing shop. The number of cases of lead poisoning in paint mixing in coach works is very small, because they are only grinding sufficient for use on their own premises, and they do it all in pug mills. It is not like the paint and colour manufacturer who is grinding white lead in edge runners.

225. Do I understand from that that the mixing of paint is less dangerous than applying the paint? No, it is not, but I take it that the amount of time taken up in mixing is so small that it is negligible compared with the amount of time that is taken up in actual painting operations.

226. Assuming that the man mixes his paint? If the man is engaged in mixing he is running infinitely greater risk unless there is very efficient exhaust ventilation.

227. Do I understand, with regard to notification by doctors of lead poisoning, that they are paid for notifying?—Yes, they are paid half-a-crown.

228. Lead poisoning is a case where a man would be compensated under the Workmen's Compensation Act, is it not?—It comes under that Act, but the workman has to apply, and he has to get a certificate from the certifying surgeon before he can claim.

229. Not from the ordinary medical man?—No. The medical man's notification would not help him at all in regard to compensation. He has to apply to the certifying factory surgeon even if he is a house-painter.

230. I asked that question because I rather thought that the returns for workmen's compensation did not sufficiently indicate the amount of lead poisoning in the trade?—No, they do not. I feel sure that that is because so many workmen do not know that lead poisoning comes under the Act yet, and they do not know how to proceed about getting their claims established. They do not know that they must go to the certifying factory surgeon. They do not take action in a slight case.

231. If the doctor certified a man to be suffering from lead poisoning, you do not think that he would say to him: "This is a case under the Workmen's Compensation Act," and explain how he can claim?—If he were to do that, no doubt they would proceed further, but I should imagine that most doctors would be unaware of it themselves.

232. And yet they would receive the payment on application to your department?—Yes, but you see the factory department has nothing to do with the Workmen's Compensation Act. The Workmen's Compensation Act is a Home Office matter. The Factory Inspector wants to be impartial. He has to be impartial, and it is not his business to tell the workman who is suffering from lead poisoning that he comes under the Workmen's Compensation Act. The workman may have reasons of his own for not wishing to apply.

233. The doctor to whom the men go for lead poisoning might suggest it?—He ought to.

234. With regard to the leaflet you referred to, was that sent to all employers, or only to employers whose workmen were suffering from lead poisoning?—The decorating firms.

235. But to the employer of men suffering from lead poisoning?—Yes.

236. Not to every employer?—No.

237. Assuming that an employer had no men suffering from lead poisoning, he would not know of this leaflet?—No, he would not.

238. You do not make a distinction between painters and plumbers? You bring painters and plumbers into your statistics?—Yes.

239. But in your statement with regard to cases of lead poisoning you do not mention any cause that applies to the plumber, as far as I can see. You use the term "house-plumber"? I take it that the house-plumber gets his poisoning from making red lead paste and applying it, and from handling the old lead pipes, which have got oxide of lead formed on them. In cleaning them he would detach dust. He gets it in these ways from the dust of the red lead, from the dust of the oxides of lead on the pipe, or from contamination of his hands, and so transferring it to his mouth.

240. With regard to the 387 fatal cases in 10 years, by some calculation you make out that the number of persons suffering in the time was 9,516?—Yes; I take that from the death certificates that were received from the registrars. We know, under the Factory Act, the various lead industries, and how many deaths there are in a year. There are usually about 30, and we know that those 30 deaths represent 600 or 700 cases of lead poisoning that are reported. The number of deaths amongst house-painters is usually about 40, and, assuming that there is the same incidence generally, those 40 deaths would mean 900 cases.

241. But you have only had notified in that time a very much smaller number?—Yes, but you see we make no effort to get house-painters notified. It is all done by the medical practitioner thinking: "This is industrial lead-poisoning; I must notify it." He does not look at that section which says that it has to be contracted in a factory or workshop before it is notifiable. Then we were getting into difficulties with the medical men. We were not paying them, and they got annoyed at not receiving their fees, and we had to go into this question. It was useful to have the information. Some of them may have been due to poisoning in the workshop, and we could not say when a case was or was not properly reportable; and so we agreed to pay them.

242. Then this is quite an estimate on your part?—It is an estimate, but it is based on an accurate figure of deaths.

243. On the deaths in another trade?—No. We know the deaths amongst the house-painters. They are sent to us from the district registrars. As you have referred to that point I might say that I have prepared a table showing the main symptoms appearing as the cause of death, and the average age at death entered on the death certificate.\* With regard to lead poisoning in house-painters and plumbers the usual cause of death is Bright's disease, or cerebral hemorrhage, which is due to Bright's disease, or paralysis from lead poisoning. Nearly all those are chronic Bright's disease. Then there are a certain number which are due to brain symptoms. They are quite small in number. There are others which are put down as chronic lead poisoning. Phthisis and all sorts of things may appear in association with lead poisoning. There are a certain number which I should hesitate to call lead poisoning. For instance, in looking through this list I have down here "Lead poisoning, diphtheria." That man undoubtedly must have died of diphtheria; but it is included as a case of lead poisoning.

244. That man would be a painter who died of diphtheria?—Yes, but he had lead poisoning associated with that condition, and he is entered as a lead poisoning case. Then I have one "chronic lead poisoning, acute pericarditis." He died of rheumatic fever. The acute inflammation called pericarditis here would mean rheumatic fever, but he had lead poison in his

\* See Appendix X.

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

system. Then another is "typhoid fever." He died of that. The lead poisoning was there. So there is a certain number of these to which I attach very little value.

245. That would be a small proportion?—That would be a small proportion. It would be perhaps 10 per cent.

246. Is it possible for anyone not working with lead to have lead poisoning?—Yes, through drinking water.

247. It is not possible unless one comes in contact with lead to have lead poisoning?—No.

248. And yet lead poisoning seems to cover many diseases that are common. I gather from your evidence that the symptoms which are characteristic of lead poisoning cases are common symptoms?—It sets up a change in the blood, anæmia, which other things cause also, and you cannot distinguish the anæmia of lead poisoning from the anæmia set up by other causes.

249. Arthritis and gout have been referred to. Is it not possible for that to be hereditary?—Yes.

250. There is no reason why a painter should not suffer from hereditary gout or hereditary arthritis?—None at all. It is found that a large number of painters also have gout, and therefore the gout is associated with lead poisoning, and similarly with Bright's disease. Many people die of Bright's disease who have never come into contact with lead; but it is found much more frequently amongst lead workers than it is amongst the general population. It is based on numbers. One therefore cannot deny that it is a sequela.

251. These figures are more of an estimate, and cannot be actually set down to lead poisoning. That is the whole point of my question?—Some of them are open to doubt.

252. (Chairman.) You say the figures you refer to reported by the certifying surgeons are open to doubt to a certain extent?—Yes.

253. But the figures which you have given to us are less open to doubt?—Yes, after I have excluded the 10 per cent. I feel that I cannot touch a death certificate; I dare not do so. I definitely make it a rule to include all cases where on a death certificate lead poisoning is entered as directly or indirectly a cause. Once you begin to try to separate in death certificates, you do not know where you are.

254. If you take the deaths as absolute cases, have you made a reduction of 10 per cent.?—No, not from the deaths, but from the notifications.

255. So the figures you gave us are accurate?—With the exception of the small percentage of cases that may be doubtful.

256. (Dr. Collis.) Are you dealing with factory cases?—There is a possible point of confusion there. We are dealing now with the house-painters. Seeing that we do not make the same inquiry into house-painters that we do in the factory cases, I have not the same knowledge from the certifying surgeon's reports as to whether a case is a case of lead poisoning or not, and therefore I include all the house-painters. You see they are tabulated separately in the returns in the "Labour Gazette" from the factory cases, and they are not subject to this 10 per cent. reduction for doubtful cases.

257. (Mr. Rice.) They are returned as lead-poisoning cases?—They are all notifications of lead-poisoning cases. At the outside I should say 10 per cent. are doubtful.

258. You say it is not possible to get lead poisoning in the case of persons who do not come into contact with lead?—Yes.

259. For how many hours could a painter work with safety?—It would all depend on the amount of dust to which he is exposed. If you had complete absence of dust the ordinary 10-hour day would not expose him to any greater risk.

260. I was rather interested in the question of certificates of good health of workers. They adopt that arrangement in Germany, where they have a six-monthly examination?—A six-monthly interval is too long to be of much use.

261. You think it is not possible to do that here I gathered?—That German regulation dates from 1909.

262. 1905 according to my note here; Belgium is 1909?—A six-monthly examination does not seem to me likely to influence the matter one way or the other. It does not say that the doctor who makes the examination can do anything more than make recommendations as to treatment.

263. Are there any penalties for having cases of lead poisoning?—No.

264. You do not think that the change of employment from painting to something else that you referred to undermines a man's constitution in any way which makes him susceptible to lead poisoning?—Do you mean transference to other work for a time?

265. Yes?—I think it very good.

266. You referred to the trade being seasonal, and to the men as being a migratory class?—Certainly the change ought to do him good if it is good employment.

267. So that the fact that the trade is seasonal is a little safeguard? Yes. That had not occurred to me; I think that that may influence it.

268. You mentioned the rush of trade and working overtime?—Yes.

269. You think that that is a considerable cause?—In the presence of dust.

270. Only in the presence of dust? Yes, or getting the hands specially contaminated.

271. That could be remedied by frequently washing, I suppose?—The contamination of the hands?

272. Yes?—Well, they would soon get them dirty again.

273. Have you any suggestion to make with regard to the possible cleanliness of the painter, and as to how that could be enforced, assuming that an employer was desirous of meeting every requirement and provided towels and hot water?—My feeling about that always is this, that unless you can go to the fountain head of the mischief—the dust—and stop that you are not going to secure much improvement by all the personal cleanliness in the world.

274. So it comes to this, that unless the dust can be stopped, it is not much use doing anything else?—That is my feeling exactly.

275. (Mr. Parsonage.) With regard to painters following other occupations in what is called the slack season, does that obtain to such an extent that it would be of any value to consider it?—I should have thought it did; but I am not sufficiently familiar with the ins and outs of the trade.

276. In my experience as a painter for 30 years, I do not think it would apply to one in 500 of painters. I am referring to men who learn painting as a skilled trade and who are brought up to the trade of a painter. Unfortunately there are men brought into it who are not skilled, and those men in my opinion contract lead poisoning because they are not aware of the danger of the work which they are put to?—That is profoundly important.

277. But skilled painters, those who have served an apprenticeship to the trade, do not follow any other occupation even in the slack time?—My colleague, Dr. Collis, has brought out the fact that attacks of lead poisoning are commonest in the first and second years of employment, and it would be amongst those who newly came in, especially if they were ignorant of the care that is necessary, that you would get most of the reported attacks.

278. You mentioned certain towns where it was most prevalent. I have been taking out statistics with reference to cases that we take up for compensation. I place London first and Manchester second. You gave Manchester as third I think?—Yes.

279. Taking the whole of England, in London and Lancashire we get far more lead poisoning cases there than anywhere else?—That is probably because the population is greatest.

280. And in London particularly, because more white lead work is done there than in any other town, and also the preparation of work between coats is mainly done by glass-paperying or sand-paperying, as

22 February 1911.]

Mr. T. M. LEGGE, M.D.

[Continued.]

you term it. Would you not really place that as the first cause—the preparation of work between coats, the dry rubbing with sand-paper?—Yes, I thought I did do so.

281. You placed it third. I would place it first?—I should be quite ready to admit that I was wrong.

282. With regard to the mixing of white lead, it is not the mixing of dry white lead. The white lead is already moist when it is mixed?—That may be so, but it used not to be so.

283. It is so now. In not one of a hundred cases would they mix the dry white lead in ordinary work. It is already moist, so that there would not be the lust from that that there is from the other? No.

284. With regard to the certifying surgeons examining the house-painters, are instructions issued to each certifying surgeon that he must examine a house-painter for lead poisoning?—No. We do not control the house-painting trade at all. It would require special legislation.

285. Is it compulsory on the certifying surgeon under the Factory Act to examine house-painters?—No.

286. He can refuse to do so?—Do you mean for workmen's compensation?

287. Yes?—He is bound under the Workmen's Compensation Act to examine, but unfortunately it is a very complicated Act, and some certifying surgeons have not studied the Act, and, because a house-painter has come and he is not under the Factory Act, they have told him erroneously that as he had nothing to do with the Factory Act they could not see him. Whenever such a case comes to the knowledge of the Home Office they write at once to the certifying surgeon to tell him that his duties do apply to house-painters.

288. I had one particular case in which we had certificates from three doctors certifying that the man was suffering from lead poisoning. We sent him to the certifying surgeon, who absolutely refused to examine him. I had to write to the Home Office for instructions to be sent to him. That caused a delay of eight weeks. When he examined our member after that, he certified him as not suffering from lead poisoning, and the man got no compensation, although we had three certificates previously?—With the introduction of a new Act, you have hardships and stupidities.

289. Would it be possible for a list of certifying surgeons to be supplied to persons like myself who are taking up these cases and continually dealing with them? We find a difficulty in getting the certifying surgeons' addresses in many places?—Yes. I think such a printed list has just been prepared, and, no doubt, by writing to the Home Office, you can get one.

290. I have written, and I was informed that one will be prepared. Now with reference to painters reporting themselves as suffering from lead poisoning and claiming compensation, do you think that the fact that insurance companies are discriminating, when a man has received compensation, is now operating to prevent men claiming compensation and reporting themselves?—No, I should not have thought that that was sufficiently widely known.

291. Insurance companies are now refusing to re-insure men who have claimed compensation for lead poisoning?—Then the burden of compensation will fall directly on the occupier. Do you mean that he will not employ such men?

292. It prevents the man getting employment, and for that reason the man prefers to take the ordinary sick benefit to claiming compensation, because he knows that to claim compensation against his employer means that he will not get a job in the shop again. The insurance companies are issuing notices to the effect of what I have stated?—I do not think that has operated so far. The statistics I have given you are not complete.

293. Would you advise compulsory notification of all cases in house-painting?—I think it is certainly worth considering.

294. It should be so?—I think it is a useful provision.

295. (Chairman.) You mean notification by ordinary medical practitioners?—Yes, in the same way as lead poisoning in a factory or workshop is reportable.

296. (Mr. Parsonage.) With regard to the difference in the number of coats when using lithopone or oxide of zinc preparations, the technical information is very nearly correct, as far as I can gather. It is about as exact a proportion as it could be?—Yes.

297. (Mr. Gardner.) With regard to these 387 deaths you quoted during 10 years, are they plumbers and painters combined or purely painters?—Plumbers and painters, but I gave you the proportions. It is rather remarkable that so far as the deaths are concerned the incidence seems rather higher on plumbers than on painters.

298. Are those who are returned as painters all men employed as house-painters, or do any work in ship-yards, do you know?—No; ship-building is under quite a different heading. I classify ship-building under a separate heading of its own.

299. All lead poisoning cases in shipyards are put in an entirely different statement?—Yes.

300. But with regard to many of these certificates which you get from a registrar, the man simply says he is a painter. He will not say ship-painter. These are all taken into your forms for painters?—Yes, but I do not know that I should quite agree that the registrar would not say "ship-painter."

301. There is no difference between a ship-painter and a house-painter. One man may say he is a ship-painter, but only one in a thousand may say it. The industry is the same all through, although the men work in shops in one case and in ship-yards in the other, except the man who works as a red-leader?—Even if ship-painters were in this table, the number of deaths among painters would not be so large as to indicate much error in the figures of reported cases.

302. You are of opinion that the danger from white lead is due to the dust from sand-papering work and dust from paint which has dried on the overalls, and which cracks up and gets into the atmosphere, the dust being absorbed through the mouth?—Yes.

303. You do not think that paint getting on the hands under the nails or into a cut creates lead poisoning? It may create blood poisoning apart from lead?—Yes, except with regard to its getting on to the food.

304. What do you say with regard to the use of spraying machines for putting paint on? Would, not these be very dangerous machines?—Extremely dangerous.

305. Extremely dangerous for applying white lead paint?—I cannot conceive anything more dangerous. My colleague investigated the use of such an apparatus in railway carriage works in Lancashire. I think it was given up.

306. I am sorry to say that it has not been given up everywhere. Among the 387 you include every case in which lead is put in as a subsidiary or indirect cause of death?—Yes.

307. You take them all?—I take them all.

308. You say it has been found that plumbism affects house-painters more in the first and second years of their employment?—That was based on the examination of a large number of these reports.

309. In that case it would affect in the north of the country lads from 14 to 17 years of age. Have you any knowledge of the ages?—Yes, the ages are given.

310. Can you say if that is borne out?—No, I should not have said that it was so. Mind you, everybody who works in lead is not going to get lead poisoning. It all depends on the dust.

311. You will find that in the second or third year's employment, because we deal largely with the apprenticeship system, boys are very largely employed in doing sand-papering, the polishing between coats, and these would be lads whom you would think would suffer most from the trouble?—But are you certain that lead enters into the paint that they sand-paper, or that it is not much diluted?

22 February 1911.]

Mr. T. M. LEDGE, M.D.

[Continued.]

312. All the paint has white lead as a ground except dark paint?—If they were sand-papering a paint that contained 10 or 15 per cent. of white lead in the base, I should not anticipate anything like the same amount of poisoning from sand-papering as I should if it contained 75 per cent., because of dilution.

313. Have any females been certified as suffering from white lead in the painting industry?—Only in perambulator works, I think. They are employed a little there.

314. (*Dr. Collis.*) On the question of the ship-painter and the possibility of the ship-painter being included as a house-painter, a ship-painter would be under the Factory and Workshop Act, and we should get information in the Department?—Yes.

315. (*Lord Henry Bentinck.*) Are you prepared to give the Committee an opinion about how far the wet process of rubbing down is possible in house-painting?—No, I am afraid I cannot.

316. There has been introduced lately some substitute for turpentine, has there not, called "Russian turpentine"?—Yes.

317. What is the effect of that substitute; is it injurious to health?—We have had cases of eczematous conditions produced on the hands, and I should anticipate that they would occur.

318. It is not so healthy a material as turpentine?—No.

319. It is cheaper?—It is cheaper.

320. Is zinc sulphide the same thing as what they call "zinc white"?—No, zinc white is zinc oxide.

321. Zinc white used to be used in the trade some years ago?—Zinc white very often now means a mixture of zinc oxide and zinc sulphide. They are both white. Zinc sulphide is a white colour.

322. That is a substitute for lead?—Yes. Zinc white is a wider term.

323. Why was it abandoned?—Because zinc sulphide was found to be better, and, combined with zinc oxide, better still.

324. (*Mr. Sutherland.*) More body?—More body.

325. (*Lord Henry Bentinck.*) Zinc sulphide was in use some time ago, was it not?—Not to the same extent, I think.

326. (*Mr. Sutherland.*) Would not anything that tended to encourage the men to clean habits be a good thing?—Undoubtedly.

327. Have you examined many painters' workshops?—A good many.

328. What condition are they in?—There is usually too much paint.

329. And are they dirty on the whole?—Yes, they are.

330. Very dirty on the whole?—Yes.

331. What lavatory accommodation is there?—Very little.

332. Not even basins?—Practically none; merely a tap over a sink.

333. It would be a good thing if there were soft soap and basins, and baths even?—Yes. I think that those are all admirable from the general point of view, but I doubt whether they will do much to stop lead poisoning.

334. If a man mixes his paint in a shop, should not he wash his hands before his meals?—He gets his injury from the dust in doing that mixing, and it will not stop his getting lead poisoning to go off and wash his hands. It is a good thing for him generally to wash his hands, I quite admit.

335. It has been suggested to me that it would be a good thing if every chargineman in charge of a gang of men were to carry a bucket and soft soap, so that men might wash their hands before they had their meals?—If they are using paint and getting it on their hands, I am entirely with you there.

336. Do you think that it would be possible to carry that out and enforce it?—Yes, I think it would.

337. Overalls are at present supplied by the men, are they not?—Yes.

338. In Germany they are supplied by the masters?—Under all our factory regulations they are supplied in nearly every instance by the employer. Personally, I do not see why the workman should not provide his own overalls. He will take more care of them.

339. Yes, but if they are the men's the master cannot see that the overalls are clean, but if they are his own, he will see that they are clean?—Yes, that is a point. Overalls again may be a source of danger from the dust given off.

340. If they are clean there is not that danger?—No. I should advocate some washable material, some impervious material, or waterproof material that could be sponged—an apron, for instance, over the overall, which would take most of the paint.

341. In the German regulations there is one to prevent scraping and chipping off before moistening. Would such a rule be possible in England?—Yes, I think so. That would be a wet method.

342. Could not mixing in shops be done under an exhaust process?—You would want power for your fan.

343. They have no power?—No.

The witness withdraw.

Captain I. S. FLATAU and Mr. FRED H. MILNES examined.

344. *Chairman (to Captain Flatau).* You are attending to-day as a representative of the Rabok Manufacturing Company, of Sheffield?—Yes.

345. What is your speciality?—We make a carbon paint only.

346. Is that intended to be used as a substitute for the lead base of paints used by house-painters?—Yes.

347. Have you brought a sample of your paint with you?—Yes, we have a small sample with us of the material from which it is composed.

348. What is the composition of your paint?—We have a flaked graphite from Ceylon, and you cannot grind it in a common grinder; therefore we ball-roll it into a flour; and we have the purest hydrocarbon, from which we make an oil that we suspend the paint in, which is a substitute for linseed oil. Those are the component parts of the paint. Therefore, it would be a high grade graphite with a very pure plumbago suspended in hydrocarbon oil instead of linseed.

349. Is it then entirely non-poisonous?—Perfectly so.

350. Have you brought with you specimens of surfaces painted with Rabok paint?—Yes.

351. Will you show them to us?—Yes. (*Samples were produced.*) I also brought some Government tests to show its not being destroyed by the strongest

acids. That is a piece of steel painted with this paint, and then subjected to 20 per cent. of sulphuric acid for 400 hours. It destroys the steel, but does not hurt the paint. To prove that the paint is very elastic, the hydrogen gas blows that paint into those little balloons, and does not burst them. Here are some boxes of paint (*some boxes were produced*). I have been trying to do this for a long time, and I think I have done it. There is a hydrocarbon that we make that we convert into an oil, which is as durable as the pigment, or the substance of the paint. Other paints only live the life of the linseed oil. That is their life. Oil made from 99 per cent. pure hydrocarbon has almost as long a life as the pigment. The pigment of plumbago and pulverised flake graphite is as durable as time. It floats on water. It is 99 per cent. pure.

352. Do you make white paint?—No, we do not make white colours. But that is a primer over which white colours made from non-poisonous whites may be applied without the least danger of discolouration. It is a good paint; it will stick to the skin, and any paint that will do that will stick to paint.

353. Can it be used in a similar manner to ordinary lead paints?—Yes.

354. How does the cost compare with that of an ordinary lead paint?—Half the price.

22 February 1911.]

Mr. FRED H. MILNES and Captain L. S. FLATAU.

[Continued.]

355. Does the paint deteriorate when stored for any length of time?—We have had it under test by the American Government, in the Navy and in the Army, and we have watched it closely for seven years. Where it has been painted for four years and a half it looks to-day like it did 60 days after it was applied; therefore the American Government has adopted it, because salt water has no effect upon it, barnacles will not adhere to it, and no sea moss will gather on it. It was designed by me for the Navy for gun carriages for coast defence and all steel structure works exposed to the salt atmosphere. Nothing will destroy it.

356. What is its covering capacity as compared with a lead paint?—It covers the same quantity depending on the gravity. If you wanted to put a coat of paint on and only used one coat that should be heavy. It would cover the same amount of squares that red lead would cover, which is 500 squares to the gallon. The gallon weighs 9 lbs., and if you put the paint on as it should go on it will cover from 600 to 700 squares per gallon.

357. What do you call a square?—10 feet every way is a painter's square—10 by 10.

358. Does it retain its colour for a length of time unchanged?—The natural Rakok paint is a dark steel grey, and we colour it a maroon and an olive green, which are the standard colours in our country for painting bridges and boats and all structural work. It is not supposed to be a fancy paint, but you can rub your piece of paint so bright that you can see your face in it. It is a fine surface for finishing bodies like coach bodies and automobile bodies—anything where you would like the surface just like glass without having varnish, and so on. That will do it.

359. Is it a suitable base for mixing with the pigments or colouring ingredients in common use by painters?—Yes. They can colour that any colour they want, but it would be detrimental to this paint to mix common oxides or leads with it. It has a sort of a nature of its own, you know, and it doesn't like to have anything to do with any other kind of paint. If you understand that paint as it is composed, if you put lead in it, it would become a lead paint. If you put common English oxides in it, it would soon be nothing but an oxide paint; but as it is, it is a metallic paint.

360. Can it be used with the same vehicles and thinners as the painter would use for ordinary lead paint?—Yes. There are no instructions at all, except to keep it agitated while applying, because the pigment is very heavy and does not stay in suspension very well. Therefore, in stirring it, you apply the substance on the parts to be painted, and the colour just appears on top and floats. If you put oxide in it, the oxide will float and give it the colour, yet this pigment is underneath it. So with the olive green.

361. Is it supplied in powder form?—No; we supply it ready for the brush—ready to be put on.

362. It is of the utmost importance for our present inquiry to ascertain the durability of the various available substitutes for white lead; first, as regards interior decoration, and, secondly, as regards exterior decoration; that is to say, on surfaces exposed to all weathers. Will you please give us particulars of a few buildings where your paints have been used, first, for internal decoration?—We have a catalogue here (*producing the same*). We do not think that you can destroy it outside by any process. No climatic conditions would have any effect on it whatever; no acids, no gases, no fumes from any source, and, of course, inside, the very building and roof, the enclosure, would protect it, and I think it would be perpetual almost.

363. Can you tell us a few particulars of buildings where your paint has been used, first for internal decoration?—Well, I would not say decoration. If they used the paint as they should use it, they would use it as a primer, which would stop all corrosion and adhere to the steel indefinitely, to which they might apply any beautifier they chose. Therefore it has been used in all the big packeries in America. They have never been able to find anything that would stand

the salts and fumes from the cattle. In packing houses this paint has proved perfect. That is indicated in one of the catalogues here, and in a letter from the biggest packer in the world—Armour.

364. Can you give us particulars of any buildings in England where your paints have been used, first for internal work?—(*Mr. Milnes.*) Tennant's Brewery, Sheffield.

365. For any other internal work?—One minor one in the London City and Midland Bank for damp-proof work, but that is a very small quantity. It has been as satisfactory as they wanted.

366. Have you used it very largely in America for internal work?—(*Captain Flatau.*) Not in America for internal work. It is mostly outer.

367. Do you assume that it is efficacious for internal work?—Yes, it is quite satisfactory.

368. But you have no proof of it?—(*Mr. Milnes.*) Not for inward application.—No. The Sheffield Corporation have it for outward application.

369. Can you tell us whether your paints were applied (I am speaking now of internal work) over former coats or priming coats of white lead, or not?—In the London City and Midland Bank, Bank Street, Sheffield, it was applied over the bare walls. The old paint, which had become damp and mouldy, was fetched off, and our man applied it practically direct to the bricks.

370. Can you give any other instance?—The Sheffield tramways. We have a testimonial in the latter part of these books.

371. Did you apply it over former coats?—That was applied in some cases over old coats and in some cases on absolutely new.

372. Will you now name a few buildings where your paints have been used for exteriors?—I refer you to the town clerk of Sheffield, who used it on his own private house, and the Sheffield Corporation applied it to the electric standards, near the gasworks and elsewhere. It has been most satisfactory, and beyond others, and they have adopted it for the whole of their electric standards throughout the city. You will find a testimonial in the book.

373. Are there any other buildings where it has been used externally?—(*Captain Flatau.*) They are so numerous that I hardly know how to tell you.

374. Tell us two or three?—(*Captain Flatau.*) One of the largest buildings in St. Louis is the American Tobacco Company, I suppose. It is one of the largest concerns, too, in America. They use it throughout their entire place everywhere, internally and externally, and they have it internally applied to cover the vats that hold the mixture that goes into tobacco. The mixture will destroy copper, and they paint the vats with the paint to preserve the copper. That is very strange, you know. We claim that it is far superior to galvanising iron. Galvanised iron is expensive and it is deceiving. Galvanised iron is always the commonest iron they roll in the mills, and they cover up the little bad places by galvanising. They buy good straight clean black iron and paint it with this paint, and we guarantee it that it will outlast any galvanising.

375. What other buildings besides that at St. Louis can you name?—The next greatest building we have and the greatest company in St. Louis are the Union Electric Light Company. They generate the heat, light, and power for St. Louis. They use it internally.

376. And externally?—Yes, and externally.

377. On what dates were these exteriors painted?—(*Mr. Milnes.*) With regard to the Sheffield Corporation, twelve months ago, I should say. They have used it since. (*Captain Flatau.*) The places I named were painted some five years ago.

378. It is quite satisfactory now?—Oh, yes. It has been tested by the Navy. We have that report here. It was declared to be far superior to lead, and stood in their torpedo boats where lead or white lead would not stand.

379. Now, speaking of the external painting, were your paints applied over former coats or priming coats of white lead, or what?—We generally advise those who are going to use them for a test to sandblast the

22 February 1911.]

Mr. FRED H. MILNES and Captain L. S. FLATAU,

[Continued.]

work and get all foreign matter off the material to be painted. But where you scrape down with a steel brush red lead or white lead; and that which adheres has not set up corrosion beneath it, it is pretty apt to be a fixture, and we apply the paints over it. We do not ask anything more than just what is done with other paints.

380. To sum up, then, so far as your experience goes, do you assert that you have found your paints to be efficient substitutes for ordinary lead paints?—Yes. We claim no equality. We claim double superiority and absolute non-poisonousness. I have worked 18 years to accomplish that. We have no patience with white lead or red lead at all, none in the world. It is very expensive. All the great gasometers in St. Louis and in Denver, Colorado, and other places could not give up red lead. Your Government and every other government knows that red lead has been the best paint that was ever applied upon anything. It has never met its Waterloo unless it has met it in this liquid carbon of ours. Now all chemists know that the life of red lead is about two years and a half or three years, and its life would be ten years, but at the expiration of two years if you examined it with a microscope you would find that it had become porous and was admitting oxygen, which sets up fire and sets up corrosion. Then it must be scraped and painted again. But they have found after four years' experience with these gasometers that this is the way to paint them. They are the hardest things in the world to maintain with paint on them, rising and falling as they do in that gassy water, and when they give them a rub with red lead and let it dry and then give them a coat of this non-porous paint, no pores ever form; the red lead adheres well. They feel satisfied after long experience with red lead that that is the stuff, and this will keep it from becoming porous, and they declare now that that is the way to paint a gasometer.

381. Have you used the paints for any other buildings in America, New York or Washington or Chicago, for instance?—Yes, in Chicago.

382. We do not want any particulars. Have you used it in New York too?—In New York, and in many countries in South America, in China and in Japan, and almost every foreign country. I am here to-day. I have been in Sheffield, where we have just finished a plant. I go from here to Naples, Italy, to put in a plant for an Italian company. I go from there to Paris, France, to put one in for a Paris company; and I go from there to Berlin to put in one for a Berlin company, because of their personal knowledge of its superiority over anything they ever experienced or could inquire about in the way of paint. It is not only a good paint, but it is the best paint to-day in the United States or any other country, and you can make 50 barrels a day of that paint with the machinery I have furnished, with one man and a helper.

383. (Mr. Sutherland.) In what way does it differ from ordinary graphite paint?—Ordinary graphite paint is sold to you from many places. It is very common, and it is more or less full of dust and impurities, but I am sure the finest lubricant we have and the finest graphite is the flake. It is in flake, and looks like isinglass. So that graphite is formed from the flake, which is ball-rolled in a ball mill to flour it, and the plumbago that is in there is just as pure as Ceylon can afford. This is graphite too, if you please, but that is not the secret of that paint. Those two pigments are imperishable, non-destructible by fire or any other process ever known to the chemical world. You cannot destroy them.

384. Is the secret in the vehicle?—The secret is in the amalgamation and the formation of the oil from the pure hydrocarbon.

385. What makes it so coarse?—The graphite. It is hard to pulverise, and it is better coarse than smooth.

(Mr. Milnes.) We have it much smoother than that.

386. (Mr. Rice.) If used as a priming coat, would it be necessary to rub it down, and would there be any dust coming from it?—(Captain Flatau.) Yes, if you

had a piece of sand-paper you could rub it, and the oil that floats is rubbed away.

387. Will it produce a dust?—Not enough for you to detect it. It packs. But you do not have to do that. If you wanted paint to adhere nicely, you would like it to penetrate the wood. A penetrative paint adheres and penetrates the wood, and hangs with millions of little pointers, if you understand, in porous wood. You ought to have a penetrative paint for a priming coat. Then you would put on the next coat and the next coat. That put on as a primer adheres and penetrates the wood. It leaves a rather rough surface, and the coat of finish that you put over that would fill the little pits, the little roughnesses, and it would hang better, and the next coat would finish it without any rubbing down.

388. (Mr. Parsonage.) This would not apply to indoor painting at all for finishing?—No, unless you wanted to rub down and varnish.

389. It is useless for indoor work. If that door (indicating a white painted door) had to be re-painted, would it be advantageous to give it a coat of this material?—If I wanted to finish the door as it should be finished with the highest finish, I would burn everything off the door and rub it down with sand-paper.

390. That is the point I wanted to get at?—I would give it three coats of Rabok paint, and the other process is the same as in finishing a coach or anything. I would rub it down till it appeared just like a brass finish, and you could see your face in it. Then I would give it any colour you like it to have, or any transfers that you liked to have. And then I would give it two coats of varnish.

391. It would cost a good deal?—Just half what any other would cost. It would not take three or four days to dry.

392. How many coats of white paint would it require to cover with that material?—One, and not the least discoloration. It has no effect on other paint at all, except to hold it on.

393. (Mr. Robins.) I can hardly conceive, as a coach-painter, that you could put one coat of white on that graphite to make a cover. You have the surface black to start with. I speak from experience?—You will understand, if you know anything about painting, that I would not profess to attempt to make a finishing job with white zinc or any other white colour over a dark. In putting on the priming coat you put on lead and oil with a little lampblack in it. You would lead it up first.

394. Do you say that one coat of white would do: To put one coat of white on that surface would not cover at all? I do not mean that that would finish. It would cover it and not discolour. You would put two or three more coats on to get a fine finish.

395. But a white is a white; it is not partially white?—No.

396. It would require three or four coats before it was white?—No. The second coat would be a perfect snow white, just as white as the door.

397. After my 30 years' or more experience, I am surprised?—There is a piece. We have brought that here for you to have (producing a specimen). The proof of the pudding is eating it, and if you take that dark piece or any piece, and take a white-lead brush and stroke over it white lead or any other whitening or zinc, if the white is not too thin it will cover. You will not see any dark beneath it at all. It would not be a good job without another coat. We do not put that paint up as a fancy paint. That paint was intended as a primer, or for the preservation of great structural work, railroads, bridges, and cars, and steel, and we have exposed it to fire. It will not burn. If you were to hold a match to that piece it would burn, but take a wooden railroad bridge, where the cinders fall out of the engine, and burn up the bridges, if you paint up the tops of the bents and stringers with that paint you can go there and build a fire on it if you want to, and it will not catch fire. It is a fire shield. If you paint a shingle roof with it, it will stop it from leaking. It looks like a slate roof. You cannot set-it

22 February 1911.]

Mr. FRED H. MILNES and Captain Mr. L. S. PLATAU.

[Continued.]

on fire with coal unless you go there and tear up the shingles and build a fire where there is no paint.

398. (Chairman.) Have you had experience in using your paint and then finishing it off with white paint?—Yes.

399. How many coats have you generally used on those occasions?—Two coats.

400. Would the cost of the original painting, plus the two coats of white paint, be as cheap as doing it in the ordinary way with white paint?—It would be cheaper. It would be a heap cheaper than three coats of white paint.

401. (Mr. Robins.) I can see one advantage with regard to it, and that is, that it would prevent the use of white lead. That is the most beneficial thing we have had to consider with regard to anything of this kind?—(Captain Platau.) I have some very fine letters in my pocket from the best men in America, including the Secretary of State, and several Congressmen and Senators and Attorney-Generals and Governors, and they would back me up in what I am about to say, if you please. I have worked for 20 years to get a substitute, and you know as well as I do, speaking from the painter's standpoint, that there never was a painter of any good or any intelligence that had not

hoped some day to be able to invent a substitute for linseed oil, and you know as well that at an early date when they made white lead, and made it honestly, it was like tanned Russian leather, and when you got it out of the tan bark it was pretty good stuff, but it is very bad now. It is very poisonous. Instead of being made in seven weeks or months, it is made in seven days or seven hours. It is not white lead; it is destroyed. I have worked for 20 years to try to get a substitute for linseed oil to beat lead paint. Well, I think I have done it. With regard to my experience, I have been in seven or eight paint factories, and I have been in the paint business for about 18 years on my own account. Our success has been that Englishmen have thought we had a pretty good thing, and they have put their money into it, and so have the other countries I have mentioned. I am not here to sell Rabok paint. All the interest I have to-day is this: that this Committee should see fit to make a close examination and criticism of it in every way. The best old judge of paint is time. They have plenty of the paint in Sheffield, and it is just as free to you as the water—two barrels—any amount you want. Put it anywhere you want, under the most scrutinising critics, and if it does not stand the music, why, I will take a buck seat.

The witnesses withdrew.

Mr. C. H. BYWATERS examined.

402. (Chairman.) You attend to-day as a representative of the Granitic Paint Company, of Barking, London?—Yes.

403. What paints do you manufacture?—The Astrium paint we manufacture principally, a paint that was originally suggested by Sir Henry Tanner.

404. Do you manufacture other paints?—Yes. We have an enamel paint, Rystolite, and we also supply general paints to builders.

405. Are the Astrium paints intended to be used as substitutes for the lead base of paints used by house painters?—Yes.

406. What is the composition of your paints?—The base of the paints is zinc oxide.

407. Is no white lead used in any of them?—No, no white lead at all; they are absolutely free from white lead.

408. Is no poisonous ingredient used?—There are other lead compounds.

409. What are they?—Mostly the oxides to a very small extent, and the chromates of lead.

410. That is for colouring?—The oxides are used for drying purposes, and the chromates are used for colouring purposes.

411. What are the colours in which they are used?—The chromates are yellow, and they form the greens as well. There is only a limited demand for yellow paints.

412. Could the use of chromate of lead not be dispensed with?—We could dispense with that entirely, I think.

413. Have you brought with you specimens of surfaces painted with Astrium paint?—Yes. (Some specimens were produced.) They were special tints of Astrium paints, if I may say so, made for the Government Labour Exchanges.

414. Can they be used in a similar manner to ordinary lead paint?—Yes.

415. How does the cost compare with that of ordinary lead paint?—As a rule, the zinc paints are five to ten per cent. cheaper. To-day there is not very much difference, but they are a shade cheaper. That is due to the present high prices of the linseed oil.

416. Does the paint deteriorate when stored for any length of time?—No; it keeps quite well.

417. What is its covering capacity compared with lead paint?—Do I understand that you mean the area?

418. Yes, the area which a given amount will cover?—Bulk for bulk it would be the same.

419. Does it retain its colour for a length of time unchanged?—Yes. It is better than white lead in

that respect because the atmosphere of the towns has no chemical action on it, or not the same action. In towns and manufacturing districts, the sulphurous gas in the atmosphere has a chemical effect on the paints. On the white lead it forms sulphides. Lead sulphides are black. On the zinc oxide it also forms sulphides—not so readily, perhaps—but those are white, so it does not discolour white paint.

420. Is it a suitable base for mixing with the pigments or colouring ingredients in common use by painters?—Yes, I think it is more general than white lead. It will mix with every colour, I should think.

421. Can it be used with the same vehicles and thinners as a painter would use for ordinary lead paint?—Yes. There is a slight variation with regard to the oil. The oil is treated a little differently. That is the only thing. It is the same oil.

422. What is its durability with regard to interior painting?—Apart from losing its colour, do you mean?

423. Yes, its lasting power?—It is quite as good. It will stand as well as white lead. I do not see any difference. In fact, the chemicals in the atmosphere would not act on it, as they will act on white lead.

424. Will you give us a few particulars of buildings where your paints have been used?—Yes. In this building it has been used.

425. For internal decoration?—For internal decoration it was used here about three years ago, on the second or third floor; I could not tell you which till I saw it. It is at the end of the corridor running parallel with Charles Street, I think.

426. That was three years ago?—About three years ago.

427. Have you inspected it since?—No, I have not seen it since. I only thought of it this morning.

428. In what other places have you used the paint internally?—Practically all the Labour Exchanges, and there have been some 250 of those. In most Government buildings it has been used to some extent, and at the new General Post Office, that huge building in the City. Astrium and Rystolite are practically made in the same manner. Some 4,000 gallons were used there under Sir Henry Tanner's instructions.

429. You are speaking of internal painting?—In all these places it was internally and externally used, and in some of the museums in London.

430. What test have you given this paint with regard to internal painting?—Only length of time. It has had four years.

431. Have you examined the places which you painted four years ago?—It was not used in a practical way four years ago, but three years ago it was. We

22 February 1911.]

Mr. C. H. BYWATERS.

[Continued.]

used it ourselves in our own works and painted doors and so on, and watched it.

432. Do people who have used the paint tell you that it is entirely satisfactory?—We have been told that it has been satisfactory, but paint manufacturers do not hear when paint is satisfactory; they generally only hear complaints, and we have had few. When we first brought out the paint we did receive certain complaints, due chiefly to its not drying sufficiently quickly for some of the purposes for which it was used. It was easy to accelerate the drying, and such complaints do not now reach us.

433. Have you had such satisfactory results that people have recommended you?—Yes.

434. Have you any specific case of that to tell us?—It has been used for the War Department, and they have recommended it to the different Division Officers and different surveyors, and one has used it after the other. It was originally used at Kingston Barracks.

435. Will you send us a list of places that you have supplied it to for Government purposes?—It is difficult to do that. We supply the contractors for the Government, and not the Government direct, and we seldom know where it has actually been used.

436. You have made certain statements this afternoon which would lead us to believe that you know where it was used?—We do know in certain cases. It was used in this building as I have said, and at the Post Office I have seen it.

437. You have given us other illustrations which could only convey one meaning, and that is that it has been used there?—Yes, but the buildings are so huge that I could not point out the paint to you where it has been used in them. That is what I mean.

438. How do you know it has been used?—The Office of Works told us so.

439. Would you give us a list of places, which the Office of Works have told you it has been used in?—I can give you a list. It will not be complete. In the Labour Exchanges I know it has been used exclusively.

440. Your evidence will not be of much use to us unless we can have specific information as to where it has been applied?—I can give you that in many cases. In all the Labour Exchanges throughout the country it has been used.

441. We shall have to have some places other than those. We should like to have the dates when the painting took place, so that when we care to we can examine and see how we think it has lasted. Can you tell us whether your paints were applied over former coats or priming coats of white lead or not?—When it has been new work with regard to woodwork they have generally had a priming coat of lead first. That is not supplied by us. Before the joinery leaves the works it is generally done with a very thin coat. On plaster work no priming has been put on, and our paint has been put on direct.

442. You might let us know, in the information which you supply us with, the places that you have painted externally as well as internally, and the dates when the painting took place, so that we can judge as to its durability. Then, to sum up your evidence, do you assert that, so far as your experience goes, you have found your paints to be efficient substitutes for ordinary lead paints?—Yes; they are free from white lead, and I think that we can make them free from lead of every kind.

443. (Mr. Fell.) Have you tried this paint at all on vehicles?—No, we have not supplied carriage builders at all with it.

444. (Mr. Sutherland.) It is quite modern, is it not—quite a new invention? How long have you had it?—This particular paint only goes back four years, but we have been making zinc oxide paints for many years.

445. (Mr. Rice.) You say in this little book which has been handed to us, "His Majesty's Government has been for some time desirous of discontinuing the use of white lead on account of the danger to the health of those employed in its manufacture and use." Did you design your paint to meet this requirement?—Yes, on the suggestion from the Office of Works we made this particular paint.

446. On their suggestion?—On their suggestion.

447. And they tried it before they used it?—Yes; they experimented for about a year with it.

448. Have you any chemical expert's evidence that it absolutely fulfils this condition?—Yes; and their own chemists at the Office of Works have tested it.

449. You have not a chemist of your own like Sir Boverton Redwood to give an opinion?—No, but we know what is in the materials that we put in that paint.

450. We do not, and I want to know whether any chemical expert says that it fulfils this condition?—No, but we know that it does. The Office of Works check us; they draw samples from time to time. We make this paint under guarantee to the Office of Works, really.

451. (Mr. Gardner.) You do not supply this in paste form at all?—No. It is ready mixed for use.

452. If the painter wants to alter the tint it can be tinted with the ordinary pigments?—Yes.

453. Your paint is no use for filling purposes?—No. We should supply the zinc oxide for that purpose.

454. When you say that this was supplied for the Labour Exchanges exclusively, do you mean to say that every Labour Exchange throughout the country was painted with your paint?—Yes, and the tints were specially got up.

455. Specially for the contractors who had Labour Exchanges to paint?—Yes.

456. (Mr. Parsonage.) Was that specified by the Government?—It was specified by the Government—those particular tints.

457. If it is supplied ready mixed, how long will it keep without requiring thinners?—It does not require thinners as a rule. It becomes thick sometimes.

458. A sediment?—No, there is no sediment, but it becomes thick.

459. Is that the fat?—Hardly fat. It can be got over by the addition of linseed oil—a spoonful or two.

460. Coat for coat, will it cover like lead paint?—Yes. You are speaking of the area.

461. What do you say about the body?—The body is practically the same.

462. Three coats of this will be equal to white lead paint for finishing and for body?—Yes.

463. (Dr. Collis.) Do you think that you could get rid of the chromates of lead for producing yellow colours?—Yes.

464. By using chromate of zinc?—Yes.

465. Would it increase the cost appreciably?—Not appreciably. The yellows we supply are very pale colours.

466. If you wanted to obtain a deep yellow would it be more expensive than?—Yes, for deep yellows it would be. The white Astrium paint is absolutely leadless. It contains no lead of any kind.

467. (Lord Henry Bontinck.) Was the suggestion of the Board of Works, with regard to experimenting, made to your firm alone?—I expect they asked other manufacturers. I expect our paint was tested against that of other manufacturers. There were three or four, I know, because I saw the samples. I do not say that they use our paint exclusively. Do not let me mislead you.

468. Not for the Labour Exchanges?—Yes, for the Labour Exchanges they are used exclusively, but for other work they are not.

469. (Chairman.) When giving us the list of places you have painted internally and externally, will you tell us specifically those which you have painted with white paint?—It is more the toned whites.

470. (Mr. Parsonage.) It would be white used in this building, would it not?—No; it was stone colour used in this building; I think.

471. (Chairman.) Have you made no experiments with white paints in any building?—Yes; we have made the same experiments with white paint.

472. Have you used the white paint in any appreciable amount in any building you can mention?—Yes, one I can call to mind is the new General Post

22 February 1911.]

Mr. C. H. BYWATERS.

[Continued.]

Office, King Edward's Building. A vast amount was used there.

473. Was that internal or external?—Internal. I think outside it was not quite white.

474. Can you mention any place you have painted with your white paint externally?—I could not tell you from memory.

The witness withdrew.

Mr. A. F. HEYDORN examined.

478. (*Chairman.*) You are attending to-day as a representative of Ragsone & Co., Limited, Bow, London?—Yes.

479. Are you concerned in the manufacture of a non-poisonous paint?—Yes.

480. What is it called?—"Dixon's White."

481. Is it intended to be used as a substitute for the lead base of paints used by house-painters?—Yes.

482. What is the composition of your paint?—I am afraid I could not tell you the composition.

483. Is it entirely non-poisonous?—Entirely non-poisonous.

484. Have you brought with you specimens of surfaces painted with Dixon's White paint?—No, I have not, but I can produce them if required.

485. Will it answer all the same requirements as white lead?—Almost entirely. There are one or two requirements which I should not recommend it for.

486. Which are they?—For sign-writing, for instance, if thinned with turps.

487. Can it be used in a similar manner to ordinary lead paints?—Yes, absolutely.

488. How does the cost compare with that of ordinary lead paint?—The same cost as lead paint.

489. Does the paint deteriorate when stored for any length of time?—No; it has the same durability as white lead.

490. What is the covering capacity as compared with lead paint?—It has a greater covering capacity than lead paint.

491. In what sense are you now using the expression "covering capacity"?—I define covering capacity as spreading capacity and obliterating capacity. As far as spreading capacity goes, Dixon's White is undoubtedly far superior to white lead. It will go much further than white lead. As regards obliterating capacity it is equal if prepared properly.

492. What do you mean by obliterating capacity?—Opacity.

493. What do you say with regard to the tendency of the paint to chalking or flaking?—Dixon's White will not chalk or flake if prepared in the right way—that is, if thinned in the right way.

494. Please explain exactly what you mean by chalking?—I take it that from the point of view of a painter, chalking would mean that after a surface painted with Dixon's White was exposed for a number of months it would rub off. That is a term used in the trade, which I think those interested in the trade will understand better than those who are not.

495. What is the exact meaning of "flaking"?—To define it exactly I should say it is chipping off.

496. Do your non-poisonous paints retain their colour for a length of time without change?—My non-poisonous paint retains its colour considerably longer than white lead. It will not change colour at all within a certain number of years.

497. What have you to say as to the spreading capacity of zinc paints?—The spreading capacity of zinc paints is much superior to that of white lead paints.

498. Is it a suitable base for mixing with the pigments or colouring ingredients in common use with painters?—Yes.

499. Can it be used with the same vehicles and thinners as painters use for ordinary paint?—Yes, it can.

500. Can you tell us of any places where your paints have been used for internal decoration?—In practically every town in England, and many towns in Australia, Turkey, and Roumania.

475. Will you look it up?—I will look it up. It is difficult to know where the paints go to.

476. But that is the only test we can apply?—You see my difficulty—we supply the contractors.

477. But you can easily find out, if you are supplying contractors with this paint, where the contractors use it?—Yes, I can find out.

501. Can you give us any particulars of actual buildings where your paint has been used?—With the consent of my directors, I am prepared to supply a list of about 200 or 300 places where it has been used.

502. I will ask you to do that?—Our managing director not being in London at present, I shall have to get his consent to that, I think.

503. Can you tell us of a few buildings where your paint has been used for exteriors?—No, but I can obtain that information quite easily from our customers.

504. Perhaps you will ask your managing director if he will be kind enough to send us a list of those places, and also the dates when these interiors and exteriors were painted?—Yes.

505. Can you tell us whether your paints were applied over former coats or priming coats of white lead?—Yes, they were applied over former coats and priming coats.

506. Have you done any considerable amount of work in white painting?—Yes, principally white painting.

507. When you send us the list of places you will define those?—Yes. With regard to the nature of the work done, the material will require to be collected from the painters.

508. Does Dixon's White replace white lead for priming?—Yes. The thinners are always the same as in white lead, but we suggest a different proportion of thinners.

509. Do I understand that you can use your Dixon's White without any use of lead?—Yes, absolutely.

510. For priming or anything else?—Yes, excepting for the particular purpose I have just mentioned—that is, for sign-writing.

511. (*Mr. Sutherland.*) When you say that the spreading capacity is superior, you mean that you can spread a given amount over a larger surface?—Yes.

512. But the covering capacity is only equal to white lead?—Only equal to white lead.

513. So that practically the spreading capacity is a defect?—It is a defect in a sense.

514. Cannot that be modified in some way?—It would appear to be a defect, but really I do not think it is, because the non-poisonous pigment, being ground so very much finer than white lead, requires a thinner layer, if I may use that expression, to obliterate equally as well as white lead.

515. Do you mean to say that its covering capacity is greater than that of white lead?—If you take spreading and covering capacity together it is greater than white lead.

516. A pound of your material would really spread over a larger surface than a pound of white lead?—Yes.

517. But it would not give the density of white lead?—No, not the density.

518. So that to get the density we should have to go over it again or use it thicker?—To obtain the density you would have to use it thicker.

519. That practically brings it to the equivalent of white lead?—I quite agree.

520. You say that it does not chalk?—Yes.

521. Can you prove it?—Yes, I am prepared to prove it by testimonials from leading decorators.

522. It has a zinc base?—Yes.

523. I do not want to know the secret of it. Does it not chalk on outside work?—No. At first we had great difficulty with outside work, but during the last two years we have made it for outside use quite successfully. We have had experiments made by

22 February 1911.]

Mr. A. F. HEYDORN.

[Continued.]

decorators who have actually used it in many places for outside work with satisfactory results, and they are prepared to testify to it. If I may explain, the principal reason for that efficiency is, in my opinion, the medium which we use.

524. Do you send it out in paste form?—Yes, only in paste form—not dry. We make it up as paint if required.

525. You sell it in bulk—per hundredweight?—Yes.

526. Is it thinned with the normal thinners—turpentine and oil?—Yes, precisely, with the normal thinners.

527. (Mr. Rice.) Before you applied the second coat, would there be much dust in rubbing down?—No, not any more than with white lead. I am told by painters (I have no personal experience) that they think that less dust comes off it, and I have one letter to that effect to submit to the Committee if it will interest them.

528. There is less dust given off in rubbing down, you say?—Yes.

529. Is the dust that is given off at all injurious?—No.

530. Quite uninjurious?—Absolutely.

531. (Chairman.) You take it into consideration that all dust is injurious?—Yes, to a certain extent, of course.

532. But there is no poisonous matter at all in this, you mean?—No poisonous matter at all.

533. (Mr. Gardner.) Your paint is supplied in paste form?—Yes.

534. To be thinned up by the ordinary materials?—Yes.

535. Why do you not recommend your paint for sign-writing, because it would require to be diluted with turpentine? You dilute all paint with turpentine?—Yes, but a certain proportion of oil is required.

536. When writing a sign we mix our paint much in the same proportion as we do for ordinary paint. Your paint then is not much good for a flatted surface, is it?—We have supplied Dixon's White for writing names on railway trucks, and for that particular purpose they use it in a certain way. I am told that they thin it with turps. I understand for that purpose it is no use. We still have an inquiry pending as to the reasons for its being no use. I give you the information for what it is worth. We have not proved the case. It is the case of a big colliery owning many hundreds of trucks.

537. Does not that rather seem to point to the want of covering power in your material?—I should say not. My explanation would be that non-poisonous pigments of that particular nature require certain mediums. If a dry pigment is not properly enclosed, if it has not a proper film all round every molecule, it does not form an efficient paint. In that respect I believe that white lead is superior, because it has a very peculiar character—the character of absorbing or of being absorbed into the surface on which it is painted.

538. I am dealing with your paint from the standpoint of a man putting it on every day of the week. If it cannot be diluted with turpentine it would be no use for a flatted wall. You said in your examination in chief that your paint spread better than white lead, that it was of greater density and that it was more opaque than white lead. In answering Mr. Sutherland you said that it did not cover so well and that you required to put it on thicker to get the same body?—I think I defined covering capacity as spreading and obliterating capacity. I think I admitted to Mr. Sutherland that as far as obliterating capacity goes it is equal to white lead, and as far as spreading capacity is concerned it is better than white lead.

539. A pound of your paint would go further than a pound of white lead?—Yes.

540. And it would cover as well?—Yes.

541. That was not quite clear. You said that it would not cover so well?—It has not the same density

542. (Mr. Sutherland.) I asked you if it was equivalent to white lead and you said "Yes"?—Equivalent in obliterating capacity.

543. (Mr. Gardner.) Could you make a filler for filling up the roughnesses and inequalities out of your paint?—Yes; you could use it for flattening, as you term it, particularly for enamelling. That is one of its principal uses.

544. I do not follow you: You would seem to require to have it with turpentine for flattening?—It is used for that purpose.

545. (Mr. Parsonage.) You mix this with more linseed oil than with turpentine?—Yes.

546. How do you say that it is more suitable for enamel or varnish finish? To finish with enamel you want a flat surface, but you say that this is mixed more with linseed oil than with turpentine?—When I say that it has to be mixed more with linseed oil than with turpentine I am referring to a ready mixed paint as a finishing coat. If you have a flatted surface on which you want enamel, you can with equally good results thin it with turpentine.

547. I happen to know personally that this has been used and gives a better result, and answers the purpose for enamelling as well as, or equal to, white lead. Now with regard to using it for filling, how would you stiffen it up? What would you put into it? It is not sufficient for filling as it is?—I am afraid that I cannot give you that particular, but I am prepared to get you any particulars you like from customers.

548. It would spoil the usefulness of it if we had to mix it with lead or any poisonous substance for filling. Would it mix with whitening or something of the kind?—Yes, you could mix it with whitening, or with white lead, for that matter.

549. But we do not want to do that if it is to be non-poisonous. Would it rub down if you mixed it with whitening?—Yes.

550. It would require oiling over then?—Yes, I suppose so. You quite understand that I am a manufacturer; I am not a painter, and therefore I am quite prepared to submit to your superior knowledge as far as uses by painters are concerned.

551. (Chairman.) We want you to supply particulars of places you have painted, and the times at which you painted them, and to tell us, whether internally or externally, the colour of the paints you used, and whether your clients were satisfied?—Yes.

552. (Mr. Parsonage.) If this work had to be finished with varnish or enamel, would two coats of your paint answer the purpose better than any other?—The general opinion is that it does—I cannot say more—and we are constantly overcoming certain convictions in that way.

553. I am speaking from my own personal experience of the material?—I am prepared to agree with you.

554. For priming, your material would not answer the same purpose as white lead, but for finishing or enamel or varnish purposes it may be superior. Do you agree with that?—I do not agree with the first part of it. I do not say that it is not equal to white lead as a priming coat, but I say that I have heard it stated, I have repeatedly heard it said, that the best results are obtained by first having a coat of white lead.

555. (Mr. Sutherland.) And then finishing with this?—Yes, and then finishing with it. I also know many cases where painters say that the best results have been obtained by using nothing else but Dixon's White.

556. (Chairman.) You have rather a conflict of opinions?—We have all sorts, I am afraid. We have had to work our way up for the last six or seven years, and every year has meant a step towards perfection.

557. Did your firm introduce this paint for humanitarian purposes, or was it entirely a matter of business?—It was entirely a matter of business.

558. Because you thought that it was a better paint than white lead paint?—Yes, and because we thought that sooner or later non-poisonous pigments would come into favour.

22 February 1911.]

Mr. A. F. HEYDORN.

[Continued.]

559. You had the humanitarian idea at the back of your mind all the time, then?—We had that, I suppose, in view more or less. In our works we use nothing poisonous, and it is the decision of our directors wherever possible not to do so.

560. (Mr. Fell.) Have you used this paint at all on vehicles?—We have not.

561. But have you sold it for that purpose?—We have supplied it to coachbuilders.

562. You said just now that you did not recommend it where there was any sign-writing or anything of the sort?—Yes.

563. Most public vehicles are covered with signs?—Yes.

564. How does your paint act under those conditions?—We have had no experience of that. One experience we had was with a colliery company who were using it for lettering, as they term it, for their trucks. Although we have supplied our paint to other colliery companies we have had no complaints except from this one company. That rather made us think that we have not the proper thing yet for sign-writing, and we have ceased selling it for that particular purpose. But I cannot say that it is not suitable for it.

565. You do not know whether it has been used for painting tramcars or anything of the sort?—No.

566. You could not give us the names of any places where it has been used?—No. One railway company have used it for various purposes, and I propose to call on them and get their opinion. They may have used it for purposes such as you describe.

567. (Mr. Kinggate.) You might ask the coachbuilders whom it has been supplied to what uses they have put it to?—Yes, I could get that information.

(Mr. Robins.) I would like to speak about one expression which has been used this afternoon by our friends on the opposite side of the table, and that is the word "flat." It may be conflicting. What the house painter calls "flat" is a dead colour, but with regard to coach painting as a rule when we say "flattening" it means rubbing down with pumice stone or a cloth.

568. (Dr. Collis.) Do you get every colour from your paint without ever introducing a small percentage of lead?—You can use any kind of stainer with it, the same as with white lead.

569. But do you obtain every colour without even a small percentage of lead?—That I could not say. As you are probably aware, some colours have all sorts of chemical combinations. Some of them contain lead, particularly greens, and there are some colours even more poisonous than lead. So it does not follow that, while Dixon's White is non-poisonous, anything you mix with it is also non-poisonous.

570. Do you only issue your paint in the form of a white?—It can be used in precisely the same way as white lead. It can be mixed with stainers.

571. But as a matter of fact do you issue this in various colours or only as a white?—We only send it out as white, and leave it to the painter to mix it up in whichever way he likes.

The witness withdrew.

## SECOND DAY.

Tuesday, 28th March 1911.

PRESENT :

SIR ERNEST F. G. HATCH, BART. (Chairman).

Lord HENRY BENTINCK, M.P.  
Sir GODFREY BABING, Bart, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER } (Acting  
R. U. SHAXBY } Secretaries).

Mr. G. G. LAIDLER examined.

572. (Chairman.) Are you a master house decorator?—Yes.

573. Where is your business?—In Newcastle-on-Tyne.

574. How long have you been engaged in the painting trade?—About 90 years, my father and myself.

575. How long have you yourself been an employer?—I have been an employer for 48 years.

576. Were you apprenticed to the trade?—I was.

577. How many men have you employed during these years?—From 80 to 120.

578. Were they all painters?—All painters.

579. Perhaps you would tell us the average yearly number of painters you employ?—About 80 or 90.

580. Have you an even run of business all the year round, or do you have a busy time of year and a slack time?—We have a very good run all through the year. For April, May, and June we generally employ perhaps 30 or 40 more men.

581. What happens to your men in the slack time; are they discharged?—They are discharged.

582. Do you employ the same men year after year?—We do.

583. Do they come to you as boys?—They are all bound by indenture.

584. Do many leave you of their own accord?—We like them to leave after they have served a year and then come back again.

585. What reason have you for that?—We want them to get experience outside of the shop.

586. Do any of them leave the trade because of ill-health?—I do not remember any.

587. Do you take on and discharge your men personally?—Either myself, my son, or my foreman.

588. Do you make inquiries when a man is away as to whether he is ill, and if so, what is the matter with him?—Oh, yes, as a rule we do. We have a little Benevolent Society in the shop where the men contribute so much a week; and when they are ill and laid by for two or three weeks they receive 10s. or 12s. a week from that fund.

589. What sort of paints do you apply? Do they all contain lead compounds?—Two-fifths of them do.

590. I should like to know what quantities you use of (1) white lead, (2) red lead, and (3) Brunswick green, and other paints containing lead chromate?—I think we use about 18 tons of what is called genuine white lead; that is, by preference, a mixture of stack white lead, and that made by the Chamber process of manufacture.

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

591. And red lead?—We use very little red lead.
592. Any Brunswick green?—Yes; we use probably a ton of Brunswick green in the year.
593. And other paints containing lead chromate?—Yes, not more than perhaps a ton and a half during the year, in addition to the 18 tons of white lead.
594. What quantity of red oxide of iron do you use?—It is included in the ton and a half; I should think not more than perhaps 6 or 7 cwt.
595. What quantity of zinc oxide do you use?—Very little.
596. Practically nothing?—Practically nothing at all.
597. Do you use lithopone?—No.
598. Do you use carbon or graphite paints?—No.
599. Do you use any particular brand of leadless paints?—No.
600. Then do nearly all your paints contain lead?—About 18 to 19 tons contain lead, and about 20 to 25 tons do not contain lead. I include all these distempers that we use—Duresco, Walpamur, and so on.
601. (Mr. Sutherland.) Some of those are based on lithopone?—Yes, I did not follow that.
602. (Chairman.) Then you do use lithopone?—I do not know it by that name.
603. May I put it in this way—that about half the paints you use contain lead, and half do not?—Yes.
604. Is that substantially correct?—Yes, the larger proportion is leadless.
605. You are sure that the larger proportion is leadless?—We use 18 or 19 tons of lead paint and from 20 to 25 tons without lead.
606. Now, about lead poisoning or painters' colic, have you known any cases of it?—Not in our shop. I heard it mentioned when I was a boy as painters' colic, but I have had no experience of it.
607. Do you mean that you have paid no compensation, or that your men have not, to your knowledge, broken down on account of lead absorption?—No, none.
608. Have your men had occasional days of sickness due to lead?—No, not to my knowledge.
609. Do you have periodical medical examination of your men?—No.
610. Then it is possible, perhaps, that some of them may be suffering from the slower and more insidious forms of lead poisoning?—I have no knowledge of that at all, so I cannot say.
611. You know, I suppose, that lead poisoning frequently undermines the health without immediate violent manifestations?—Yes, I know that.
612. The first point in your evidence amounts to this, that you are not aware of any damage being done to your men by their contact with lead paints. Is that correct?—Yes, that is correct.
613. I suppose you take precautions to guard against your men being lead poisoned?—We try to make them do their work as cleanly as we possibly can, and in every way we make them carry out the work as perfectly as possible.
614. I will now take the principal painting processes and ask you what precautions you adopt in each of them. Let us begin with mixing. Do your men do any paint mixing?—Yes.
615. Does one man do it all, or does each man do his own?—If it is a small job every man mixes his own paint.
616. Where is the mixing done?—On the job; not in the shop.
617. Is it all done outside the shop?—It is all done outside. We employ very few men in the shop.
618. Do you use a grinding or mixing mill?—No.
619. Do you mix any dry powders with liquids to make up filling or stopping, for example?—Yes, we do.
620. Do you mix white lead or red lead in this way?—Yes, we do.
621. Do you do any mixing by hand on a slab?—By hand. Yes.
622. On a small slab?—Yes.
623. What precautions do you take? Of course you have a lavatory at your headquarters where the men can wash?—Yes.
624. What accommodation do you give them? How many men are there to each lavatory basin?—We have a lavatory and closet for the men. We do not employ painters in the shop at all.
625. I am speaking about the men who mix the paint. I am taking each process separately, and I want to know precisely what precautions you adopt to protect your men?—We do not take any precautions at all.
626. What accommodation do you provide, with regard to washing, for the men who mix the paint?—We do not give any accommodation at all.
627. Do they have any place to wash in?—If it is an empty house, they use the lavatory or the basin in the house.
628. Do they have hot and cold water supplied to them necessarily?—We do not provide accommodation.
629. You do not know whether they have soap or nail brushes and towels?—They always have soap. They can heat the water, and they do, I believe. We do not provide any accommodation.
630. You do not know whether any provision is made for them or not?—We do not provide any; they provide everything themselves in the shape of washing.
631. Is it easy to remove paint from the hands?—Yes, I think so.
632. I should have thought it was very difficult?—A clean workman does not need to have his hands messed with paint.
633. That is not the point. Is it easy to remove paint from the hands when it is once on them?—Yes, I think so.
634. With cold water?—No.
635. Then you think it is essential that they should have hot water?—I think so. It requires turpentine and a cloth to remove paint. I always use hot water myself.
636. Do you think it possible for them to have hot water in houses where they go to paint?—Yes, always.
637. Do the men wear overalls?—Yes.
638. Who provides them?—Themselves.
639. Who washes them?—I suppose their wives probably. We do not wash them.
640. Do you know how often they are washed?—Once a week.
641. Are you sure of that?—We compel every man that comes to the shop to have clean overalls every Monday morning.
642. What steps do you take to prevent dust from the mixing getting into the air that the men breathe?—We have very little dry paints used. They are nearly all ground in oil.
643. But if they are not ground in oil, do you have the work done under a hood connected to a fan or exhaust of any kind?—No.
644. Now the next process I wish to ask you about is smoothing or rubbing down. Is much of your work rubbed down?—Yes; the principal part of the work is filling up.
645. I am coming to that in a moment. Would you kindly answer my questions as I come to each process. I want to know whether you do much rubbing down?—Yes.
646. Do you use dry sandpaper or German brick?—We use dry sandpaper for ordinary walls and ceilings, but mostly woodwork is rubbed down with pumice stone and water.
647. Have you used wet sandpaper?—No.
648. Do you use pumice stone and water a good deal?—Yes, a good deal.
649. About what proportion of the work is rubbed down with pumice stone and water?—We always use it. The work is commenced by rubbing down with pumice stone and water.
650. How many times do you rub down?—Between each coat.
651. Are all the undercoats rubbed down?—Yes.

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

652. Do you rub down mouldings and curves, or only flat work?—Yes, we rub down mouldings and curves, and flat work as well.
653. Can you use wet methods throughout?—Yes.
654. But you do some dry rubbing down?—No.
655. You said just now that you used sandpaper?—Not on woodwork.
656. I did not ask about woodwork only; I mean all work?—Yes. We do walls and ceilings with sandpaper.
657. You do dry rubbing down of walls and ceilings?—Yes.
658. Do you do anything to prevent the dust being breathed?—No.
659. Are overalls worn at this work?—Yes.
660. Do you arrange for washing appliances at the jobs, or is that left to the painters themselves?—It is left to the men themselves.
661. What do the available appliances consist of as a rule?—If there is a lavatory basin in the house they use that; if not they provide themselves with a zinc pail and hot water.
662. Do you know of your own knowledge that the men wash at every opportunity?—I think they do—Yes.
663. Can you speak from your own knowledge?—Yes.
664. How do you get that knowledge?—I have asked the men.
665. The men themselves?—Yes.
666. Now, would you tell us about your stopping? What do you use as stopping?—A little dry white lead. We use very little of that in the year.
667. How is it applied?—It is applied by a knife process.
668. Can the workman avoid getting his hands soiled with this stopping?—Yes.
669. How?—By keeping his hands out of the paint. He need not touch it.
670. But if it does come in contact with the hands, can it be got off with cold water?—No.
671. He must have hot water?—Yes, he must have hot water.
672. You think it absolutely essential that they should have hot water near at hand?—I think so.
673. In every case?—Yes, in every case.
674. Now, as to scraping and burning off; when you are repainting, how do you deal with the old paint?—If it is in bad condition we burn it off to remove it.
675. Do you sometimes scrape it off?—We scrape it off, or burn it off, or use solution.
676. What is the proportion of scraping off to burning off?—I can hardly say; it is mostly burnt off if the woodwork requires it to be burnt off; it is not scraped off. There may be a little scraping where the paint has become dry with the sun; that is scraped off. The other is all burnt off, as a rule.
677. Can you give us any idea of the proportion?—A hundredth part of the work is scraped off, as a rough guess.
678. Do you burn off interior work as well as exterior?—Yes.
679. Is this ever done where space is limited?—It does not matter about the space; if the work requires to be done in that way it has to be done.
680. When scraping off is done, is the paint hard or soft?—It is generally very dry indeed; and that is the reason it is scraped.
681. Does it chip off?—Yes; it will scrape off with a knife.
682. Have you noticed if there is ever any dust or small particles?—Yes, there is dust.
683. Do painters carry a brush amongst their tools?—Yes.
684. What is that for?—For dusting purposes.
685. What do you do to prevent inhalation of fumes from burning off?—We do not use any precautions at all, and never have.
686. What precautions do you use in regard to dust from scraping?—We do not take any precautions at all, nothing beyond the care that a man would have of his own health.
687. It comes to this, that your men seem to be so unusually careful that you have no precautions, and the men are absolutely immune from any danger?—Yes.
688. Is not that rather a remarkable situation?—I do not know that it is; it is my experience. We do a very good class of work, and we employ most careful men.
689. If what you tell us was general, there would be no necessity for this inquiry at all?—In my case there is absolutely none.
690. And yet the incidence of lead poisoning amongst house painters is terrible?—It is not my experience. I never knew a case amongst our men.
691. Now with regard to the application of wet paint; does this necessarily involve soiling of the hands?—No, you need not soil the hands at all, a dirty man would certainly do so.
692. Have you ever seen a painter working without soiling his hands if he is painting all day?—No.
693. Do you not think, then, that it necessarily involves soiling the hands?—Not the mere painting, but the work generally.
694. I mean the work that the man is employed in; you do think that it necessarily involves soiling the hands?—Yes, to a certain extent, very small.
695. And I suppose his garments too?—Yes.
696. Do fine specks of wet paint get upon the hands and clothing or are there only large splashes?—It depends on his work. If he is painting railings or anything outside, there would be a good deal of splashing there, and in trellis work too; but it is not necessary in painting ordinary woodwork in a room.
697. I suppose overalls are worn during actual painting?—Yes.
698. Do your other remarks, about washing and the like, apply in the same way?—Yes.
699. So far you have told us that there are no particular precautions adopted by you in these various processes. I want to ask you a few questions as to general precautions. First about meals. What time do your men commence work in the morning?—6.30.
700. Do they have their breakfast before they begin?—No.
701. How long do they have for breakfast?—From 8.30 to 9.
702. Do they go home for that as a rule?—No; it is taken on the job.
703. Do any of them take their breakfast in the paint-mixing shop?—I should think they generally breakfast where the paints are. They have a fire there and probably sit round it and smoke afterwards.
704. With dirty painty hands?—No; I should think the men as a rule would wash their hands before.
705. You think they might?—Yes.
706. But they might not. Do they breakfast ever in the plumbers' shop?—We do not have any plumbers' shop.
707. Do you provide a messroom at your headquarters?—We have a large shop. We have no particular messroom.
708. You do not have a messroom?—No, we do not have a messroom.
709. Do they sometimes have all their meals away on the job where they are working?—Yes, on country jobs and jobs a distance from their homes.
710. You have told us that they eat their meals where their brushes and pots are?—Yes, as a rule.
711. Can you say what is the average wage for a working painter?—The wage for the painter right through the year, do you mean?
712. Yes, an average?—38s.
713. Is this in the busy season, including overtime?—No.
714. What are the usual hours of work?—Fifty a week.
715. What would be the maximum at times of great pressure?—In all country work the men work two hours overtime, and in the busy season they work probably eleven hours a day and two hours extra sometimes.

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

716. Can you tell us whether the men are well fed; that is an important matter?—Yes; I think so.

717. An important precaution which is required in, I think I might say, all the regulated dangerous trades involving exposure to lead compounds, is a periodical medical examination. You have already told us that you have not adopted such a precaution?—No.

718. Do you insure against your liability under the Workmen's Compensation Act?—We do.

719. Can you tell us whether the rate you pay is heavier for painters than for paperhangers, plasterers, and so on?—We pay the same rate for paperhangers and painters.

720. And for plasterers?—We do not employ plasterers.

721. Then the rate is the same for all your men?—Yes.

(Mr. Sutherland.) It is less for plasterers.

722. (Chairman.) For painters it is higher?—Yes.

723. How much higher?—I do not know. The rate is about 13s. or 14s. per cent. for painters and paperhangers.

724. Will you take it from Mr. Sutherland that the rate is higher for painters than for plasterers?—Yes.

725. It is a very important point. It shows how Insurance Companies regard the danger. Would you suggest that this increased premium is due to any other cause than the risk of lead poisoning which the painter has and the plasterer has not?—I could not answer that question.

726. Has the rate changed since the Employers' Liability Act came into force?—I think we pay about the same. I do not know that there has been any difference. It may be a little more—yes, it is probably a little more.

727. I have the impression from your answers that you have hardly realised the magnitude of this lead poisoning evil. Do you know that the Registrar General has recorded no less than 234 definite deaths from lead poisoning amongst house painters in the last ten years?—I was not aware of it.

728. And that his mortality figures show, for painters, a death rate considerably higher than the normal; from troubles which are the frequent effects of exposure to lead, such as Bright's disease and nervous diseases?—Does the question relate to house painters?

729. Only house painters?—No; I was not aware that there was that mortality amongst them.

730. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the same ten years?—No.

731. I am sure you will agree with me that all this sickness and death is very deplorable?—It is very deplorable. I was not aware that there was so much sickness and death from that cause.

732. There seem to be only two ways by which this state of affairs can be remedied. One remedy would be to prohibit the use of lead compounds, or to restrict them to say 4 or 5 per cent. of the whole material used, and the other method would be to regulate the trade very strictly. Do you agree with either one way or the other being adopted?—No, I do not agree.

733. But you agreed just now that this sickness and death is very deplorable?—It is so.

734. Something ought to be done to stop it?—Yes.

735. Then there seem to be only two ways by which this state of affairs can be remedied: either to prohibit the use of lead compounds or at least to restrict them to say 4 or 5 per cent. of the material used, or to regulate the trade very strictly. Do not you think that one of those two methods is absolutely essential?—Some regulation, yes, but not the restriction of lead. May I give my opinion upon that?

736. Certainly.—The reason is that I think that many of these men are sick through their want of cleanliness in their work—entirely. Dirt produces illness—

737. (Dr. Collis.) What disease?—Lead poisoning, I should say. If men keep their hands clean, they are not liable to be attacked by these diseases.

738. (Chairman.) It seems that there are already a lot of substitutes for lead paints on the market. What

do you say about those?—I have no experience outside my own particular trade. I do not use substitutes of any kind.

739. Will you tell us what attempts you have made to get a substitute for white lead paint that is suitable for your work in all respects?—I have never used any and never tried any.

740. Have you made any experiments to compare the behaviour of substitutes with the white lead you are now using?—None.

741. I have just explained to you the lamentable position of workmen in the painting industry. I gave you some figures which indicate the extent of lead-poisoning that is going on. Can you offer any suggestions for appreciably relieving all this suffering?—I am quite surprised to hear about it really, because my experience that I have spoken of is quite the reverse.

742. Can you offer any suggestions for the relief of that suffering?—I should say that great precautions ought to be taken to see that the men keep themselves clean and that the conditions of their work are the best possible in every respect.

743. You do not think that this deplorable state of affairs should be allowed to continue?—No; I think it ought to be remedied.

744. Do you think that it is possible to invent any apparatus which could control effectually all the dust that at present gets into the atmosphere breathed by the workpeople?—I cannot say.

745. Then either painters must go on suffering or the use of lead paints must be prohibited. That seems to be the only corollary?—I think if the conditions of the work were altered, this mortality and suffering amongst the men would be considerably reduced.

746. But I ask you, do you think it is possible to invent any apparatus which would control effectually all the dust which gets into the atmosphere breathed by these people whom we are talking about? If you cannot make a suggestion, what are we to do but to prohibit the use of lead?—I cannot say. I am quite surprised to hear that there is so much against the use of lead.

747. Do you know anything of the position abroad in regard to this matter of lead poisoning?—I know it is prohibited in France.

748. You know that in France a law was passed on the 20th July, 1909, which prohibited, five years from that date, the use of white lead in the interior as well as on the exterior of buildings?—Yes, I know that they have prohibited the use of lead.

749. Do you know that in Austria the use of white lead for the interior of buildings has been prohibited since the 1st April, 1909, by a decree dated 15th April, 1908?—No, I do not. I only know that with reference to France, because I have employed French people myself.

750. Have you heard that many Governments and Municipal Authorities in such countries as Switzerland, Germany, and Belgium have prohibited the use of white lead in works undertaken on their account?—No.

751. Are you conversant with the classical experiments which the Dutch Government have carried on for the last five years?—I am not.

752. Do you know that they got excellent results with zinc paints for interior work and also for exterior work, except for iron bridges, &c., exposed to exceptionally severe smoke conditions?—I know that zinc paint is very largely used. I was not aware of any action taken by the Dutch Government.

753. I will not weary you with any more questions regarding the painting industry in foreign countries, but I should like to know if you are aware that Germany and Belgium have strict regulations for the use of lead paints?—Yes.

754. Do you not think it regrettable that this country should be behind other nations in this respect?—As I said before, I think that precautions ought to be taken, but what these precautions should be, apart from the cleanliness of the men and seeing that they do their work in a clean manner, I cannot say.

755. Do not you think it imperative that we in England should be well abreast of foreign countries in

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

this respect and protect the men in every possible way?—I cannot see why the use of white lead should be prohibited—from my experience, at all events, and that of many others that I know. They rarely have a case of lead poisoning, and we never have had a case. It must be the conditions that the men work under.

756. There are a large number of businesses in England where lead is used, and it is a well known fact that contact with it does produce such results?—I should think the conditions under which these men work are very different from the conditions that our men work under.

757. What is there in your particular business that makes it different from that of other master painters?—Do you refer entirely to house painting?

758. Speaking of your own business, why is your business so different from that of other house painters?—I do not know that it is so much different.

759. Then how do you account for the immunity of your men?—Simply from the conditions which the men work under.

760. Do you train them to be very careful?—Very.

761. Have you a school in which they paint and learn care?—Yes, we have a technical school that boys are trained in, and during the winter time we give the boys, day after day, time to train themselves, along with men in the shop, to be competent workmen; and cleanliness is the first thing that we impress upon them.

762. Is that a novelty in your particular firm?—No.

763. Is it general in other firms?—Yes.

764. Then why should you be immune and other people not?—I do not know that other people are not. I say, as far as I know, other shops are in the same position as ourselves.

765. (Lord Henry Bentinck.) Do all the boys go to the technical school?—Most of them go. We require them all to go, and we have no improvers. They are all indentured; every boy is indentured after a few months.

766. You put the immunity down to their training?—Yes. For 40 years I have had breakfast at half-past five in the morning so that I might get down to my men and be amongst them constantly.

767. (Chairman.) Do you know that, for the last four years at least, His Majesty's Office of Works have dealt with many thousand pounds worth of paint yearly and have been using non-poisonous zinc paints almost entirely?—No.

768. With that information before you, do you still say that it would be unwise to prohibit the use of lead?—I can only repeat again what I have said.

769. I will put it in this way: If we can prove to you that the Office of Works for the last four years have been using non-poisonous paints with the best effects and preventing this evil, would you then say it would be a wise thing to prohibit the use of lead entirely?—I think it would be unwise.

770. Why would it be unwise, if you can get the same effect without letting the men run these terrible risks? I will put the question again: If it can be proved to you, beyond question, that His Majesty's Office of Works have for the last four years been using non-poisonous paints with the very best results in every respect, would you then not say that the Home Office ought to prohibit the use of lead throughout the country?—No.

771. Why?—For the reasons that I have already given you from my experience.

772. But that is not the point. I have told you that we have independent testimony that the incidence of lead poisoning amongst painters is deplorable. You naturally regret that incidence. Then I go on to say: if it is proved beyond question to you that you can get the same good results from non-poisonous paints, do not you think that, in view of protecting the workmen in this country, we ought to prohibit the use of white lead?—Well, I cannot say that the use of white lead should be prohibited altogether.

773. But why? I cannot understand your objection. If you can get the same results without exposing

these people to this dreadful risk, why should not you protect the men?—I am surprised at the dreadful risk at all.

774. But that is not the point. I want you to assume what I have put to you, and I ask you if you can get the same results with these non-poisonous materials, would not you yourself advocate, as a humane gentleman, that lead should be prohibited so that we might protect the workmen from these deplorable results?—But you cannot get the same results.

775. I am putting it to you with that as a proviso; if you can get the same results?—Yes, but you cannot.

776. But, if you can get the same results, then would you think it would be a right thing to prohibit the use of white lead?—How long is the experience?

777. Four years?—I do not think it is long enough.

778. I want an answer one way or the other. Will you tell me whether, if you can get the same results from the use of non-poisonous paints, you think the Home Office ought to prohibit the use of white lead?—I am sure the experience is not long enough. Probably if they had used lead compounds they would have found the same results.

779. I want to know what you would say should be done if you can get those results?—But you cannot get them.

780. That is not the point. If you can get the same results do you think the Home Office ought to prohibit the use of white lead?—I cannot accept the "if."

781. (Lord Henry Bentinck.) But if you can get the same results you will have no objection?—If, after a long experience, it was found that there was no mortality amongst the men, then I would say "Yes." But after such a short experience as four years I would say "No."

782. You said that employers should give facilities to their men to enable them to keep clean. What facilities can you suggest beyond what they do get at present?—I think that painters ought to be trained from their youth to be clean in their work and clean in themselves and their clothes.

783. But it must be very difficult for men on a job to keep themselves clean and wash their hands?—No, it is not difficult.

784. Why? Supposing they are in an empty house, they cannot get water. Do you think that the masters should supply buckets?—They do.

785. Do your men not supply their own buckets?—No.

786. I thought you said they supplied them?—No.

787. Do you think that all employers should supply buckets?—Yes, and soap, and we do supply them.

788. That would be a step in advance?—Yes.

789. Is it possible to pumice stone and water walls and ceilings when you rub down?—If they are painted walls we use pumice stone; but if they are unpainted walls, in preparing for paperhangers, they are sandpapered.

790. If you were going to paint this wall, would you pumice stone it or sandpaper it?—We should use pumice stone and water.

791. Would it be possible to make it compulsory to pumice stone and water all walls and ceilings?—You must do so if they are painted walls; but, if you are pumice-stoning on an unpainted wall, you would take the skin of the plaster off.

792. You must sandpaper it, then?—You must sandpaper it. You sandpaper the rough surface.

793. Is it known throughout the trade that walls which are painted must be pumice-stoned?—Yes.

794. And all wood-work?—All painted wood-work must be pumice-stoned, and any work that is not painted is sandpapered.

795. Do you say that you have no evidence that painting causes an increase of sickness? You said that you had a sick fund?—Yes, amongst the men.

796. Have you no evidence to prove that in the painting trade the nature of their employment causes sickness?—No. It is only a small fund. The men

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

contribute 2d. or 3d. per week, and if they are off had they have 10s. or 12s. from the fund.

797. Do you inquire why they are off?—Yes.

798. You know it?—Yes, always.

799. What are the chief reasons that they go off for?—Perhaps colds.

800. Nothing to do with the trade?—No. I have no experience of lead poisoning in my business. I do not know anything about it.

801. (*Sir Godfrey Baring.*) Do you really say you have never in your experience known a man suffer in health from lead poisoning in your employment?—No.

802. Nor from indirect causes?—No.

803. Up to what age do you find that men can do a full day's work in your business?—I have men working with me now who were apprenticed to me 44 years ago.

804. You have no experience of men prematurely breaking down at a comparatively early age?—In my own employment?

805. Yes, in your own employment?—Yes, I have.

806. With regard to empty houses, do you say that in an empty house, at times of pressure in your business, it is always easy for a man to obtain hot water?—Yes, always.

807. Even at times of greatest pressure?—Yes.

808. If hot water was not provided in the house the men would provide it themselves?—Yes, they would.

809. With regard to scraping off, when scraping off is going on there is a considerable amount of dust, I suppose?—Yes.

810. And the men would be compelled to breathe that dust?—Yes.

811. And in the dust there would be a large admixture of white lead?—Yes.

812. That would be inevitable from scraping off?—Yes.

813. Have you anything to recommend with regard to obviating the dust in scraping off? Is there any way of preventing it?—The scraping off is a very small proportion compared with burning off. Burning off the paint causes it to crumble away as it were, and there would be probably a little sandpapering after that, mostly pumice stone and water.

814. If a man was scraping off, it would be inevitable that he would be breathing dust all the time?—Yes, in the scraping.

815. And there would be no way of correcting that?—No, I have nothing to recommend. But the scraping is only a hundredth part of the preparation.

816. I understand that the extra regulations you recommend are chiefly with regard to washing?—Yes, I think so. I think if a man is clean over his work he takes the best precaution for preventing himself being struck with illness.

817. But even the most careful man at his work must inevitably get paint on him. There must be a great deal of paint on his hands and overalls?—There may be—yes.

818. Your experience is that, before their meals, the men take the precaution to wash in hot water?—Yes.

819. No matter what the pressure of work may be?—Yes.

820. (*Dr. Collis.*) My experience of house-painting is slight. It has always appeared to me, and I wish to ask whether you agree, that the occupation should be a very healthy one in that the men have plenty of fresh air and plenty of change. Do you agree with that?—That they have plenty of fresh air.

821. Yes?—I think they have. The occupation of a painter is a very healthy one. He travels all over the country. Many of our men spend half the year in the country.

822. And his work is not laborious?—No, it is not.

823. And does not expose him to any great extreme of temperature, like working before furnaces?—That is so.

824. How is it that when we look up the Registrar General's Report on plumbers, painters, and glaziers,

we find him stating that they have 11 per cent. of mortality above the standard?—I do not know.

825. Is it not rather curious that you should be an employer of many people for this length of time without having taken the trouble to look into the health question of your people? You say that you and your father have been for 90 years employing people in house painting?—That is so.

826. Perhaps you would be able to give us some information, or perhaps you will be able to claim acquaintance with some statistics which were published many years ago—in 1854—about the commencement of the time you were interested in the trade—by the Registrar of Friendly Societies for England and Wales. Are you aware that at that time he was unable to class painting with other forms of labour because of the extra danger that he found that painters were exposed to in their trade?—I was not aware of that.

827. There are four extra-dangerous trades. One of the four extra-dangerous trades is that of painters. Are you not aware of the fact that all workpeople are occasionally prone to illness? I suppose your men have occasionally been ill?—Yes.

828. Have you ever kept statistics of the number of days that they have been off their work?—No.

829. Then how are you able to say that your trade was more healthy than others?—I have not said more healthy than others.

830. Or as healthy as others, unless you can compare them with the amount of sickness and illness that your men suffer? The statement is a little *ex parte*?—I do not know exactly what you mean.

831. If you have never taken the trouble to look into the statistics of illness which men suffer from, and compare them with the statistics found in other trades, you are not able to say that your trade is either healthy or unhealthy. You have no opinion on the point?—It is a healthy one.

832. On what do you base your statement?—Experience.

833. But your experience is not statistical?—No, it is not.

834. (*Mr. Parsonage.*) With reference to the use of pumice stone and water in preparing the work, you use pumice stone and water on old work?—Yes.

835. After you have given it a coat, and you are going to finish the work with three or four coats, you do not use pumice stone and water on that same work again?—No.

836. You use sandpaper between each coat?—Yes, a little.

837. You must rub it down with something?—Yes.

838. Then you only use pumice stone and water once?—No, we use ground pumice stone and water afterwards.

839. For the finishing coat, I suppose; but between each coat you use sandpaper?—Not always.

840. In ninety-nine cases out of a hundred you use sandpaper between each coat?—No; we use felt and pumice stone.

841. I am speaking as a painter who has served an apprenticeship to the trade and has thirty years' experience. Now on extra good work you may use felt and ground pumice stone, but in ordinary work between each coat you use sandpaper?—Not always.

842. You use nothing at all?—We do the filling up; we fill up with knives. You know that process?

843. Yes, I know all that?—And we get a perfectly smooth surface.

844. Taking new woodwork, you prime it?—Yes.

845. You do not put pumice stone and water on that?—No.

846. Sandpaper?—Yes, a little with that class of work.

847. It all depends what kind of finish you want?—Yes.

848. You use sandpaper between each coat?—Yes, a little.

849. I want to demonstrate that that is the usual thing, and that pumice stone and water is not used between different coats?—Always for rubbing down.

850. At first you rub down the old work?—Yes.

28 March 1911.]

Mr. G. G. LAYDLER.

[Continued.]

851. But between the coats you use sandpaper?—Not always.
852. What do you use?—With varnish we use felt and ground pumice stone.
853. You would not use felt and ground pumice stone between each coat?—No, towards the finishing coat.
854. Mainly you use sandpaper?—A little fine sandpaper occasionally.
855. But is it occasionally or mainly? It is a very important point. My contention is that sandpaper is used between every coat after the work is rubbed down in the first instance with pumice stone and water. This is an important point, because the dust arising from sandpapering is, in my opinion, the main cause of lead poisoning, and I wish to prove conclusively that the wet process in rubbing down paintwork between coats is not used at all. It is very very little used except on special work where an extra special finish is required?—Yes. That is the class of work that we use it in.
- (Chairman.) Perhaps that is the reason—because he uses felt—that his men are immune.
856. (Lord Henry Bentinck.) Would it be possible to use pumice stone and felt between each coat always?—No, not always.
857. (Mr. Parsonage.) I will give you a practical instance. If you were going to paint this room, and going to finish the woodwork in the room flat, you would not use felt on that?—Yes, we should.
858. You would?—Yes.
859. To finish it in flat colour?—Yes.
860. Well, I am surprised. I could understand if you were going to finish it in varnish, but I cannot understand that you would use felt and ground pumice stone. You would use sandpaper?—I want to impress upon you, gentlemen, that we use wet processes in rubbing down and smoothing in preference to dry processes, because we get finer results from them.
861. But between each coat you use sandpaper?—No, not always.
862. In five out of six cases you would use sandpaper?—No.
863. You would not paint a door at all without using sandpaper on it?—We should certainly use a little fine sandpaper.
864. (Chairman.) Is the use of felt and ground pumice stone more expensive than sandpapering?—Yes.
865. Would it take longer to rub down a door with ground pumice stone and felt than with glasspaper?—It would take longer.
866. Far longer?—Yes.
867. And must, therefore, be a more expensive operation?—Yes.
868. Is that why sandpapering is done in preference to the other?—I use the wet process in preference to the dry process.
869. I did not ask that?—Is it done sometimes on the score of expense?—It is more costly to use the wet process than it is the dry process, but we get finer results from it, and that is why we use it. It is not a question of expense with us.
870. (Mr. Gardner.) But it is only used in special jobs?—No; we constantly use it and we fill up most of our work.
871. (Mr. Parsonage.) You estimate for work in competition with other firms in Newcastle?—Yes.
872. You do not merely have your own special customers?—We have our own special customers.
873. I have worked on some—I know that—but you estimate against other firms?—Yes.
874. Is it a usual thing for these firms in Newcastle to use the wet process for preparing paint work?—I should say so.
875. You think so?—It ought to be so.
876. I am acquainted with many painters in Newcastle, and I know some of the work too. You do not say that the wet process is mainly used in Newcastle?—I do.
877. In your own shop?—Yes.
878. But if you used that and other firms used a much cheaper one, you could not compete with these people?—No; that is so. Do you know my business in Newcastle?
879. I have known some of it in London?—You know the quality of my work?
880. Yes, I do, and I know it is above the average?—It is got by the wet process and not the dry one.
881. I wish to bring out clearly the fact that glasspapering or sandpapering between coats is always used?—Yes.
882. Pumice stone and water is used for rubbing down the old work?—Always.
883. Afterwards it is sandpapering mainly?—Not with me.
884. But it is generally?—It is probably owing to the process that I use that we have such a clean bill of health in our shop. I think, if the wet process was more used than it is now and the men were compelled to be cleanly over their work and the employers took certain precautions, there would not be such dire results and these cases of illness and mortality amongst the men.
885. In taking on your men you make no inquiries as to whether they have served their time at the trade; you simply go by their ability? As a painter any man that comes to your shop for a job would be taken on, and his being kept on would depend on his ability?—If he was not a bound apprentice. But we make inquiries as far as possible. I am very sorry to say that a large proportion of these men have never been bound owing to the carelessness and indifference of the employers. We never employ a boy unless he is indentured, and if he is bound as apprentice to serve his time with us he will turn out a good man.
886. You would think that a boy apprenticed to the trade and brought up to it would be more cleanly in his habits than a man who comes into the trade casually?—Certainly.
887. You have had no cases of lead poisoning in your firm?—No, none.
888. Not to your knowledge?—Not to my knowledge.
889. But there may have been many cases that you have no knowledge of?—That is so.
890. I could mention to you names of men employed by you who have suffered from lead poisoning?—Indeed! I was not aware of it.
891. I could give you names and call them to your mind now, but I should not wish the names to be reported?—I was not aware that we had ever had a case of lead poisoning in the shop.
892. We have cases of lead poisoning every year from Newcastle the same as from other places?—Indeed!
893. There may be 100 men at work in your shop who had lead poisoning and you would not know it?—I have given you my experience.
894. It has not come to your knowledge?—That is the fact.
895. Now you mentioned that you used 19 to 20 tons of lead?—I said 18 tons of lead.
896. And 25 tons of leadless paint?—I said 20 to 25 tons.
897. Do you use any of this leadless paint on woodwork? Does the 20 to 25 tons include distemper?—Yes.
898. It is not used on woodwork?—No.
899. It really does not come into this question at all?—But I was asked the question.
900. I want to show that this quantity of 20 to 25 tons includes distemper, and that does not come into the question of woodwork in any way. You would not use Duresco on woodwork?—No.
901. We class that as ordinary distemper, and the 20 to 25 tons is not relative to this inquiry in any way?—I see.
902. (Chairman.) I am afraid that you inadvertently failed to apprehend the meaning of one of my questions, because you certainly implied that you used a much larger amount of non-lead paint than lead paint?—Yes.
903. But you did not mean that?—Yes, I meant that. You asked me how many tons of lead paint I used and how many tons of leadless paint I used.

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

904. (Mr. Parsonage.) Do you term distemper "paint"?—Yes, it is a water paint.

905. You would apply that term to ordinary distemper?—Yes.

906. You would use no substitutes for white lead on woodwork at all?—None.

907. You use nothing but the ordinary white lead mixed with oil or turps?—That is for painting.

908. The other is merely distemping work?—Distemping; or whatever it may be.

909. (Chairman.) We are here to inquire as to painting, not distemping or anything of that sort?—At all events, the men are employed for a large portion of their time in using these distempers. They are not always painting. A man may not be painting more than half the time during the year.

910. (Mr. Parsonage.) That is right. Now you say painting is a healthy occupation, and the men get a good many changes. I know that your firm sends men all over the country and they are away a good deal. Their hours of labour are from six in the morning in the summer?—6.30.

911. Until 7.30 in the evening?—About that.

912. Twelve hours?—Eleven. They are very anxious to work twelve, but we try to limit them to eleven.

913. In many shops they work twelve?—Yes.

914. They have half an hour for breakfast?—Yes.

915. They sit in the paint shop?—Yes, I think so as a rule. I always did.

916. And for the dinner hour the same?—No. If it is fine they will sit outside.

917. They will have their dinner there or go outside and get it?—As a rule they are provided with a mess room on a country job; the men may pick a room out in the house for their meals.

918. Until when do they work on Saturdays?—To five o'clock.

919. I should think they would get very little time for fresh air if they started at 6.30 and worked till 5.0 on Saturday. They would get a chance on Saturday, but I do not see how it can be a healthy occupation with those hours?—The house is in the open air and there is plenty of fresh air coming into the house. It is not like a street.

920. You cannot work in a room with windows open. You must keep them shut or you will get the dust all over the paint work?—Yes.

921. With regard to insurance, you mentioned painters and paperhangers. You pay the same rate?—Yes.

922. Do you employ one in twenty paperhangers to painters?—One in ten.

923. Do the painters do the paperhanging?—Occasionally. We generally employ paperhangers to do that and nothing else.

924. As a rule, in the country, painters would do the paperhanging?—Yes.

925. So there is really not so much distinction between painters and paperhangers?—There is not any.

926. You have had no experience whatever of substitutes for lead, so it is useless asking you questions about them?—No.

927. (Mr. Gardner.) In the 20 to 25 tons of leadless paint you use, you include all the greens, the oxide of iron, browns, and all the other paint materials used in the shop with the exception of white lead?—In addition to the 18 tons of lead we use about a ton and a half of other paints that contain lead.

928. But many of these paints do not contain lead—some of the oxides, the greens, and the chromes?—I put them amongst the others.

929. That helps to bring it up?—It is only a small proportion. There are the siennas and all the different over-glazing colours.

930. You say that, from your experience of the trade, you have had to take no special precautions whatever in the shop, and that so far as you know the men have taken no special precautions?—Yes.

931. The only time you mix white lead in the dry state is when it is used for filling?—I do not think we use two hundredweights of dry white lead in the year. We use that for hard stopping.

932. You use it very seldom then?—I use the filling up that was introduced in the year 1870 by some French refugees from the Franco-Prussian war—they were fillers or enduiseurs. I have used that ever since.

933. Now, Dr. Collis referred you to a report of 1854 of what the Registrar-General said in connection with illnesses of painters at that date. Was there not a good deal of dry colour mixed in the paint shops at that time—dry white lead? Each paint shop was then practically its own grinding shop?—Yes, I believe the conditions were quite different from what they are now.

934. I cannot go back to that but I expect you will be able to?—Yes, I can go a long time back.

935. So that the conditions, generally speaking, of the trade are altered very much since 1854?—Yes, probably.

936. I think it has been proven here that the inhalation of dust is a great cause of lead poisoning. When you speak about scraping paint and burring off paint, do you mean that you scrape off the paint from window sashes that has been burnt by the sun without using any solvent?—Yes.

937. That causes dust. When you speak of burning paint do you mean burning by lamp or burning off by a solvent?—We use both.

938. Both terms are used to mean the one thing. In what proportion would you use the lamp to the solvent?—Three to one; I think.

939. The men are more exposed to the fumes of burnt-off paint in these processes during that time?—Yes I think so.

940. You do not think that the men require to soil their hands very much?—I do not think that they should.

941. You could not stipple a ceiling or a wall without soiling your hands?—I have not stippled a ceiling for years.

942. It is still done?—They are obsolete terms to me.

943. The man would be covered with a multitude of small spots if he did it; he could not do it without?—No.

944. It would require hot water to take it off. If the men only got half an hour for breakfast and were working in an empty house, who would provide hot water?—If I wanted hot water I could get hot water.

945. But you said in your examination that the men could get hot water. Now, I say if the men have only half an hour for breakfast and they require to get hot water in an empty house, how are they going to get it? Does the employer provide any facilities for enabling them to get hot water?—Yes.

946. That is what I want to know?—We generally send an apprentice to the job, and he puts the fire on and gets the hot water, and warms the men's breakfasts.

947. (Chairman.) You said "generally." Is it a specific order?—Yes. We always send an apprentice or, if it is a large job, one man is deputed to look after it. In an ordinary case we always send a boy to put the fires on and heat the water and warm the men's breakfasts.

948. Does the boy take coal and wood?—Yes.

949. Do you provide coal and wood?—Yes. If the men are at a country job near the cottage where they lodge, generally the landlady provides them with their meals and they go there. In nine cases out of ten the men get their meals in the houses where they lodge. It is only in isolated cases where they do not.

950. (Mr. Gardner.) Take an empty house in town where the men cannot get home for food. Would it surprise you to know that in not one case out of a hundred does the boy heat water for washing the hands?—I do not know what people do outside, but I know what I do in my own business.

951. But I am taking painters working on a job. The employer cannot always be on the job. It is a fact that in not one case out of a hundred does the boy, who is heating the men's breakfasts, heat the water for the washing of the hands?—He ought to do so.

952. But he has no orders to do it, and that is the danger?—That is the fault of his employer or the foreman.

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

953. That is what I wanted to get at. It is the fault of the employers because they do not do it. Do you use much sharp or flat for bringing up your work?—No.

954. Generally oil colour and varnish. In polishing that down with sandpaper, there is not a good deal of dust floating about?—No.

955. The particles stick to the surface of the sandpaper?—We do not use much sandpaper, as I have told you before.

956. In your establishment, no, but, taking the general rule of the trade, is it not the case that between coats the work should be sandpapered? It is only when you come to an enamel finish that you use the felt and pumice stone?—No. If we get it up in varnish colours we always use the wet process.

957. I am rather astonished. I am afraid that it is not a general rule in the trade. Paperhangers would be more apt to inhale dust than painters?—I quite agree with that.

958. Of course, it is a different class of dust?—Yes.

959. Is your sick fund a sick club or an accident fund?—No. It is merely a little fund; it is not much.

960. (Mr. Sutherland.) You have made a speciality of good work in your firm?—Yes.

961. You have a reputation for it all over the north of England?—I have.

962. You take a pride in it personally?—Yes.

963. So that that character which your firm possesses sustains what you have stated here?—Yes.

964. With regard to the difficulty that has been suggested in obtaining hot water on a job, is it not a fact that the men have control of the situation and they can, if they wish, get hot water?—Yes.

965. They have the buckets and they have the fire?—Yes.

966. And it really rests with the foreman or the men themselves, and if they wish to wash their hands in hot water they can do it?—Yes.

967. Then with reference to the general health conditions of a house painter, the daily work of 12 hours when working in the country is not 12 hours painting. It is 12 hours on varying jobs, is it not?—Yes.

968. Stripping?—Stripping and distemping.

969. And washing off, with open windows and pleasant surroundings?—Yes.

970. In the country jobs very often the meals are taken, as you suggest, in the cottages where the men lodge?—Yes.

971. Very often the cottages are near to the jobs in the country?—Yes.

972. And it is the wish of the men always on country jobs to work as long as they can?—Yes.

973. It is not imposed upon them by the masters?—No. They would not work on a country job unless they could work overtime.

974. Do your men complain of long hours at the instance of the masters?—No; the longer the better for them.

975. Another point that Mr. Parsonage asked you was about the stippling and flatting. The introduction of these non-poisonous paints in the way of washes and distempers has changed a good deal of the character of the work?—Yes.

976. And has done away with a good deal of flatting which was very injurious. If not poisonous it created headache and sickness?—I do not think we have flattened a ceiling once in the last six years.

977. The distempers are zinc paints, soluble in water?—Yes.

978. Have they superseded flatting to a very great extent?—Yes, and the operation of paperhanging as well.

979. Another point that bears on the question that Dr. Collis asked you about the Friendly Society's report of 1854 is this,—that the character of the men has changed very much?—It has.

980. Have they a very much higher character than the type of men we got 40 years ago?—Yes.

(Dr. Collis.) I gave you first the Registrar-General's most recent statistics, and then some of the oldest I could possibly get, to show that there was no difference in the last 50 years in the incidence of lead poisoning in the trade. I did not suggest that the painter of to-day was the same as the painter of 50 years ago; but I wished to give the extreme period over which I thought you might have experience—at both ends of your time.

981. (Mr. Sutherland.) The general type of painter is a very much superior man to-day?—Yes.

982. It used to be common years ago for half the men to be away on the Monday morning?—Yes.

983. Stopping off through drink?—Yes; 50 years ago it was a very common thing in the trade.

984. Less than that—30 years. It is not so now?—No; it was worse 50 years ago.

985. With reference to the Office of Works' experience of non-poisonous paints, do you think that four years is adequate to pronounce a judgment upon?—No, I do not.

986. What do you think would be adequate experience?—I do not know, I am sure.

987. (Lord Henry Bentinck.) For how long does your paint last in smoky cities?—I do not know. We have work now in Newcastle that we did fifty years ago in good condition yet.

988. Exterior?—I should think every three years an outside ought to be painted.

989. You say that an experience of four years by the Office of Works is no good?—I thought you meant with regard to the health of the men.

990. No. On the result of the work?—The weather would affect the paint.

991. If paint lasts four years, it has done fairly well on the outside?—Yes. I should like our customers to paint every three years, but four years would do perfectly well.

992. You said that the experience of the Office of Works which lasted over four years was not sufficiently long?—No.

993. You say that if paint lasts three years it does very well?—I say that an outside ought to be painted every three or four years. I should like it to be painted every three years.

994. In other words your lead paint is not calculated to last more than three years in a smoky city?—It depends on how many coats it has on and how it is done. If you give it one coat it will last for two years; if you give two it will last for three years; and if you give it an extra coat, it will probably last for five years. It depends entirely how the work is done. If it is carelessly done it will not last so long.

995. (Chairman.) You did not understand my question before, apparently. I will repeat it. If the Office of Works prove to the Committee that they have given non-poisonous lead paint four years' trial and it is proved to be in every respect as efficacious as lead paint, would you consider that that is a sufficient test and that the Home Office would be justified in prohibiting lead paint being used for exterior work?—All conditions being equal?

996. Yes?—All the results the same.

997. I put that as a specific and clear question with no equivocation or qualifications at all?—Well, I do not know, I am sure, what to say about that—the results being all the same and the conditions being all the same.

998. You surely could not, under the circumstances, object if it was proved to us on four years' trial that the non-poisonous paint was as good as lead paint?—What kind of paint would it be?

999. I do not care what it is. I simply call it non-poisonous paint; that is all?—Before answering that question I would like to know all the conditions.

1000. No, I want you to answer the specific question: If we are told that the non-poisonous paint is as good as the lead paint and that it lasts four years, would you say that this Committee were bound to prohibit lead in future?—Could you tell me what paint it was that was used?

28 March 1911.]

Mr. G. G. LAIDLER.

[Continued.]

1001. No. I do not want to go into that at all?—Well, I should say that four years' experience would not be sufficient.

1002. I say it with all respect that your answers to this question will not look very well in the evidence, because you told Lord Henry Bentinck that three years was about the average time that you liked paint to be renewed?—Yes, for outside work.

1003. When I tell you that the Office of Works have four years' experience you will not give me a direct answer?—I should like to know all the conditions.

1004. That is not a fair answer; with all respect to you, you decline to give me a direct answer to a direct question, and that must go down in the evidence and must be brought out in the report?—Well, I cannot help that.

1005. (*Mr. Sutherland.*) Do you think that there is any satisfactory substitute for lead as a paint?—I do not; I do not know of any. As I told you before, I have never tested these others. I have no experience of them.

1006. Is it not the fact that for the last 100 years chemists have been devoting their attention to the production of something that should take the place of lead?—Yes.

1007. And have they produced anything out of all the tests?—I do not know—not to my knowledge.

1008. I put this question because I do not think your answer should be characterised as unsatisfactory. You do not think that the four years' experience of the Office of Works without any knowledge of the conditions under which the work was carried out, is sufficient to set aside the practice of a hundred years?—No, it is not.

1009. Then you are in favour of enforcing some regulations in the practice of the trade to minimise the ravages of lead poisoning if it can be done?—Yes, I quite agree.

1010. But the difficulty is the difficulty of oversight, is it not? A staff of men are distributed all over the country and the employer is in the hands of his foremen, and he has to depend in the last resort on the character of the foremen for the enforcement of these things?—Yes.

1011. If no regulations can be devised and put in operation to mitigate white lead poisoning, what would you say?—To begin with, what I should like to see is the re-establishment of the apprenticeship system, by which boys could be trained up, not only in the trade, but in how to deal with paint and keep themselves clean and do their work in a cleanly manner. These boys would be trained up to be cleanly workmen, and precautions ought to be taken by all employers to see that their work is carried out in a cleanly way and to use the wet process as far as they possibly can. That would mean, of course, an increase in the price of the work, but that increased price has never stopped me from doing good work. The cost of the work has never been a question with me—as to whether I could save a little by using sandpaper for pumice stone and water. The wet process is the most expensive process, but it produces the best results and you leave your work to speak for your character after you have left it.

1012. (*Dr. Collis.*) The apprenticeship system was in vogue 50 years ago?—Yes. It was more in use then. I have indentures going back to 1812.

1013. I have already quoted figures of 50 years ago to show that this trade was one of the foremost of the dangerous trades then known?—I do not know that. I have no statistics.

1014. I have them here. I quoted them to you?—Yes.

1015. So that your remedy, perhaps, would only put things back as they were 50 years ago, when it was recognised as one of the foremost of the dangerous trades?—That is so.

1016. (*Mr. Sutherland.*) It is the practice for men to wash their overalls every week, is it not?—Yes.

1017. You would not allow a man to start with dirty overalls?—No, we would not allow him to start.

1018. The question of mixing does not apply much to the painters' shop, does it?—No.

1019. There is very little mixing done in the painters' shop?—Very little.

1020. It is done on the job?—Yes. The paint shop is a store shop.

1021. Is there not a provision in most of the working rules between the masters and the men that they shall have hot water provided? In the working rules between the employers and the operatives in towns, that is a specific rule that is put in?—Yes.

1022. They must have hot water provided and time allowed for washing?—Yes, in some of them.

1023. It is so in Manchester?—Yes.

1024. If it is not in Newcastle, it is the fault of the men in not providing for it?—We always provide it.

1025. (*Mr. Parsonage.*) There seems to be a tendency to put the blame on the foreman that he does not allow the men to get the hot water. If definite instructions were issued from the employer to the foreman that the men were to be allowed reasonable time to wash their hands, has the foreman any object in preventing the men having the hot water?—He could not prevent them.

1026. Would he have any reason to prevent them?—No.

1027. The reason why the hot water is not provided is that definite instructions are not given by the firm that at reasonable times hot water must be provided?—I do not know what other people do; I only know what I do myself.

1028. You would say that, if it is not provided in your shop, you would blame the foreman?—No; I say if a man wants hot water he can get it. If I want it, I can get it.

1029. But it is left to them to do it. If an employer came on a job, and he found the men two or three minutes to one washing their hands, what would he say to the foreman?—I do not know.

1030. What would you say yourself?—I am always glad to see them washing their hands.

1031. But I mean before the time. They have half-an-hour for breakfast, and have to go to the cottages to get breakfast in half-an-hour. You would not allow them to start at five minutes to eight to wash their hands to remove the paint. They must do it in their own time?—I would not object.

1032. In your time?—Yes, in my time.

1033. In nine cases out of ten, the employer would get on to the foreman and say: "What right have you to allow these men to be washing their hands before time?" That is a fact, is it not?—I know nothing outside. I do not know what other people do.

1034. But it is probable?—Yes.

1035. A foreman is a workman to-day and a foreman to-morrow?—Yes.

1036. He is a man just in charge of the work?—Yes.

1037. The inference is this—he is so anxious to further his employer's interest that he makes an enemy of all the men he is working with?—Those points are too fine for my comprehension.

(*Mr. Parsonage.*) You are trying to put the whole of the blame on the men put in charge of the job. I say that it is because the employer refuses to allow proper facilities to be provided and that is an undoubted fact.

1038. (*Chairman.*) I suppose there are a certain number of new houses you send your men to where there are no appliances for hot water or any water?—It does not matter where the men are they can get hot water, and they do get it.

1039. (*Mr. Parsonage.*) They would require that in the trade for melting size, and so on?—Yes.

1040. (*Chairman.*) They must have it?—Yes. Coal and firewood are sent on to all the jobs.

The witness withdrew.

28 March 1911.]

Mr. GEORGE DOBSON PATTERSON.

[Continued.]

Mr. GEORGE DOBSON PATTERSON examined.

1041. (*Chairman.*) You attend here to-day from the Office of Works?—Yes.

1042. What is your position there?—Clerk of Works in charge of the Western District.

1043. Can you tell us how long the Office of Works has been interested in non-poisonous paints?—For about nine years.

1044. Have experiments with lead substitutes been going on for that period?—Yes.

1045. Have you had to do with those experiments?—Yes. I have been in charge of them under the instruction of the principal architect, Sir Henry Tanner. I have personally carried out the painting of test boards in order to ensure the uniform application of the paints being employed.

1046. I suppose Sir Henry Tanner chose you to give evidence before these Committees because of your intimate acquaintance with the experiments which have been made?—That seems a reasonable assumption.

1047. Have you had a long experience of painting work?—I had a year in coach painting shops. I have had 20 years in the supervision of new buildings, and the last eight years in the maintenance of the Crown buildings in the western part of London, and special interest in paints.

1048. Can you give us some idea of the magnitude of the painting operations which the Office of Works has to deal with?—Yes. The contract for paints amounts to something like 5,000*l.* a year, and the cost of preparing for and applying the paints will run to about 17,000*l.* or 18,000*l.*

1049. Where is this painting done?—In all parts of the world.

1050. Mostly in the British Isles?—Chiefly in Great Britain.

1051. Will you tell us roughly what places the Office of Works has in its charge?—The Palaces, the Houses of Parliament, the Government Offices, the Crown Courts, Post Offices, and Inland Revenue Offices, in Great Britain; and the Foreign Consulates.

1052. Do the conditions in these widely distant places vary very much from the point of view of paint suitability?—Yes; we have to meet almost every conceivable condition.

1053. What quality of paints do you use?—Broadly, we have three grades.

1054. In what situations and for what purposes do you use the lowest grades?—For ordinary external painting, and for the lower class interiors.

1055. Where do you use the other qualities?—We use the medium enamels for general interiors, and the best enamels in the better class rooms only.

1056. What are the chief reasons why some paints are dearer than others?—The quality of the oil and the quality and the amount of the varnish, for instance, are important factors.

1057. Has the pigment—white lead, zinc oxide, lithopone, or barytes, or whatever it is—much effect on the price?—Yes. The pigment constitutes roughly half the paint, and as pigments differ widely in price, the price of paint is relatively affected.

1058. Are your remarks comparing zinc oxide paints with white lead paints likely to require modification according to the different grades of paint?—No. What I have to say applies about equally to the various qualities in similar shades of lead and zinc paints. They would be approximately the same, and we buy them at the same price.

1059. Are there any objections to lead paints apart from their poisonous effects?—Yes. The defects are discoloration by combining with the sulphur in the atmosphere, and chalking in chemical and seaside atmospheres. It has a great tendency also to blister and scale very much on hot pipes and surfaces.

1060. Have there been many difficulties in your quest of non-poisonous substitutes?—Yes.

1061. Have you had serious opposition from paint-makers?—No. They naturally lean a little to the lead, of which they have had long experience, but most of them now make zinc paints, and the qualities of these are improving with experience.

1062. Have the workpeople themselves appreciated the efforts made to lessen their risk of ill-health?—No. We have had little help from the painters, and much disinclination to face any change. They do not realise, it is feared, the danger to themselves in using lead.

1063. What substitutes for lead paints were available nine years ago?—Commercial enterprise had already introduced to the paint trade cheaper substitutes for white lead, such as lithopone, and others, but zinc oxide then, as now, is the only serious competitor with lead, though others are doubtless possible.

1064. Will you please describe the main characteristics of zinc oxide?—It is a fine, white, easily worked paint base, non-poisonous, and practically permanent in colour. It has been found particularly valuable in chemical and seaside atmospheres, and makes whiter and better enamels than were possible with white lead.

1065. Were the zinc oxide paints satisfactory when first tried?—No. When these paints were first used in 1902 by us they were too slow in drying; but their chief defect was lack of opacity, needing three or four coats to equal two of white lead paints. They were far from satisfactory when first tried.

1066. Where were they obtained?—From the usual paint-makers, or in some cases they were mixed by the ordinary painters, who were treating zinc oxide according to their experience of white lead.

1067. Did not zinc oxide respond to the treatment appropriate for white lead?—No.

1068. Then your earliest experience of zinc oxide was not very favourable?—No, partly because the workmen did not understand the material, and partly because we did not get good paint at first from the ordinary makers.

1069. Were you experimenting at about this time?—Yes. The principal architect was already having elaborate comparative tests carried out on the iron plates of the Patent Office roof in Chancery Lane in paints of various makes, some of white lead and some of oxide of zinc base. At his request a systematic study of the subject of a non-poisonous substitute for white lead was begun at the Savings Bank in 1906.

1070. Did you make up trial paints yourselves?—Yes, and it was soon discovered that when zinc oxide was mixed with refined boiled linseed oil, with the usual thinners, and a trace of litharge and borate of manganese driers, such paints dried quite well.

1071. Was the initial lack of opacity remedied?—Yes. It was further found that thicker zinc oxide paints could be used quite freely, in fact with as much as 60 to 70 per cent. of zinc oxide, and that when so used they were of equal opacity to the usual white lead paints. Moreover, while at least three coats of paint have generally been given on bare plaster walls, many post offices in the western district of London have been successfully painted with two coats of zinc paint.

1072. Then when you got to understand zinc paint a little better you were actually putting on less coats of it than you would require of white lead?—Yes.

1073. Did you use the same mixtures for finishing as for undercoats?—No. It had long appeared that the best paint for undercoating differed materially from that of a best finishing coat. After many trials, therefore, and much investigation, a specification of zinc oxide paint was drawn up, embodying the general results of our experience for undercoating, and finishing in white, brown, and green as representative colours.

1074. Have paints to these specifications been used on a large scale?—Yes. In 1906, as the paintings became due, the Crown buildings in the Savings Bank district were painted with these oxide of zinc paints, and since 1907 zinc paints have been used generally. Since that time systematic observations have been made, and records kept, of the various makes and compositions of paints used.

1075. Do I understand that you have complete records of all the paints used since 1906?—Yes, in the western district, with which I have had to deal.

1076. How much of the paints you have used in the last four years has been based on lead?—Only a

23 March 1911.]

Mr. GEORGE DONSON PATTERSON.

[Continued.]

small proportion for primings on new work, and red lead used on iron.

1077. What proportion of all the paint used in the last four years has contained more than 5 per cent. of lead?—Probably about 10 per cent. of the paints have contained more than 5 per cent. of lead.

1078. What quantity of lead did that 10 per cent. contain?—Some of it would probably contain, as, for instance, in primings, chiefly white and red lead, and the other part of it, for iron work, would probably be almost entirely red lead.

1079. What are the chief results of your experience of zinc oxide paints?—Our experience is that zinc oxide as a paint-base is a good substitute for white lead for most ordinary purposes in white and kindred shades. In colour and wear it has stood very well internally, and also externally where used on old lead paint, with slight exceptions.

1080. Have you not used zinc paints on new work at all?—Yes, on bare plaster walls we have used a good deal. We have also used zinc paints on wood and iron in both internal and external situations on new buildings since 1907.

1081. Why has most of your zinc painting been done over old lead paint?—Because most of the painting work needed was on buildings previously painted. The new buildings since we have been using zinc paints are, of course, only a fraction of all the buildings we paint.

1082. Have you used lead undercoats in your zinc painting?—No. In the case of old work we prepared the surfaces originally painted with ordinary lead paints, and then applied the full two or three coats of zinc paint. The undercoats were zinc paints as well as the finishing coats.

1083. What do you mean by "preparing the surface"?—Washing and rubbing down generally.

1084. The zinc painting on new work which you have done totals a considerable amount, I suppose?—Yes.

1085. Would you go so far as to say you are confident from your own knowledge that you can get as good effect from zinc oxide for white and kindred shades as from a lead-base?—Yes.

1086. Suppose there was any doubt in your mind on this question, would the addition of say five per cent. of lead compounds remove all shadow of doubt as to its absolute ability to take the place of lead?—Certainly.

1087. Do your remarks apply equally to white and to coloured painting?—Not as regards external work. The greatest difficulties have not been experienced in the white and kindred shades of paint, but in the total abandonment of white lead and lead salts generally in the dark colours.

1088. I want to get this quite clearly. Do I understand that you have purely zinc paints now which are perfectly satisfactory in all colours for interior work?—Yes, with a few exceptions in damp situations and dark colours.

1089. Are they equal to the lead paints they have displaced?—Yes, with the above exceptions, and these we find can be overcome by the addition of a little lead.

1090. What added quantity of lead do you suggest?—For stability, something like 5 per cent.

1091. Not more?—Not more—apart from colour.

1092. Now as regards exterior work, do the zinc paints in the white and light shades give full satisfaction?—Yes.

1093. But for the darker colours only in the case of exterior work your zinc paints are not at present all you wish?—No.

1094. Are these darker paints an important part of the work? Do they constitute a large proportion of the total or not?—They are not more than perhaps 15 per cent. of the whole.

1095. Are the deficiencies of this one particular paint very serious?—No, the deficiency was not very serious; it amounted to a softening after a winter's exposure to the weather, which had not appeared in lead paints, and our desire was to get as good results as we had been having.

1096. Have you been investigating the reason why this solitary result was not so entirely satisfactory as the others?—Yes.

1097. What zinc oxide have you used? Was it derived from the metal or direct from the ore?—Chiefly zinc oxide by indirect process from the metal, used, but a little by direct process from the ore.

1098. Have you taken any precautions as to the fineness of the grinding?—No precautions have so far been necessary, zinc oxide being generally very fine, but iron oxides, siennas, browns, and blacks are often coarse, and there is much to be desired in the way of agreement in the trade of a definite standard to which all pigments shall be ground.

1099. Was any oil other than linseed oil tried?—Yes; paints with Chinese Tung oil have been tried with success.

1100. Have you varied the driers used?—Yes; and, so far, the use of a litharge and borate of manganese drier has given the best results.

1101. What percentage of lead compound in the paint does this represent?—About 1 per cent. as drier, but great improvement has been found from the addition of lead oxides as pigments in dark browns and greens up to about 4 per cent.

1102. What is about the proportion of lead salts usually present in zinc oxide derived direct from the ore?—From one up to four or even more, according to the character of the ore used.

1103. If 4 per cent. of lead salts in the pigment is allowed, would your difficulty with the darker shades for outdoor painting disappear?—Five per cent. would dispel it so far as stability is concerned.

1104. Why do you qualify your answer by saying "so far as stability is concerned"?—Because lead compounds may be needed and may be found necessary beyond the 5 per cent. for the production of dark greens, as in lead chromates. They are rather popular, are the greens nowadays, and there is the difficulty.

1105. Could you use zinc chromates instead?—They would be more expensive, and so far they have not been found so satisfactory or so opaque or so fast, but that might be got over possibly by chromium oxide or other substitute.

1106. It is only in the dark shades of outdoor paint that you wish to have any lead compounds at all?—Yes. We can get very good paints in all shades with a maximum of 5 per cent. of lead except in the dark greens of which I have spoken.

1107. You have told us the present position of the Office of Works' paints, namely, that zinc oxide pigments practically free from lead are being satisfactorily used in all cases except for certain of the darker shades of exterior paint, in which you prefer lead compounds to a limited extent. Will you please give us your experience of the vehicle appropriate to the pigment?—The character of the medium by means of which paint pigments are spread and covered is of equal importance, we think, with any other. Refined boiled linseed oil is doubtless one of the best mediums for zinc oxide paints, both because of its colour and superior drying properties.

1108. Is this good both for under-coats and for finishing coats?—It is good for under-coats, but it makes the paint rather rosy and of uneven surface if used alone as a finishing coat medium.

1109. Can this royness easily be avoided?—Yes, it is effectively overcome by the addition of a certain proportion of good oil copal varnish, which improves the appearance and protective power of the paint, and gives it a flow. The proportion of varnish used may vary considerably according to pigment, quality of varnish and purpose of the paint.

1110. What proportions have you found to answer best?—In the tests carried out for exterior paints one part of varnish to three of oil were found to give the best results with zinc oxide, while for iron oxide and other dark paints, one of varnish to two of oil were found best for a protective gloss paint.

1111. Do you consider any other oils equally good with zinc oxide?—Yes; Chinese Tung oil is largely and successfully used in America, China, and Japan, and increasingly in England, as a paint medium. It

28 March 1911.]

Mr. GEORGE DOBSON PATTERSON.

[Continued.]

dries with a hard, yet elastic, film, and our experiments show that paints in which this oil displaces linseed oil as a medium are superior to any other as protective paints, the pigments being equal.

1112. Then, to make a satisfactory paint, you attach considerable importance to the vehicle as well as to the pigment?—Yes, a good paint depends on many factors, not least on the quality and condition of the materials used, and an analysis, though helpful, gives little or no indication of the quality of the constituents, nor the amount or class of varnish or oil used. The physical test is the only one which can be regarded as reliable and final in estimating the worth of a paint.

1113. Will you please tell us the comparative costs of zinc and lead paints?—Zinc paints cost us the same as lead in the market.

1114. In the cases where you used two coats of zinc instead of, as formerly, three of lead paint, it would work out cheaper, I suppose?—Yes, about 2½d. per yard in the saving of a coat.

1115. If the use of lead paint were prohibited, should you expect the price of zinc paints to rise on account of increased demands?—No; I think there would be no difficulty on that score. There would simply be an increased production of zinc oxide, provided that due notice were given of the change to be made.

1116. Do you think there would be any supreme difficulty in the application of such a prohibition? Would there be great inconvenience in transferring from lead to zinc paints?—No, but there would be likely to be much prejudice to meet. But what other countries have done in this way should not be difficult for us to follow in the interests of the workers.

1117. Would you, from the point of view of the great Department you represent, consider it a dangerous thing to introduce the prohibition of lead paints?—No. I would rather welcome it within the limits previously stated. We have been expecting such a step for some time, hence the purpose of our experiments.

1118. To sum up your evidence, the Office of Works has for some years been using paints practically entirely free from lead?—Yes, with the slight exceptions named.

1119. On the whole these paints have been decidedly successful for interior work and also for exteriors, and the cost is about the same as the cost of lead paints?—Yes.

1120. You would prefer for the present, at any rate, to be allowed a lead content in some of your paints not to exceed 5 per cent.?—Yes, and if 10 per cent. could be allowed in the dark greens (that is the chromates) even that difficulty would be overcome. Chemistry, I think there is little doubt, will overcome that as it has done many other difficulties of the sort. They are all feeling after it.

1121. Are you of opinion, with all your great experience, that, except for this limit, the use of lead paints might very well be compulsorily abandoned?—Yes.

1122. What you have told us is the result of your own practical demonstrations?—Yes.

1123. (*Sir Godfrey Baring.*) You spoke at the beginning of your evidence as to a certain disinclination you had found amongst workmen to use zinc paint. Do you think that that disinclination comes from the fact that it is new or from any practical difficulties in manipulating the paints?—Probably from our inherent conservatism; and that, where we have had experience of a thing, we are more or less loth to embark on experiment unless we are impelled by some force—self or other interest. If the painter does not realise his danger, he is very apt to put any little failures down to new material.

1124. There is no special difficulty in using zinc paints?—No.

1125. No practical difficulty?—No.

1126. Do you find that zinc paints are specially adapted for exterior work in London and in manufacturing towns where there is a great deal of smoke and sulphur in the air?—Yes.

1127. You say you can get almost better results in manufacturing towns than from lead paints for external use?—Yes.

1128. Do you find that there has been improvement in the quality of zinc paints recently?—Yes, a steady improvement.

1129. Do you think that that improvement will probably continue in the future?—I think so.

1130. There are still improvements to be made in the manufacture?—I think the improvement will continue as we become more acquainted with it.

1131. Speaking generally, you think your experience has been sufficient with the zinc paints to speak with authority as to their value. You think you have had sufficient experience for that?—We feel convinced of that or we would not continue it. Ours is an intensely practical Department.

1132. (*Dr. Collis.*) Do you keep any statistics at all of the amount of illness that occurs amongst the work-people of the department?—No. The contractors take all responsibility for that under the conditions of their contract, and when a workman falls out of the ranks we know nothing of it. They have to take any burden in that way.

1133. So that you do not know what the contractors pay for insurance?—No.

1134. (*Mr. Sutherland.*) How would you define zinc oxide or zinc paints? For instance, if the Office of Works specified lead paint they would term it "genuine white lead." Could you specify anything parallel to that in referring to zinc paints?—Yes; we do specify it now—pure oxide of zinc with a certain amount up to, I think, in our present specification, half per cent. of impurity.

1135. Is zinc oxide paint genuine zinc oxide with no adulterant—no carrying matter?—It is a good deal a matter of percentage or chiefly a matter of the percentage of lead that goes down in the precipitation.

1136. I do not mean the structural percentage of lead—that comes into it.—but I mean the mixed paint. If I went into the open market and ordered zinc paint, I should get probably 70 per cent. of barytes or sulphate of barium in it as carrying matter?—Not if you stipulated or specified a pure zinc paint any more than with lead. You are no doubt familiar with the fact that you are getting, in the same spirit of adulteration, a good deal of barium sulphate in place of your white lead.

1137. Not if I specify genuine white lead?—If it is genuine white lead no, and just the same if it was genuine zinc oxide, within say, half per cent., or within say, 5 per cent. you would expect to get it. You would get it only if you saw you got it.

1138. There is a margin. Does the Government in its specification impose an absolute test of the purity of zinc oxide in the paint it gets?—Yes, we have been specifying that we should have pure zinc oxide when analysed with not more than half per cent. of impurity.

1139. Would you call 3 or 4 per cent. of lead salts an impurity?—I would extend it up to five, I would allow that in my definition of pure zinc oxide paint.

1140. I have had no experience myself, but I am talking of pure zinc oxide and adding something to get body to it?—I think the highest grades of zinc oxide come to within the half per cent. that I have been speaking of.

1141. I should take that as a pure zinc?—I think you may take that as a pure zinc. We have been using that and find we get very good results.

1142. Have you not to use it very stiff?—Yes, it is used stiffer. There is a greater bulk of pigment not weighing so much. It is perhaps a little stiffer to use, but the nature of the pigment is vastly different from lead and it goes on greasily and easily.

1143. Greasily and easily are distinct terms. It is the fact that it goes on greasily that the painter objects to?—I found no objection.

1144. I am not thinking of Office of Works painters; but where zinc paint has been introduced it is the very fact of it slipping over the wall that has created prejudice on the part of painters?—We have not found that that has been so. We have found they complain

28 March 1911.]

Mr. GEORGE DOBSON PATERSON.

[Continued.]

sometimes when we have increased up to 70 per cent. that it began to get stiff for the elbow; but for paint round and about 60 to 70 per cent. we have not had such complaints.

1145. Seventy per cent. of what?—Pigment.

1146. And the rest what?—Medium.

1147. What do you call the medium?—The oil or varnish, with turps as thinner.

1148. If you put lead in the hands of 50 men promiscuously gathered together, they can mix it from their general knowledge and familiarity and it will work right. That is the great advantage of it. If you put zinc and gave them all the materials to mix it, probably only one in 50 would mix it correctly so that he could use it?—Naturally, because the material is new to them. They have had experience in one case and not in the other; but time will mend that.

1149. That raises the question—provided the Government want to make this change and to enforce it, what length of time would you consider sufficient? We know that in France the men work this as simply as we work lead, but it is because they have been trained to it almost from apprenticeship. Our men, speaking generally, of the painting trade throughout the country have not been used to it. It is quite a new thing to them, and to force it on them would be not only a serious thing to lead manufacturers (we are not concerned with them) but it would prejudice the men themselves in their trade, though it might improve their health. It would certainly prejudice the position of the masters with their customers until they became masters of the material. What term do you think the Government ought to allow for the change?—I should think anything from, say, two to three years.

1150. You cannot change the habits of a trade and of men in middle life with confirmed practices in two years?—I said two or three.

1151. Or three?—But I would remind you that apprenticeships are usually for five-year terms, and when I remind you that this is only unlearning or learning something in a particular direction and not the whole of the trade and that you have all the assets of a man's experience as an advantage, whereas an apprentice has no knowledge at all, I think anything like two or three years would be sufficient to familiarise the paint trade with the new introduction. And I would remind you further that this familiarity or this experience has already begun. We are considerably advancing in that direction. Many of the paint manufacturers are using not the old lead but a mixture of the two things, and they are gradually leaning over to the other direction.

1152-3. Prepared paints for the last few years have come on to the market and they are mixed by the manufacturers?—Yes.

1154. I get six samples of non-poisonous paints, and the proportions are these: zinc about thirty—I am not confining myself to fractions—and carrying material in the way of sulphate of barium about sixty, and then the oil. The difficulty appears to me to be this, that if the Government insists on this in their specifications we should have to convince contractors and the architectural profession. As a rule it is white lead and pure linseed oil that is specified. It would have to filter down through those channels to the public before you could make a definite change, and I do not think it could be done in three years?—I do not quite gather the change you are hinting at. If the prohibition were only that there should not be more than a certain percentage of lead, that would leave the paint trade free to use any non-poisonous material there might be. It would allow chalk or anything you liked to put in so long as it was non-poisonous and the lead salts did not exceed 10 per cent. at the outside.

1155. I want to know, can they (either the Government or architects) by specifying "pure zinc oxide" get a satisfactory paint?—Yes.

1156. Without qualification?—If they specified definitely the paint they want. We have been specifying it. We did not find that either genuine white lead or genuine zinc was sufficient. We had to give some

more specific indications of what we meant in the composition of the paint.

1157. That is one of the difficulties that would ensue on any prohibition of white lead. I foresee that it would take time to educate the profession and the trade, and to be fair to the manufacturer?—It is all a matter of price and of letting people know what you want, and of paying for it. May I say that in making an estimate of the time it is fair to discount the fact that everybody has not been anticipating this as we have, and if the time is too short, that is for the Committee.

1158. (Mr. Gardner.) Do you think that the disinclination to use zinc oxide exists among employers or among the men?—We have not hitherto asked employers what they thought. We have put in our contract in the first place, lead and zinc, and then we have specified in the carrying out of our orders what the paint shall be, and we have left the contractor no option but to supply it.

1159. You found that the practical painter at once adapted himself to the new material?—Not altogether. We found that a certain amount of that innate conservatism in all of us was manifest in him also, and that he was perhaps inclined to blame for any fault that might be found, the new material rather than anything else.

1160. But not more so than if he was getting a new enamel to use?—I am afraid that his disinclination has arisen from the fact that he does not appreciate the poisonous nature of the material which he has been using and has been brought up to.

1161. It is not a great difficulty. He would not need to learn a new trade. Dr. Legge told us the other day that practically the painter would require to learn a new trade to use zinc paint. Do you agree with that?—No.

1162-3. What about a substitute for lead (either white lead or red lead) on stucco and ironwork?—That is a very important question. I have carried out a series of experiments upon tanks (inside cast iron tanks), and you probably follow me when I say that the line by the fluctuating surface of the water is one of the most difficult places for a paint to be got to stand upon, and in that case we have found red lead little better than many other things. Probably a mixture of several things is better than any one. We have found, and that was what my answer particularly denoted, that in the presence of water and on ironwork we have been driven to attach more importance to the medium than to the pigment.

(Mr. Gardner.) That just brings me to this; it is usually said that red lead is the best article to put on outside ironwork. I attach more importance to the medium. I experimented on iron in my own house with red lead made up in the usual form and with white lead made up with steam boiled oil, as we call it, instead of refined boiled oil. I found that the white lead lasted much longer than the red lead.

1164. Do you not think that in painting your walls two coats, the refined boiled oil also had a good deal to do with the wearing properties?—Probably, and also the way in which it was put on. Some firms in London here have been feeling after this for many years, and all credit is due to them.

1165. Have you not found that anilines are very dangerous for painting over afterwards. They strike through, no matter what you put on top? We do not find that in the reds. We get splendid reds now.

1166. But if you paint on the top with another colour, do you not find that they strike through?—We have not found any difficulty. This bleeding is no longer a difficulty.

1167. That is one of the difficulties a painter has to contend with just now?—It has been a very difficult matter. They have flown, they have done all sorts of things, but these last two or three years we have been getting very satisfactory reds.

(Mr. Gardner.) Our experience in the trade has been what I have put.

1168. (Mr. Parsonage.) A good deal of your work is sublet, is it not, the palaces and so on?—No. The

28 March 1911.]

Mr. GEORGE DOBSON PATERSON.

[Continued.]

contracts up to 300*l.* are all done under one general schedule. In the London district, for instance, Messrs. Mowlem have employed their own men.

1169. The work done by White and Allan at Buckingham Palace would come under this head?—There are special contracts over 300*l.*

1170. The best work?—Either best or ordinary; if it came over 300*l.* there is a condition in our contract which states that the Commissioners shall be able to call for competitive tenders above a certain amount, and those you refer to might probably come under that head.

1171. Do you specify zinc white in any of what I term the best work in Buckingham Palace done by outside firms?—I have not had Buckingham Palace under my charge, but the whole of our specifications now stipulate for zinc oxide paint.

1172. Would that apply to an outside firm that contracts for the work?—So far as I know that would obtain also with all contracts.

1173. Up to three years ago the best rooms of Buckingham Palace were done by outside firms and they were done with ordinary white lead. There were no requirements by the Office of Works that any non-poisonous substitute should be used; and I should have thought that as this was expected to be the best work in the best rooms, surely they would have stipulated for it being used if it is so much better. That was up to three years ago?—I have no personal knowledge of that so I cannot reply.

(*Mr. Parsonage.*) And Marlborough House the same; the stipulation there was for genuine white lead. I should have thought they would have stipulated for the other if it is so much better.

1174. (*Chairman.*) You speak of Government specifications. May we have a specification of such paint as you find satisfactory put in?—I submitted that in the following table:—

SUGGESTED COMPOSITION OF OFFICE OF WORKS STANDARD PAINTS, 1911.

| Description.                 | Zinc Oxide. | Chalk, Silica, or Barium Sulphate. | Lead Compound. | Lead Oxides Litharge. | Prussian Blue. | Iron Oxides. | Refined Boiled Oil, Driers, and Varnish. | Best American Turps. |
|------------------------------|-------------|------------------------------------|----------------|-----------------------|----------------|--------------|--|----------------------|
| Ivory white undercoat - - -  | 58          | 10                                 | —              | —                     | —              | —            | 17                                       | 15                   |
| Finishing coat - - - - -     | 56          | 2                                  | —              | —                     | —              | —            | 36                                       | 6                    |
| Brown T 12 undercoat - - -   | 20          | 10                                 | —              | 3                     | —              | 15           | 37                                       | 15                   |
| Finishing coat - - - - -     | 3           | 5                                  | —              | 4                     | —              | 22           | 60                                       | 6                    |
| Green No. 49 undercoat - - - | 20          | 10                                 | 6              | 2                     | 2              | 8            | 37                                       | 15                   |
| Finishing coat - - - - -     | 3           | 8                                  | 8              | 3                     | 2              | 12           | 58                                       | 6                    |

1175. (*Mr. Parsonage.*) Have you had any experience with zinc paint mixed with raw linseed oil. You have spoken of boiled oil all the time?—We have only tried it once, and we found that it did not dry at all. The drying properties of the oil are an immense factor; much more so than in the case of lead; and you have to unlearn the mixing of raw oil with the pigment in the case of zinc.

1176. It would therefore be no use in coach painting at all?—I am afraid raw oil and zinc oxide would be useless in coach-painting.

1177. (*Mr. Fell.*) Is the experience of the Office of Works based on London only, or have they any experience of seaside places or anything like that?—One of the questions already answered covers that, that we deal with the whole of Britain in our control, and the whole of the Government buildings accordingly at seaside and other places have been dealt with in this way.

1178. So that your standard specification is based on a sort of general experience and not local experience in London?—Exactly.

The witness withdrew.

Mr. THOMAS JORDAN examined.

1179. (*Chairman.*) You are attending here to-day to give evidence regarding the painting department of the carriage and waggon works of the Midland Railway Company, Derby?—Yes.

1180. What is your position there?—I am the chief foreman painter.

1181. What experience have you had in the painting of railway carriage and waggon rolling stock?—About forty-five years, on the London and North Western and the Midland Railways.

1182. Do the Midland Railway Company use any white lead for carriage or waggon painting?—Not at present.

1183. How long is it since the use of white lead was discontinued?—Six or seven years.

1184. What has been in use during the last six or seven years as a substitute for white lead?—White zinc.

1185. Do I understand that to mean zinc oxide and zinc sulphide?—Yes, both.

1186. Has this paint, in your experience, proved equally as durable and as good in other respects as white lead paints?—It does at present for our purposes.

1187. Has the substitution of zinc paints for white lead stamped out lead poisoning at the carriage works at Derby?—Not entirely.

1188. Have the cases been much fewer?—Much fewer. From 1900 to 1905 we had 30 cases. We

were then using principally white lead with a small portion of zinc. From January 1st 1906 to December 31st 1910 we have had four.

1189. How do you explain the fact that there are any lead cases now-a-days?—I cannot explain it, unless it was in the system and developed itself afterwards.

1190. Do I understand you to mean that some lead colouring matter is used sometimes?—No, we do not use that.

1191. Could you account for these cases of lead poisoning by the fact that old carriages and waggons, painted before white lead was given up, come from time to time to be scraped for painting?—No. I should attribute it more to this, that the cases were cases of men who had been employed and perhaps had been using lead paint elsewhere. I can give you an example, if you like.

1192. Yes, please do so?—We had two cases: one was that of a gas fitter who had not used any lead at all since he came to us a few months ago. And another was that of a painter who, previous to coming to us about nine months ago, had been engaged by a builder and had been using lead largely for the builder. Both of those men were scheduled as suffering from lead poisoning, but they had used no lead with us.

1193. I quite follow. You would naturally expect—in fact there can be no question about it—that if you discontinue lead your employees cannot get lead poisoning?—Certainly I do.

28 March 1911.]

Mr. THOMAS JORDAN.

[Continued.]

1194. I understand that you are prepared to give evidence with regard to the various processes of coach-painting in detail, including the preparation of the woodwork?—Yes.

1195. Can you tell us, with regard to jointing, whether lead is still used in the Midland carriage works?—No, it is not.

1196. What do you use instead?—It is called jointing paste, and it is composed of zinc oxide and barytes.

1197. Is that satisfactory for the attachment of ironwork to the under-frames of vehicles?—Yes, quite so.

1198. Will you please describe the priming process?—That is two coats of colour prepared from zinc and vegetable black.

1199. Is there any difference between the behaviour of zinc and lead paints when used for priming?—None whatever.

1200. What are the next coats of paint called?—Filling up.

1201. What material do you use for filling?—It is an earth consisting of silica and alumina chiefly, with the natural adulterants that are found with it. It largely consists of silica and alumina.

1202. Do you find leadless filling to be entirely satisfactory?—Yes. We put zinc into the filling that we use, not lead.

1203. And it is quite satisfactory?—Quite satisfactory. It is a very good filling.

1204. Will you tell us what you understand by stopping?—That is a thick paste which is used for filling up holes.

1205. What material do you use for stopping?—White zinc.

1206. Do you find that it is quite as satisfactory as the lead stopping previously used?—Quite so.

1207. Will you tell us in what way the rubbing down between successive coats of paint is done in the Derby carriage works?—With sandpaper.

1208. Will you now describe the method of applying the finishing coats, and the materials used?—After the second or third coat of lead colour (I am not speaking now of lead but of the zinc tinted with black) is applied we give it a coat of what we term lake grounding; that is an iron paint consisting of about 97 per cent. of iron oxide; and afterwards we give it three coats of lake, which consists of cochineal and a paste which is alumina.

1209. And last of all does the carriage body receive a coat of varnish?—Four coats of varnish.

1210. Why do you varnish?—To preserve the paint and to produce a smooth surface for cleaning purposes.

1211. And I suppose that it improves the appearance?—Certainly it improves the appearance, but it is also a preservative.

1212. Would the paint be durable in bad weather conditions if you did not give it a protective layer of varnish?—No.

1213. Do you use leadless paints also for the lining and for decoration?—Yes; for lining we use vermilion, which is composed of mercury.

1214. Are you able to dispense with the use of lead even for sign writing?—Yes; we do not use lead at all for any purpose.

1215. I mean for painting on waggons not varnished?—We do not varnish the waggons. We rely on boiled linseed oil for protection there.

1216. Do you use much paint that is thinned with turpentine?—Yes, all the paint is thinned with turpentine for carriages.

1217. Is the grinding and mixing of the various paints entirely under your charge?—Yes.

1218. What are the principal colours used in the Midland carriage works?—White, black, brown, yellow, lake, vermilion; and umbers, ochres, and siennas. I think those would be the principal colours.

1219. Do you use any green?—No.

1220. And in all these cases are the Committee to take it that you have found it quite practicable to dispense with the use of lead?—Quite.

1221. Have you found the leadless paints as durable as those compounded with white lead?—Yes,

we find them so now after the experience that we have had with them in the mixing.

1222. Even when used on waggons and not varnished?—Exactly. We use nothing but boiled oil in the paint.

1223. You find it just as durable even on waggons which are not varnished?—That is so. We rely upon the boiled oil.

1224. In short, have you found the leadless paints equally satisfactory in every respect?—Yes, we have.

1225. (*Sir Godfrey Baring.*) You have experienced no practical inconvenience whatever from the abolition of lead?—We do not at the present time. We have had a long experience and have had to find out a very great deal for ourselves.

1226. Would you say six years' experience is sufficient to enable you to speak with confidence?—Yes. I have had 20 years' experience with this altogether.

1227. Yes; but I understood that you had only abolished lead altogether for six years?—Yes.

1228. Have you experienced any disinclination amongst the men to do without lead and to use these substitutes?—Not at all.

1229. They have not complained of any difficulties in working?—Not at all.

1230. (*Dr. Collis.*) Do you insure your men at all?—No.

1231. There is no different rate of insurance according to whether you use zinc paint or lead paint?—No. We do not insure at all.

1232. So you cannot tell us about that. With regard to the use of vermilion, what is vermilion?—Mercury chiefly.

1233. You are aware that it is an innocuous form of mercury?—No, I do not think it is.

1234. It has that reputation?—Yes, I know.

1235. Have you ever found any trouble arising from it?—No, we do not use sufficient for that. We only use small quantities, and it is never issued to the men dry.

(*Dr. Collis.*) I want to bring out the point that the vermilion is used as a substitute for lead, and that it is a harmless substitute.

1236. (*Mr. Fell.*) Do you use canvas on the top of your vehicles?—Yes.

1237. Do you bed that down with leadless paint?—No, we bed it down with jointing paste.

1238. Without any lead in it?—It is composed of zinc and barytes.

1239. Do you find that there is any difficulty arising from that powdering?—No. We find we get very good roofs.

1240. You find that the weather does not affect it?—No. Of course it is underneath.

1241. You do not have it at the top?—No, we do not use it on the top.

1242. Not on any of your waggons or anything?—No. We use zinc paint on the top.

1243. You said just now that you use three coats of varnish?—Four.

1244. How often do you re-varnish?—Every year.

1245. So that, practically, you never get down to your paint?—No.

1246. So when you rub down you only rub down to re-varnish?—That is so; we just rub the surface off.

1247. In the annual overhaul of your vehicles there would be no lead dust through using lead paint?—None whatever.

1248. How do you work your shifts in the shop?—We have only one, from six in the morning to half-past five at night.

1249. You do not work it with a single break?—No. We work from six to a quarter past eight; from nine till one, and from two till half-past five.

1250. There are no meals taken in the shop?—None whatever.

1251. Did you find before you used leadless paint that there was a great difference? I mean to say, did you have more cases of lead poisoning in the body shop or in the paint shop?—More in the paint shop.

1252. That was an ascertained fact?—Yes.

1253. Have you any figures upon that?—Yes; 18 against 12. In the first five years—18 painters and

C 2

28 March 1911.]

Mr. THOMAS JORDON.

[Continued.]

12 employed in other work, and in the second five years there were three painters and one bodymaker.

1254. Do you keep special men for working outside upon the vehicles and others for working inside?—Yes.

1255. Do you find that in the case of the men who work on the inside of the vehicle there are a larger number who have lead poisoning than amongst those who work on the outside of the vehicle?—There were 13 out of the 18 that worked inside. Five worked outside.

1256. Do you find that the bodymakers as a rule are more likely to get white lead on to their clothing than painters are?—No.

1257. Do you not find that men who are working partly on woodwork and partly joining up wipe their hands more on their clothes and so get more white lead on to their clothes?—No, I do not find that. They do not.

1258. Are the same washing facilities provided for the men working with white lead in your body shop as in your paint shop?—Yes, exactly the same.

1259. Do you supply overalls for the men?—Only for those who work in the colour room—the colour mixers. They have a clean suit of overalls every week.

1260. Do you have any systematic examination of the men when they go out to their meals?—No.

1261. As to whether they are clean?—No. We provide them with facilities for washing. The facilities are there if they like to use them.

1262. (Mr. Mason.) How do you find that the cost of your present painting compares with your old lead painting?—It is cheaper.

1263. Rather cheaper?—Yes.

1264. Is there the same amount of paint used?—Not the same amount of paint. It is specifically lighter.

1265. The same number of coats?—The same number of coats.

1266. I take it that there is no particular difference between the painting now and when you were painting with lead?—None.

1267. You spoke of four cases between 1906 and 1910, and you told us two of the cases. Could you tell me the other two?—Those occurred this year.

1268. Since you gave up the use of lead altogether?—This refers to a gasfitter. He went to a doctor after he had been away from work for a week. The doctor said that he was suffering from lead poisoning. That was reported to the medical officer who comes and inspects the works, Dr. Greaves. He says that he has been advised that a man has been suffering from lead poisoning, but, in his opinion, he does not think he had. The other case was that of a man who works for myself, a labourer who has never used any paint at all since he came to me. The doctor gave him this certificate, "This is to certify that ( ) is now able to resume his employment. He has been apparently suffering from lead poisoning." The doctor does not say that he has been, but he says, "apparently."

1269. (Dr. Collis.) Was the last case that you mentioned investigated by the certifying surgeon?—Yes.

1270. You do not know what the certifying surgeon said?—Yes. He said that he did not think that he was suffering from lead poisoning.

1271. I thought you said that he was apparently suffering?—No, that is the first case.

1272. Did the certifying surgeon examine the first case too?—No.

1273. He did not have to examine that case?—No.

1274. (Mr. Mason.) You were speaking of the first two cases?—Those are two cases that have occurred this year.

1275. I understand that from 1906 to 1910, those being the years in which you used no lead, you have had four cases?—Four cases.

1276. Of those, two you referred to are not included?—No. Those cases occurred this year.

1277. What were the other four?—Do you mean the occupations?

1278. Yes?—One was a coach trimmer, and how he got it I could not say. One was an outside painter,

one an inside painter, one a painters' labourer, and the other a bodymaker.

1279. In the 18 cases that you gave us between 1900 and 1905, you say that 13 of the 18 were inside painters?—Yes.

1280. Your experience points then to inside painters being more liable to lead poisoning than the others?—Yes, according to that, it is so.

1281. Can you advance any reason why that should be so?—They get dirtier. They are not such skilled men and they are more careless.

1282. An inside painter then is a different class of man from a coach painter?—Quite different.

1283. Would that class of inside painter sleep in the same shirt that he wore during the day, do you suppose?

I should think that many of them do, if not most of them.

(Mr. Mason.) He probably would, from my knowledge of that class of man.

1284. (Chairman.) Would you not rather say that the reason was that with regard to the inside painter the air was confined and the dust always adjacent to the worker, whereas in the case of the outside painter the air would be dispersed and he would not come into contact with it so much?—But there is no dust at all inside. They do not sandpaper the work at all. He gets dirtier in his work, he is more confined with his work, and he gets more on his clothes and more on his person, and he is not so clean in his habits.

1285. (Mr. Mason.) Would the inside painter during the five years use lead at all?—Yes.

1286. He would use lead on the roof, not an enamel or anything of that sort?—No, he would use lead.

1287. What do you use for bedding lights?—Felt soaked in boiled oil.

1288. Do you find that satisfactory?—Yes, as far as it goes.

1289. As satisfactory as lead?—No, I do not think so.

1290. Do your carriages come in for re-varnishing more than those of other railway companies do?—I do not know what the practice of other railway companies is. Our practice is that they are varnished once a year. They are generally repaired and painted the next year. We bring them in and clean them and give them a coat of varnish. The second year we do all the repairs that are necessary, thoroughly touch them up and give them one coat of varnish. The third year we clean them and give them another coat of varnish, and the fourth year we repaint them. We repaint them as nearly as possible to the fourth year.

1291. Would you be surprised to learn that with companies using lead paint and only two to three coats of varnish, a coach will last for three years before it is re-varnished?—But does it look as well?

1292. That is another point. You mean to say that the London and North-Western coach does not look as good as the Midland coach?—No, I do not say that; but I do say this, that I receive congratulations from all parts of the country and from all parts of the world, from people who say that the Midland stock looks as well as any in the country.

1293. It is very good stock, indeed—there is no doubt about that. Do you think that a zinc paint requires more varnish than lead paint?—No, I do not think so.

1294. Do you not find that with zinc paint the writing on the waggon tends to chalk?—Yes, but that is not so much because of the zinc, because white lead will do the same. That arose in great measure from turpentine becoming so dear three or four years ago. We were then trying to use a turpentine substitute in the place of turpentine, but it was a failure for practical purposes. That was the reason of the chalking. Lettering or white done with white lead chalked just as badly as when done with zinc, so it was no inherent quality of the zinc that caused that. But we have overcome that by a different mixing in using it, and it does not chalk now.

1295. Are you still using a turpentine substitute?—Oh, dear no.

28 March 1911.]

Mr. THOMAS JORDAN.

[Continued.]

1296. You have gone back to turpentine? Yes, and in addition to the turpentine we put varnish, which makes it adhere and it is satisfactory. Those are things that we have found out in practice.

1297. You have had no experience of zinc white in painting the outside of a coach? Yes, we use nothing else.

1298. Not as a white?—No.

1299. You have had no experience of white uppers?—Yes. When I was on the North-Western, it was white lead and Cremnitz white that was used then. I do not know what is used now.

(Mr. Mason.) It is much the same, but we have not a zinc paint.

1300. (Mr. Robins.) Do you find that the general health and vitality of the men, since you have introduced zinc white, is better than it was in the years when they used white lead?—I could not speak about their general health. I only give the cases of lead poisoning which we are obliged to collect and report on.

1301. But from outside observation, have you observed that the general health of the men and their vitality are better than they were when they were coming into constant contact with lead? No, I have not observed that.

1302. (Chairman.) Mr. Robins wants to know whether, although the men may not get lead poisoning, you have noted that the fact of inhaling lead dust pretty continuously in small doses rather impairs the constitution?—I follow.

1303. (Mr. Robins.) I have had over 30 years' experience, and I have noticed that the men have a more languid appearance when using white lead. Their vitality is much lower?—I could not say at all: I have really not observed that point. But taking the

difference between the two periods of five years that I have given, the health of the men has certainly improved, comparing the using of zinc with the using of lead.

1304. You have not observed carefully that those men who were not actually scheduled as victims of lead poisoning had better health?—No, I have not.

1305. With regard to filling up, do you find that zinc white in filling up is as good as white lead in binding the filling up together?—We do not rely on it for binding.

1306. In the filling up you use zinc?—Yes. We only rely on it to give it body.

1307. Do you find it quite as good for giving it body?—Yes, quite.

1308. Do you find any difficulty with regard to the coach painter in the introduction of zinc white?—No.

1309. Do you find that he readily applies himself to it? I speak as a painter myself?—He does not object in the least.

1310. Do you find that it takes a long time for a man to learn the difference of treatment between white lead and zinc white? As far as the painter is concerned, there is no difference. He simply has to put it on. We prepare it for him.

1311. You do not think that he would want two or three years in which to learn it?—No.

1312. If he could not learn it in a month he would deserve something, you think? Now you say that your coaches are repainted once every four years?—Yes.

1313. You have been using zinc white consistently now for six years?—Yes.

1314. Do you think that is a fair test?—Quite.

1315-7. Has it answered successfully?—Yes.

The witness withdrew.

Mr. JOHN I. STEINITZ examined.

1318. (Chairman.) Are you the manager of the Falcon Works, Loughborough?—Yes.

1319. What does your firm manufacture?—Amongst other things, tram-cars and rolling stock generally.

1320. Have you come here to tell us the experience of your company in the matter of lead poisoning?—Yes.

1321. What cases have you had?—Previous to the end of 1904 white lead was used for jointing materials on our cars, and a considerable number of cases of lead poisoning occurred. After investigation it was decided to stop the use of white lead, and from the beginning of 1905 until July 1910 we used a non-poisonous white paint, which we found quite as good for the purpose as white lead. During this period we built and delivered the equivalent of 4,000 cars and railway carriages, and in no case had we a single complaint from our customers in connection with jointing or roofing material where this white paint was used.

1322. Have you had complaints in other respects?—We have had complaints from time to time but nothing in connection with the use of the jointing material.

1323. What is the composition of this non-poisonous white paint which you use?—The makers will not tell us, but the works' chemist made an analysis. It is made up of linseed oil 20 per cent., barytes 72 per cent., and oxide of zinc 8 per cent.

1324. What is it called?—We know it as a non-poisonous white paint.

1325. Where do you purchase it?—Perhaps it would not be quite fair to say.

1326. You would rather not say?—Yes, seeing that the people will not tell us the composition.

1327. I will not press that question. Did you have any cases of lead poisoning at all in these six years?—Yes, we had two.

1328. What were they due to?—We could find no trace. They were men who had never had anything to do with any but non-poisonous paint or with the painting of the cars. They were entirely concerned with the inside finishing, so that if any men ought to have been safe they ought to have been.

1329. Do I understand that they did not come into contact with lead at all?—Absolutely not at all.

1330. Do you think that they must have had it in their systems when they came to you?—Presumably, but each man on starting signs a form saying that he is free from any of those diseases that are notifiable to the Home Office.

1331. Was there any doubt about the cases?—None. The medical people certified them as being cases of lead poisoning.

1332. They were submitted to the Home Office?—Yes.

1333. Do you paint these tram cars and railway coaches throughout, or do the purchasers themselves put on their special colours and designs?—We paint them throughout.

1334. Did you use any lead paints at all in any of the processes of coach painting in the six years which you mentioned?—Yes—only in the painting, not in the jointing. White lead is the basis of a great many paints, but we have never had a case of lead poisoning in the paint shop.

1335. What percentage of lead do you use in the paints?—I really do not know; it varies.

1336. What jointing materials have you been using since July 1910?—Genuine white lead.

1337. Why have you not used non-poisonous paints?—Because genuine white lead was specified.

1338. You mean that it was specified in the orders given to you?—Yes, it was specified in the orders given to us.

1339. But if it had been left to you to adopt any paint that you chose, would you have used non-poisonous paint?—Yes.

1340. Being quite sure that it would have the same effect?—Quite.

1341. Have you had any case of poisoning since July 1910?—Yes, we have had three actually reported, and we have several men at the present time under observation.

1342. How do you account for that?—Well, we are using white lead. The men undoubtedly handle it, and they have not been brought up to be as careful as painters, who are really warned from the time that they start their apprenticeship. The painter gets to be

28 March 1911.]

MR. JOHN I. STEINITZ.

[Continued.]

naturally a clean man, but a body maker does not wash, and you cannot make him do so.

1343. How many men do you employ who have to do with paint?—On the average I suppose about 250 in painting and jointing.

1344. How many of these come into contact with lead paints, or are in the same room, and so exposed to the same condition as regards lead dust in the air?—The whole of them.

1345. Do you use the aerograph?—No, I have never heard of it before.

1346. Do you do any dry rubbing down?—Not in connection with painting or jointing.

1347. How about curves and mouldings, are they sand-papered dry?—Yes, they are.

1348. Is practically all your work rubbed down or only a very little of it?—It is all rubbed down wet.

1349. Are all the coats rubbed down, or only some of them?—The majority.

1350. What general precautions do you take? Do your men wear overalls?—No, not necessarily.

1351. If they are using lead paints do you compel them to wear overalls?—No.

1352. If they like to bring them you do not mind?—No. Some men work in them.

1353. What about washing accommodation. Do you provide hot and cold water?—Yes.

1354. Soap?—Yes.

1355. Nail brushes and towels?—Yes.

1356. Are clean towels supplied daily? The towels are clean daily.

1357. How many basins are there to how many men? I would not like to be quite sure, but there are about 20 basins, I think, for 250 men.

1358. That is 12½ men to a basin. Is that not very few basins?—I may be wrong. The factory inspector was down the other day and said that we had more than were required.

1359. If the men all left off work at the same time and they had to wait in a queue with 12½, it would take a long time before they all got a turn?—We give them time to wash in our time.

1360. Do you give them an extra 10 minutes?—About 5 minutes.

1361. Out of your own time?—Out of our own time.

1362. That is very good. I am glad to hear that. Do you take any steps to see that your men use the washing accommodation?—In the paint shop, yes. We tried it in the body shop, but not very successfully.

1363. What shape have the steps taken?—In the paint shop we have a clock and the men book off. They turn a key in the clock when they leave off work, and the foreman inspects every man's hands, and if they are dirty he sends the men back, but the body makers will not put up with it.

1364. That is a very admirable system. I suppose that you do not do any scraping or burning off of old paint?—None at all.

1365. All your work is new work, is it not?—Yes.

1366. Do you provide a mess-room for your work-people?—No.

1367. Do you have a periodical medical examination in your works of lead workers?—No, only young persons.

1368. Not lead workers?—Not lead workers—only young persons are medically examined.

1369. Do you insure your liability under the Workmen's Compensation Act?—Yes.

1370. Can you tell us whether the rate that you pay is heavier for your painters than it is for your other workmen, for instance, your joiners?—No. We have one rate for all classes.

1371. (Sir Godfrey Baring.) Speaking generally, has your firm been entirely satisfied with the substitutes that you have used for white lead?—Yes, entirely.

1372. If it was left to your firm's choice, you would continue to use them?—Certainly.

1373. Have you found any disinclination amongst the workmen to use the substitutes?—None at all.

1374. They have not complained of any practical difficulties in their work?—None.

1375. (Dr. Collis.) With reference to the two cases that you had during the period that you were not using white lead, do you know for how long those men had been employed by you before they fell ill?—Probably for a couple of years. They certainly were not new-comers.

1376. Those cases, I presume, were notified to the factory inspector?—Yes.

1377. I suppose that you do not know whether the certifying surgeon agreed with the original diagnosis?—I do not know.

1378. In what years were the cases?—I have not the years with me.

1379. I am rather interested in those cases?—I could let the Committee have them.

1380. If you could send the names of the men and the years to the Secretary, I would like to look those two cases up to see whether the certifying surgeon agrees?—Very well.

1381. During the last year you had several other cases amongst men who were using lead?—Yes, three, and several under suspicion.

1382. Three up to January 1911?—Yes.

1383. Have you renewed your workmen's compensation policy since?—No. That comes up for renewal at the end of this month.

1384. I would like to know how much the company charge you?—We are an engineering firm too and we have many more accidents on the engineering side. We only have one rate, so that it would be very difficult to say why they put the rate up, but it goes up each year. Our insurance premium over the whole works, i.e., engineering and coach-building, has gone up 50 per cent.

1385. I notice, on looking through the figures, that there is a tendency for insurance companies to charge higher for painters?—Yes.

1386. (Mr. Fell.) I understand you built about 4,000 cars during the time that you were not using white lead in your jointing?—Yes.

1387. Could you supply the Committee with a list of places where you supplied those cars to?—Certainly.

1388. Do I understand that all the cases of white lead poisoning that you have had have occurred in the body shop?—All.

1389. They were either men who were jointing or men who were putting canvas on the roof using white lead?—Yes.

1390. Do you have the body shop swept up at regular intervals?—Yes.

1391. Therefore, every day you cause a certain amount of dust in the shop?—Surely.

1392. I suppose that there is a certain amount of white lead lying about on the floor?—Yes, undoubtedly there must be.

1393. Have you tried watering down the shop?—We always water down before sweeping up.

1394. To prevent the dust flying?—Yes.

1395. I believe that in your shop you work what is known as the one-shift system?—Yes.

1396. Perhaps you would explain to the Committee exactly how the men work?—The men work from half-past seven to half-past twelve and from half-past one until six. Probably your point is that the management wink at the men having something to eat about 11 o'clock.

1397. That is the point which I wished to make, that these men must probably in the long time between 7.30 and 12.30 want to have something to eat?—Yes.

1398. They eat it in the shop?—Yes.

1399. When they have that meal they do not wash, do they?—Most likely not.

1400. Have you not had any cases of poisoning in connection with white lead in your paint shop?—Never once.

1401. In the whole time that you have been there?—In the whole time that I have been there.

1402. Do you put that down to the fact that the men in the body shop come more into contact with white lead than the men in the paint shop, or to what do you attribute it?—I put it down to the fact that the painter, right from his apprenticeship as a boy, is compelled to wash. He is cuffed if he does not, and

28 March 1911.]

Mr. JOHN I. STEINITZ.

[Continued.]

the foreman makes him wash, and it becomes second nature.

1403. Do you suppose that the men in the paint shop also have a meal in the middle of the morning? Undoubtedly, and they go and wash before they have it.

1404. That makes the difference between the two classes of men?—Yes, that is so. You see the one is continually using paint and the other is using it just occasionally.

1405. I understand that you provide exactly the same washing facilities for the men in the body shop as you do for the men in the paint shop?—Yes.

1406. So far as that is concerned, they have the appliances for use?—Yes.

1407. Do you supply overalls to these men?—No.

1408. In neither shop?—In neither shop.

1409. (Mr. Mason.) You said that there were 250 men in your works using lead, and the Chairman, I think, asked you how many of them were exposed to lead dust and you said the whole lot?—Yes.

1410. Do I understand that the jointing is done in the paint shop?—No. About equally they would be exposed to dust. There is a certain amount of lead in the dust in the paint shop and a certain amount in the body shop when we use white lead.

1411. What causes the dust?—It dries out.

1412. (Chairman.) Does it arise from splashes on the floor and so on?—Yes.

1413. (Mr. Mason.) It is not the same dust as the dust from rubbing down?—No.

1414. There would be more dust in the paint shop owing to the men rubbing down?—Yes.

1415. Do I understand that the non-poisonous white paint which you referred to is really a jointing paste and not a paint?—It is really a jointing material. It is not a paint.

1416. Have you had any experience of non-poisonous paints for the outside of tram-cars and carriages?—No.

1417. You have not used them at all for that?—No.

1418. (Mr. Fell.) In connection with sweeping down the shop, do you sweep down the paint shop as well?—Yes.

1419. I can understand your sweeping down the body shop, because you have shavings and so on amongst the cars, but in the paint shop there might not be that necessity?—We always do it regularly.

1420. At what time of the day do you do it?—In the evening after it is closed down.

1421. (Chairman.) So that the dust has all settled before the workpeople return in the morning?—As far as possible we have no one there. We have a certain number working overtime. We try to keep clear of it, but there are a few men there.

1422. (Mr. Fell.) How do you heat your paint shop?—By steam pipes.

1423. You have no fans?—No.

1424. No circulation of the air?—No. We have steam pipes in the basement.

1425. (Mr. Robins.) Do you use sandpaper stopping?—No.

1426. Your last remark was with regard to the sweeping of the body shop and the paint shop, I presume?—Yes.

1427. These are done at the close of the day?—Yes.

1428. Do you think it satisfactory to sweep a paint shop at the close of the day when the paint is drying?—You cannot very well sweep it during the day when the men are all about.

1429. In the afternoon or the latter part of the day men are painting and varnishing, and that is wet?—Yes.

1430. It would not be a great advantage to sweep the shop then and spoil part of your day's work?—I agree, but after all it is not the painting of broughams and private carriages that we are doing, where there must be no dust at all, but it is the average article of commerce.

(Mr. Robins.) Knowing a good deal about tram-car work and coach-painting work, some of your work

looks very superior, and does not look as if it was brought out of a shop where you sweep the paint shop at the close of the day. I am very glad to hear that you do not use sandpaper stopping.

1431. (Mr. Kinggate.) You stated that the men, when they are employed, have to sign a statement that they are not suffering from any complaint which brings them under the Employers' Compensation Act?—Under the notification to the Home Office.

1432. Do they have to supply a doctor's certificate?—No.

1433. It is only their own statements that you rely on?—That is all.

1434. And with regard to the number of cases of lead poisoning, is it not possible that many of those that suffer from lead poisoning do not assign the cause of their suffering to lead poisoning simply from fear of being discharged?—I do not quite see why they should be discharged. Do you mean when they have once suffered?

1435. Yes. Personally I know men who are employed by you who have suffered very much from lead poisoning. I think, perhaps, that one of the reasons why you have so small a proportion or no cases at all in the paint shop is the fear of being discharged?—Of course, if they left us, or stayed away, and did not get any compensation, we should not know what they suffered from. If they stayed away and got compensation we should. Unless the medical fraternity are not giving us true reports, I think that you must be wrong.

1436. It is possible that a man may say to the doctor: "Do not put down lead poisoning." Personally, I have suffered from gout through lead poisoning. If I say to the doctor: "Do not put down that I am suffering from lead poisoning; say that I am suffering from gout"; that is a perfectly true statement. To say that I was suffering from lead poisoning might prejudice me in my employment?—We should not pay compensation for gout.

1437. A man would forego compensation because of the fear of being discharged. You supply the same washing accommodation for body makers as you do for painters?—Yes.

1438. You do not allow them time for washing the same as you do with the painters, do you?—No; we have just started that.

1439. What is the objection on the part of body makers to washing their hands the same as the painters do? I understand that they are obstinate?—They are obstinate. They ought to wash, but I suppose that it is not a practice inborn in them, as with a painter from his apprenticeship upwards.

1440. As a matter of fact, the body maker is handling lead a great deal more than the painter?—But a great deal more seldom. He handles it less frequently.

1441. But everything that he puts together is put together with white lead?—True.

1442. He gets it on his hands, and it is quite as necessary for him to wash as with the painter?—Yes.

1443. Is not some of the priming done in the body shop?—Yes, occasionally.

1444. They sandpaper down the first coat. You sandpaper the panels?—It is rubbed down wet.

1445. Not the first priming coat?—Surely.

1446. No, they could not do it. If the first coat is lead, the air is impregnated after the rubbing down, and the man inhales that more than even the painter does?—It is rubbed down wet.

1447. It should be, but it is frequently done with sandpaper. I refer to hard stopping?—We have a sandpaper machine in the saw mill.

1448. (Chairman.) Do you find the cost of non-poisonous paint to be more or less than that of lead paints?—The actual material is cheaper, but there is more of it used. I think that the net result is that the non-poisonous paint is a little cheaper.

1449. Do you tell the Committee that your company would welcome the abolition of lead altogether?—Certainly.

C 4

28 March 1911.

Mr. JOHN I. STEINITZ.

[Continued.]

1450 (*Mr. Robins.*) I should like to ask you whether I understand you to say that time is now allowed to the body makers to wash?—Yes.

1451. Have the men notice of that? Do they thoroughly understand that they are allowed to wash

in the company's time? Certainly, but it has only just recently been introduced.

(*Mr. Robins.*) I hope that it will have a happy result for good.

The witness withdrew.

Mr. D. WAIT examined.

1452. (*Chairman.*) Are you the works' chemist of Messrs. R. Gay and Co., Ltd., Paint Manufacturers? Yes.

1453. Does your firm make lead paints and also leadless paints?—Yes.

1454. Will you describe both and compare them?—Yes.

1455. Will you tell us which paint materials contain lead?—The materials containing lead are chiefly pigments, and the most frequently used are, white lead (carbonate and sulphate), red lead, orange lead, litharge, Brunswick greens, chromes, vermilionettes, fast reds, Chinese reds, sugar of lead, terebine, varnish, mastic and vulcan cements, and patent driers. Most of these substances are dry powders, but are supplied to the painter mixed into a stiff paste with oil and are thinned (or mixed) by him to a suitable consistency for application, the medium being oil, turpentine, &c. Many manufacturers now supply paints mixed ready for use.

1456. Do some painters have the colours and mix their own paints?—Yes, particularly red lead. This is dangerous for the workman on account of the dust given off.

1457. Do you mean that he is liable to be lead poisoned?—Yes; from the dust. My point is that this mixing of dry lead compounds is not necessary. It can be better done in the factory by the paint maker.

1458. Would you say it is unnecessary, apart from the question of ceasing to use lead paints, for the painter to have dry colours at all?—Yes. Ready mixed paints supplied by the manufacturers are now far in advance of those mixed by the painter. The use of such paints dispenses with the danger and risk involved when the painter mixes his own paints, both in the dry and paste forms. Such paints, being better ground and mixed, produce a surface which does not require so much rubbing down, thereby still further lessening the danger to the painter.

1459. By ready mixed paints do you mean paints quite ready for application?—Yes.

1460. Is not paint frequently supplied by the maker as a thick paste which can be thinned by the painter?—Yes, and when the paste is unduly stiff it is a fairly common practice for the painter to place his hand in the paint and break up the hard lumps with his fingers. White lead paint becomes stiffer with keeping, and some painters believe they get a better result with white lead in this condition. To meet that prejudice, manufacturers grind the dry lead with the minimum quantity of oil, and thus give the product the appearance of aged white lead, and the painter has to suffer by the extra labour entailed in mixing, and uses his hands willingly to mix such lead.

1461. And ready mixed paints avoid the danger from the dust that is occasioned by dry mixing, and also the danger from manual contact with lead pastes?—Yes.

1462. Can you suggest other dangerous processes in painting with lead paints?—Yes. Small drops of paint are atomised from the brush in the course of painting, especially when paints, which have been thinned with turpentine, are being used in order to produce a flat finish. The larger of these particles of paint can be seen on the floor where painting has been done and on the hands of the workmen, and no doubt the smallest particles float in the air and are breathed by and settle on the workmen. I wish to demonstrate that point to you. The witness produced a tin of white lead paint and demonstrated the formation of particles in brush work, showing how they fall on the workman when overhead painting is being done.

1463. Do the small particles dry quickly?—Very.

1464. Do you believe that this is a potent source of danger? Yes, particularly in confined spaces, as in painting ships with flat paints. There is a custom to give a coat of paint and then fling powdered cork on to it, and then paint on top of the cork with flat paints, and during that painting there is an enormous amount of these small drops.

1465. Are there any other processes you wish to mention?—Yes, rubbing down. The practice of rubbing down with sandpaper produces visible amounts of dust. This is done on old work to level the surfaces and produce a key for the fresh paint to adhere to; also on undercoats, to smooth down the brush marks. I might mention further that what are known as surfacers are made containing lead. These are applied to rough castings to level the surface and produce a smooth surface for the paint to go on, and in the sandpapering of these dust is also produced. These can be produced without the use of lead.

1466. Do you think that there is danger in connection with scraping and burning off?—I do not think there is much danger there—not from lead. From arsenical paint there is.

1467. You mentioned lead sulphate. Is that put forward as a non-poisonous substitute for white lead?—It is by some firms, but I do not agree that it is entirely non-poisonous. It is certainly less poisonous than the carbonate white lead.

1468. You would not call it quite harmless, then?—No.

1469. Can you tell us whether it makes a good paint?—Yes; it is useful in many cases. When this is mixed with the same amount of oil and turpentine as white lead it produces a paint which is thicker in consistency and works greasy, being rather difficult to spread free from brush marks, the coat of paint having neither the opacity nor whiteness of carbonate white lead. These points are accentuated by the addition of more oil, which is usually added by the painter, in order to make the paint more workable.

1470. How does the paint compare with white lead when it has been spread?—As a result of the large amount of oil absorbed in the grinding and mixing of basic sulphate, the film produced is more glossy than that of white lead; after an exposure of 15 months the film of sublimed lead has more gloss than white lead, is not quite so much discoloured, but contains numerous small cracks.

1471. Sublimed lead is lead sulphate I take it?—It is a basic sulphate.

1472. What is white lead exactly?—White lead is a hydrated basic lead carbonate.

1473. Will you tell us your experience of leadless pigments? What are they made of?—The principal white leadless pigments are lithopone and zinc oxide.

1474. What is lithopone?—A white pigment; a mixture of zinc sulphide and barium sulphate.

1475. Is it expensive?—No; it is cheaper than zinc oxide.

1476. Can it be used for both outside and inside work?—Not satisfactorily; only for inside work, because the film is not sufficiently resistant and it turns grey in direct sunlight.

1477. Is lithopone used only for white paints?—No, for colours also.

1478. Does lithopone make a good paint? Is it as satisfactory as white lead paints?—For outside use it is not suitable. It is useful for inside use, but not quite so satisfactory as lead paints.

1479. Please tell us about your zinc oxide paints. Do you make them both for interior and exterior work?—Yes, for both.

28 March 1911.]

Mr. D. WAIT.

[Continued.]

1480. And are they as good as white lead paints?  
—Yes. For interior decoration, where purity of tone and permanence of colour are desirable, zinc base paints are highly to be recommended. These can be made to give any surface from a flat finish to the highest enamel gloss. For exterior work, zinc base paints applied on suitable zinc base under coats are equal in wearing qualities to white lead base paints and are more permanent in colour.

1481. Should you say zinc paints are as popular as lead paints?—No.

1482. Why not?—Zinc white is not such a favourite as white lead for two reasons. In the first place it is more expensive than lead, weight for weight, but gives a larger volume of paint on mixing, so that the mixed paints are of approximately the same cost by volume. In the second place, few painters have yet learned how to mix zinc paints to the same perfection as lead. In the best known book on house painting there are 24 mixings given for white lead paints, and zinc white is passed over by saying that it is mixed in the same way as white lead, which is not the correct way to produce the best results. In all cases zinc-white paste should be mixed for use with boiled linseed oil in place of the raw or refined oil generally used by the painter, and turpentine may be added to thin it to the proper consistency. Ordinary liquid driers may be used, but if the so-called zinc driers (consisting of manganese salts) are used they should be added just before the paint is applied, as they gradually form a double salt of zinc and manganese, which has considerably less drying power.

1483. Can you give us the name of any public offices where your zinc paints have been applied?—The following buildings have been painted with Gay's zinc paints with highly satisfactory results: Buckingham Palace, Home Office, Admiralty, War Office, new Local Government Board Offices, Savings Bank, General Post Office, also branch post and sorting offices in London and the provinces, British Museum, Science and Art Museum, National Gallery, Victoria and Albert Museum, St. Thomas's Hospital, &c.

1484. You say with highly satisfactory results. For how long have these different buildings been painted?—They are constantly being painted in different portions; in some cases for four years, to our knowledge, the paint has been standing outside, and is still in fair condition.

1485. Do you consider four years a good test?—No. Zinc paints have not been made long enough by us to be tested to the same extent as lead paints.

1486. But do you think that four years is sufficiently long to have tested the durability of zinc paints?—It is comparatively. If you put a lead and a zinc on, in two years you might give an opinion as to which is going to last the better.

1487. In your opinion, speaking of the various offices that you have referred to, the trial has been highly satisfactory?—Yes, they are still going on using zinc colour. People are gradually using it more every year.

1488. Have you had any complaints at all of any kind?—We have had some complaints, but no more complaints with zinc than with lead.

1489. They are used both externally and internally?—Yes.

1490. Both white and coloured paints?—Certainly.

1491. (Sir Godfrey Baring.) I understand you to say that there is a growing desire to use zinc paints, not only on the part of the Government, but on the part of private individuals?—Yes.

1492. Your orders for zinc paints tend to increase?—Yes.

1493. (Mr. Sutherland.) What is the composition of your zinc paints?—Do you mean the percentage composition? It varies for the undercoats and finishing coats.

1494. Will you give us the two. First of all, what is the under coat?—With regard to the under coat, I will quote from the Office of Works specification, because that is a paint which we have found to be entirely satisfactory. The undercoat contains:—Zinc oxide, 60 per cent.; chalk, silica, or barium sulphate,

10 per cent., refined boiled oil and copal oil varnish, 15 per cent., American turpentine, 15 per cent. For the finishing coat:—Zinc oxide, 56 per cent.; chalk, silica, or barium sulphate, 2 per cent.; refined boiled oil and copal oil varnish, 36 per cent.; American turpentine, 6 per cent.

1495. What is the price of that?—Per gallon?

1496. Do you sell it in gallons?—Yes, we sell it in gallons. It is 8s. 6d. per gallon at the present time.

1497. How does that work out per hundredweight? How many gallons to the hundredweight—eight?—In the last (1908) specification, the under coat was specified to be 21 lbs. per gallon, and the finishing 19.

1498. Was the 8s. 6d. for the finishing or the under coat?—Both.

1499. What is the formula for your own paint?—We have 101 different formulae. I cannot give you them all.

1500. I want to know whether there is a definite standard formula for zinc paint?—I do not know of any, except that it should be made as I have said.

1501. Every manufacturer has his own standard and his own formula?—Yes, and different standards for different work and different prices.

1502. That is not the case with white lead?—Yes.

1503. Genuine white lead is "genuine white lead"?—So is genuine zinc white "genuine zinc white."

1504. But you cannot use genuine zinc by itself. It has to be mixed?—It is used by itself.

1505. But not for large surfaces. It wants something with it to give it a body?—No, it is not necessary. It has body.

1506. It has spreading power, but it has not body?—It has opacity too, very considerably.

1507. Could they sell zinc white to a standard as genuine white lead is sold?—As a guaranteed paint?

1508. Yes?—Yes.

1509. Would it be serviceable to the painter?—Yes.

1510. Would it last like white lead?—Yes, it would last quite as well.

1511. Where did you get your authority for painters working with their hands in the paint?—I have seen them myself. I may quote to you from Pearce's *Painting and Decorating*, 1907 edition, page 11. Under the paragraph "Causes of Bad Health among Painters" it says, "Second, the filthy habit of putting the hands into colour when mixing, a habit as unnecessary and absurd as any in the trade, but clung to by ancient and thoughtless practitioners as a sort of fetish."

1512. (Mr. Parsonage.) Does that apply to oil paint or distemper?—Oil paint.

(Mr. Sutherland.) It is common enough when men are mixing whitening but never when mixing paint.

1513. (Mr. Parsonage.) I have never heard a more absurd statement made?—There you have it.

1514. It is taken out of a book. Is that what you call the best work on mixing colour and on painting?—One of the best.

1515. (Mr. Gardner.) I want to draw attention to the fact that through not knowing all the technical terms in the trade you have mixed up vastly different things. No painter would mix oil paste colour with his fingers. If he did he would be at once thrown out of the shop. Is your paint all supplied ready mixed?—No, we supply paste zinc and paste lead also. We specialise in mixed paints though.

1516. You say that it would be much better that red lead should be mixed in a factory instead of in a workshop. In what condition would a tin of red lead be after it had stood for a month in a shop?—Good condition. I have some that has been standing for over six months.

1517. The use of ready mixed paint would not obviate the spots falling?—Not at all, but the use of zinc paint would obviate poisonous spots falling.

1518-24. (Mr. Parsonage.) You say that you have seen painters put their hands into lead paint?—Yes, on two occasions I have seen it.

1525. Painters?—Yes.

1526. Where were they?—One was in Scotland and the other was in the north of England.

28 March 1911.]

Mr. D. WAIT.

[Continued.]

1527. I am glad that they were a long way up north. But you would not attempt to say seriously that that is a common practice—for a man to put his hands into lead paint?—I quote this.

1528. I do not want you to quote that. Would you seriously contend that a man brought up to the trade of a painter, or in fact any man, would put his hands into white lead paint? You are not confusing distemper with oil paint, are you?—No, certainly not.

1529. Do you say that a man would put his hands into oil paint to mix it up?—I am not an authority on the way in which painters mix their paints. I know how we mix our own. The custom of the painters' trade is different from the custom of the paint manufacturers' trade, so I cannot give evidence on that.

1530. You think that paint ready mixed and sent you is better than paint mixed on a job?—Yes.

1531-5. Do you know any paint that stands for a time that does not require thinning up before you can use it?—If the can is not open there is no alteration.

1536. But when it is open, if you get a gallon can which you do not use right away, it has at all events a tendency to become fat?—Yes.

1537. Then it requires to be thinned by the painter?—If he keeps it for a long time.

1538. If he keeps it for a week?—No.

1539. When the air gets to it it starts to get fat?—Not if it is hermetically sealed with the lids which we supply.

1540. (Chairman.) With regard to the cost; supposing that I were to have the outside of my house painted (which I am proposing to do) and I employed your paint, would the builder charge more or less than he would if he used white lead paint?—We could supply a white lead paint exactly the same as the painter would make.

1541. So that my builder should not charge any more?—Certainly not.

1542. (Mr. Fell.) Has your paint been used for painting vehicles?—Ready-made paint is not used so much for fine carriage work—for coach-building.

1543. Has it been used for painting under carriages and trucks?—Yes.

1544. Can you say where?—Yes. Our paints are used abroad by several railway companies.

1545. Are they used by any tramway companies?—I cannot answer that offhand.

1546. Perhaps you would let us have a list of the places where they are used?—I will let you have a list of a few tramways and railways.

(Chairman.) And carriages, particularly motor cars.

1547. (Mr. Fell to the witness.) You do not know how it stands under those conditions?—It must stand as the best lead paint would stand or the best zinc paint would stand.

1548. With a great many of these things there is no must. They ought to, but they do not?—Are you asking about lead or zinc?

1549. I am talking about your zinc paint. You do not know how it stands under these conditions?—I do not know how it stands on motor cars.

1550. (Mr. Mason.) You spoke a moment ago about paint being mixed. Has not the red lead an action on the oil without the presence of free oxygen in the air? On linseed oil, yes.

1551. You cannot prevent it in any way?—It thickens to a paste. It goes into a solid hard lump.

1552. You say that you can keep it for six months?—Yes, ready mixed.

1553. You were speaking of lead sulphate a short time ago. What experience have you had of that beyond the test board which you painted?—Simply testing—that is all. I have made two or three of these tests.

The witness withdrew.

Mr. J. CRUICKSHANK SMITH, B.Sc., examined.

1554. (Chairman.) You attend here to-day as an expert in paints and painting?—Yes. I have had 20 years' intimate practical acquaintance with the manufacture, use, and properties of paints generally.

1555. What are your qualifications?—I am a Graduate of Aberdeen University, B.Sc., a Fellow of the Chemical Society, a Member of the Society of Chemical Industry, a Member of the International Testing Association, and a past President of the Paint and Varnish Society.

1556. Have you written various books and papers on the manufacture and use of paint?—Yes. Shall I enumerate them?

1557. You might mention them?—In 1901 I published a book on the Manufacture of Paints; in 1910, a book on Oxide of Zinc, its Nature and Properties; in 1904 I read a paper before the Royal Institute of British Decorators on Oxide of Zinc considered as a Paint Material, and I have written various other papers at various times.

1558. Are you at present actively associated with any manufacturing firm?—I am a Director of the Indestructible Paint Company. I joined the board about three months ago. I also act as their technical adviser.

1559. Your managing director is prepared to give evidence?—Yes. Mr. Depiorres, the managing director of the company is, I believe, coming before the Committee later on.

1560. For what purpose?—So far as I understand to give evidence as to the nature of the materials dealt in by the company, and his experience as a practical manufacturer in that company.

1561. Will he give evidence with regard to zinc paint, and also deal with the products of the company?—I understand so; but I do not know from my own knowledge.

1562. Will you give us evidence of a similar nature yourself?—No, I am not here for that purpose.

1563. Will you tell us, to begin with (it is a very elementary question) why paint is used?—Paint is used to protect surfaces and to decorate or adorn them.

1564. Please explain what you mean by protective painting?—Protective painting is painting, I take it, in which the first and, in some cases, the only consideration is the protection of the surface, quite apart from the final colour, and of course that applies chiefly to iron and steel, very often, and more and more every day, to cement and stone, and less frequently in this country to wood.

1565. And decorative painting?—Decorative painting is painting where the protection of a given surface is of less importance than adornment. I should place most ordinary internal house painting under this heading. A third class might be added, namely, coach painting, where protection and decoration are both required; for example, railway carriage painting and motor car painting.

1566. Of what constituents is paint, actually ready for application, normally composed?—Two essential parts, the liquid part, or the vehicle; and the solid part, or the pigment.

1567. What is the function of the pigment?—The pigment is the material which obscures the surface which lies beneath the paint and is the protecting material, and in many cases it also acts as the carrier or base for various tinting materials known to painters as stainers.

1568. And the vehicle?—The vehicle or liquid portion enables the pigment to be applied to the surface evenly and gives it coherence and durability. A necessary property of the vehicle is that it should harden within a reasonable time.

1569. In connection with driers have you anything to say?—The word "driers" opens up a tremendous subject.

1570. What does the painter call "thinners"?—What a painter calls thinners, as I understand the term,

28 March 1911.]

Mr. J. CRUICKSHANK SMITH, B.Sc.

[Continued.]

is a mixture of oil and spirit, which a painter would add to his stiff paste to bring it to a working consistency.

1571. What is volatile spirit used for?—The volatile spirit would be used as an ingredient of the vehicle to open out the paint and to make it dry with a more or less flat surface. That is the essential object of spirit in paint.

1572. What do the stainers do?—Communicate colour to the paint.

1573. They change the hue?—Yes, they change the hue of the preponderating pigments.

1574. Do the different purposes for which paints are used make it necessary to employ widely different materials?—Yes.

1575. Then no one paint could possibly prove suitable for every situation?—No.

1576. In what ways must the composition of paints be varied according to the use for which they are intended?—A range of paints suitable for somewhat different applications can be obtained by varying the proportions of the ingredients—the relative proportions of pigment and vehicle or the intrinsic parts of pigment and vehicle; but for other purposes again it will be necessary to include new substances or to omit certain ingredients altogether.

1577. What are the main substances commonly used for paint-making. First, as regards pigments?—White lead, red lead, and other lead compounds, and oxide of zinc in its various modifications, sulphide zinc white, leaded zincs, sulphate of barium, carbonate of calcium, under various names, such as whiting, Paris white, and so on, silicate of magnesium, oxide of iron, native or artificial, and native earths such as umbers, ochres, siennas, carbonaceous pigments, including bone black, lamp black, vegetable black, carbon black, graphite, and a very wide group of colours, commonly grouped as chemical colours, which includes the chromes, Prussian blue, ultramarine, lake colours, and vermilion.

1578. What do you mean by "sulphide zinc white"?—Sulphide zinc white is a convenient term to apply to the complex white pigment produced by the simultaneous precipitation of sulphide of zinc and barium sulphate.

1579. What do you mean by "leaded zincs"?—That is a convenient term to apply to a complex white pigment produced by the roasting under suitable conditions of ore containing both lead and zinc.

1580. What are the principal substances used as vehicles?—Oils, spirits, varnishes, and combinations of these.

1581. Are the vehicles used for zinc and lead pigments much the same?—Not as a rule.

1582. In what way do they differ?—First, as regards the proportion of the various constituents of the vehicle, and secondly, as regards the mode of preparation of the vehicle. That particularly applies to oils.

1583. What are the materials used as thinners?—I understand by the word "thinner," the vehicle.

1584. Are the thinners commonly used for white lead paints suitable also for zinc paints?—Sometimes, but in many cases the proportion and the mode of preparation of the vehicles or thinners should be different.

1585. What materials are used as driers?—Under the popular acceptance of the word "drier," compounds of lead and manganese are frequently employed as driers.

1586. Can the same driers be used for zinc as for lead paints?—They can be used, but variation in the proportion and mode of preparation is frequently necessary.

1587. Would you name some of the principal stainers?—Oxides of iron in various forms, Venetian red, umber, ochre, sienna, and carbon black.

1588. Are these in general equally suitable for lead and for zinc paints?—The ones I have enumerated are perhaps equally suitable, but there is a wider range of tinting colours which can be used only with certain pigments; for example, pigments which contain sulphur in a free form cannot be used under any consideration with white lead; also certain lake colours

cannot be used with white lead although they can with proper zinc white—oxide of zinc;

1589. To sum up what you have been telling us about the component parts of paints, there is a very wide difference in the treatments appropriate respectively to white lead and zinc pigments?—Yes, there is a difference due to the essential difference in the nature and character of the two materials.

1590. Has this fact been realised by painters?—Not very largely, I am afraid.

1591. To what do you attribute this?—Partly to the disinclination of the average working painter to deviate from stereotyped methods—in fact, largely to that.

1592. Should you say that it is easier to use lead paints than zinc paints?—Not so far as the actual painting process is concerned. At the same time, lead paints can be used in many cases under more disadvantageous circumstances than zinc paints can. But that again can be, in my opinion, frequently and usually corrected by a suitable adjustment of the vehicles and driers as I have already described.

1593. Is it a question of the painter changing his habits, then?—Yes, largely.

1594. What have been the practical consequences of the failure to understand the differences of character of lead and zinc bases?—I think the result in many cases has been that owing to the non-employment of suitable vehicles and driers, finished paint work in zinc pigments has not proved so successful as it might have done had the characters of the pigment and vehicle and drier been thoroughly understood. The enormous development during the last ten or fifteen years, perhaps twenty years, in the use of white enamel goes to prove that contention, because in the case of white enamel, which is based on oxide of zinc amalgamated with suitable vehicles and driers, on the whole perfectly successful results have been obtained, whereas had the painter been asked to amalgamate oxide of zinc with vehicle and drier, he probably would not have had a successful result at all.

1595. What is white enamel composed of, then?—White enamel, using the word as indicating a material of the best class, consists in the pigmentary sense of oxide of zinc with an appropriate vehicle, and the vehicle contains the necessary driers.

1596. To return to the painter and the differences of lead and zinc paints, what remedies would you suggest?—In view of the fact that the difficulty in using zinc paint seems to lie with the man who is using it, a very commonsense suggestion is that it should be supplied in the form in which you can use it, namely, in a semi-thinned form.

1597. How are paints usually supplied now by the makers?—Either a paste, in which form the painter has to add all the vehicle or thinner, or as completely ready mixed paint.

1598. What objections are there to supplying paint in both these forms?—The objection to supplying paint to the painter in the paste form is that as a rule the painter is ignorant of the composition of the paste, and he has to work in an unscientific, haphazard, and rule-of-thumb way in mixing his vehicle or thinner with the paste. The objection to the ready mixed form of paints is that it allows little latitude to the painter to vary the consistency or temper of his paint to suit the nature of the job he is working on. The suggestion I make, therefore, is in the nature of a compromise, namely, that the manufacturer should supply the paint in a semi-thinned form, which means that it should contain the necessary drier, but that the final adjustment with regard to the vehicle, especially the spirituous part of the vehicle, should be left to the man who is applying the paint.

1599. Is that never done now?—Yes, it is done.

1600. The plan you advocate is sending out semi-thinned paints which allow of final adjustment by the painter according to the weather and other conditions?—Yes. I think that my previous answer would rather cover this question.

1601. What can you tell us from your practical experience as to the comparative efficiency of white

28 March 1911.]

Mr. J. CRUIKSHANK SMITH, B.SC.

[Continued.]

lead and zinc paints?—The answer to that question depends entirely on the meaning we attach to the word "efficient." So far as protective painting goes, painting on iron and steel, I unhesitatingly say that I have found from my experience zinc paints give very much better results than white lead. From the point of view of withstanding the action of the atmosphere, especially the atmosphere of large towns such as London, white lead has proved a disastrous failure. There is no building in London painted with white lead which retains its colour for more than a very few weeks.

1602. Then with regard to other kinds of painting, what do you say?—With regard to the painting of wood, especially in the priming and undercoating of wood (I am talking now entirely from the point of view of efficiency and leaving other matters entirely out of consideration) I consider that white lead holds its own.

1603. Would you say that paints other than white lead, for all practical purposes, in the treatment of wood, are as good as lead paints?—I would say this— it is possible to manipulate zinc pigments in such a way as probably to give as good results as white lead. But it is not so easy to do. It is a more difficult problem. White lead on wood is a most excellent priming ground. I am talking entirely from the point of view of efficiency. I am not dealing with poisoning or anything of the kind.

1604. That is what I wanted to get at. What do you say about ordinary plaster walls?—There I should say that lead was inferior to zinc, if the zinc is suitably prepared.

1605. May we take it that, with the exception of wood, you unhesitatingly affirm that zinc paints are much to be preferred to lead paints?—Yes, they are to be preferred; and with regard to wood, I say that zinc paints can be made to be practically as good as white lead, but it will be a more difficult problem.

1606. It is not a simple one?—No, by no means.

1607. Will you tell us in this connection what your practical experience has been?—In what respect?

1608. You have given us a very strong opinion in favour of zinc paints?—Yes.

1609. I want the Committee to know on what you base that opinion?—The opinion, so far as it refers to the treatment of iron and steel, has been based on the examination over a very great number of years of panels of iron and steel, and actual structures of iron and steel, treated comparatively with white lead and oxide of zinc. One set of experiments is being conducted now by an important railway company in this country. I am unfortunately debarred from mentioning the name of the company to the Committee, but I can mention it privately to any gentleman who wishes to know it.

1610. We had a witness here a short time ago representing a large railway company who told us that they had abandoned the use of lead for painting their carriages, and that the zinc paints were in every way as efficacious as the lead paints. You are not surprised to hear that?—No.

1611. Now, about the maintenance of colour, speaking principally of inside work?—It is a matter of common knowledge that white lead is very liable to change colour in the presence of impure atmosphere.

1612. And durability—first as to inside work?—If by durability you mean maintenance of colour, the question is answered. If by durability you mean the maintenance of a firm film, a hard surface, that depends on the suitability of the thinners or vehicles used with the pigments.

1613. Assuming that they are all in order, then what is your opinion?—Then I say that for inside work oxide of zinc or other suitable zinc pigment is superior to white lead.

1614. And for outside work, with due regard to the vehicle?—The same applies.

1615. As regards price, how do you find the lead and zinc paints compare?—The question of price opens up a very wide subject, and its effects press differently on the different persons concerned. The cost of raw material to the paint maker, the cost of the finished

product to the user, and the cost of the completed work to the property owner, are three separate propositions.

1616. But I want to know what are the net results as to cost with regard to zinc paint or lead paint?—The net cost to whom?

1617. Supposing you were to paint a house, would the cost of painting in zinc paint be more or less than if it were painted in lead paint?—At the present time I should say the cost perhaps in using zinc paints might be a trifle more. I am talking about the cost of materials.

1618. Take the case of a property owner. How is his interest affected by the use of lead or zinc paints?—The property owner first of all has to consider the maintenance of his property, and if the maintenance of his property depends on the using of a suitable protective paint, and the nature of his property is iron or steel or some of those surfaces on which zinc paints are superior to lead, then it is obvious that his interests are best served by adopting a zinc paint.

1619. How does the cost work out to the master painter?—I am afraid that is a question which, not being a practical master painter myself, it is very difficult to give any very valid judgment about. But I do not see how the cost per yard super of finished paint work can vary very much as between using white lead and zinc paint.

1620. For the paint grinder, which material do you estimate to be the more expensive?—What are the materials we are comparing?

1621. Oxide of zinc and white lead?—The dry oxide of zinc at the present time is more expensive than dry white lead.

1622. Would not the precautions required by the Factory Act have to be added in the case of lead?—Yes. I was talking of the cost of raw materials. When we come to establishment charges and things of that sort which must be faced, the whole of the incidental costs and outlays and outgoing, I do not know exactly how it works out, but from year to year the cost is increasing in connection with the grinding of white lead. I have not worked it out to-day.

1623. Would you go so far as to say that you have found in your own experience that zinc oxide paints can take the place of lead paints without increased cost and with improvement in results?—Yes, if you omit the word "oxide," and admit zinc paints generally.

1624. Have you any suggestions to make as to what steps might be taken conducive to the reduction of the risk of lead poisoning to workmen?—In view of the fact that a very large number of cases of lead poisoning amongst painters are reported to the Home Office when they need not be reported, it would appear to me that if some compulsory reporting of cases of lead poisoning were enacted, more precautions would be taken by master painters and by journeyman painters, and, therefore, failing the total prohibition of paint containing more than 4 per cent. of lead salts, I would suggest that the mixing of ground white lead or any stiff paint containing more than 10 per cent. of lead compound with linseed oil or turpentine should be deemed to be a manufacturing operation, and any place where such mixing is carried on should be deemed to be a factory and should, therefore, come within the scope of the Factory Acts.

1625. In order that the process might be regulated, I suppose, in the way that paint factories are at present?—Yes. In other words, every case of plumbism, however incurred, ought to be automatically reported to the Home Office.

1626. What other suggestion have you to make?—In order that persons using, either mixing or applying or having applied paints containing lead, should know that the material that they are using is a dangerous one, I suggest that packages containing stiff or mixed paints containing more than 10 per cent. of lead compounds should bear a label to that effect.

1627. You would label cans "poisonous," "containing lead paint"?—I do not go so far as to indicate in what manner they should be labelled, but they ought to bear a notice that they contain lead.

28 March 1911.]

Mr. J. CRUICKSHANK SMITH, B.Sc.

[Continued.]

1628. Is it possible to your mind to invent practicable apparatus which would have the effect of removing this evil of the dust?—This is really a question for master painters to deal with, rather than a paint manufacturer. Cases of plumbism appear in many cases to result from the inhalation of dust containing large quantities of lead due to rubbing down or dry polishing of old lead-painted surfaces. It would appear, therefore, that some regulations in connection with dealing with such surfaces, either in the way of using hoods or masks or something of the sort, ought to be adopted.

1629. In connection with painting the inside of a room, is it possible to get any effective apparatus which would have the effect of removing the evils of dust?—I have not given my inventive capacity to dealing with that subject. I leave that to others. I deal with it from the theoretical standpoint.

1630. You have no practical suggestion to make on that point?—I have no practical suggestion to make.

1631. Then, either the men must go on suffering or the use of lead paints must be prohibited?—It must be prohibited or regulated.

1632. What do you mean by regulated?—In such a manner as I suggested before with regard to the deeming of places where they mix lead paint as factories and in the compulsory registration of cases of plumbism.

1633. (*Sir Godfrey Baring.*) I understood you to express a very strong opinion as to the value of white lead paint for external use in London and the manufacturing towns. You would say that it is absolutely unsuitable for external use, would you not?—From a decorative point of view.

1634. From the point of view of retaining its colour and that sort of thing?—Yes.

1635. Would it be true to say, speaking generally, that there is a growing appreciation of the value of zinc paint amongst the general public?—I think there is.

1636. (*Dr. Collis.*) You suggested that all places where paints are mixed should be considered as factories under the Factory Acts. Am I right in supposing that paints are very often mixed in the private house being painted?—Yes, perhaps it might be.

1637. You appreciate the difficulties of the factory inspector marching into a private house to inspect a painter mixing paints?—Yes.

1638. An Englishman's house is his castle?—Yes. I must leave it to the ingenuity of the Home Office to get out of that difficulty.

(*Dr. Collis.*) I can frankly say that the ingenuity of the Home Office is rather nonplussed at the prospect. If it were not for such difficulties we could deal with the whole matter.

1639. (*Mr. Sutherland.*) You were asked, could zinc oxide take the place of white lead without increased cost, and you said "Yes, if you take out the word 'oxide' and put in 'zinc paint' "?—Yes.

1640. Why?—Because by using the term "zinc oxide" we eliminate that very useful group of pigments known as sulphide zinc whites, which for undercoating and bodying up are in many cases quite equal to white lead.

1641. Can zinc oxide be used in absolute purity, or is it improved by carrying another body with it?—You mean, if you got approximately pure oxide of zinc would it be the best pigment you could get?

1642. Yes?—No, it would not.

1643. That is what I asked this morning, but I did not get a definite answer from the witness. What makes the best composition?—It depends on the purpose. If it is a question of making the very finest enamel, where colour is very important, in fact, a dominating factor, then you must eliminate as much as you can all other bodies and get as near as you can to chemically pure oxide of zinc.

1644. But considering it as a paint, what do you say?—As a paint the chief ingredient of commercial oxide of zinc would be about 4 per cent. of a basic sulphate of lead.

1645. And nothing else?—The other things would be so infinitesimal that they are not worth talking about. They would only be traces.

1646. Are not most zinc paints that are put on the market very largely charged with sulphate of barium?—That gets on to the sulphides. That is not oxide of zinc paint. That is why I eliminate the word "oxide" here. That is a different group of materials altogether.

1647. They come in as non-poisonous?—Yes.

1648. The commercial aspect of it is very largely a question of the carrying matter, like sulphate of barium?—Yes. The question was asked, "What is sulphide zinc white?" and I said "Sulphide zinc white" is the complex white pigment produced by the simultaneous precipitation of sulphide of zinc and barium sulphate." The two things are produced together, and the result is absolutely different from that which would be obtained by mixing mechanically exactly the same proportions of pure sulphide of zinc and pure barium sulphate. That is a very important point.

1649. Do not they hold the relation of something like 30 to 65?—Yes.

1650. One compound with the two constituents?—Yes. If you take ordinary barytes and mix 70 parts of that with 30 parts of zinc sulphide you get an absolutely transparent useless pigment, but if you take the material produced by the simultaneous precipitation of these two bodies you get a pigment which weight for weight equals, and in many cases exceeds, white lead in opacity.

1651. It is better than oxide of zinc in opacity, is it not?—Yes.

1652. (*Mr. Mason.*) When you spoke of the use of turpentine to open up paint, I did not quite understand?—That is a practical painter's term.

1653. We are not all practical painters on the Committee, and I thought it might be better if we understood?—I mean by that to make the paint work more easily, take away the drag from it, just to make it flow better, and spread better.

1654. In saying that zinc oxide was a better paint for metal than lead, do you mean by that white lead or red lead?—White lead. I understood that we were talking only of white lead here.

1655. No, not altogether. Is it better than red lead?—It all depends.

1656. Upon what?—That opens up a whole commission by itself.

1657. We always understand that red lead paint is as good as anything for ironwork?—Yes. I was basing my view on some comparative experiments recently made, most authoritative experiments. I cannot give my authority, but will give it privately to anyone who wishes to know. They are tests with regard to the prevention of rust on iron and steel structures by using paints made respectively on bases of lead and oxide of zinc. I have examined them, and I have found this: In the case of lead paint rust is beginning to form below the film, and is coming through in yellow and brown spots, but with the zinc it is not doing so. There are a great many different opinions about the use of red lead for the protection of iron. One cannot say it is better or it is worse. Everything depends on the mode in which the red lead is ground, and the vehicle with which it is used. It is possible to make a red lead for ironwork very good indeed, and it is possible to make a red lead for ironwork very bad indeed. The way that is adopted to make the red lead paint is to stir it into the oil, not to grind it into the oil, and if the oil happens to contain a proportion of free oleic acid you get corrosion below the film, and that leads to disaster.

1658. If the use of white lead were prohibited altogether, would zinc paints go up in price, or would there be any difficulty in supplying zinc paints?—Not the slightest. I think they would probably become cheaper.

1659. (*Mr. Robins.*) You mentioned the difficulty of the painter in thinning the zinc paint. With the abolition of white lead (and the wish is father to the thought) do you not think that the difficulty with regard to the house-painter would swiftly disappear? You do not think it would take long for a painter, if

28 March 1911.]

Mr. J. CRUICKSHANK SMITH, B.Sc.

[Continued.]

he had any common intelligence, to learn how to treat zinc paint as he would white lead? No, I do not.

1660. (*Mr. Parsonage.*) Is not paint mixed on the job, taken generally, better than paint ready mixed?—Very often it is.

1661. (*Mr. Sutherland.*) Why do you say that for primary coats white lead is better than zinc?—On wood it is.

1662. Why? I can only go by the results one finds. I make the proviso that it is not impossible, it is done every day, to make zinc coats which have as good priming properties as lead coats, but taking the ordinary commercial use of the two things, it is easier to make a good priming coat for wood from white lead than from zinc.

1663. (*Mr. Kinggate.*) What are the difficulties in making it equal the lead for priming coats?—It is a question of the relative affinity of the two pigments for oil. You can grind dry white lead in a little over 6 per cent. of oil. Most paint grinders cannot grind oxide of zinc in under 14 per cent. of oil. If you want to get a paint that will permeate a surface you want to get that oil reduced. That is the practical difficulty, but it is capable of being surmounted.

1664. Dry lead is very rarely used for priming coats, paste lead is generally used?—Yes, but I was only thinking of the pigment.

1665. Is it possible to obtain any other pigment apart from lead for use in priming?—Yes, it is possible. It is done very largely in America. It is a compound of a form of oxide of zinc with certain other pigments communicating tooth and bite.

The witness withdrew.

### THIRD DAY.

Wednesday, 29th March 1911.

PRESENT :

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Sir GODFREY BARING, Bart., M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. F. G. RICE.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. C. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER } (*Acting Secretaries*).  
R. U. SHAXBY }

Professor E. C. C. BALY, F.R.S., examined.

1666. (*Chairman.*) I should like to explain to the Committee that at a recent inquiry that was held at the Home Office in connection with the earthenware and china trades, the Home Office appointed Mr. Duckering, one of their inspectors, to collect the dust from certain workshops with a view to determining the presence of lead in the air of those workshops, and I understand that Professor Baly has endeavoured to obtain similar results by analysing the light passing over newly-painted surfaces, which he finds to throw off vapours which can be proved to contain lead. I want to preface Professor Baly's evidence with that observation, because it is quite a new theory; and, when I tell you that in making those experiments Professor Baly contracted lead poisoning himself, I think you will agree that this line of research is very important. (*To the witness.*) Will you please tell us your qualifications?—I am a Fellow of the Institute of Chemistry, a Fellow of the Royal Society and of the Chemical Society of London.

1667. Are you at present the Professor of Chemistry in the University of Liverpool?—That is not the exact title. The exact title is Grant Professor of Inorganic Chemistry in the University of Liverpool.

1668. Have you come to describe to us a research which you have made recently?—I have.

1669. When were your experiments carried out?—During the last three weeks.

1670. Will you state briefly what you sought to ascertain?—I undertook the work in order to find whether there was any truth in the statement, which I have heard at various times from painters, that there was a definite smell in white lead paint which was not possessed by other paints. It occurred to me that it might be worth while, in view of the interest in the problem, to submit the matter to a scientific investigation, and that is why I undertook the experiments. You ask me what I sought to ascertain. The object

was to ascertain whether there was any definite vapour or volatile compound coming off white lead paint which was not given off by any other paint.

1671. Why were your experiments undertaken? What gave rise to them?—My answer to that question is really covered by the answer to the previous question. It was through Mr. Hardwick happening to meet me in an official capacity as regards the Society of Chemical Industry in Liverpool to see the apparatus for determining absorption spectra, and the question at once arose in conversation whether there was any truth in the stories one has heard in regard to the smell of white lead paint. I at once suggested that we might put it to the test in the way that I have described.

1672. Will you now describe to us how your experiments were carried out?—If I may ask for the tube I will show you (*handed to the witness*). Perhaps I may explain to the Committee the fundamental method of working. I will try not to be too technical, but perhaps you will understand that one uses to a great extent in modern chemical research the absorption of light by chemical compounds in order to determine their nature and the amount of them which may be present. I have carried out a great deal of work in that direction during the past ten years. With regard to the method of experiment, if I might explain that to the Committee, I will endeavour to be as little technical as possible. It is a very simple method. One takes some source of light—it does not matter what source of light. One may take an arc lamp such as is used in the street, or an electric spark passed between any suitable metallic points so as to give a light which, when analysed by means of the spectroscope, that is to say, subdivided into its definite rays, is perfectly characteristic and easily recognisable at any time. The method of experiment is simply this: you take a photograph of all the various colour

29 March 1911.]

Professor E. O. C. BALY, F.R.S.

[Continued.]

rays which are being given out by the particular source of light which you elect to use, and that serves as a standard of comparison; then you interpose, somewhere between the source of light and your photographic plate, a vessel containing the substance or gas which you wish to investigate. You take then a second and a third photograph or as many photographs as you wish. Then if the substance which is under investigation exerts any absorption of light (which a great many substances do) I think it will be understood that on comparing the photographs taken after the substance has been interposed with the photograph which is taken without any absorption vessel there, one can easily estimate and measure the amount of light which is being absorbed by the substance under investigation. That is the method. In the particular experiment which I wish to describe to the Committee, of course it was a question of looking for a volatile vapour, and so, as the Chairman has already mentioned in his introduction, we had to pass the light over a freshly painted surface. The first experiment which I did was to take a small tube about a foot long. We coated it inside with what I believe is known as stiff white lead—that is to say, white lead containing, I believe, 10 per cent. of raw linseed oil. That was smeared, as one might say, all round the inner side of the tube, leaving a clear passage through the centre of the tube for the light to pass, so that there was a very large surface of paint or material over which the light passed. This tube was gently warmed in order to increase the presence of the volatile material if such existed, and then these photographs were taken in the way that I have described, and we obtained certain results which, I understand, will be referred to in a later question. These were so interesting that I decided to do the experiments on a much more scientific basis, and if I may have that long copper tube I can explain it much better (*handed to the witness*). This is the tube in which the experiments were done. It is merely a copper tube. It is 1½ inches in diameter, and it is so arranged that it can be heated from about 20 degrees centigrade, which is just the temperature of an ordinary warm room, to any temperature one wishes, by electric current. One can slip inside the tube a glass tube which is coated on the inner side with any paint one wishes to use. This is simply put up in front of the spectroscopic, and one can measure the absorption due to any of the paints which one wishes to investigate. (*Other tubes were handed to the witness*.) Here are some tubes which have had three different sorts of paint in them. I need not go into them in detail at the present moment. You can see on looking down them that there is a perfectly clear passage for the light. That, I think, answers the question with regard to how the experiments were carried out.

1673. What results did you obtain?—The first experiment we did was to investigate the absorption, if any, produced by zinc white. I found that, on slowly increasing the temperature from ordinary room temperature up to somewhere about 50 degrees centigrade, no absorption whatever made its appearance. It did not appear until a temperature of 105 degrees centigrade, and then a very distinct and decided absorption made its appearance. That I assumed to be, and I wrote it down, the characteristic absorption which may be due to the linseed oil itself, because I did not think the question of any volatile zinc compounds could enter into the problem. Then I put an exactly similar tube containing white lead basic carbonate.

1674. Have you made quite clear what the result of the first experiment was?—I think I said that there was no absorption whatsoever until the temperature reached 105 degrees centigrade and that then a very sharp and strong absorption suddenly made its appearance, and that we ascertained to be due to linseed oil itself which was distilling off the zinc white. Perhaps I had better explain why it is that we knew that the absorption of light which began at 105 degrees centigrade was due to linseed oil. It is perfectly evident that owing to the fact that the windows, which were closed, at the end of this tube got all coated with linseed oil, the linseed oil was distilling, as we call it in chemistry,

volatilising away from the paint and condensing on the coolest surface like any ordinary liquid does.

1675. I am afraid that this is a little too technical for us, and that it will be difficult for us to embody it in the report. I want to know the precise results which you obtained in connection with the inquiry that we are holding. I understand that you made experiments with zinc white and white lead?—Yes.

1676. I should like you to tell us as shortly as you can what you found from those experiments?—I can do that in about three sentences. White lead gives a very strong absorption of light at quite a low temperature. Purex, which is a basic sulphate of lead, and zinc white are absolutely identical in the absorption which they give, that is to say, they give no absorption whatsoever except what is due to linseed oil. Perhaps I may put that less technically and say they contain no volatile compounds whatsoever, as far as I am able to determine, except linseed oil. White lead, however, does contain some volatile compounds other than linseed oil.

1677. (*Lord Henry Bentinck*.) What is the effect of smelling these volatile compounds in the air? Do they affect the health in any way?—I can only answer that in this way—that after smelling these tubes, as I did, I suffered at three distinct times, after smelling three distinct white lead tubes, from what is known, I believe, as sub-acute lead poisoning.

1678. (*Chairman*.) How many different substances did you subject to spectrum analysis in this way?—Only three in connection with this particular investigation—zinc white, white lead, and basic sulphate of lead.

1679. Did you repeat your experiments more than once for each material by way of verifying the results?—Several times. If I may extend the answer, I confirmed the volatile compound in the case of white lead by working at a very low temperature indeed, that is to say, one which could be easily reached on a warm summer's day, namely, about 80 degrees Fahrenheit.

1680. Did you use more than one make of white lead and zinc white, and so on?—As far as I know, not. I think it was all one make.

1681. Did you try any lead compounds other than Purex and white lead?—No.

1682. How were the coats applied to the insides of the tubes?—An ascertained amount of the paint was taken, and it was simply smeared round the inside of the tube by means of a wooden rod or a similar glass rod. It was quite simple to do.

1683. Were they allowed to dry before the observations were commenced?—No.

1684. Did you weigh the amount of each material put on, and did you know what proportion of each part was pigment?—In answer to the first portion of the question, I did not definitely weigh the substance, but I took as closely as possible the same amount. In answer to the second portion of the question, I am informed that there was the same amount of pigment in each, or approximately the same, of the samples of materials that I used.

1685. You say that you are informed?—Yes. Mr. Hardwick told me so. I did not analyse them.

1686. Did you arrange that these matters should be uniform in all cases?—As far as I possibly could.

1687. What were the lengths and diameters of the tubes which you employed?—They varied in different experiments from 1 foot long to 2 feet long, and from three-quarters of an inch to 1½ inches in diameter.

1688. Would you expect to get stronger absorption by longer tubes?—Yes.

1689. How many observations did you make at temperatures below 50 degrees centigrade?—In one experiment, which I referred to just now, I definitely observed the evidence of this volatile compound below 50 degrees centigrade. It was about 80 degrees Fahrenheit.

1690. Did you get no measurable emanations at ordinary air temperatures?—That is a very difficult question to answer. I got in one photograph evidence of a small amount of emanation, but it was very small at ordinary temperatures. I would not like to stake my reputation one way or the other upon it.

29 March 1911.]

Professor E. C. C. BALY, F.R.S.

[Continued.]

1691. Was it practicable to use tubes long enough to yield effects at temperatures lower than 120 degrees Fahrenheit?—I think my answer to a previous question really covers that. I had already got an effect with the tubes that I was using below 80 degrees Fahrenheit.

1692. Were you able from the character of the spectrum to determine of what the emanations consisted?—No.

1693. What absorption bands do lead salts show? Are they not definite and characteristic?—As far as I am aware at the moment, I think that lead salts have never been worked at all in solution, and I very much doubt whether they would have any characteristic absorption at all in solution.

1694. Is it not possible to compare, by the use of a reflecting prism covering half the collimator slit, light passed respectively through your experimental tube and through lead vapour?—Yes, it would be possible, but it would be a difficult experiment to do. I must say that it is possible to do it.

1695. Have you ascertained in any other way what the emanations from white lead paint were?—Yes. Chemical tests showed that lead was present in it.

1696. Will you please explain what the chemical tests were and how they were carried out?—The air in these tubes was drawn by means of a suction apparatus through, in one particular set of experiments, fuming nitric acid, which was then tested in the usual way for the presence of lead, and in a second set of experiments through what we call alkaline hypobromite of sodium, and we found the presence of lead in small quantities in every case.

1697. Then to sum up your evidence, it amounts to this, that you found no emanations from paints based on zinc until at high temperatures the oil began to manifest itself?—Yes. The answer to that question is in the affirmative.

1698. As regards lead paints, Purex gave the same negative results as zinc oxide, but you found considerable emanations from white lead, and these were chemically found to contain lead compounds?—Yes.

1699. Mr. Hardwick will tell us what conclusions he wishes us to draw from your experiments as regards the product he is concerned with, I suppose?—Yes. I think he will.

1700. I can only say that this is a most interesting line of research, and I am sure we all hope that you will pursue your investigations further and even more closely, if that is possible. Perhaps you will be good enough to communicate with us if you make further discoveries?—May I reply to that, that I hope you will understand that I look upon these experiments as only quite preliminary, and that I hope to be able at a future date, if I am to be allowed, to bring to the Committee the actual volatile lead compounds. I shall not feel myself perfectly satisfied until we have the volatile compounds of lead, so to speak, in our hands. I am perfectly convinced, as I think you will see, that there is something volatile from white lead, but I am not able to express any opinion about its nature beyond the fact that it appears to contain lead. I feel extremely obliged to the Committee—in fact I am honoured—for allowing me to put this evidence before them. It seemed to me of such interest that it ought to be at once reported to headquarters.

1701. The Committee feel that it is a matter of profound importance. If, by chemical demonstration, by analysing the light passing over newly-painted surfaces which are shown to throw off particles, you can prove clearly that the emanations contain lead, it is of paramount importance to this Committee's inquiry?—That is what I felt, and that is why I am so pleased to come here. Though I have spoken very strongly on the matter, and though I feel very strongly that there is something of great importance in this, I do not view the experiments as absolutely concluded. I want to make that quite clear.

1702. (Lord Henry Bentinck.) You will forgive my ignorance, but is a volatile compound of lead the same thing as lead dust? Has it the same effect as lead dust?—No, not at all. My opinion is that a volatile compound of lead would be an exceedingly toxic substance (that is poisonous substance), because in every

case that we know in chemistry of volatile metallic compounds like arsenic, mercury, and those things, they are always very much more poisonous than the corresponding salts of the metals.

1703. With regard to the sensations which you felt after smelling these tubes, did you consider them to amount to absolute poisoning?—I only have my medical adviser's opinion on that. I certainly felt uncommonly uncomfortable, not to say very seedy.

1704. For how long do you think the paint throws off these volatile compounds—only when it is fresh, I suppose?—I would say that it would go on throwing them off until the film of oil had hardened.

1705. (Sir Godfrey Baring.) For how long did you suffer from these disagreeable effects of the inhalation?—If I may describe the symptoms, I can explain at once. About a quarter of an hour after smelling the tube I developed very considerable localised (as we say) headache—just in one portion of the head. Shortly after that a period of very great lassitude supervened, when I could not do anything at all. I had to sit down. That, after dining, usually passed away. The next day there was an attack of diarrhoea. I did not think it was anything very serious, but I spoke to Dr. Goodbody, who at times has acted as my medical man in London, and he said at once, "It is lead poisoning." I thought that would interest the Committee.

1706. (Lord Henry Bentinck.) Is painter's colic the same thing as you experienced?—I understand that it is exactly the same, but I did not have the pain. It was not acute enough with me. I did not try to martyr myself in any way by smelling more than was necessary, but I wanted to know whether it smelt.

1707. (Dr. Collis.) Do you think that it would have been possible, if you used longer tubes than those that you have already used, to demonstrate whether ordinary white lead paint gives off this emanation at lower temperatures than 80 degrees Fahrenheit?—Certainly.

1708. You see the great importance of the point?—I do.

1709. It is at lower temperatures that painting is usually done, and we should like to know whether the painter using white lead paint is exposed to danger in this way at the temperatures at which he ordinarily works?—I think that it would be perfectly possible to determine, by using longer tubes, whether the same volatile compound is present at ordinary temperatures as you suggest.

1710. Another point which, personally, I should like to have information upon is with regard to heating old dry lead paint, if the experiment is possible, to the temperature at which paint is ordinarily burnt off?—I do not think that I can carry out the absorption investigation there, because, no doubt, one would get a very large amount of other materials coming from the burning oil, which I am afraid would rather confuse the issue.

1711. You mean that the burning oil would mask the lead?—I think that it would mask the lead. Would you be satisfied if one could carry that out in a tube like this and investigate whether any volatile lead was obtained?

1712. Yes. I would like to know whether volatile lead comes off when old paint is burnt off?—Very well. I was thinking that we had done the experiment, but we have not.

1713. Did you go higher than 105 degrees centigrade?—I went actually up to 150 degrees simply because there were a certain number of photographs that I could take. I simply went up, and up, and up, until I came to the end of my tether. Then in order to get everything parallel I used exactly the same temperatures all the way through the three experiments. Having found that there was a big absorption at the higher temperatures, I did not bother about higher temperatures afterwards. You see the three tubes that were used. Those have been carried up actually to 150 degrees centigrade. In the one on the right-hand side of the three (white lead) a definite reaction has set in. You notice that its colour has gone. It was perfectly evident when we took the tube out of this vessel here that some chemical reaction had set in at

29 March 1911.]

Professor E. C. C. BALY, F.R.S.

[Continued.]

that temperature, which is not apparently evidenced in the case of Purex or zinc white. That all seems to fit in with the fact that there was some definite reaction.

1714. Did these two start at the same colour?—Yes, absolutely.

1715. They are not the same colour now?—The zinc is the blue one. They did not change during the experiment. That is all I can say. They may have changed a little bit since.

1716. There is less difference between the two leads than there is between the Purex and the zinc?—All I can say is that the Purex and the others were the same when we started, but they have been lying about my laboratory for several days.

1717. So that the possibility of basic lead sulphate giving off vapour at a higher temperature than 150 degrees has not yet been tested?—No, it has not.

1718. Could that possibly be tested in any way by eliminating the oil in the test? It could be tested very easily with regard to the question of detecting lead in the vapour in the absorption experiments.—I mean to say, in the analytical experiments for volatile lead, we found that the amount of lead which came off Purex was vanishingly small. I would not say there was none.

1719. It was only tested to 150 degrees?—No, it went to 200 degrees in those experiments.

1720. Would it be possible to use other lead paints?—Yes; I had forgotten to say that I have used litharge with linseed oil, and then I found that the reaction in the spectroscopy observation was more marked than I had ever seen it—far more marked.

1721. Ordinary red lead?—No.

1722. Black litharge?—I do not know what colour to call it. It was puce-coloured litharge, the ordinary colour of the lead which they use for glazing. They do not use red lead for glazing, do they? It is not what the plumbers use. It is litharge. One is PbO and the other Pb<sub>3</sub>O<sub>4</sub>.

1723. Plumbers use red lead?—Do they? I do not know whether you would care to see these photographs. (Photographs produced.)

1724. (Mr. Sutherland.) For how long were these tubes sealed up?—For two hours in the one set of experiments, but the low temperature ones were sealed rather longer—about three hours.

1725. The proportion of lead here is almost a hundredfold what it would be on an ordinary painted surface, is it not?—Certainly.

1726. So that the consequent proportion of volatile vapours given off would be very much greater?—For that area of surface, yes; but you will notice that that is only about 10 square inches, and is very small compared with the area of an ordinary room.

1727. It is more than 10 square inches?—My arithmetic is very bad, and I cannot calculate it.

1728. Sixty-six square inches?—Half a square foot, is that not?

1729. Very nearly, not quite. A painter would probably use a tenth or a twentieth, or considerably less, so that you would have to have a very large room to give off the vapours that you get from these?—I think that it is perfectly possible by increasing the linseed oil in the paint to increase the amount of volatile lead, because it is due, I believe, to a definite reaction between the pigment and the oil. That is one of the things that I want to ascertain.

1730. Was this an ordinary strength of paint?—Yes, the ordinary commercial material.

1731. But with regard to the thickness of it, is it stiffer?—It is the stiff stuff.

1732. Could you not paint a room and ascertain the vapours given off from that room? I think that I might, but it is rather a cumbersome experiment.

1733. That would bring the experiment very much nearer to practical conditions?—Yes.

1734. And would consequently be more valuable and more easily understood by normal men who are not chemists?—I quite see your point, but it is rather a cumbersome experiment to do. You have to get a room, and you have to paint it, and it is rather difficult to carry out. I hope you will understand what my

point is about the first part of your question—and that is that the stiff paint which is in those tubes is not what the actual painter works with his brush. He thins it down with oil first of all, does he not?

1735. Certainly?—I am not prepared to say that thinning it down with linseed oil would not increase the amount of volatile compound.

1736. But he would get less lead in it?—He might get more, because there might be a more definite reaction by increasing the linseed oil.

1737. You think there might be more lead in the volatile vapour, but there would be less lead in the paint?—Some members of the Committee might assume that if you decrease the actual amount of pigment in the paint that was applied, therefore there would be less volatile compound, but I think that that would be an unfair or unwise conclusion to come to.

(Chairman.) We want to approximate to the actual conditions that the workmen find themselves in.

1738. (Mr. Rice.) On the last question, do I understand the thinner the paint the more volatile compound there is?—No, I did not go so far as to say that. I said you must not *a priori*, so to speak, assume that if you decreased the amount of pigment in the paint, you would therefore get less lead coming off. I think that it is probable that it might be the other way.

1739. That is what you wanted to imply?—That is what I wanted to imply, but I have no definite evidence.

1740. That, I take it, is only an assumption?—That is only an assumption.

1741. Not from actual practice?—Well, I do not really assume it, but I do not want you and the other members of the Committee to assume the other thing. I am absolutely certain that, whatever it is, it is due to a reaction between pigment and oil.

1742. Linseed oil is the most likely to produce the volatile compound?—Certainly. May I explain why? We tried it with the dry pigment, and there was absolutely nothing given off from it.

1743. Nothing at all?—Nothing at all.

1744. From dry white lead, nothing?—Nothing.

1745. But with linseed oil in varying proportions, the greater the volatile compound?—I do not know about the greater. You must not try to get me to say that.

1746. I do not want to get you to say anything that is not the fact?—There is no reaction with dry pigment and there is no reaction with linseed oil, but mix the two together and there is, and something comes off.

1747. And the greater the proportion of linseed oil the greater the volatile compound?—No. You would have to get it in chemical proportions to get the maximum effect, and the chemical proportions would be very much in the nature of actual paint put on.

1748. I understand you to say that you suffered from lead poisoning as the result of these experiments. Are you usually affected by the smell of paint?—No, I never have been in my life before.

1749. You have been in contact with paint before, but you have not been affected?—No. A chemical laboratory is nearly always painted with white lead paint—I do not know why, but I suppose that is because it is clean and white.

1750. (Mr. Sutherland.) Is not a chemical laboratory painted with zinc white? (Chairman.) As the evidence is only in the experimental stage, we had better leave it, I think at what the Professor has told us, unless there is anything very important that you want to ask. He will make his further investigations and report to us.

1751. (Mr. Parsonage.) I consider this the most important evidence we have had up to now. I think it is vitally important to prove that the vapour that arises from lead itself is sufficient to cause lead poisoning. I should like to ask you whether you have any personal knowledge of the use of non-poisonous paints in Liverpool University on the work inside the building?—How do you mean?

1752. Non-poisonous substitutes for lead are used in Liverpool University on the interior portions of the

29 March 1911.]

Professor E. C. C. BALY, F.R.S.

[Continued.]

building, in the Muspratt Laboratory of Electric Chemistry?—Yes.

1753. Is it not a fact that all the materials used for painting inside the building are non-poisonous substitutes?—I am afraid I cannot answer that question.

1754. But they are used there?—I do not know whether they are or not; I know nothing about them myself, you see I am quite new. It is a question for Professor Donnan. The Muspratt Laboratory was built long before I went to the University.

1755. Professor Donnan is at the University now?—Yes.

1756. He subjects to scientific tests all the material there is in the building. You would not know that?—No.

1757. (*Mr. Gardner.*) In carrying out your experiment you used linseed oil as the medium. As painters, we do not look upon that as being volatile, but we use a good deal of turpentine, which is a volatile medium. Do you think that that would have a greater effect in bringing out lead fumes?—I am afraid I could not answer that question until I have actually tried it.

1758. You might try that in your next experiment?—I will.

1759. (*Chairman.*) Would you make your experiments in the future by observing the same conditions which obtain in the ordinary painter's work-a-day life?—I quite understand the importance of that. I think that is a very fair criticism. If this is a very poisonous material, and it is given off in a big room, you will

The witness withdrew.

Mr. WILLIAM ROSCOE HARDWICK, B.Sc., examined.

1764. (*Chairman.*) Are you a consulting chemist?—I am.

1765. What are your qualifications?—I am a Bachelor of Science. I am also a Fellow of the Institute of Chemistry.

1766. I think you are the consulting chemist to Purex, Limited?—I am.

1767. What does your company manufacture?—A basic sulphate of lead.

1768. And have you come here to-day to describe the character of this product?—I have.

1769. Is it designed to take the place of white lead for every purpose?—It is.

1770. Will you please tell us the main uses of Purex?—Purex is a dry pigment, and may be used for all purposes—woodwork, ironwork, and plaster.

1771. Are paints both for coach painting and for house painting made up with Purex as a base?—Yes.

1772. Are they confined to white and the lighter shades, or are all colours obtained with Purex?—Practically all colours may be obtained with Purex, but naturally the darker colours would contain very little of the base.

1773. What do you understand by the base?—The base is, putting it one way, the greatest weight of material in the paint. That would be considered the base upon which the paint is built. Generally speaking, the pigment is considered a base.

1774. Are priming, stopping, and filling compositions all made up from Purex, or only the finishing coats?—All the coats.

1775. How does Purex compare with white lead for opacity?—Of itself and by itself, when applied with the ordinary brush or tool, it has not the same obliterating power as white lead. I may add, and I must add, that this is not because, weight for weight, it does not possess the power, but because the method of application and the tools used in applying it are not of a character to produce that obliterating power which it is really and truly possessed of.

1776. How does Purex compare with white lead for whiteness?—Purex, as it is made to-day, is unquestionably whiter than any white lead which I have seen on the market.

1777. Does it keep its colour better than white lead?—It keeps its colour very much better than white lead when the same conditions are observed.

get a very fair quantity in actual weight—quite enough to poison a man. In order to detect that you will have to investigate the whole air of the room, which is quite a big business. I am perfectly willing to try, and I will endeavour to do the best I can to get near to the actual conditions, but you realise I have to work from the end I started with. I have to get the actual evidence first of all, and then I have to get down and down and down nearer to the actual conditions.

1760. (*Chairman.*) Some of the Committee would like to visit the laboratory?—I should be very honoured if you would.

1761. (*Mr. Mason.*) There seems to be some misconception as to the application of the word "absorption." It is not absorption of lead fumes by the air, but the absorption of the rays in the spectrum that you refer to, is it not?—Yes. You have seen those photographs?

(*Mr. Mason.*) Yes.

1762. (*Chairman.*) We are extremely grateful to you. We will not detain you any further, but you will keep in touch with us?—I will. Shall I communicate with you whenever I am ready.

1763. (*Chairman.*) Yes, and some of us will make arrangements to come to your laboratory, because it is very important?—It would be very much more satisfactory if some of the Committee could come to see it, because it would save all this long, technical explanation if you could see the things being done.

1778. How does Purex compare with white lead for durability?—The durability of Purex has, as far as I have been able in the time that I have been connected with it to observe, given the same conditions, approximately three times the life of white lead.

1779. To what do you attribute the durability of your product?—Partly to its physical, and partly to its chemical, nature.

1780. Is there no tendency for the film of Purex paint to crack after exposure for some time?—There is not the same tendency for the film to crack after exposure with Purex as with other pigments, because the Purex pigment is a pigment which fortifies the oil film, and it is not a question of the oil film fortifying the pigment.

1781. What is the cost of Purex; is it dearer or cheaper than white lead or zinc oxide?—It is rather cheaper than white lead and very much cheaper than zinc.

1782. Does a house painter or coach painter using Purex material go through the same processes as he would with white lead?—Absolutely, if working as directed.

1783. What do you mean by that?—I mean that the want of obliterating power can be easily corrected by the addition of coarser material.

1784. Is Purex put on in the ordinary way?—Yes.

1785. Then why did you qualify your last answer? I asked you, Does the house painter or coach painter using Purex material go through the same processes as he would with white lead?—When the paint is sent out—if paint which would be applied in the ordinary way is sent—it is of a coarser character, mixed with a coarser material, to imitate the ordinary carbonate, which has been for so long established that the very tools that the workmen use are made to fit in with the carbonate, and not the carbonate to fit in with the tools.

1786. Would the ordinary house painter have any difficulty in using Purex if he had been used to white lead or zinc oxide?—Not if he allows Purex Limited to send him the material which they would wish.

1787. I do not understand that?—I know it is difficult. I feel that my position is very difficult indeed.

29 March 1911.]

Mr. WILLIAM ROSCOE HARDWICK, B.Sc.

[Continued.]

1788. What I want to get at is this: Would the ordinary painter have any more difficulty?—If he were to ask for Purex, no; but then he makes various stipulations, "Genuine white lead" and a hundred and one other things.

1789. Is rubbing down required with Purex paints, in the same way as with others?—No.

1790. Is it as easy to spread Purex paints free from brush marks as with ordinary white lead, for example?—Yes.

1791. Do you mean that less rubbing down should serve with Purex paints?—Yes.

1792. Why does Purex require less rubbing down than other paints?—Because rubbing down is simply a process of selection of the finest particles, and since the Purex particles are the finest conceivable, the finest of the fine, that selection of the finest particles becomes unnecessary.

1793. Can all the necessary rubbing down be done by a wet method?—Yes.

1794. Not excepting curves, mouldings, and iron-work?—Yes, certainly.

1795. In repainting old work, would rubbing down be required? No, because Purex tends to wear rather than perish.

1796. Why does Purex tend to wear and not perish?—Because the ordinary white lead perishes owing to the fact that it is a carbonate, and all carbonates, being extremely unstable chemical salts, are liable to the action of the prevailing sulphuric acid of the atmosphere of towns particularly. It decomposes, and when decomposing cracks, and this cracking tends to cause a subcutaneous (if I may use that word) action on the paint film. That is the sense in which I speak of perishing. Purex, being a basic sulphate, is not liable to be acted upon by the acid of the atmosphere, and when the paint film (I speak of the oil) has become removed and the pigment itself has become exposed to the atmosphere, it presents a surface which is not acted upon as the carbonate is acted upon. The consequence is that if the paint deteriorates in any sense it is simply a deterioration which can be described as wearing rather than a deterioration, which is of a more subtle subcutaneous and perishing nature.

1797. Can burning off or scraping off be dispensed with in the case of Purex painting?—I could not tell you; I cannot answer that question at all.

1798. You are aware that a large amount of lead poisoning has occurred and is still happening in the painting industries?—Yes.

1799. What can you tell us about Purex from that point of view? Do you say that Purex is less poisonous than white lead?—Yes.

1800. Do you know the test for solubility laid down in the Earthenware Special Rules?—Yes.

1801. Can you tell us the solubility of Purex judged by this standard; in other words, what percentage of Purex is soluble in excess of dilute hydrochloric acid—0.25 per cent. solution?—That varies and has varied very much with our method of manufacture. We originally were making a material of an extremely basic character, that is to say a material which would contain a large proportion of oxide of lead. Since, however, we have got our plant tuned up, so to speak, we have produced what we set out to produce, and that is the much whiter and much more durable and less toxic Purex of to-day, which contains very much less oxide; not more than one-fifth of the whole probably.

1802. That is to say 20 per cent. of solubility?—Approximately. It is rather more, taking everything. It is about 25 on the average.

1803. What is the solubility of white lead?—One hundred per cent.

1804. You know that a 5 per cent. solubility standard was adopted in 1903 in the Earthenware and China Special Rules?—Yes.

1805. What you claim amounts to this—that Purex is four times less poisonous than white lead. You do not claim that it is entirely innocuous?—I do not. I should like to qualify that answer very much indeed. If you consider the poisonous action of a material, you have to consider all the points which are liable to

cause the poisoning, quite apart from the absolute eating or swallowing of the pigment.

1806. I do not agree. The standard quantity of lead in the earthenware and china glazes is approximately about 20 per cent., and that creates a vast amount of injury in that industry. If you claim that your paint contains 20 per cent. of soluble lead compound, you are in no better position than the vast numbers of earthenware and china manufacturers who have been proved by that standard to do an immense amount of harm?—Really, Sir, I beg to differ. In one case you have a powdery dry material, but with the Purex you have material which is to a certain extent, a very large extent, harnessed by the linseed oil.

1807. Can you tell us whether any cases of lead poisoning have been traced to Purex?—Yes. I remember that some two years ago, I think it would be, at Earlestown in Lancashire, in the North Western Railway Company's waggon works in fact, they were painting their wagons by the spraying operation, and they were using a non-poisonous paint—lithopone as a matter of fact (I analysed it)—and I recommended them to use Purex. The engineer at that time made such experiments as to satisfy him of the far greater durability of Purex. Having done that, I suggested that the spraying would be possible, provided that the men wore masks.

1808. How many cases of lead poisoning did you have last year?—None whatever.

1809. Have you heard of any cases of lead poisoning?—None whatever.

1810. Do I understand that, since your paint has been on the market, you have heard of no case of lead poisoning?—None, except what I mentioned.

1811. Was that only one case?—I do not know how many there were. As a matter of fact, I understand that the men who were working the machine were not poisoned, but cases of lead poisoning occurred in other parts of the works.

1812. To sum up your evidence generally, you claim that Purex has advantages over the old white lead, that it makes a better, more lasting paint, and is on the whole less poisonous?—Yes.

1813. Should the use of lead paints be restricted or prohibited in this country at any time, would this mean serious loss of business for your firm?—It would mean absolutely closing the works.

1814. If substitutes for lead paints can be found which will alleviate the sufferings of a vast number of people in the painting industry, you would think it not unreasonable, I suppose, if the Home Office should prohibit the use of lead paints?—If by practice they are shown to be dangerous, I should not. If by practice they are shown not to be dangerous, I should.

1815. (*Sir Godfray Baring.*) How long has Purex been on the market for sale?—I think two or three years; I do not know exactly.

1816. Do you find that there is a great demand for it?—Yes, rather.

1817. Would you give us the names of any big firms who are large users of it?—I do not want a long list?—Yes. Here is a picture of my native city, Liverpool. I thought it might interest you. I will show you exactly what we are doing. It has been tried by the leading architect in Liverpool, at my instigation, and, he having satisfied himself of its far greater durability, they are painting the Liver Buildings—there in the front of the picture—with Purex. The Liverpool dock offices are also painted with Purex—right on the pier head.

1818. Has it been used at sea?—It is particularly useful where salt water is concerned.

1819. If this Committee came to the conclusion to restrict or regulate the use of white lead in paints, do I understand you to say that a product like Purex should be specifically excluded from the prohibition?—Yes; I feel quite satisfied in my own mind about that. With all the precautions which painters are supposed to observe, I am sure there would be no case of lead poisoning.

1820. (*Dr. Collis.*) I understood you to say that Purex has only been on the market for two or three years. It has been manufactured for longer than that,

D 2

29 March 1911.]

MR. WILLIAM ROSCOE HARDWICK, B.S.C.

[Continued.]

has it not?—Yes, in small quantities. Spasmodic attempts to succeed in its manufacture were made 25 years ago really. As a matter of fact the problem was put before me as a chemist, and I at once said, "There is no possibility of its being a success, because of the supposition with regard to basic carbonate and the ordinary white lead," which I then proved was quite incorrect, and I took up the question of Purex four years ago, or perhaps a little longer, certainly before the inception of the company, Purex Limited.

1821. Any illness during these early times you would not consider showed in any way the noxious qualities of the material?—I see what you mean. No. I think that all attempts that were made to manufacture without getting the thing fully under control would hardly fairly show what could be done when the thing was properly running, but I must say that all the time we worked for instance with our coolers, and with the leaking of Purex out of leaky filter bags, none of the men suffered. Sometimes the place has been so thick that you could not see your hand before you.

1822. Do you know what happened at Wolverhampton?—No. I know nothing about Wolverhampton.

1823. You know what process was carried on there?—Yes, I went to see it. It was a development of that process that I followed.

1824. Do you wish us to understand that any damage that occurred to the health of the workers then was not to be put down to the finished product but to the process of manufacture or otherwise?—I did not know about it, but I have been told. If damage occurred, I should put it down to the fact that we were making an extremely basic material, and the more basic the material the more soluble it is, and the more likely to be toxic in its effect.

1825. So that the 20 per cent. solubility we have heard spoken of to-day does represent absolutely noxious qualities?—Yes.

1826. So that it is not impossible that cases of lead poisoning might occur from its use?—No; with proper use it is impossible, but with careless use it is not.

1827. With reference to the evidence we have had from Professor Baly, am I right in supposing that he has presented from one point of view only the painter's problem, namely, the possibility of vapour being given off by wet lead paint? The evidence we have already had before the Committee goes to show that the chief danger to the painters is from lead dust, so am I right in presuming that Professor Baly's evidence to-day, tending to clear the character of Purex from giving off vapour when it was wet, would not clear Purex from the possibility of causing lead poisoning when surfaces are rubbed down and dust is given off?—That is a big question. Here are two boards. You can see what I mean by the film. In my evidence-in-chief I tried to explain what I meant by the film.

1828. I am referring to the removing of old lead paint?—If you examine those two boards by the light you will see that the face of *this* is already prepared. The other paint is all perishing, and would have to be removed by the rubbing down process before the further application of paint. The elasticity of the film produced through the drying of the Purex admixture with the oil causes a result which does not perish but wears. When you want to put a fresh coat on old Purex you do it without attempting to remove the paint by rubbing down; in fact, rubbing down is an impossibility, it rolls up. You do not rub down. Here are micro-photographs, magnified a great number of times (*producing the same*). *That* is red lead. *That* is graphite; *that* is ordinary white lead; *that* is barytes; *that* is zinc; and *that* is Purex. (*The witness explained by pointing to the photographs*) *This* material has large rocks, as I call them. As a matter of fact, they are extremely fine. If you rub down you remove these big pieces, or cut them in halves, and just leave the little tiny particles, but in the case of Purex there are no big ones to remove. The temperature of combustion of metallic zinc is not as high. (*The witness further explains by photographs*.) *This* is 625 magnifications.

1829. Are they all the same?—No. *These* others are magnified only 500 times.

1830. Your point is that rubbing down with sand-paper is not necessary with Purex old paint as it is with white lead paint?—That is so.

1831. How about burning off?—I cannot speak of burning off, because really I do not know that Purex has ever perished to that extent. I have tried to get these fumes by heating a tube to a high temperature, and I have certainly got lead fume from the Purex, but to nothing like the same extent as with ordinary white lead.

1832. You, I am sure, quite appreciate the point that, should this Committee decide on any extent of abolition of lead paints, it would be very hard for them to put in an exception for a material which, when sprayed, has caused any lead poisoning?—I do not see that it is so. Nobody would dream of spraying Purex. It is tempting Providence to do so.

1833. I suggest to you that great damage was caused in the old days, when the Mander Hannay process was carried on at Wolverhampton?—You are speaking now of manufacture, which is a different thing. It is localised; it is under your control, so to speak, and you can see exactly what is going on, but when the paint is distributed throughout the length and breadth of the land you cannot possibly follow it. The two things seem to me to be so totally different.

1834. My point is this—that a material which, in the course of manufacture, has caused trouble, is likely to be dangerous in use?—I do not agree.

1835. Do you wish to contend that it was a different product which, in the course of manufacture, caused illness, and not the final product?—I think that is quite the correct way of putting it—that the product leaving our works is a different product from the product which could, or might, or has caused lead poisoning in course of manufacture.

1836. Could you establish that fact (which is rather your place than ours) and show that it was a different product which caused trouble in the works from the final product which went out of the works?—I do not quite see what you want me to say.

1837. I mean this—that we know that trouble has occurred in the course of its manufacture. As far as we are aware, it was due to the product itself. If your contention is that it is due to some product manufactured before you got to the final product, we require demonstration of that fact before we can accept the material as being non-poisonous?—My proposition is really this. If you take this pigment and allow the fumes to pass from the furnace into the atmosphere it will travel some miles before it comes to the earth, and although the specific gravity of the material is rather greater than that of ordinary white lead, you see the excessive fineness, in that it is able to travel as I have described. If you take that fine powder and keep it, so to speak, harnessed by means of bagging and so forth, until the oil is admixed with it, all that inherent danger, owing to its excessive fineness, is done away with, and you have, to all intents and purposes, a different material to offer to the public from the material of which I was speaking. To all intents and purposes, the toxic effect is really and truly different when bound by the oil from what it is when this is in a state of dry, as it is called.

1838. Allowing your point for a moment, you have already instanced to us the cases which occurred at Earlestown after the Purex had been mixed with oil?

Yes, because there again I contend that the system of painting at Earlestown was not to be considered as in any sense in accordance with ordinary precautions.

1839. No, but I want to make my point clear. Before this Committee could consider the question of giving exemption for any lead compound, it would have to be one which was capable of full proof. That is the way in which it is viewed in the Factory Department. You can hardly speak of Purex in that category?—No, you could not use it with a spruy.

1840. (*Mr. Sutherland.*) In what respect do they differ from the Mander Hannay process?—Less basic material. Mander Hannay had a process of smelting lead in his furnace, and he could not get any of the volatile products without a certain proportion of lead,

29 March 1911.]

Mr. WILLIAM ROSCOE HARDWICK, B.Sc.

[Continued.]

which oxidised in the furnace. These quantities of lead oxide are, as you know, very very poisonous.

1841. How did that differ from the Glasgow white lead?—He got so much of the basic material that he had to deal with it by sulphuric acid. All the lead came together in great big crystals. It has no covering power whatever if you once get the particles wet with water or sulphuric acid. The pigmentary power is killed altogether.

1842. Would you make a distinction between that and the ordinary stack white lead? The ordinary painter applies the normal stack lead because of its biting power?—By the addition of an entirely innocuous substance you could get it so that he could not tell one from the other.

1843. By the addition of barytes or barium sulphate?—Yes.

1844. That would give the same stopping texture?—Yes, it coarsens it. If you mix the extremely coarse and the extremely fine you get what a man really wants when working with ordinary tools.

1845. I do not think that the insurance company would accept that lead as non-poisonous?—I do not see on what ground they should not.

1846. Twenty per cent. of solubility?—That is quite another thing, is it not?

1847. Yes. Twenty per cent. would be fatal in the eyes of the insurance company?—It might be if you took it just on those terms, but my contention is that the lead poisoning was due to constantly inhaling the vapour of which Professor Baly has spoken. I do not want to go into that, as he has dealt with it. When I smelt that tube I was very bad. The other tubes had no effect whatever. If a man was spending his life in such an atmosphere there might be something to say.

1848. The French have debarred the use of white lead inside?—I do not know what the idea is. I do not know whether it is founded on concrete knowledge or not. I take it that it is because, when freshly applied, it gives off these irritating noxious vapours.

1849. (Chairman.) In France it is prohibited inside and outside?—Do not they use white lead now?

(Chairman.) The French decree includes both interior and exterior painting, but it only comes into force in 1915.

1850. (Mr. Sutherland) (to the witness). The fact that your production is 80 per cent. less soluble than ordinary white lead is in favour of your particular make from the non-poisonous point of view?—If a man has to absorb four times as much, he probably gets poisoned four times more quickly. I think that is the proper way of looking at it.

1851. (Mr. Rice.) Purex is made as a paste ready for mixing and put on the market?—Yes.

1852. It is mixed with ordinary linseed oil and turps in the ordinary way?—No, linseed oil only. We talk of grinding, but you cannot subdivide those particles.

1853. It is sold in a paste to be mixed?—Yes.

1854. You were speaking of the difficulty of using ordinary tools. Would you explain that?—If I can I will.

1855. I ought to ask what tools should be used in applying Purex?—Very much finer.

1856. It is only a question of finer tools?—Yes. Well, not perhaps only that. If you have finer tools and a man has to get up into a corner, with a stiff bristle he can brush the paint in, but with a soft bristle he cannot. But that is quite overcome by the admixture, which has proved absolutely satisfactory. Since Mr. Mason brought the subject before me I have been telling the works to dissociate themselves from white lead. If people say they want genuine white lead, then we say, "This is not genuine white lead."

1857. (Mr. Gardner.) What you intend putting on the market would be a commercial product? I intend to put it on the market with just sufficient to add to its opacity and covering power. I am putting it on the market now.

1858. If you exposed your material to the heat of the sun for a number of years, would it not crack and blister?—No, it does not. The paint film formed

(there are chemical and other reasons which I cannot go into now) is very much like the skin of your own hand. My laboratory walls were painted with it two years ago, and the paint sticks at your touch like that, and it has all the nature of linseed oil left in it, whereas on the other side of the wall the carbonate is all perishing.

1859. Do you say that, if we sandpaper it, the dust would be absolutely non-poisonous?—But dust does not form. I want to make that quite clear.

1860. It must form?—It does not. That is the unfortunate part of it in one way. You have the elastic film which the painter does not like. The coachbuilders, Hooper's in Liverpool, are using absolutely nothing but Purex, and they do not rub down. They paint coat after coat with an enormous saving and a vastly improved finished article.

1861. (Chairman.) May we apply to them?—Certainly, with pleasure.

1862. (Mr. Parsonage.) With regard to the spraying machine, do you think that such things should be allowed to be used at all in connection with painting?

—Really, I could not answer that question. I know that they should not be allowed with Purex. It is tempting Providence to do that. I do not think that the atmosphere produced by a spray, even if the so-called non-poisonous paint were used, could be healthy to any man's lungs.

1863. And especially when using lead paint. A man would be literally smothered with the stuff?—Yes, literally.

1864. They may as well poison the man at once as allow such a thing to be used?—Yes.

1865. (Mr. Fell.) Would you say that, in connection with carriage work, they would not have to do any rubbing down or burning off. I understand it with a new vehicle, but unhappily it is not a question of simply the paint wearing out, but of repairing damage, and you must rub down or burn, to get to the bottom of that damage?—My answer to that would be that in the case of damage this paint film would be movable. It would be like paring organic matter, the nails of your hands and so forth. It adheres; the paint film becomes to all intents and purposes india-rubber. If you can imagine rubbing down india-rubber, you get very much at what is at the back of my mind which I have tried to explain.

1866. I fail to see how you can get out of rubbing down?—You must remove it but not rub down.

1867. (Lord Henry Bentinck.) How would you deal with a panel of a coach?—As I say, I have not had experience of rubbing down.

1868. (Mr. Fell.) My point is that, if there is any rubbing down, and your stuff is ground so much finer, there must be more dust in the air, and therefore there would be a greater tendency for people to breathe it?—If you look at those two boards for a moment you will see exactly what I mean. (Two boards were produced, and the witness explained.)

1869. Could you give us the names of some coach painters and other people who use Purex, so that we may inquire from them how they manage?—Yes.

1870. (Mr. Mason.) I would like to ask you whether it is possible to make this paint come down to a 5 per cent. solubility standard and still keep its properties?—No. If you put in 50 per cent. of barytes you would only bring it down to 10.

1871. (Chairman.) The Home Office accepts 5 per cent. as rendering a substance practically safe?—Yes. I do not want to labour the point. I think the poisonous nature of the material as swallowed is only a very small part of the question.

1872. (Mr. Mason.) Could you give us the name of any ironwork where your paint has been used?—It has been used largely in ships because salt water has not the same action on it as it has on zinc. Zinc is largely used, but the magnesium chloride, which is common to sea water, affects the zinc very rapidly, and when the oil has perished then the zinc is destroyed.

1873. (Mr. Sutherland.) There is a big bridge at Runcorn painted with it? Yes, quite three years ago. The bridge at Runcorn was painted with Purex and boiled linseed oil. The bridge was in a very bad

29 March 1911.]

Mr. WILLIAM ROBCOE HARDWICK, B.Sc.

[Continued.]

condition, and it was painted with only one coat of the Purex and linseed oil, and this one coat has stood till to-day. I think they are considering the repainting of it now.

1874. (*Mr. Mason.*) That is considerably longer than white lead would stand?—Yes; nothing has ever stood it as long as that before.

1875. (*Mr. Sutherland.*) One coat only?—One coat only.

1876. I heard of it last November. I heard that it was standing well?—It has stood wonderfully well.

1877. (*Mr. Robins.*) As a coach painter, I can see certain impossibilities in the use of Purex, and although Mr. Hooper, at Liverpool, is using it, I would like to ask you if he is using it direct on the bare wood. Is he using it for priming? Is he using it for the nail and screw holes which occur? You cannot build a coach without them. Is it used for nail holes, screw

holes, dents in panels, and how does it suit the grain of wood? If you coat it ever so evenly there will always be holes. I do not know whether you claim that the Purex can be mixed into a stiff paint. If you do that, then there is an unevenness of the surface when that has set; if you coat it with another coat it would be morally impossible to produce an even surface on that coat without rubbing down?—That is a question for the users of the paint.

(*Chairman.*) Yes, I would reserve those questions.

(*Mr. Robins.*) The witness said that Mr. Hooper was using it, and I would like to say as a practical painter that I can see an impossibility about it.

1878. (*Mr. Kinggate.*) Can you use turps with it?—Yes.

1879. I understood you could only mix it with oil?—No, you can use turps.

The witness withdrew.

Mr. JOHN DIBBLEE CRACE examined.

1880. (*Chairman.*) Are you a master house decorator?—I was for 45 years, but am not now. About 10 years ago I gave it up—or 12 years ago.

1881. You are President, I think, of a Trade Society?—No, not of the Trade Society, but of the Institute of British Decorators, which includes employers.

1882. What was your business?—Decoration.

1883. What class of work did you do?—What may be called first-class sort of work. I decorated the National Gallery, the Houses of Parliament, and the Leeds Town Hall.

1884. You were in the trade 45 years, do you say?—Yes.

1885. Were you an employer all that time?—All that time.

1886. Were you apprenticed to the trade?—I was. My firm has existed for five generations succeeding from father to son.

1887. How many men did you employ during those 45 years?—It is impossible to say.

1888. Per annum, I mean?—It varied very greatly; from 100, sometimes to 200 or 300 probably.

1889. Were they all painters?—I had other men also, but I am speaking of painters now.

1890. Did you have an even run of business all the year round?—No. In the later years, it very much dwindled in the winter; always, in fact, all through, but much more latterly.

1891. What happened to your men in the slack time; were they discharged?—Yes, they went off according to the work. There might be 200 men one week and only 100 the next week on the completion of a large work.

1892. Did you employ the same men year after year?—To a certain extent. There were certain men who were practically always in our employ.

1893. Did they come to you as boys?—Some of them, but that was not so much the case in the later years.

1894. Did many leave you of their own accord?—I think they always left because there was not sufficient going on.

1895. What reasons would be given?—The engagements were never supposed to be for more than from week to week, but, as a matter of fact, when we found valuable men we always endeavoured to keep them and made work of all kinds.

1896. Did any of them leave the trade because of ill-health?—I would not say that they never did, but it never came to my knowledge. In fact, I might say that the painters that I have had in my employ were a more healthy-looking set of men than probably the joiners and carpenters.

1897. Did you take on and discharge your men personally?—All my work was conducted personally.

1898. Did you make enquiries when a man was away as to whether he was ill, and if so as to what was the matter with him?—Now and then I should; but unless a man went from the country I should hardly

know, because the number of men would have to be kept up to what was necessary. In country work I should know, but in work in London I should not probably know.

1899. Did all the paints which you used contain lead compounds?—All the white paints. Lead compounds are in a comparative minority for the stainers; umber and ochre, and so on, are not lead compounds.

1900. You did not use all lead compounds?—No, certainly not. I should say that was rather exceptional.

1901. What quantity of white lead did you use?—That varied too, very much. I have no longer got the books to refer to; but I found, since the question was raised the other day, that in the last five or six years it averaged about three tons a year.

1902. And red lead?—To a certain extent for outside work.

1903. Did you use much red lead?—No; comparatively a very small quantity, because it was only used for outside preparatory work.

1904. With regard to Brunswick green and other paints containing lead chromate, what quantities of those did you use?—Chrome yellow was used in a very small proportion.

1905. What quantity did you use of red oxide of iron?—That was used exclusively outside. I should say it would be only on iron work. It would not be very great.

1906. Did you use zinc oxide at all?—At one time we tried it, but we did not find it work satisfactorily, and the men did not like it.

1907. Did you give it up because the men did not like it, or because it was not satisfactory in other respects?—It is a long time ago. It was through the men's expression that they could not get on with it that it was given up. It was taken up quite experimentally.

1908. Did you use lithopone?—No, not under that name. I do not know what it is.

1909. Did you use carbon or graphite paints?—They are more recent inventions. I have used them of late years for outside work.

1910. Did you use any particular brands of leadless paints?—No. Leadless paints would only apply to the stainers, and would be comparatively small in quantity.

1911. Then, to sum up, have nearly all your paints contained lead?—All the white paint was white lead.

1912. Did you ever hear of any of your men suffering from lead poisoning?—I can only recollect one case, about 20 years ago. It was a man who had been a great many years with us, and had never been in really good health, and I think was constitutionally open to be affected by it. He was in charge of work, and was very earnest in his work, and very apt to neglect the necessary precautions really.

1913. Do you mean that your men did not, to your knowledge, break down on account of lead absorption?—It is a most exceptional thing. With good men it is a very unlikely thing.

29 March 1911.]

Mr. JOHN DIBBLEE CRACE.

[Continued.]

1914. But I want you to answer the question—do you mean to say that to your knowledge none of your men broke down on account of lead absorption?—I only knew of one man breaking down from that cause.

1915. In how many years?—Forty-five.

1916. Did your men have occasional days of sickness due to lead?—Yes. I should think I heard that perhaps six or eight, or five or six, who would be away for a day or two and come back.

1917. Five or six in the course of 45 years?—I should think that is about all I have heard of.

1918. Would all the cases come before you?—Yes, the foreman would always report them. In fact, in the cases I can call to mind, he would sometimes come and ask me if I could provide him with an immediate remedy.

1919. Did you have periodical medical examination of your men?—No.

1920. Then is it not possible that some of them were suffering from the slower and more insidious forms of poisoning?—I cannot express an opinion on that. The men that I knew best came to me year after year. In fact, when last I renewed the decoration of the House of Lords, I had a man in my employment who had been in mine or my father's employment when the House was originally decorated in 1847. It was 1893 when the House was restored, and I found that that man had been actually at the work when it was first done. I suppose there were a number varying from a dozen to perhaps 30 or 40 who were constantly with us, and among those I never knew a case.

1921. I suppose you took precautions to guard against your men being lead poisoned?—The precautions were that they were always to wash their hands on leaving work or before meals.

1922. Did you insist on that?—The trained painters knew it quite well.

1923. But did you have any system in your organisation by which the men were obliged to wash their hands?—They would have been found fault with if they were found not to have done it. The foreman on the work was responsible for it.

1924. Did you give them any extra time in which to wash?—There was always water and soap and towels provided, and it was a question of a couple of minutes.

1925. How many men to each basin?—There was a pail; we did not get to the refinement of basins.

1926. That is a more modern luxury?—I have often washed in a pail myself.

1927. Did you provide hot and cold water?—That would depend very much on whether the house which they were working on was an occupied one or not. If the house had servants in it they would make arrangements with them to bring hot water.

1928. When your men were working on a job outside, how did they get their towels and nail brushes and soap, and so on?—They were always provided on the premises.

1929. By you?—Yes.

1930. Did your men wear overalls?—Yes, they always wore Holland overalls.

1931. Did you provide them?—No; that was part of their kit.

1932. And they washed them themselves, I suppose?—They brought them with them and took them away with them always.

1933. Did you take any steps to prevent dust from getting into the air?—There is no dust in house painting.

1934. I will return to that point presently. Did you ever do any mixing?—Yes.

1935. Where was that done?—On the spot; at the work.

1936. At the place where the work was being conducted?—Yes.

1937. Was there no dust from that?—Certainly not; it is all in oil.

1938. But they must get it out first in a dry state?—No; they never had white lead in a dry state. It always came mixed all ready in oil—a stiff compound.

1939. It came from where?—The manufacturers.

1940. So that your men never came in contact with any dry white lead at all?—No. They might use it on some small scale for special purposes, but it would be only a few ounces then and quite an exceptional thing.

1941. With regard to house-painting, was much of the work rubbed down?—Yes, always.

1942. Did you use dry sandpaper for that?—No, except upon old paint sometimes which would be rubbed down, but the rubbing down generally was done with pumice stone and water.

1943. I have asked you whether you used dry sandpaper. You said that on some occasions you did?—Yes, it would be used on old work.

1944. Would there be no dust then?—I suppose there might be a little dust from that.

1945. Did you generally use a wet process?—Yes.

1946. Invariably?—Pumice and water.

1947. How many times did you rub down your work?—It is difficult to say. It would depend entirely on the condition of the work.

1948. Were all the undercoats rubbed down?—No.

1949. Did you rub down mouldings and curves?—Yes.

1950. Can the wet method be generally used throughout?—Yes.

1951. I suppose overalls were worn in this work?—Always.

1952. Will you tell us about your stopping. What did you use as stopping?—It would vary a little according to the work, but it would be white lead in Japan gold size or sometimes in varnish made into a stiff paste.

1953. How was that applied?—With a knife.

1954. Can a workman avoid getting his hands soiled with the stopping? No. He would probably get as much on his hands as he would in painting. He is not obliged to touch it, but he invariably does.

1955. Is the stopping easily cleaned off the hands?—Yes, if it is done properly before leaving off for meals.

1956. Was not the white lead handled dry in making the stopping?—It may have been sometimes, but I really do not recollect that it was. We always had our white lead in oil, and it was from that that the stopping was made. Very often some sorts of stopping would be made with very little lead at all.

1957. Do you think it is easy for the men to wash their hands in cold water with paint on?—Yes. You cannot get hot water in such a building as an unfinished Houses of Parliament or an unfinished National Gallery—it is not at hand—or in an empty private house.

1958. When you were repainting, how did you deal with the old paint?—On walls, it was slightly rubbed over with sandpaper.

1959. Did you scrape it off or burn it off?—Burning off would be the exceptional thing rather. In fact, it would not all be scraped off for ordinary work. It is only for such work as blistered paint, or where it has been unsoundly done originally.

1960. What is the proportion of scraping off to burning off?—It would not be often scraped off at all unless it was very bad painting and had to be replaced.

1961. Did you burn off interior work as well as exterior?—With such things as shutters, if the paint has to be removed. You generally use some solvent for interior work. Burning off makes a very disagreeable smell.

1962. When scraping off is done, is the paint hard or soft?—The scraping off, as I say, would only be an occasional thing. The paint may be assumed to be hard. It would be old paint.

1963. Do painters carry a dusting brush among their tools?—Yes; they are supplied by the employer.

1964. I suppose the application of wet paint involves soiling the hands?—Yes, almost inevitably.

1965. And the garments?—Yes, splashes on the garments.

1966. And on the overalls?—Yes.

1967. At what time did your men commence work in the morning?—When I first recollect, they began at six in the summer and seven in the winter, but during

D 4

29 March 1911.]

Mr. JOHN DIBBLEE CRACE.

[Continued.]

the later years the hours were very much changed by the trade union arrangements.

1968. Did they have breakfast before they began?—Very few did. I expect they generally broke off for breakfast.

1969. How long did they have for breakfast?—Half an hour, I think it was.

1970. Did they go home for that, as a rule?—No; they generally brought something with them.

1971. Did any of them take their breakfast in the paint-mixing shop?—No; they were supposed to find a place where there was not any paint, but we had not much control of that. Some of them would go to a coffee house or go to a public house.

1972. If they had their breakfast in the place where they were at work, what then?—In the country we always used to try to arrange with the owners of the house to set apart a room in which they could take their meals, and we generally provided a man to act as cook.

1973. A witness told us yesterday that the men invariably took the meals in the places where the painting was going on?—That is a mistake, if it is a well-conducted firm.

1974. Can you regulate that when the men are away from you?—You can do a good deal towards it by making some arrangement with the owners of the house that your men may use a certain room. I should say that they never took their meals in the place where the painting was.

1975. Yesterday a witness said that they always did?—They do not always do it. I never would let it go on if I saw it.

1976. What are the usual hours of work amongst painters?—About 52 hours a week I think it was latterly.

1977. Do they work overtime?—Yes, in emergencies.

1978. Are the men well fed?—To judge of their appearance; I should say there were some who were remarkably fine-looking men among my people.

1979. You told us that you did not adopt periodical medical examination?—No; it was never thought of in those days. It is a modern invention.

1980. When you were in business, there was no liability for lead poisoning under the Workmen's Compensation Act?—No.

1981. Have you ever studied the Registrar-General's report as to the lamentable amount of disease and illness in this industry?—No.

1982. You have never done that?—No.

1983. Do you know that there were no less than 284 deaths from lead poisoning amongst house painters in the last 10 years?—No, but I should say that, if that were inquired into, it would be found that all those men were men who had not been originally trained as painters; but had been brought in for a cheap job.

1984. Do you know that the mortality figures show for painters a death-rate considerably higher than the normal from troubles which are the frequent effect of exposure to lead, such as Bright's disease and nervous diseases?—I have never heard that Bright's disease was more common to painters than to other people.

1985. Would you be surprised to hear that it is very much higher amongst house painters than any other class of workers?—I should be rather surprised to hear it. They are exposed in outside work a great deal more than many men.

1986. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the last ten years?—I should be very much surprised. I have had thousands of men in my employ.

1987. But I want to point this out to you. You are surprised to hear it?—Yes, I am.

1988. I am sure you will agree with me that all this sickness and death is very deplorable?—Of course anything of that kind is deplorable.

1989. There seem to be only two ways in which this state of affairs can be remedied. One method would be to prohibit the use of lead compounds, or at least to restrict them to four or five per cent. of the whole

material used. The other method would be to regulate the trade very strictly?—I am not clear what is intended by lead compounds.

1990. Oxide of lead and carbonate of lead and chromate of lead—all compounds containing lead. When you were in the trade were you a member of your trade organisation?—No; there was no organisation.

1991. The master painters were not organised then?—They were in parts of the country, but I never joined.

1992. Now I have told you what I think are the lamentable conditions to which this industry is at present exposed. Can you offer any suggestions to alleviate the evils which these men suffer from?—I think it ought to be made compulsory that provision should be made for the men to wash, and, if omitted, the foreman or the employer, as the case might be, should be subject to some penalty.

1993. Are you cognisant of the position abroad with regard to this matter of lead poisoning?—No, I cannot say that I have definite knowledge of it.

1994. Do you know that in France a law was passed in 1909 which prohibited, five years from that date, the use of white lead in the interior as well as the exterior of buildings?—Yes, I know that they have such a law.

1995. And that in Austria the use of white lead for the interior of buildings has been prohibited since the 1st April 1909?—I did not know that that was so in Austria.

1996. Have you heard that many Government and municipal authorities in such countries as Switzerland, Germany, and Belgium have prohibited the use of white lead in work undertaken on their account?—For interior or exterior?

1997. Interior and exterior?—No, I did not know that they had.

1998. Or that in Germany and Belgium very strict regulations have been introduced for the use of lead paints?—I heard that they had regulations, but I do not know what they are.

1999. Do you not think it is regrettable that this country should be behind other nations in such a matter?—Yes. I think that regulations to a certain extent would be a very good thing. I think really that so far as there is mischief in the country it probably is largely due to the men not having been trained and to insufficient insistence upon cleanliness. Perhaps you may be able to tell me what the percentage of the deaths from white lead will be to the whole?

(Chairman.) That is a point we are going into later.

2000. (Lord Henry Bentinck.) You say that it is not necessary always to burn off, do you not? You can use a solvent?—Yes; it is very often done.

2001. And it is not really necessary to burn off always then?—No. It is rather an exceptional thing. They burn off paint from front doors.

2002. Why cannot you use a solvent there?—Because it is very unsatisfactory to use any water in the process because it is more liable to blister from the effects of the climate—particularly alternations of hot sun and rain.

2003. What means can you suggest of training the young painters in their work?—The good thing is apprenticeship; unfortunately, that is not always done.

2004. That is not in practice nowadays?—It is in practice but not in London. All the best painters come from the north where they are apprenticed. All the best men I had came from the north of England or from Scotland.

2005. Then you would like to see some technical schools, I suppose, in London or an extension of the technical school system?—I am on the managing committee of one, but I do not think that a technical school ever supplies the place of apprenticeship.

2006. Do you think it is impossible to revive the apprenticeship system in London?—That is a very difficult question and one that I am not prepared to answer. It would be a very good thing if it were revived.

2007. Failing apprenticeship, the only remedy is to have technical schools?—Yes, and I approve of having

29 March 1911.]

Mr. JOHN DIBBLEE GRACE.

[Continued.]

technical schools, but I do not consider they are a substitute for training in the workshop.

2008. I do not think that they themselves pretend that they are?—In technical schools a youth never comes across the accidents of practice that actually occur.

2009. (*Sir Godfrey Baring.*) How many years is it since you retired from business?—I retired at the end of 1899—at the end of the century.

2010. So your evidence relates to the trade conditions of some time ago, does it not?—From 1854 to 1899 altogether.

2011. What is your experience with regard to the average age at which painters have to retire from a full day's work? Do you find that men can go on to a good age doing a full day's work? Yes. I met one of my old hands some time ago, one Sunday, and walked with him to Regent's Park. He narrated to me how he had seen the troops come back from Waterloo.

2012. Was it your experience that men collapsed at an unduly early age?—No, not at all.

2013. You said you tried some experiments with zinc oxide paints some time ago, and those were unsatisfactory. How long ago was that? I should say it must be 40 to 50 years ago.

2014. Would you say that there has been great improvement in the manufacture of zinc paints since then?—Yes, I believe there has been.

2015. Did I understand you to say that, in your opinion, paint stains could be removed by cold water alone, effectually from the hands? Not stains perhaps, because some pigments stain very strongly, but when the colour is mixed they would be able to wash it off.

2016. In cold water alone?—Yes, with soap.

2017. On the whole it would be generally desirable to use hot water?—Yes. A man would use hot water probably when he went home if he at all regarded the appearance of his hands.

2018. On some jobs it would be impossible to provide hot water?—Yes. Very often it would be impossible to provide hot water.

2019. What kind of work is it necessary to rub down with sandpaper?—The walls of a room like this, for instance, if they have been painted. It is not to take off paint but to give a key for the new paint to hold. It is not to remove a lot of paint, but to give a surface not keenly smooth.

2020. Rubbing down with sandpaper would produce a considerable amount of dust, I suppose?—Not very much, because you do not want to remove what is on. You only want to make it fit to receive another coat.

2021. Speaking from your experience, would you deplore it if this Committee came to the conclusion that it was necessary to restrict the use of lead paint?—I should, very much.

2022. Do you think that it would be disastrous to the painting industry?—I do. I am speaking now as a disinterested witness because, as I say, I have not been in business this last 12 years.

2023. Do you anticipate that the prohibition will be disastrous in France?—Yes. I think interior decoration, where lead is not used, can never be so satisfactorily done.

2024. (*Chairman.*) In what way will it be disastrous if it is general throughout the country?—I was not thinking of it financially; I was thinking of effect.

2025. Of the artistic effect?—Yes. All the painters in the artistic part of it go on using lead now. It is only for the mechanical part that they have done away with lead.

2026. Would you be surprised to hear that the representative of the Office of Works told us yesterday that they made a great many experiments during the last nine years, and they have now arrived at a time when they much prefer zinc oxide, both from the artistic point of view and from the point of view of durability? Is it the artistic point of view in mixed colours?

2027. In all colours?—I am very much surprised to hear it. I do not know a single artist painter who uses white zinc in oil. The touches would not cover.

You use it in water, of course, but that is a different thing.

2028. Perhaps you may have lost touch, as you have been out of the trade 12 years?—But I have painted pictures in the meantime occasionally.

2029. But it is conceivable that you may have missed some of the more modern methods?—Yes, it is quite possible.

2030. (*Dr. Collis.*) Do I understand that you did not, when you were in business, take any special precautions other than other masters did to protect the health of the men?—No. I should say that probably our precautions were among the best of those who were working at the same time.

2031. So that your men would represent a fair sample of the ordinary painter and plumber?—Yes; a fair sample of the painters; I do not speak as to plumbers.

2032. You have given your opinion on the health of the men from your experience. Is your experience based on any accurate statistics?—I did not form statistical tables, but I was in contact with the men constantly.

2033. You have stated that you thought that your carpenters and joiners showed about the same health or rather worse than the plumbers, painters, and glaziers. May I draw your attention to the fact that your opinion is in direct conflict with the Registrar-General's statement when he speaks of carpenters and joiners, and says that at every stage of life the mortality of these workers is below the standard for all occupied and retired males, and as regards plumbers, painters, and glaziers, the comparative mortality is 11 per cent. above the standard?—I think you mistake my answer. I said that they were a healthy-looking set of men.

2034. But I only draw your attention to the fact that the statement is valueless unless it is based on statistics. I can always find a strong man in work that is very bad, and a very weak man in work that is very good?—Yes. I began life as a weakling. I am now 73.

2035. And you look very well too?—I have been in contact with paint all the time.

2036. One further point; you spoke of making washing compulsory. Could you give me any idea of how that could be carried out?—No, I am not prepared to suggest how. I never had any difficulty personally, but I know that a great many small employers employ men who have not been through the sort of training that leads them to be careful.

2037. You do not think it would be practicable to insist on washing accommodation being provided?—Yes, I do; I think that is quite practicable.

2038. In an unused house or building?—Yes. They can always get water, but cannot always get hot water.

2039. Can they get water where it is not laid on?—Yes; they are obliged to have water for the other work in the building. You cannot build a brick wall without water.

2040. Having got the water, how do you propose that you would be able to supervise and ascertain whether the men washed?—You could only do it through the foreman.

2041. I presume you appreciate that it would mean a large army of inspectors to go round to see that it is carried out, and then the inspector has to enter a private house?—Yes, I know, there are difficulties.

2042. They seem almost insuperable?—Well, I do not think that is insuperable. The only thing that I can suggest is that the master should be made responsible if it was not done.

2043. But how are we to find out, unless we have inspectors to go and see?—You would find men complaining, I imagine, if their health were so much affected.

2044. But the men are not going to complain if they have not washed?—They could complain if the means of washing were not provided.

2045. That might be. Our experience of factories is that we have to watch both men and occupiers to get regulations carried out, and then only by having an army of inspectors to watch things can we possibly do it?—Yes, I know men are very careless of their own health.

29 March 1911.]

Mr. JOHN DIBBLEE GRACE.

[Continued.]

2046. You suggest that it is only the untrained men who really get lead poisoning?—No, I do not go quite so far as that, but I say it is only the untrained men who neglect the precautions.

2047. And you think that neglect does lead to lead poisoning?—Yes.

2048. (*Mr. Sutherland.*) When you say the men cannot get hot water on the job, they always make provision for water, pails, and so on, for ordinary purposes, and there is always water on the job?—There must be, of course.

2049. For the carrying on of the business?—Yes; in fact, it is very often made a condition of the contract—that the client shall provide water in case they are not living in the house.

2050. Coal is supplied by the employer, and sent on to the job, or coal is on the job. Even in new work there are facilities for heating water?—You cannot always get hot water.

2051. But you can always make it hot by using a bucket of water and putting it over a coal fire?—Yes.

2052. And that is very often done?—It is very often done. It is done more in the winter when the men feel the cold water very hard.

2053. Generally speaking, there are no difficulties in getting hot water?—There is no impossibility. It can be done without much trouble.

2054. Generally, there are provisions for obtaining hot water?—Yes. There are many processes in painting in which you must use hot water, like washing off old distemper.

2055. They can get it then for their meals or for washing the hands?—Yes.

2056. Soft soap is always sent on the job, is it not?—Always, but that is not what the men ordinarily wash with.

2057. No. Sometimes they soften the paint with a little oil and then they proceed to wash with soft soap?—Yes.

2058. You consider, from your experience, that there is no insuperable difficulty in getting the hands washed?—No.

2059. Do you attach much importance to the theory that, as far as our business is concerned, there is danger from the dust created by rubbing down?—There is very little dust. What is described as rubbing down the walls is merely glass-papering the surfaces. Rubbing down, as technically we understand it, is rubbing down woodwork where fine surfaces are required, such fine surfaces as painted columns, for instance, or where the work is going to be done in imitation of wood or marble. That is always done with pumice and water.

2060. Not much dust arises in that connection. Do you hold that there is much dust from rubbing down walls?—I do not.

2061. If there was any difference between your men and the average man, it would be in favour of the former. The better class of men sought to get into your shop?—Yes.

2062. The men brought their own overalls, and they were usually washed once a week?—Yes; they took them away with them in a little bag which they always brought.

2063. They brought clean overalls every Monday morning?—Yes.

2064. You would not have kept them on if they had not had clean overalls?—No. It would not have answered in good houses for people to see the men going about dirty.

2065. (*Mr. Rice.*) In your 45 years' experience, you only had one man who suffered from lead poisoning?—Who died from lead poisoning.

2066. But you had some who suffered from lead poisoning?—I have had some cases occur which a man has got over in a day or two. This has been quite exceptional, not one a year.

2067. They may not perhaps have been your regular men?—No. The case I have mentioned of a man dying is the only one I can recollect of my regular men. The other cases have been of men I had as additional hands, probably painters, but I have no intimate knowledge of the men.

2068. But were they sufficiently long with you to have acquired that complaint in your employ?—I can hardly say. I dare say some of the men were with me five or six weeks and that sort of time, from a week to five or six weeks. They would generally be people who were taken on and put on particular work in a busy time.

2069. They would not be your regular hands; they would be more chance men?—They would be men out of the societies.

2070. Probably qualified men, but chance men?—Yes.

2071. You would not be able to watch them the year through?—No. I would not be able to say what their history was at all.

2072. Probably they may have been out of work before you had them?—Yes, possibly.

2073. A proper painter always keeps himself clean?—Yes.

2074. That is his natural pride?—That is a happy result of his knowledge of the benefits of washing.

2075. He sees that the overalls are clean?—A good painter will always have his overalls decent looking; they will not be very clean at the end of the week of course.

2076. You said just now you thought there should be some penalty for not providing washing arrangements at works for the men?—Yes.

2077. Do you suggest any penalty for workmen for not using them?—That really ought to follow, but I do not know quite how you would get at it.

2078. You have not known cases, I suppose, where men have refused to use water. Have they always been anxious to use water?—Always. Directly the bell or the whistle sounds the men all rush to buckets of water and wash their hands before they do anything more, and it was so much the general practice that the man who did not do it would be rather noticed for not doing it, and probably if the foreman saw him he would send him to do it.

2079. You have never heard of cases where masters have refused to allow the men to wash?—No, I have not.

2080. (*Mr. Gardner.*) During your 45 years' experience, did you ever work as a journeyman; going out to a job and working from morn to night?—No, I never did that, but I was constantly visiting all the work that was going on.

2081. Some of the employers who are practical painters have served an apprenticeship. They have worked at the trade when they were boys and have put in time like other men. Your experience is simply from visitation of works. With regard to washing, did you ever send coal and firewood to a job for the men to heat water?—Yes.

2082. And towels?—Yes.

(*Mr. Gardner.*) I am very glad to hear it. It is quite an unusual thing.

2083. (*Mr. Parsonage.*) You are obliged to have heat to melt size?—Yes, you could not distemper a ceiling without having those means.

2084. (*Mr. Gardner.*) But what about unoccupied houses?—Then you must make provision for heating water.

2085. I understand that your work was largely work of a high-class nature?—Yes.

2086. If men went out to coat down a number of fronts and there was nothing else to be done on that job, would you send washing-materials for the men's hands?—Those would generally be domestic houses, and there would be water.

2087. Would the men get access to the houses for washing purposes?—Yes.

2088. Did you ever know of painters lifting white lead from a tub and mixing it with their hands?—No. I should not think any first-rate man ever did that. It would be great neglect not to have a wooden spatula to take lead out of the tub with.

2089. A gentleman told us yesterday that it was a common practice to mix it with the hands?—I never saw it done.

2090. You would be rather astonished to learn that when men are working out on a job, from 80 to 90 per

29 March 1911.]

Mr. JOHN DIBBLEE ORAGE.

[Continued.]

cent. take their meals where the paints are?—I should be rather astonished.

2091. What would you say was the average wage of an ordinary man? I do not mean the staff man who is on all the year round, but the ordinary man who comes on and goes off?—Per week or per annum?

2092. Per week?—I could not say. It would very much depend on the season. In some seasons, some exceptional public event may throw a great many men out of work.

2093. I want to know whether you can give us an idea to compare with information which we had before?—No.

2094. (*Mr. Parsonage.*) Your work was mainly decorating work?—It included a great amount of plain painting.

2095. But you could not compare it with the work of firms like Messrs. Maples, say. You said you used three tons of lead in a year?—That was in the later years when I was really shutting down.

2096. It would not be fair to take as a criterion the few lead poisoning cases that come to your knowledge, because the work you generally did was more in the nature of high class decorating work than ordinary house painting?—I dare say it was, but I did a great deal of ordinary house painting.

2097. There was generally more decoration, and in later years a great deal of your work was washing old decorated work of your own?—Some of it was.

2098. A great deal of it?—I would not go so far as to say a great deal.

2099. I would put it to you that you did more of that class of work in the later years that you were in business (washing and restoring your own old work) than any other firm in the west of London?—It may be so.

2100. I do not want to take any advantage. I am speaking from my own knowledge as being in the west end of London for about 30 years?—It is quite possible. In the case of clubs that would happen, because a club does not want to interrupt the course of business for longer than necessary. If they were having work done they would probably have as much as possible washed and touched up, and one or two rooms done.

2101. Taking another firm in the west end of London who employed 50 men, and supposing you employed 50 men in the year, your firm would use much less lead and do far less painting work than the other firm?—I do not know about that.

2102. I should say they would. Now, with regard to rubbing down with glass-paper and pumice stone,

you use pumice stone and water. Between the coats you would rub down with glass-paper?—Yes, very slightly, just to disturb the surface.

2103. You would not pumice stone and water again?—No.

2104. Did you provide nail brushes for the men?—No.

2105. Only water and soap?—Yes, and towels.

2106. If men have brushes for their own purpose, they keep them themselves. The brushes usually used are to dust down the work?—Yes.

2107. Not for men to use for the purpose of cleanliness?—No.

2108. With regard to apprentices in London, whose fault would you say it is that the apprenticeship system has died out?—I could not say.

2109. Would you agree that painting is a skilled trade, and that there should be a standard rate of wages for painters in London? You always paid the rate yourself?—Yes, I did, but I do not believe in it.

2110. You do not believe in it?—No, I think a man should be paid according to the quality of work he can do.

2111. Would you admit that a man requires to get experience to use paint?—Yes.

2112. And having given some years to get this experience, you think that afterwards he should be paid the same as a labourer who is picked up and put on?—Not at all.

2113. You do not agree with that?—No. What I mean is, that there are a great many men who can do very little except put on paint and who can go no further. The men who are really skilful in other ways in connection with painting ought to have a higher wage than the men who can do nothing else but lay on the paint.

2114. There should be a minimum rate?—I am not prepared to go into that. I have always paid the rate.

2115. When you took men on you used to send to the Painters' Society for your men?—Yes.

2116. And you used to give preference to Union men—Society men?—I always had the Society men, not from any conviction, but because it was the simplest thing to do. The foreman took the men. The best men, in fact, joined the Society.

2117. You used to send to the Society house for them?—Yes.

2118. You will admit that these men were generally very cleanly in their habits and very careful?—Yes, as a rule they were.

The witness withdrew.

Mr. C. COOKSON examined.

2119. (*Chairman.*) You attend here to-day as the representative of Messrs. Cookson and Company, Limited, Newcastle-on-Tyne?—Yes.

2120. What does your firm manufacture?—We desilverize, and we manufacture white and red lead, litharge, and also antimony.

2121. Are you one of the largest manufacturers of white lead in England?—Yes. We are, I believe, the largest.

2122. By which processes is your white lead made?—By what is generally known as the stack process, or the Dutch process, and also by the process which is known sometimes as the chamber process or the German process.

2123. Are there many other firms operating the chamber process?—No; I believe we are the only ones in the United Kingdom.

2124. Will you please tell me the main uses for your white, red, and orange leads and litharge?—They are chiefly used as a protective covering for different materials.

2125. Do you handle any substitutes for lead paints?—No, none.

2126. Should the use of lead paints be restricted or prohibited in this country, at any time, would it mean serious loss of business to your firm?—Yes.

2127. But as you deal in so many other materials not used in the paint trade, you would not feel this so severely as firms solely occupied in the manufacture of white lead?—It would mean generally that our white lead works would become worthless, and they represent a very large investment.

2128. But if substitutes for white lead could be found which would result in the alleviation of the sufferings of a vast number of people in the painting industry, you would think it not unreasonable, I suppose, that the Home Office should prohibit the use of white lead paints?—Provided there was some compensation or some form of recompense for the loss of our capital and the loss of employment to all of our men. White lead works cannot possibly be converted, and there are none of the so-called substitutes at present in use which could be made by white lead plant, and therefore the whole of our plant would become worthless.

2129. Supposing you had a very hard-hearted government in power who refused to give compensation, would you say that the workpeople should still suffer?—I do not say that they do suffer now provided reasonable precautions are taken; I do not admit that they do.

29 March 1911.]

Mr. C. COOKSON.

[Continued.]

2130. But you will admit this; that the figures published by the Registrar-General show a most deplorable condition of suffering amongst house painters and coach painters?—Yes, but I do not admit that the whole of that is necessary.

2131. Have you any suggestions you would like to put before us as to precautions?—To begin with, I do not see why house painters and coach painters should not be inspected—medically examined—in the same way as other people who handle lead are, and I think there are certain precautions which could be taken which would very much minimise, if they did not entirely do away with, the danger.

2132. But medical examination would not by itself do away with the danger?—No, but it tends to lessen it. If the medical man sees the beginning of a case and the man is suspended or some precautions are taken, the case instead of becoming a bad one never gets any worse.

2133. That may or may not be the case, but medical examination would only enable you to deal with the case when it arose. It would not stop lead poisoning from taking place?—Not in itself, but it would make the cases much less severe.

2134. Do you think that washing facilities should be provided wherever the painter is working?—It is very difficult to do that in certain places unless you have a portable washing apparatus that you can take about. I consider that cleanliness is of extreme importance.

2135. Do not you think that hot and cold water and soap, and nail brushes, and clean towels daily should be provided?—I do not see how you can do it unless you have a washing place on wheels to take about from one job to the other. I presume you are referring to house painting?

2136. Yes?—I do not quite see how, at any rate, the small painter is to provide that.

2137. How, then, are we to obviate the evils which exist?—I think if he washes in cold water, it is as much as he can get and that should be insisted on.

2138. Do you think that cold water would get rid of all the paint on his hands?—If he washes thoroughly. He can use a certain amount of alkalis and so on in the water which will take up the oil and allow the wet lead paint to come off more easily.

2139. I heard a witness in a recent inquiry that I was holding state that cold water was better than hot, because if it was cold water he would have to scrub harder to get the paint off. The Committee I am speaking of laid it down as a cardinal point that in future hot water must be provided?—Where it can be provided I quite admit that it should be, but I think it is almost impossible for a small builder, when he is erecting a cottage in the country, to do it. I do not see how he can do it, although it would be desirable.

2140. Have you any other suggestions to make as to precautionary measures?—First of all, some men are much more liable to lead poisoning than other men. Another thing which affects it very much is the sobriety or otherwise of the men.

2141. I should not press that too far, because we proved in another inquiry that the women suffer a good deal more than the men?—Yes, but amongst men I think there is no doubt about it. There are two reasons for that; first of all if he takes drink in excess it does not do him any good, it lessens his resisting power; and once he gets into that habit, he gets slovenly and careless generally, and once he gets slovenly and careless he is far more likely to feed with dirty hands or chew tobacco touched with dirty hands.

2142. But you cannot legislate against that, can you?—No. Then I think that when they are using sandpaper or pumice or anything like that, if it is done dry they ought to use some form of respirator, something to cover their mouths.

2143. Have you ever heard of a respirator that was comfortable to wear?—At first they are exceedingly uncomfortable, but afterwards the men get quite accustomed to them.

2144. Have you ever known any set of men who have got accustomed to them?—They cease complaining

about them. I do not know that they get accustomed to them.

2145. Do they wear them?—Yes; our men always do, and they seem to wear them of their own accord. We hardly ever catch a man without one.

2146. For what periods do they wear them?—They wear them the whole time when they are in any place where there is likely to be any dust.

2147. For how long at a stretch?—We go on the theory of keeping our men at the work as short a time as we can.

2148. For how long at a time do they wear the respirator?—Do you mean straight on end without taking it off the mouth?

2149. Yes?—I do not suppose it is for more than an hour without taking it off the mouth to spit or something of that nature. But they always wear them.

2150. Would you allow dry rubbing down?—No, I would not.

2151. Would you make it obligatory that all rubbing down should be wet?—Yes, I would, because I think that anything that causes powder increases what danger there is.

2152. You recognise that the dust is the dangerous element?—Yes.

2153. Whatever form it takes?—Yes.

2154. Would you suggest how the wet rubbing down should be done?—I think it can be done by getting the sandpaper on some backing and then putting round the backing a wet flannel, or wet felt, sufficiently loose and damp to prevent any dust escaping. I should say that the whole thing is involved in the wet protection that is used.

2155. Is it practicable in every case to use wet methods for smoothing; for mouldings, curves and ironwork for example?—I would not like to say; I do not know sufficient about that to say.

2156. You see it is no use—I say so with all respect to you—coming before us and offering your opinion about precautions unless you can be pretty certain that they can be adopted?—In all cases?

2157. In all cases, or in the majority of cases?—What I have mentioned can undoubtedly, I think, be adopted in the majority of cases.

2158. What else do you suggest for instance, with regard to burning off; can you suggest any precautions with regard to that?—I do not think there is very much danger in the burning off; with the blowing and scraping you mean?

2159. Yes. There is a considerable amount of fumes and dust?—No, there is very little. The fumes which one sees coming off are not lead fumes but entirely oil fumes, and there is practically no dust, that cannot be avoided.

2160. There must be lead in the fumes?—But they do not get to the temperature at which the lead will begin to volatilise; you do not get the fumes until that temperature is reached.

2161. Do you base that observation on exact scientific experiments to determine what precisely the fumes consist of?—No, we have never analysed the fumes.

2162. We had a witness here this morning, Professor Baly, who stated that he discovered lead from the vapours arising from the drying of white lead paint. How do you think that is to be dealt with?—We tried some years ago taking what is known as a mash-tub when we used to grind the dry white lead with oil. Now we do not do that. When we used to do it that question was very much discussed, and we actually put an exhauster into the top of the mash tub while the mixing of the lead and the oil was going on. It gets to a considerable natural heat. We analysed that gas, and we could not find a trace of lead.

2163. Is it not probable that similar fumes to those I have referred to would arise in burning off old paint?—There might be chemical traces but I do not think there would be more than that.

2164. I think it has been demonstrated to us this morning that there is a considerable amount of lead in the fumes, and that is going to be considered by us very seriously. To sum up your recommendations,

29 March 1911 ]

Mr. C. COOKSON.

[Continued.]

you say washing apparatus, no handling of dry compounds of lead, and no dry smoothing?—Yes.

2165. Do you think that these measures alone would prevent all the suffering and loss of life that happen to painters now?—I do not know that they would entirely and absolutely stop it, because you cannot stop carelessness, and there are certain of these precautions which the men object to in a way, especially the more slovenly ones, and I do not see that any rule can always be carried out. It can be carried out in the majority of cases and so very largely lessen the trouble, but I do not see how any legislation is ever going to alter the habits of men.

2166. Do you realise the amount of lead poisoning amongst house painters which has taken place during the last ten years?—I read the Home Office report.

2167. You understand that there are about 2,000 cases of lead poisoning voluntarily reported to the Home Office in the ten years in question?—Yes, about 200 a year.

2168. And those figures by no means exhaust the number of cases of poisoning that must have happened?—Yes, but there is another thing which rather comes in there. Supposing a man complains of feeling ill; he has neuritis or something of that nature; one of the first things that the doctor does is to try to find out the cause of it. One of the first questions is, "what is your trade, or your profession." He says, "Oh, I am a leadworker" or "painter" or whatever he is by trade. So that is put down to lead poisoning. It may or may not be. If he was a pit man or a man in a steel works, it would have been ordinary neuritis and not lead poisoning.

2169. Is not that rather a sweeping accusation to make against certifying surgeons?—One has admitted it.

2170. One may have done, but the Home Office scrutinise with the greatest care every case that comes before them, and unless it is proved beyond question to their satisfaction, it is not recorded as a lead poisoning case at all. The 2,000 cases that were reported to the Home Office are cases that were reported voluntarily?—What percentage per annum does that represent?

2171. I have not the figures before me, but it does not matter what percentage it is. They are cases which could be averted if lead was prohibited?—Yes. If the stuff that took its place was not worse or as bad.

2172. Exactly. What this Committee have to deal with is a certain amount of suffering that takes place every year both in illness and in death. We are sitting here to try to propose some methods of obviating that. I suppose you will agree with me that the state of affairs being a very serious one, the question of lead poisoning amongst house painters cannot be lightly dismissed as being a mere bogey?—The statistics show lead poisoning; statistics show almost everything.

2173. Do you favour periodical medical examinations?—Yes, I do.

2174. And compulsory investigation of every case of lead poisoning?—Yes.

2175. Do you think that every package containing lead paint should be labelled "poisonous"?—I do not suppose it would make any difference whether you labelled it "poisonous" or not.

2176. Do you attach importance to the provision of properly kept meal-rooms warmed in winter?—It is desirable, but I do not see how you can do it when painting a small house and that sort of thing.

2177. Would you prohibit working men being allowed to take their meals in places where paints were mixed or where lead-dust was likely to be in the air?—Where lead dust is in the air, but not where lead paint is mixed.

2178. I will limit my question to that—where lead dust is in the air?—Yes, where lead dust is in the air.

2179. Where would you suggest they should take their meals?—Somewhere, as near by as may be, where lead dust is not in the air.

2180. I suppose you are in favour of all men wearing overalls?—Yes.

2181. It has been shown to us that overalls are a source of very great danger unless they are properly cleaned, because an accumulation of dirt gets on them and when touched sends up a dust which the men may swallow?—Yes, but is it not better to have the overalls in that condition than the men's own suits and so on, in which case they take the dust home.

2182. That is not quite my point. I was going to ask you whether you think that the overalls should be washed more frequently than once a week?—Where they are handling powder—dry lead, but not where they are handling wet lead or lead in oil.

2183. But the point is this—that the overalls get splashed with the paint which is used; the splashes dry on the overalls and form themselves into dust, and any touch raises a dust which the men swallow?—But if it is mixed with oil I do not think it is liable to go to dust. It sets in a hard skin.

2184. Do you not think it is so liable to go to dust as it would be in the case of lead glaze for instance. If you had a considerable reduction in the hours of work, do you think that would reduce lead poisoning?—I think it desirable that men should be occupied as short a time at their work as possible. If they can do the job that they have been given in less than eight or ten hours, or whatever it may be, they should be encouraged to do so, and allowed to go as soon as finished.

2185. What hours do they work now generally?—Are you referring to our men?

2186. I am speaking of ordinary painters. That you could not tell me, perhaps?—No, I cannot; we have none.

2187. (*Lord Henry Bentinck.*) I have here a lecture by Mr. Noel Heaton on "Alternatives to the use of white lead." He says "Why not use sulphate of lead in place of carbonate of lead known as white lead." What would be your objection to using sulphate of lead which is comparatively non-soluble, and therefore not so poisonous?—That I do not quite agree with. Sulphate of lead is soluble. If you refer to one of the Home Office Reports by Dr. Goadby, which I happen to have here, he gives certain statistics of experiments, and in one case he says that lead sulphate is actually more soluble than lead carbonate and in the other case practically as soluble. In a solution of lead it is difficult to precipitate the whole of the lead as sulphate of lead as some is liable to remain in solution even if an excess of sulphuric acid is used.

2188. (*Sir Godfrey Baring.*) How many men do you employ in your white lead works?—About 450.

2189. If lead paints were prohibited, do I understand you to say that you would practically have to scrap your works and your machinery and so on? Would not they be suitable for the manufacture of anything else?—Nothing else that is called a substitute at present.

2190. They could not be applied to the manufacture of anything else that you know of?—No.

2191. And I think you agree the chief danger to the worker is the dust proceeding from white lead?—Yes.

2192. Your men wear a respirator?—Yes.

2193. Was that respirator invented by your firm?—I believe we were the first to use this particular thing, and we have given samples of it to many other firms.

2194. How long has it been used in your firm?—I should say eight or ten years; I am not quite sure.

2195. The men wear it quite willingly? They do not object to wearing it in any way to begin with, do they?—It is uncomfortable because it covers up the whole of the nose and mouth with cotton wool, and flannel to keep the cotton wool in place.

2196. After a time they get used to it?—They get used to it after a time.

2197. And the men can wear it without inconvenience?—Yes.

2198. May we have evidence from some of your men to corroborate that? Could we secure the evidence of someone who has used the respirator in working?—Yes.

29 March 1911.]

Mr. C. COOKSON.

[Continued.]

2199. (*Chairman.*) Would he say he liked it?—No, I do not think he would.

2200. In the pottery industry, there was great difficulty to get them to wear respirators at all?—Because it is an innovation, but once you get it introduced, then there is no great difficulty in getting the men to wear them.

2201. (*Sir Godfrey Baring.*) Did you say that sand-papering need hardly ever be employed in rubbing down?—No.

2202. In certain kinds of work?—It has to be employed in certain kinds of work, but you can use it with certain precautions which would practically entirely do away with the dust.

2203. What kind of precaution?—By keeping the thing properly enveloped with something to catch the dust.

2204. You think that that would obviate the danger?—It would to a great extent.

2205. (*Chairman.*) Do you think that that is practicable?—Yes, by putting round the pumice stone or whatever is used a soft piece of felt and keeping that damp.

2206. (*Dr. Collis.*) I am quite in agreement with you on the value of the respirators which you have been speaking of. I first saw them in your works, and I know that the men wear them and appear to wear them with comfort in a way that other respirators which have been suggested cannot be worn. Can you go back to the time when these respirators were first introduced? Do you remember whether you had much trouble in getting the men to wear them regularly?—No, I cannot tell you that.

2207. You have suggested the inspection of house painters in connection with the mixing of paints. I presume by that you mean inspecting them as closely as men are inspected in the manufacture of white leads. Is that so?—Yes.

2208. You think that would bring down the incidence of lead poisoning?—Yes, instead of being serious cases many of them would be stopped and not get beyond the stage of slight cases.

2209. You have in your works, I know from personal experience, taken great trouble in reducing the incidence of lead poisoning; but it has been a great trouble, has it not?—Yes, but it is a trouble that can be dealt with; you can attain your object.

2210. You have all your 450 men within the curtilage of your factory?—Yes.

2211. Would it ever be possible to exert such care as is exercised in your factory with house painters who are painting perhaps 20 miles off in the country at a private house?—No; I think it would be much more difficult.

2212. The impossibility of such inspection is a matter that is seriously before us, and is one of the reasons why this Committee is sitting here to hear evidence. Can you suggest any simple method by which such inspection could be properly carried out?—Would not the easiest plan be to do it on pay day?

2213. On pay day? You could not be at the place where the work was done and see that the respirators were worn, that the overalls were clean, that the washing was carried out, that the hot water was provided, and all the other numerous details which are necessary, as you know, in works to prevent lead poisoning?—But I thought you were referring only to the inspection of the men, and not to anything else.

2214. From your own experience you would not say that the weekly inspection of the men would be sufficient without the other precautions carried on inside the factory?—No, but it is a very important part of it.

2215. But it is not the whole, although it is an important part?—But half is better than none.

2216. We want the whole?—I daresay, but when you cannot have the whole, half a loaf is better than no bread.

2217. We have to consider the question whether we cannot get the whole. May I suggest to you that it would mean a large army of inspectors, and would cost the Government a great deal of money to carry out such inspection efficiently?—You would want

more inspectors than to inspect individual factories certainly.

2218. If it were reduced to a question of pounds, shillings, and pence, it would probably be cheaper to the Government to compensate white lead manufacturers than to set up this army of inspectors? I have no idea.

2219. Now you suggested that cases that appear to be lead poisoning are perhaps only some other transient illness, but when you leave such transient illnesses alone and find a man dying, say, of Bright's disease, that accusation would not lie, would it? There would be no tendency for a doctor to notify a casual individual among his patients for Bright's disease according to his occupation, because the ordinary doctor does not particularly associate Bright's disease with lead poisoning?—The ordinary country doctor does not, but if a doctor has had experience that is one of the things he looks for.

2220. You would allow, therefore, that a case of Bright's disease notified is a genuine case of Bright's disease?—If it is notified as Bright's disease, it is probably Bright's disease.

2221. Are you aware, leaving lead poisoning on one side, that the incidence of Bright's disease, which we look upon as one of the sequelæ of lead impregnation, as you justly say, is heavier among lead workers, especially among plumbers and painters, than it is among other employees in other occupations? I admit that.

2222. So that that does establish the fact that there are illnesses associated with lead poisoning not of necessity lead poisoning itself?—Yes.

2223. If lead is getting the credit of a few odd illnesses, so to speak, to-day, which it ought not to have, it is escaping the burden of Bright's disease? In some cases possibly.

2224. The incidence of Bright's disease is heavier among these men, as I say?—Yes.

2225. There are other illnesses which lead causes, in addition to that which is called white lead poisoning?—You mean that certain cases which ought to be certified as lead poisoning are certified as ordinary Bright's disease?

2226. Certainly? I think it is more the other way.

2227. (*Chairman.*) The number of workers who die of Bright's disease is three times as high among painters, as compared with other industries?—Then what I say is that only two-thirds of the Bright's disease cases amongst painters are lead poisoning and the other third are ordinary Bright's disease.

2228. (*Dr. Collis.*) Quite so, but for that quarter lead is escaping the accusation brought against it?—It may in that particular branch.

2229. So I think you must be prepared to allow lead to bear the brunt of the accusation which should be brought against it. These are deaths, and yours are only transient cases? I never hear the point brought strongly out on the other side by people who are talking of the ills that lead causes, although I hear frequently the accusation which you have brought.

2230. (*Mr. Sutherland.*) You said you did not see why the precautions enforced on makers of lead should not be extended to painters, but you see the many difficulties that there are in the way?—There are many difficulties, but I would try to enforce precautions as far as possible.

2231. You would have to put notices up in every shop or send notices to every job. A master painter who has 450 men might have them distributed in 50 or 60 different centres and not in one establishment as you do?—Quite so.

2232. It is not possible to extend the Factory Act to painters' operations?—It is difficult I admit.

2233. You do not think there is danger arising from fumes, I think you said?—I do not.

2234. I did not catch the point of your reason for that?—You are referring now to drying paint.

2235. To the fumes arising from burning off paint?—I think the possible danger there is vastly exaggerated because the smoke from the burning oil is so very visible, and when people see the stuff falling off

29 March 1911.]

Mr. C. COOKSON.

[Continued.]

the painter's scraping knife and lying on the floor all smoking they at once say "That is lead fumes," whereas if there is any it is in very very minute quantities.

2236. You set down a particular point where it did not get heated sufficiently to do something. I did not catch what you said?—If the lead is not raised to a sufficient temperature it will not begin to volatilise.

2237. What is that temperature?—It varies with all the different oxides.

2238. Do you attach any importance to what the Chairman says as to the poisoning from vapours from ordinary drying paints lead volatilising in the vapour? I do not think that that exists practically at all.

2239. You do not think it arises? No.

2240. (Chairman.) You do not know that experiments have been made in the last few weeks? You have not heard of that?—No, I have not heard of it.

2241. (Mr. Sutherland.) The experiment is new, but the complaint of the smells arising from paint is an old one. In your opinion, it is not poisonous necessarily?—No, not in my opinion.

2242. (Lord Henry Bentinck.) If I get stomach-ache from the fumes of lead, it is not due to lead poisoning?—I presume it would be if they were fumes of lead, but you have to make sure that they are fumes of lead and not fumes of turpentine and oil.

2243. (Mr. Gardner.) One or two questions with reference to rubbing down between coats. If you have a damp flannel behind the sandpaper, how would you keep the sandpaper dry? I would not have it extremely wet. It would not matter as long as it did not get more than just damp.

2244. The dust from sandpaper in rubbing down walls does not fly about all over the room, it generally falls down the wall on to the skirting board, so the felt would not be much use?—The felt would stop any dust before falling.

2245. But it would not take anything else than that which was at the man's hand? It depends.

2246. With regard to the inspection of the men you have admitted that it is extremely difficult. I suppose you are aware that a man may be working as a house painter for an employer and never see the shop from the time he starts to the time he is paid off?—Yes.

2247. There would be difficulty in examining that man? There would be a difficulty in examining him in the shop, but he might be examined elsewhere.

2248. (Chairman.) At whose expense should the examination take place? I think the person who institutes the examination should pay, namely, the Government.

2249. Would you not rather say the employer?—No; the employer does not institute it.

2250. (Dr. Collis.) Who pays for your periodical examinations? Unfortunately, we have to, but I do not consider that it is a fair principle. We are paying the piper and someone else calls the tune.

2251. (Mr. Gardner.) Do you think that, if you burnt off the old paint to cinders, you would not set up poisonous fumes? Do you mean as an experiment?

2252. No. You burn off paint from a door, and a vast proportion of that paint is practically burnt to a cinder. It has to boil up in many cases before you get a straight run?—It softens off.

2253. Do not you think that in that case poisonous fumes arise from the lead?—No; I think it is practically non-poisonous.

2254. (Mr. Parsonage.) Have you had any practical experience of house painting?—No.

2255. And your statements are only theory?—Yes.

2256. Then I do not think I need trouble to ask you about that, if you have no practical experience of house painting. I can only say that your propositions are absolutely impossible. Now you said that, if the use of lead was totally prohibited, you considered that your firm or any firm whose plant was rendered useless should receive compensation?—Yes.

2257. What would be the position of the workman who was examined and certified to be suffering from lead poisoning and prevented from following his employment; should he be compensated in any way?

The Government say at present that the workman is to be compensated.

2258. The man may be able to follow his employment all the same, but he may show the ordinary blue line and ordinary traces of lead poisoning and he is cast aside. Should he be compensated? A man is not cast aside for the blue line.

2259. But what would be the use of medical examination if he is allowed to remain at work?—In certain cases you get a warning, and if you get warning you take precautions, you have a much better chance.

2260. You are presupposing that the man does not take precautions until he is told by someone else that he must do so, and then he will keep himself clean? Many of them linger on as long as they possibly can.

2261. You know very little of house painters. What reason have you for supposing that the man will not try to keep himself clean if he knows the risk he is running? Why do you suppose that he would not be careful to prevent himself getting this disease? I am simply judging from our own men.

2262. In your own works?—Yes.

2263. I do not think that is a fair thing at all?—It seems to me that all men are about the same.

2264. The workman who knows his business and knows the dangers attached to it, is just as careful of his own health as the employer who employs him? That is not our experience.

2265. I do not think there is any reason to suppose that the majority of men who follow the occupation of house painting are not particularly clean. In your works they are lead paint makers, not painters. Speaking of compelling the men to be clean, would you compel the employers to provide materials for the men to wash? Where it is possible.

2266. Would you put the onus on the employer instead of upon the workman? Yes, where possible.

2267. Are there any cases where it would be impossible to provide soap and water?—Occasionally.

2268. Really, then, it is a matter for the employer to make provision for his workmen to wash. The workman could not keep himself clean if the employer objected to it?—No.

2269. It is really the fault of the employer, if a man is careless?—No, I do not admit that. You are assuming that the employer objects.

2270. I am assuming that if the employer gives proper facilities for the man to keep himself clean, the man would do it. I have just as much right to assume that as you have to assume that the man is wilfully negligent of his own health. You see you put the blame entirely on the workman. You say that the workman is wilfully negligent. I say, make proper provision for the workman to keep himself clean, and he will do it, and that the blame rests with the employer?—All I can say is that that is not our experience. If you do not take proper means to see that the provisions you make are used many of the people will not use them although many will.

2271. That is in your works, but that is not house painting at all? No.

2272. Your works are inspected by a factory inspector, and you are liable to compensate any man who is ill, so it is to your interest to insist that these men shall be careful?—Yes.

2273. With house painting it is not the case. My idea is that there is far too much said about workmen not taking precautions. I contend that the employer should provide facilities, and also allow reasonable time for a man to wash his hands? I quite agree, but he has to see that the reasonable time and the means provided are properly used.

2274. Now, with regard to a question that Dr. Collis put to you with regard to other diseases arising from lead poisoning, you say that neuritis might be ascribed by a doctor to lead poisoning, because he knew that the man was a painter, but the first thing a doctor looks for is the blue line round the gums?—Yes.

2275. In a case that did not arise from lead poisoning he would find no blue line? Possibly.

2276. Then he would not certify if as being from lead poisoning, simply because he knew the man was

29 March 1911.]

Mr. C. COOKSON.

[Continued.]

a house painter, unless he saw the trace of lead?—I do not know.

2277. Do you suppose that if a doctor saw no trace of lead there and could not find the first thing he looked for, he would certify him to be suffering from lead poisoning or from a disease which he would ascribe to lead poisoning simply because the man said he was a house painter?—He should not do it.

2278. But would he do it? Would it be the usual thing for the doctor to do it at the request of the man?—I do not say it would be the usual thing. Sometimes the doctor gets a bad name as a man who will not grant certificates. He gets a bad name amongst the workmen amongst whom the whole of his practice is. Very often he is competing with the doctor next door who may be inclined to do it, and he is consequently in a very difficult position.

2279. What difference would it make to a man whether he gave the certificate in accordance with the fact or not? The man would get his compensation just the same. You are implying that a certifying surgeon who examines the painter would give a certificate for lead poisoning when the man showed no traces of it?—I do not say no traces, but I say that a blue line is not an invariable sign of neuritis.

2280. But it is an infallible sign of lead poisoning?—I do not admit that; I do not think it is.

2281. (Chairman.) It is a very strong indication that there is something a little amiss, but we have found beyond question that you get a blue line without actual poisoning?—A man may have the blue line for years and years and years, and show no other indication of lead poisoning.

2282. Every doctor and every employer has the right to submit any questionable case of lead poisoning to the medical referee, so that if there are indications of lead poisoning reported which are wrongly reported, it is the employer's own fault. He can always appeal to that independent medical referee?—Yes.

2283. (Mr. Parsonage.) Either side can do that?—Yes.

(Mr. Parsonage.) So that I see no reason why a doctor should certify a man as suffering from lead poisoning when there is no evidence of it. In my opinion there are far more cases which are not ascribed to lead poisoning which are due to it indirectly.

2284. (Mr. Fell.) I want to know whether you send out large quantities of lead in powder?—Yes, considerable quantities.

2285. Would it not be possible to send that all out ground in oil?—Yes, quite.

2286. Do you know why people particularly specify that it shall not be sent in oil?—Because they have their own grinding apparatus at their colour works, where the powder mostly goes to, and they prefer to use their apparatus instead of our apparatus, and their apparatus is suitable for mixing dry lead with oil, and not for mixing the pulped lead with oil. It needs rather a different apparatus.

2287. Would it be a very serious matter to do away with all that outside your works?—It would mean the alteration of these colour makers' works to suit the new method.

2288. (Mr. Mason.) Do you consider that there is greater danger in your works to the men employed there than to an ordinary painter?—No, I do not, because our men are under so much better supervision.

2289. Could you give me an idea of the number of cases that you would get in your works of lead poisoning?—I cannot give you exact figures, but Dr. Collis can.

(Dr. Collis.) I have no figures with me, but I will let you know them. There have been very few lately.

2290-91. (Mr. Mason.) I do not particularly want them at the moment. Supposing the precautions which you suggest were adopted, do you consider that the cases of lead poisoning amongst painters would be reduced to a less degree than they are in your works?—I do not say that, because I think it is so much more difficult to enforce rules over scattered men than over men all within one factory.

2292. They might be enforced in coach works, for instance?—Certainly—where people are all under close supervision.

2293. Do you think that, provided those precautions were adopted and carried out, there would be less danger to painters than to men employed in lead works?—Yes, I do. The stuff, when they use it, is mixed with oil, and when it is mixed with oil it is not liable to get into this very fine state when it floats about in the air except when it is sandpapered, and so on.

2294. (Mr. Kinggate.) You stated, and I agree, that some men are more liable to lead poisoning than others, irrespective of their cleanliness and carefulness. What should be done with those who, however careful they are, are liable and are told that they must leave the work?—That is a very difficult question.

2295. You were speaking of the displacement of men employed in white lead works and also the loss to the company financially. Seeing that there are people who are liable, is it not better that lead should be prohibited than that a large number of men should suffer?—But I do not think that there is a large number of men suffering in our factory, if you refer specially to that.

2296. I am not referring specially to your factory, but to coach-making generally at the present time. I know several cases of men who, although they are careful in every possible way, are exceedingly liable to poisoning, and they are told that they must get away from that industry. What should you suggest should be done with those men?—I have no suggestion.

2297. (Mr. Robins.) You made a statement which I would rather not have heard mentioned in this inquiry at all with regard to the habits of the men. You attributed one of the causes to their insobriety and not only their dirty habits. Although lead poisoning in the coach trade has increased so much during the last ten years, my experience is that there is more sobriety amongst the coach painters of to-day than ever there was since I have come into contact with them, and that is about thirty years. So that statement has nothing whatever to do with it. The men are more sober than ever they were.

(Chairman.) Both statements are *ex parte*. We shall not notice either.

2298. (Mr. Robins.) (To the witness.) Then you said that no dust would arise from burning off paint?—Very little dust.

(Mr. Robins.) My experience is that, if you leave paint on a coach after it has been burnt, it is nearly all dust when you come to sweep it off. Seventy-five per cent. of it or more is perfect dust, and that is highly dangerous no doubt in the air.

2299. (Chairman.) You are aware that the manufacture of yellow phosphorus matches has been forbidden?—Yes.

2300. That must have imposed certain loss on those who made phosphorus matches?—I do not know much about the match trade, but all I can say is that it cannot have scrapped the whole factory, because they use the same shaped match and the same boxes and the same wrappers, and so on.

2301. It must have imposed a certain amount of loss upon them, must it not, and they received no compensation?—Perhaps they did not deserve it, because in that case it was simply an alteration of their present process and it left their present plant available. I do not see that they deserved it. I do not think it necessitated scrapping practically the whole or any part of the works. It was only an alteration of the mixture with which the match stems are tipped and did not entail any alteration of plant. This slight alteration and the proposed total abolition of white lead making are totally dissimilar.

2302. I will ask you about one further point: if the Government were to restrict the amount of soluble lead permissible in paint to, say, five per cent., would not that cause a demand for insoluble lead compound which your firm could supply?—You talk of insoluble, but insoluble to what extent?

29 March 1911.]

Mr. C. COOKSON.

[Continued.]

2303. I mean what is known as insoluble lead?—But for this purpose I do not know of any insoluble lead for paint.

2304. The point is this: supposing the Home Office were to restrict the use of lead to five per cent., would your firm still have a considerable amount of business to transact?—If we were to rebuild the works to make that particular compound which you are talking of?

2305. It would not be a question of that, but a diminution in the amount of lead used, would it not?—Do you mean mixing with other substances?

(Chairman.) It would be a question of minimising the amount of lead used. I will not press the point.

2306. (Mr. Sutherland.) You do not send out lead in powder to painters, do you? It is mostly to colour grinders?—Practically not at all to painters. We send out very small quantities of red lead to painters and white lead hardly ever.

2307. The dry lead is sent out to colour grinders?—Yes.

2308. It does not affect the painting trade?—We do not do it ourselves, but it is used in the house painting trade.

2309. The grinders grind it up into paste form, do they not?—It is used to a small extent in the house painting trade, but only a small quantity—not a very appreciable quantity—for fillings, and so on.

The witness withdrew.

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and Mr. W. WONNACOTT, A.R.I.B.A., F.S.I., examined.

2310. (Chairman.) Have you come to-day to describe to us a paint investigation undertaken by the Royal Institute of British Architects?—(Mr. Munby.) We have.

2311. When was your investigation made?—From 1908 to 1910.

2312. What did your inquiry aim at ascertaining?—The properties and ingredients of commercial paints; I may say that the object of our inquiry was originally to formulate a standard specification for paints for the benefit of architects and reputable paint manufacturers. We found, however, that it was impossible to produce a specification because there were no standards upon which it could be formed, and therefore we put together this small monograph not with a view to producing actual standards, but to raise a general interest among architects and the trade in order that, later on, some consensus of opinion should be arrived at as regards a standard and subsequently a specification.

2313. Did this involve considerable research into the literature upon the subject?—It did.

2314. Have you had, in the exercise of your profession, practical experience of the different characteristics of various paints?—We have.

2315. Can you describe to us the use and nature of the several substances which go to make up a paint?—We can. The first essential is a base, which is the main part of paint. That must be associated with a vehicle, which is almost invariably linseed oil, which binds the particles of the base together. In all ordinary cases it is necessary to add a thinner in order that the paint may be suitably applied, and in some cases it is usual to add a drier (it is not always necessary) in order that the paint may dry more rapidly than it would in the ordinary way.

2316. That is an excellent way of putting it. Are you able to compare paints containing lead compounds with similar paints made on bases other than lead?—Yes, we can compare them as regards their durability and as regards their effect on the workmen.

2317. That comparison will be very interesting to this Committee, of course, but first I will ask you a few general questions. In what condition did you find the paint market? Is there much variation in quality and in composition between the products of different makers?—Yes. Standardisation is much needed.

2318. Do you find much divergence in the matter of fineness of grinding?—I believe there is a good deal of difference. I do not think that any actual measurements are made in the trade or by users of paints, but undoubtedly from microscopic investigation there is a great deal of difference in the sizes of particles, not only of different kinds of paint, such as zinc oxide and iron oxide, which must naturally differ a great deal, but also in one special kind of paint—in different kinds of white lead for example—as regards fineness of grinding. We cannot give you any data for that.

2319. Does the size of the particles of pigment exert much influence on the durability of paint?—Yes, a very considerable influence. For a given base the durability of paint increases with the fineness of the particles of that base, and a standard of fineness is much needed, and would probably remove many difficulties in paint specification. Some interesting experiments on

this subject showed that in the case of two similar paints possessing particles about 0.0080 and 0.0004 inch in diameter respectively, the life of the latter was at least twice that of the former under similar conditions.

2320. Has the size of the particle any bearing on the relative proportions of pigment and vehicle?—Yes. Does that question refer to the size of the particles of the pigment or the size of the particles of the base?

2321. The pigment?—Yes. The finer the pigment the lighter will be the colour.

2322. Then you consider the size of the pigment particles an important physical property of paint?—Yes.

2323. Is it very important?—The size of the pigment particles is most important as regards the tint of the paint, but the pigment is only a small part of the whole composition of the paint. If by pigment you mean the colouring matter added to the base, the size of the particles of the base I consider more important.

2324. Is this fact well known to the paint makers and painters?—No, I think not.

2325. Then you strongly recommend attention being paid to fine grinding as likely to improve paint quality. Does this improve zinc paints and lead paints to an equal extent?—The zinc paints are necessarily very fine. As regards the size of the particles, I think my colleague will bear me out in saying that the improvement in zinc paints is likely to be much less than in lead paints. (Mr. Wonnacott.) Yes. There is a little difficulty in the manufacture of the zinc oxide, the fineness varying according to which part of the condensing chamber the oxide is drawn from.

2326. (Chairman.) But your answer generally is that it would improve lead paint more than zinc paint?—(Mr. Munby.) Yes.

2327. How do architects specify painting—is it by the number of coats or by weight of pigment per square yard?—The number of coats invariably.

2328. Then you recommend standardisation also on the matter of the amount of paint laid on to the surfaces, and you think that weight is the best test of this?—Yes; we think that, if it is practicable to arrange that the paint work should be carried out in a suitable manner to enable the weight to be obtained, it will be very much better on the basis of weight than on the basis of covering. In the case of a piece of work which varied very much in character, to which pigments were applied very unequally in different parts, it might be impossible to specify in that way; but for a large piece of work, the specification of weight per square yard would undoubtedly safeguard a great many interests. (Mr. Wonnacott.) The best test of that would be the area; that would best govern that. We have no means of ascertaining otherwise. A certain amount of paint should cover a certain maximum area and no more.

2329. (Chairman.) Will you now give us the results of your experience in comparing zinc paints with lead paints? Do you find that the zinc paints are as suitable for interior work?—(Mr. Munby.) Yes, certainly for interior work.

29 March 1911.]

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and  
Mr. W. WONNACOTT, A.R.I.B.A., F.S.I.

[Continued.]

2330. How does their cost compare with the cost of lead paints?—In answer to that question I would refer to my colleague. (Mr. Wonnacott.) From experience we find that there is no difference in the cost of the decorative contract. We are not interested in the details of the cost of a paint, but in actual work we find there is practically no difference.

2331. (Chairman.) Is the covering power of zinc paint as great as that of the white lead paint?—(Mr. Munby.) No, it is not. These zinc particles being so very much finer will spread over a larger surface and will therefore give a much thinner layer of actual paint material than will the lead paints, and therefore the covering power is less.

2332. (Mr. Sutherland.) The spreading power is more?—The spreading power is very much more, because you get a smaller number of particles, probably because the specific gravity of one is very much less than that of the other.

2333. (Chairman.) In the end, would you say that the zinc was more expensive because more paint has to be used?—(Mr. Wonnacott.) I should say less expensive, because it lasts better. (Mr. Munby.) But more expensive in first cost. (Mr. Wonnacott.) The cost of zinc paint *per se* would be more, but from a decorative point of view there would be, I think, an immense saving, because of its permanency and durability.

2334. Do I understand that you refer to permanency of colour and durability?—(Mr. Wonnacott.) Yes.

2335. Would you say that zinc paints could replace lead paints for interior work?—(Mr. Munby.) Yes.

2336. You say that without any qualification whatever?—Yes, they could replace them.

2337. Without any particular hardship to anybody?—There would be hardship on certain manufacturers, but otherwise there would be no hardship. There would be hardship on the workman if he was asked to do the same amount of paint work and produce the same effect for the same money.

2338. My next question deals with that. Is it your experience that workmen apply zinc paints with the same ease as they apply lead paints?—No.

2339. Will you tell us now why?—More coats are required to produce the same effect, and the labour is greater, therefore, to produce the effect which you get with lead paints. A painter expresses himself vulgarly by saying that zinc paint has no guts. It does not cover anything.

2340. Do they use the same thinners and driers?—Yes, I believe they do.

2341. Do the thinners and driers which are suitable for white lead give satisfactory results with zinc paints, or should the zinc paints be treated differently?—(Mr. Wonnacott.) I should say that zinc paint which is dealt with in the same way as lead paint gives a less satisfactory result, and that is the fault with regard to the workmen. They try to treat the zinc pigment exactly as they have been used to treating the lead.

2342. (Chairman.) Do you say that you think that the zinc paint should be treated differently?—Yes.

2343. That is only a question of arrangement?—It is a question of the education of the workmen.

2344. Would you say that there is no insuperable difficulty in that?—There is none whatever.

2345. Now, with regard to exterior work. First, as regards white and the lighter shades of colour, have you found that zinc paints can be used satisfactorily for this work?—(Mr. Munby.) No; they do not weather well. They do not stand the weather as well as lead paint.

2346. You will be interested to know that His Majesty's Office of Works has been using zinc paints for four years both for interior and exterior work; and their paints generally have contained no lead at all. We were told by their representative that none of their paints contain more than 5 per cent. of lead compound, except the dark green, where they were using lead chromate to get the colour. Can you say whether there are at present available zinc paints in

the darker colours which could be used as successfully for outside work as lead paints;—Not to our knowledge. Most of the pigments for the various shades of green are made up of chrome yellow and Prussian blue. The mixture of those two pigments allows an immense amount of latitude in the actual tint attainable; and it is very difficult to obtain such a great variety of shades without the use of lead.

2347. You told us just now that in your opinion zinc paint would not be as efficacious for exterior work as lead paint. Does the experience of the Office of Works induce you to alter that opinion?—(Mr. Wonnacott.) I have never had any opinion which did not coincide with that with regard to exterior work. I do not know what Mr. Munby's experience is. (Mr. Munby.) My general experience has been that the lead paint is the better. The theory is that the lead saponifies and with the linseed oil forms a compound, whereas the zinc does not, and that is supposed to confer additional durability on the lead.

2348. I think that at the beginning the Office of Works found that they had the difficulty which you have foreshadowed, but they gradually overcame those difficulties by grinding and additional driers?—Yes.

2349. Now they have got to what they consider perfection?—I turned up, if I may mention it, a translation of an interesting book by a gentleman of the name of Petit, in which he claims to have so arranged the grinding of zinc paints that they can be made really to combine with the oil. He says that in ordinary cases the zinc paints in commercial use do not combine with the oil at all, and he claims to have made it possible. Whether the Office of Works has obtained similar paint I do not know.

2350. Would you consider that the prohibition of lead or a limitation to 5 per cent. solubility would be a serious thing for the Home Office to impose?—No.

2351. I mean for exterior painting?—(Mr. Wonnacott.) If you limit the lead in a certain paint, I agree with the practice.

2352. Supposing the Home Office were to issue instructions prohibiting the use of lead paint altogether with the limitation, I will say, to 5 per cent., would that be of any serious account to the painting trade?—(Mr. Munby.) To the painting trade or to the durability of the material?

2353. I will put it in your way then—to the durability?—My colleague does not agree with me, but personally I think that that 5 per cent. may be rather valuable as regards durability as forming a compound with the oil which may make its nature felt through the rest of the material.

2354. Mr. Wonnacott, do you differ from this view of your colleague?—(Mr. Wonnacott.) I do not quite gather the drift of Mr. Munby's objection. It is certain that in the use of zinc paint a permissive percentage of 5 as a maximum is desirable on account of the chemical advantages, and therefore the limitation by the Home Office with regard to zinc paint only would be a desirable thing from every point of view, I contend.

2355. Then you practically agree?—(Mr. Munby.) Yes, I think he does. (Mr. Wonnacott.) Possibly, I did not quite grasp your question.

2356. What I meant to say was this: Supposing the Home Office issue an instruction to limit the use of lead in the future in paints to 5 per cent., would that be of any serious account with regard to the durability and the general effect for painting exteriors?—(Mr. Wonnacott.) No, I should say not.

2357. Then you really coincide now with the views of the Office of Works?—Yes.

2358. Now, will you tell us the chief failings of lead paints?—(Mr. Munby.) From the point of view of use, the very ready blackening in an atmosphere containing any sulphur; and, of course, the poisonous nature of it, from the point of view of the workmen and manufacturers. My colleague suggests the ease of adulteration also as an objection.

2359. What are the main infirmities of zinc paints?—Lack of durability.

29 March 1911.]

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and  
Mr. W. WONNACOTT, A.R.I.B.A., F.S.I.

[Continued.]

2360. For exterior purposes only?—Yes.
2361. Are these failings invariably associated with zinc paints? Is it not possible, by the use of suitable oils and driers, and so on, to overcome any weaknesses of the kind you mention?—(Mr. Wonnacott.) I should say that these failings are not invariably associated with zinc paint. Suitable oils and driers would remove the difficulty. In my own work I have found the chief difficulty has been what is called fissuring, and that I trace entirely to the method in which the paint has been mixed, rather than to anything else.
2362. Then with the addition of the 5 per cent. of lead, you maintain that all the difficulties would be removed?—(Mr. Wonnacott.) Yes.
2363. In speaking of zinc paint, have you had in mind paints made from the oxide of zinc produced by heating metallic zinc?—(Mr. Munby.) Yes, I have. (Mr. Wonnacott.) I have had in mind both the oxide produced from metallic zinc, and also from the ore and bye-products.
2364. Do any of your remarks require qualifying in the case of zinc oxide made direct from the ore, which, I understand, as a rule, contains from 2 to 4 per cent. of lead compounds, and is preferred for paint making by certain people on account of its reputed unctuous nature?—(Mr. Wonnacott.) I do not think my remarks require any qualification with the limitation to not more than 5 per cent. You usually get less than that.—(Mr. Munby.) Might I make one addition, and that is that the zinc ore invariably contains cadmium, which is very volatile, and spoils the colour, and therefore the zinc oxide obtained direct from the ore is usually inferior to that obtained from the metal.
2365. Can you tell us anything about lead sulphate?—Yes; I have personal experience in connection with lead sulphate. It has been made for very many years. A great many attempts have been made to produce it as a substitute for carbonate. Quite recently a firm have started on the outskirts of London to make this paint, and they have produced paint which very closely resembles carbonate white lead paint. I got some of that paint and put it in the hands of a trade firm with directions to hand it out to their workmen without saying anything about it, and to allow them to believe that it was ordinary Dutch white lead. I got them to mix it with the kegs of white lead, because so much was said in its favour as to its being exactly the same thing to work with as white lead. But the men found out at once that it would not work as easily. They went to the foreman and said, "There is something wrong with it; it is a bad keg." So that, even when prepared in the very best way, there is a difference with regard to the power of the workmen to lay it on, but as regards durability it is splendid; it is absolutely permanent, although it does not saponify with the oil at all and form an organic compound.
2366. Is barium sulphate used as a paint ingredient?—Yes, it is used, chiefly as an adulterant, but legitimately in special paints.
2367. Is this substance known by other names?—It is called barytes and heavy spar as a mineral, but I do not think that the latter name is used in the trade.
2368. Is it possessed of qualities to make it suitable for paint making?—If it is sufficiently fine it is absolutely permanent, and there is no reason why it should not be used like any other inert ingredient. The chief objection to it is that it is used, as a rule, in a crystalline condition, and is too coarse in grain to be suitable for paints.
2369. What are the materials commonly used for green pigments?—Chrome yellow and Prussian blue mixed.
2370. Is that known as Brunswick green?—That is known as Brunswick green in the trade at the present time, I believe.
2371. What should Brunswick green consist of?—This name was originally applied to oxychloride of copper. It is now always understood in the trade to indicate a green prepared by mixing chrome yellow with a small quantity of Prussian blue. Even in green of deep tint, less than 20 per cent. of the pigment consists of these ingredients, the remainder being substantially some inert base, usually barium sulphate.
2372. Are these greens permanent?—No; the oxychloride of copper which you mention would, I suppose, be preferable to the lead chromate from the point of view of the health of the worker.
2373. Can you tell us how the costs compare?—The oxychloride would be more expensive.
2374. Is zinc chromate able to take the place of lead chromate for green pigments?—I do not know that I can answer that question. I think it is little used. Zinc chromate is a fairly expensive substance.
2375. What is chrome green?—Real chrome green is chromium oxide, Cr<sub>2</sub>O<sub>3</sub>.
2376. Does it make good green paint?—Yes; but it does not admit of the variety of tints as the mixture of Prussian blue and chrome yellow.
2377. Is it capable of taking the place of paint prepared from lead chromate?—Yes, within a certain range of tints.
2378. Can you tell us how green paints prepared from chrome green compare for price with paints made from lead chromate?—They would be more expensive; I cannot say how much. Chromium oxide is absolutely permanent.
2379. Now I have asked you a good many questions about pigment, I want you to tell us something about the vehicle. To make a good paint is the vehicle as important a matter as the pigment?—Yes, I should say so, certainly.
2380. Is there very much choice in the paint vehicle?—No.
2381. What is China wood oil?—It is also known as Tung oil from the Tung tree in China. My colleague says that in his experience the use of it is growing in the trade considerably.
2382. Does it make a good paint vehicle?—(Mr. Wonnacott.) Yes, and it gives a good surface too.
2383. Is it known by any other names?—(Mr. Wonnacott.) No other than Tung oil, I think.
2384. Is it commonly used in this country?—(Mr. Wonnacott.) No.
2385. Has it any advantages over the linseed oil commonly used?—(Mr. Wonnacott.) It is cheaper, I should think.
2386. That is always important?—(Mr. Wonnacott.) Yes, that accounts for the increase in the use of it.
2387. Would you say it is necessary to suit your oils and thinners and driers to the pigments and bases that are being used?—Yes, but a great deal more work and research is necessary on that subject. There is such a small choice in the matter of oils, and one hardly knows how they should be apportioned, but undoubtedly the character of the paints must vary according to the way in which they are arranged.
2388. Are the same oils suitable for lead paint as zinc paint?—Yes, as far as we know.
2389. You are, of course, aware that the Registrar General's records show 280 deaths amongst house painters from lead poisoning in the last ten years?—I was unaware of that. I had some personal experience of a rather interesting character some years ago in connection with lead work. I did some work with a chemist in the north of England. We analysed in some cases the organs of lead workers in Newcastle and found lead in every organ. I have details which are at your disposal if you think them of any importance.
2390. Is it a common practice for architects to specify in their contracts that paints containing lead shall be used?—(Mr. Wonnacott.) Taking architects as a body, I think they have no choice.
2391. Why is this done?—(Mr. Munby.) I think it is partly a matter of custom. It is a matter of experience that the lead paint is the more permanent and is generally obtainable.
2392. It is want of knowledge of the two substances?—I think so. It is want of knowledge and experience of the use of other paints, because they are less easily obtainable.
2393. Do you think architects are alive to the serious dangers involved in the use of lead paints?—Undoubtedly, they are perfectly alive to them, but

29 March 1911.]

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and  
Mr. W. WONNACOTT, A.R.I.B.A., F.S.I.

[Continued.]

it is difficult to know what substitutes to adopt in specifying.

2394. Would they welcome the prohibition of lead if suitable substitutes could be found?—(Mr. Wonnacott.) They would, undoubtedly. (Mr. Munby.) They would certainly help in any attempt to check the use of lead paint, from the point of view of its evils, if suitable substitutes could be found.

2395. If the Home Office were to issue an instruction to prohibit lead in paints or to impose a limitation of 5 per cent. of solubility, do you think that the architects whom you represent would consent?—(Mr. Wonnacott.) Considering continental experience I should say that we should be perfectly safe in assenting.

2396. (Lord Henry Bentinck.) You said that the zinc paint was not so durable as lead paint?—(Mr. Munby.) That was for exteriors, so far as our experience went.

2397. Is your experience large in that respect?—No, I cannot say that it is.

2398. On what data is that statement made?—Only on general observation of paint work which one has seen.

2399. In cities or exposed to rough weather at sea?—I have had no experience with regard to the seaside.

2400. It is more with regard to cities?—Yes, general painting work.

2401. Has zinc oxide been improved of late years?—I believe it is improved by compression.

2402. You think it is susceptible of improvement?—I personally think that it would cover better if it was in an oil of a different specific gravity from linseed oil, if one could be found.

2403. Would that make it more durable or alter it from the colour point of view?—That I cannot say. I think it is a subject for research.

2404. (Sir Godfrey Baring.) Would you say that there is an improvement in the quality of zinc paints, say, in the last ten years?—Yes, I should say so. They are more widely used; there is greater demand for them.

2405. It is your experience that there is a growing demand for zinc paints?—Yes.

2406. And therefore the workmen are becoming more accustomed to using and manipulating the zinc paints?—Yes, undoubtedly, slightly more accustomed.

2407. Two witnesses told us yesterday that they found that zinc paint was specially suitable for external use in London and other large towns?—From the point of view of discoloration—yes.

2408. And from the point of view of durability?—As far as my experience goes I would say no.

2409. Your colleagues will agree with you in that?—Yes.

2410. (Dr. Collis.) Have you read the Dutch report on experiments with regard to this question?—No.

2411. When you were speaking about the grinding of zinc paints there was one point that struck me as interesting. The Dutch Commission found a great improvement by grinding their own zinc for their own experiments. You have not tried any special grinding of zinc paints yourself?—No; I have not any facilities.

2412. The suggestion that you made that grinding would not improve the zinc paints because they were already fine, seemed to me at the moment (perhaps I speak wrongly) to be a misunderstanding of the value of grinding. I was rather under the impression that it was a question of the amalgamation of the vehicle and the pigment rather than any attempt to grind down, by attrition, the pigment particles?—I would designate mixing from that point of view. Grinding and mixing are things that one cannot separate in practice. The greater the mixing of paints the better. Zinc oxide, being merely a name, does not want grinding; it wants compressing.

2413. There seems to be a misunderstanding of the word grinding?—My answer was given with the idea of the attrition of the pigment more than anything else.

2414. The Dutch experiments seemed to point to the value from the opposite side. Now, you spoke of

the presence of cadmium in zinc white made from ore. Is it not a fact that some ore does not contain cadmium—such as Franklinites?—(Mr. Wonnacott.) That is the most suitable ore for the direct process, I believe.

2415. That is difficult to obtain, is it not?—I do not think we have it in this country?—(Mr. Munby.) There are very few that contain no cadmium.

2416. (Mr. Sutherland.) You said that the size of the particles was important?—Yes.

2417. Did you say that this was not known to paint manufacturers, or did I misunderstand you?—Perhaps that was rather a sweeping statement on my part. I think that generally the paint trade is not alive to the fact, otherwise we should have some standardisation: It is impossible now to purchase paints, as far as I know, in which the size of the particles is in any way to standard, although they can be measured.

2418. But this is a common fact of chemical knowledge, is it not, the difference of the size of the particles in pigments?—I do not know. I have not come across any practical men who have shown appreciation of it. If you take a ground-up hematite the coarseness of the particles is immense compared with fine white lead.

2419. It is a sort of fundamental thing that all up-to-date paint manufacturers would be aware of?—One would hope so.

2420. If they are alive to their business they would be, and it is discussed commonly in the chemical papers?—We can only go by the kind of paints which are used. They vary very much in character without any difference in specification. I was speaking from the point of view of the architect.

2421. When you speak of the improvements that may be expected, do you mean in the way of finer grinding?—Yes.

2422. Most people have the most perfect machinery in that respect, and I do not think it possible to grind finer. They have the stack or chamber process. Then you went on to speak of standardisation with regard to the amount of paint laid on the surface and of weight being the best test?—(Mr. Wonnacott.) Area would be the best test.

2423. The best class of paint work has always the least amount of paint per surface, and the cheapest class has always the largest amount, so that your standardisation would break down on the ground of paint per surface?—(Mr. Wonnacott.) Yes.

2424. Our association experimented some years ago on this very question; it is common knowledge, and they worked it out that the thinner the coat the better the protection?—(Mr. Munby.) Does that mean that the less the depth of the actual particles on the surface the better the protection?

2425. The thinner a coat of paint is spread on, the better it preserves the work, and in that little book by Petit that you referred to you will find the point raised, I think, with regard to successive coats becoming a definite film. If instead of five thin coats you put on an equal quantity in one coat you would have a fine film at the top, but underneath you would have a sticky matter that would take years to harden?—We wanted to prevent a man getting a pound of paint and adding any quantity of benzine to it and running through his work in no time.

2426. Some meet a specification that says "two coats" by giving one thick coat?—Yes.

2427. You agree that the covering power of zinc is not as good as that of lead?—Yes.

2428. But the spreading power is more?—(Mr. Wonnacott.) The hiding power.

2429. (Mr. Sutherland.) Yes. You say it is no good for outside work?—I do not suggest that. The only difficulty I find in external work is traceable to the workman.

2430. A point that has been made time and again here is that, if zinc paints are adopted, sufficient time will have to be given to the working man to acclimatise himself to the use of them. Undoubtedly that is a serious matter?—(Mr. Munby.) Yes.

2431. You say it takes more coats and more labour for zinc paint?—(Mr. Wonnacott.) Yes.

29 March 1911.

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and  
Mr. W. WONNACOTT, A.R.I.B.A., F.S.I.

[Continued.]

2432. Does not that increase the cost very much?—Yes, the labour does.

2433. For ordinary painting the labour is an element?—(Mr. Wonnacott.) Up to a certain point.

2434. It is something like 60 per cent. For decorative painting it is more?—For work in common colours 60 per cent. is too high.

2435. That has to be added to the cost of production?—Yes.

(Mr. Sutherland.) The ordinary proportion of labour to material, including paper and everything else in a decorator's business, is something like 50 per cent. The remainder is material of all kinds and profit.

2436. (Chairman.) Could we have something more precise than that? What would it add to the cost?—

(Mr. Wonnacott.) The cost of decorative contracts has not been materially increased. We are not able to go into the details of labour and materials at all, but speaking from practice, our decorative contracts are not more costly than formerly.

2437. In addition to that you have the advantage of the extra durability?—Yes.

2438. (Mr. Sutherland.) You say that zinc paint does not stand the weather as well as lead paint for outside work?—(Mr. Wonnacott.) I do not think I stated that.

2439. I thought one of you did?—(Mr. Munby.) I said that my experience was not large, but as far as my experience went, zinc paint did not stand the weather as well as lead paint.

2440. That is what I said. Now you always specify for genuine white lead in your specification, do you not?—Yes.

2441. You generally specify white lead, best linseed oil, Baltic or otherwise, and best American turpentine?—Yes.

2442. When you get away from those three ingredients you are landed in a difficulty. What would you substitute in a specification, if you wanted to specify other paints than genuine white lead? You do not specify a particular paint unless it is an enamel or proprietary article?—No.

2443. How would you enforce what you specify?—If I was specifying zinc white, I should say it should be composed of nothing but zinc oxide and best linseed oil.

2444. But that would not give you a serviceable paint. You must add something like barium to carry it. That is one of the difficulties?—One of my points about the grinding is the difficulty with regard to a standard of fineness.

2445. If zinc is going to be adopted, you would have to adopt some measure for including an inert matter?—Yes, I quite agree.

2446. The pure zinc of itself would not be satisfactory?—At the present time I should not dare to specify barium, because it is not in a sufficiently fine state. You get all sorts of crystals.

2447. Now, Mr. Wonnacott, you spoke of fissuring as the chief defect. Was that on a large surface?—(Mr. Wonnacott.) It was on external woodwork; that I traced to the workmen, and also to the unsuitable driers, which the workman knows nothing about at present.

2448. Would the Royal Institute of British Architects adopt the specification of the Office of Works?—(Mr. Wonnacott.) We are prepared to adopt before very long a specification, but we have drawn out this monograph for previous discussion. We shall endeavour to establish a standard specification which will include a zinc paint, but not at this stage.

2449. You do not think professional opinion is ripe for it?—It has practically not been before the profession yet.

2450. There would be difficulties in enforcing this. That is what I want to impress on the Committee. You, as representing your clients, would want to establish to your own satisfaction that any substitute for white lead was equally good in protecting property?—Yes.

2451. So the mere abolition of white lead and substitution of zinc, which might be done by Home

Office regulation or Bill in Parliament, would not solve the difficulty of getting a satisfactory paint. It might hasten it by the enterprise of our paint manufacturers?—(Mr. Munby.) It would hasten it.

2452. (Chairman.) You are satisfied, I understand, that an efficient substitute could be adopted for interior work and with the addition of 5 per cent. of lead for exterior work?—Yes.

2453. (Mr. Sutherland.) Do you think a zinc paint, with the addition of 5 per cent. of white lead, would be equal to white lead paint. Your answers seemed to imply that you did, but I was not sure whether you understood the drift of the question?—(Mr. Wonnacott.) I adhere to what I said.

2454. You think it would be equal?—(Mr. Wonnacott.) Yes—with a 5 per cent. maximum.

2455. (Mr. Sutherland.) Zinc paint made by the indirect process contains anything up to 4 or 5 per cent. of lead?—(Mr. Munby.) In what way are you speaking? Are you referring to the number of coats?

2456. I am speaking of the pigment. The number of coats you must settle among yourselves?—Do you mean, could it be worked up to be the same, irrespective of the number of coats and the question of thinness; is that what you mean? It seems to me the question raises some issues which are not dealt with.

2457. Why I put the question is, that if your answer goes forward as the answer I do not think it conveys quite what you intended—that a zinc paint with the addition of 5 per cent. of white lead is as good and as practicable as genuine white lead?—(Mr. Wonnacott.) I adhere to that. I can see certain advantages with that small percentage of lead. (Mr. Munby.) I would say yes if you want a crisp answer. But there are many more incidental points which should be mentioned.

2458. Then you quoted the view in that little book that zinc is held by the vehicle?—I was quoting the views held by many people.

2459. And never amalgamates with it?—(Mr. Wonnacott.) That is disputed.

2460. Everything in chemistry is challenged?—Theoretically, with regard to zinc oxide in linseed oil, it would be chemically about 14, but it is found to take up considerably more at a high temperature. Some of that must go in the form of an organic compound. That is how I should describe it.

2461. (Mr. Rice.) I understand that this inquiry by the Institute was made for two purposes, one with regard to the durability of paint, and the other with regard to the effect on the workmen. You have not told us about the result of the inquiry with regard to the effect on the workmen?—(Mr. Munby.) The original object was to formulate a standard specification for paints, which specification could be used by architects and reputable paint manufacturers, and would safeguard them and their clients.

2462. Was there a separate inquiry into the effect on the workmen?—There were not two inquiries. It was found that an actual specification it was impossible to prepare, because there were no definite standards in the paint trade, and therefore we drew up this little monograph with a view to interesting architects and the trade and those concerned in paints generally, in order that we might get more information, and that people might take up the question of standardisation of paint.

2463. I understood the inquiry was first of all as to the ingredients and secondly as to the effect on the workmen. Have you made any inquiries into the effects on workmen of white lead?—No. (Mr. Wonnacott.) We disregarded the workmen altogether, to put it in a nutshell. Our object was to supply architects with something which would correspond to the British standard with regard to steel, portland cement, and similar things. That was the object of the inquiry. The trade not helping us, we had to fish out information for ourselves, and we hope shortly to embark on experiments if our council has the good nature to assist us.

2464. This inquiry which has been held is in quite an embryonic state at present?—(Mr. Munby.) Yes.

29 March 1911.]

Mr. ALAN E. MUNBY, M.A., A.R.I.B.A., F.C.S., and  
Mr. W. WONNACOTT, A.R.I.B.A., F.S.I.

[Continued.]

2465. You have issued no instructions to your members?—We have issued nothing but what you have in that little book.

2466. It is preparatory to the report to the council?—It is a preparatory feeler; that is all.

2467. It was the individual opinion of you gentlemen rather than of the council that they would specify zinc in lieu of lead?—Yes. We cannot commit the profession.

2468. Has the matter been inquired into not only by you gentlemen, but by a number of gentlemen?—A sub-committee of the Royal Institute was appointed which drew up that monograph, and that sub-committee still exists.

2469. So that until your committee are prepared to recommend the use of zinc paint instead of white lead paint, specifications will be continued to be prepared for the use of paints containing white lead?—Undoubtedly.

2470. Now with regard to the cost of zinc white, I take it there is very little used at the present moment. Mr. Wonnacott, you said that with regard to contracts, the cost was about the same. I take it there are not many specifications of zinc white?—(Mr. Wonnacott.) I should say there were not. I made an experiment in a large country mansion and compared the cost with that of a former contract on the same lines. The contractor was thoroughly aware of what I was doing, and I enlisted his sympathy. He naturally wanted as much as I did to get the information as to the durability and everything else.

2471. Now have you any information as to how many more coats are required to give the same effect?—It depends on the proportions of the ingredients.

2472. That is where you want standardisation?—Yes; we cannot say off-hand how many coats will be required to give the same effect.

2473. Take four coats of white lead, for instance?—(Mr. Wonnacott.) To substitute a pure zinc oxide, the result might be disastrous.

2474. Do you take any steps in your society for the education of workmen?—We cannot; we have no means, and apart from that, we are not in touch with the labour market at all.

(Chairman.) The Office of Works in their experiments, which have been so successful, have only used two coats instead of three.

(Mr. Sutherland.) One with 5 per cent. of white lead?

(Chairman.) No; Mr. Patterson told us that he did admirably without any lead at all; and he said, "I am quite sure that if we were allowed to go up to 5 per cent., we could make a perfect paint in every colour, with the exception of green."

2475. (Mr. Gardner.) If zinc oxide was sufficiently adulterated to give it body, you might get a commercial paint which would give as good a covering as white lead?—Yes.

2476. Manufacturers in the past have been putting out zinc white in too pure a state?—(Mr. Wonnacott.) Possibly; but I think the physical state of the zinc has something to do with it.

2477. With regard to outside ironwork and stucco work, how would you account for it not standing so well?—(Mr. Munby.) As far as our experience goes. We had a report of a series of American tests on bridge work over a considerable area, and the digest of that

report led me to suppose that the two materials were absolutely identical except as regards the size of the particles. Are you referring to the instance that we quote?

2478. No. You said that zinc paint on iron or wood outside had not the same durability as white lead. Do you know why that should be so?—(Mr. Wonnacott.) I should not be inclined to inquire as to the composition of the paint, but I should be rather inclined to inquire how the surface was prepared, and how it was put on, and so on. I think that is where zinc paint fails on ironwork. (Mr. Munby.) There is one very important question which has not been raised with regard to zinc paint. The discussion has turned on zinc oxide. There is zinc sulphide, which is very deleterious on ironwork. When mixed with oil there is a reaction, iron sulphide is formed with decomposition of the zinc sulphide.

2479. (Mr. Parsonage.) There is a vast amount of adulteration in white lead, is there not?—Yes.

2480. You would not expect to get more adulteration with zinc paint if you had a standard specification than you get in what is termed genuine white lead?—(Mr. Wonnacott.) I should expect far less. (Mr. Munby.) Certainly not more.

2481. There is more adulterant in white lead than in anything else used in the painting trade?—Yes.

2482. So that a specification now for "genuine white lead" really carries nothing with it?—No.

2483. With regard to the use of zinc oxide, you speak of its being mixed in exactly the same way as white lead. If zinc white was mixed properly, would it not cover coat for coat the same as white lead, supposing that refined boiled oil was used instead of ordinary raw linseed oil?—I should say not, because its specific gravity is much less; and it would float longer on the oil and be drawn out.

2484. I have reason to believe that mixed with a certain proportion of barium, it covers equally as well as white lead?—(Mr. Wonnacott.) Yes, when it has a small proportion of body to it.

2485. If a man is a painter, or whatever trade he is in, he can adapt himself. It would be only a question of the man. It would not be an insuperable objection or obstacle to the use of the material at all?—Not at all.

2486. It is really only a question of a standard of specific gravity?—(Mr. Munby.) Yes, as far as my experience goes I should say so. You say a certain proportion of barium.

2487. Yes. Then it could be used coat for coat with white lead?—I do not see why it could not be used.

2488. The only reason why it will not cover coat for coat to-day is that the zinc oxide must be absolutely pure, whereas "genuine white lead" can be adulterated to any extent. That is about the difference. If there was an equal amount of mixture with other materials one would cover as well as the other, and it would wear equally well?—My experience does not go sufficiently far to enable me to confirm that view, but I feel inclined to agree with it as far as my experience goes. That is all I can say.

2489. I think I shall be able to demonstrate to this Committee that what I state is true, and also that there are painters to-day well able to use the zinc white. If it is introduced, men will at once accommodate themselves to the conditions?—Yes.

The witnesses withdrew.

Mr. J. W. GARRON examined.

2490. (Chairman.) Do you represent Messrs. Lewis Berger and Sons, Ltd., paint manufacturers, of Hometon?—Yes.

2491. What is your position there?—Managing director.

2492. What paints do your firm manufacture?—We make a full line of paints, and we specialise for certain purposes.

2493. Do you make paints for coach work as well as for house painting?—We do.

2494. Do you make any paints on a zinc base without lead compounds?—Yes.

2495. Are your zinc paints as good as your lead paints?—In the matter of quality or durability do you mean? We make pure zinc paint and pure white-lead paint.

29 March 1911.]

Mr. J. W. GABSON.

[Continued.]

2496. I will put it in this way: for practical use, how do they compare?—For practical use, taking them individually, they are equal in quality. As to durability I would like to deal with that in another way.

2497. I will put the question again to you. I ask you whether your zinc paints are as good as your lead paints for all practical purposes?—Yes.

2498. Are they suitable for interior work?—Yes.

2499. And for exterior work?—We recommend lead in preference to zinc for exterior work.

2500. On what ground do you recommend lead for exterior work?—We find that it is more durable. It is more lasting as a surface coat and also as a protective coat.

2501. How does the cost of your zinc paints compare with that of your lead paints?—Compared with that of the lead paints, there would not be a great difference. Lead would be the cheaper.

2502. What are the covering capacities of your lead paints and your zinc paints?—The zinc would be probably 10 to 25 per cent. more than the lead.

2503. The covering capacity of the zinc would be 10 per cent. more than the lead, you think?—Yes, but it would not have the same opacity, in my opinion, as the lead.

2504. Do the zinc paints retain their colour for a long time unchanged?—They do.

2505. Are they better in that respect than the lead paints?—I think they are.

2506. Can they be used with the same vehicles and thinners as painters would use for ordinary lead paints?—Yes, but the proportions would have to be modified.

2507. To what extent?—A very small extent. Lead would take less drier than the zinc—a weaker drier, that is to say. Zinc would require more thinners up to about 25 per cent.

2508. Now, with regard to durability. First as regards interior decoration, can you give us a few particulars of some buildings where your zinc paints have been used for internal decoration?—I have not the details before me, but from our own experience I should say that for internal decoration the life of the zinc would be about the same as the lead.

2509. And secondly, with regard to external decoration, that is to say, surfaces exposed to all weathers?—I should imagine with regard to surfaces exposed to all weathers that zinc would only have about two-thirds of the life of lead unless it can be specially treated. If it is protected with varnish that would be different, but taking the zinc and oil, and lead and oil, I should say that the life of the zinc would only be about two-thirds. Zinc could be treated in such a way that it might have equal life with the lead.

2510. What special treatment would be required to accomplish that?—With the addition of varnish it would stand outdoor exposure longer.

2511. Would the addition of five per cent. of lead assist the durability?—It would.

2512. Would it make it equally as durable as lead paint?—Five to ten per cent. would bring it closer to lead probably, but I do not think it would ever equal lead unless by the special treatment which I speak of.

2513. Can you tell us whether your zinc paints were applied over former coats or priming coats of white lead or not?—Yes; it is mostly recommended that they should go over a flat coat which is usually prepared from white lead.

2514. Can you tell us of a few buildings where your paint has been used for exteriors?—I have not that information with me; I could procure it and send it on.

2515. Please let us know also the dates at which these exteriors were painted?—I will give you that information, too. You understand we only supply the painters.

2516. Do you make enamels?—Yes.

2517. Are they built up on a lead base?—No, on a zinc base.

2518. The Office of Works have been using, almost exclusively, for over four years, zinc paints both for internal and external work?—I am familiar with their formula.

2519. Does that in any way influence your answer to my last question?—No, I think not. Their formula is one specially prepared and is not in general use. It would not be adapted. Their experience has been that zinc, treated in the way that lead would be, is not so durable for outside exposure.

2520. My point is this, that the Office of Works have prepared a formula which has proved to be as perfect for exterior painting as lead paint?—I was not aware of that until now that you make the statement.

2521. That is the evidence we have received. That is news to you?—Yes.

2522. It shows, does it not, that the difficulty can be overcome?—I was not aware that they had arrived at any definite formula yet. They are continuing to improve it.

2523. It shows that by continuous experiment you can arrive at the perfection of paint without using lead?—Yes. They have modified their formula in the way that I have suggested. By employing a certain percentage of varnish you can improve it.

2524. You are aware, I suppose, that in France a law was passed in 1909, to take effect in 1915, which prohibits the use of white lead in house-painting?—Yes.

2525. May I take it that you know that in other countries the use of white lead in house-painting has been strictly regulated—in Germany and in Belgium, for example—while in Austria white lead was prohibited in 1909 as regards interior work?—I was not aware of Austria. I have heard that it was so in other countries.

2526. What is your view with regard to the prohibition of the use of lead in paint in this country?—As a paint manufacturer I am not interested. It would not affect our firm. Do you mean generally on the trade?

2527. What effect would it have generally?—The consumer and also the householder would readily fall in with any suggestion as to a substitute for white lead, and I think he ought to do so. It would have the effect of improving probably the present merits of zinc-white, or it would have a tendency for the manufacturer to look round for other substitutes than zinc-white. There are others. We have not mentioned lithopone, but that is a very good substitute.

2528. You mean to say that the prohibition would give an impetus to the manufacturers to seek for an efficient substitute and possibly a better substitute?—Yes, for something that would be quite equal to white lead at least.

2529. Do you think that that would be possible?—Yes; we and other manufacturers are experimenting on it at the present time. I have brought down some panels showing our own tests. There you see the merits of zinc and lead.

2530. (Sir Godfrey Baring.) Would you say that there has been an improvement in the quality of zinc paints during the last 10 years or so?—Yes, I think there has. Many of the zincs on the market contain a large proportion of lead that is detrimental. We are now able to obtain zincs which are quite free from lead.

2531. That improvement will probably be progressive in the future?—We have every reason to believe so. As far as that is concerned, the impurity of lead is quite eliminated now.

2532. Is it your experience that there is an increasing demand for zinc paints?—A very small increase in this country as far as my observation goes. In foreign markets there is a very large increase.

2533. In England there is a slight increase?—In England, I believe, there is a slight increase as far as my observation goes.

2534. Would you agree with some of the evidence that was given by two witnesses yesterday, that zinc paints are specially suitable for external use in London and other large manufacturing towns?—No; unless treated specially as the Office of Works has done.

2535. Unless so treated, they would not be specially suitable?—I do not think so.

2536. Would not they, so far as durability of colour, is concerned?—Yes, but on the question of

29 March 1911.]

Mr. J. W. GARBÓN.

[Continued.]

protective qualities I should say they are not equal to lead at the present time.

2537. You said, in answer to the Chairman, that with a slight admixture of lead, up to 5 per cent., it would be materially improved?—Yes, but it would still be deficient.

2538. But it would come nearer with regard to durability?—It would come nearer.

2539. (Dr. Collis.) At your works do you employ men entirely on making zinc paints, in contradistinction to the men employed on making lead paints?—I cannot say they are employed exclusively so. We have lead mills and zinc mills. We do not mix them up. We do not grind zinc with a lead mill.

2540. Do you separate the men?—We keep the same operators on each mill, as far as we can.

2541. Do you insure them separately or as a whole?—As a whole.

2542. Would it be possible for insurance companies to take them at lower rates if lead was eliminated?—I am sure we could get a lower rate than we do as lead grinders.

2543. You have to pay a high premium?—But our risk has been very small. I am glad to say we have not had a case to report since October 1909.

2544. That is a matter which has pleased us quite as much as you?—I am pleased that you have noticed it.

2445. (Mr. Sutherland.) It is quite immaterial to you whether you use lead or zinc, as a firm of paint manufacturers?—Yes.

2546. You have to produce it one way or the other?—We have to produce it one way or the other.

2547. A question was asked as to Tung oil. Is that a commercial product for paint?—No. It can be procured, but in very small quantities.

2548. There is nothing so good as pure Baltic linseed oil, is there?—That is the very best medium that is known at the present time. Although considerable research is being made for a substitute for linseed oil, no substitute has been found suitable.

2549. For external work you think that lead is better than zinc?—That is our experience.

2550. But for internal work zinc can be used quite as well as lead?—Yes, for ordinary purposes.

2551. Do you think that, if white lead is prohibited, the consumer (by that I presume you mean the painting trade) would fall in with it?—They would have to; they would have no alternative.

2552. Yes; but would they do it graciously, do you think?—I think the painter is really in the same position as the paint grinder. If he does not sell lead, he is going to sell zinc. It is only the lead corroder who would suffer.

2553. There is nothing, in your opinion, before the public that is equal to white lead for external work?—No.

2554. (Mr. Robins.) Do you send zinc paint abroad?—Yes, very largely.

2555. Are good results obtained from the use of it abroad?—Yes, I believe so. It is particularly suitable for the climates where it goes—South America, China, and Japan.

2556. I am thinking of the Continent just now?—Probably lithopone and other substitutes are very largely used, in France particularly. I do not know if zinc-white has taken the place there of white lead. The import duty is prohibitive, so it is quite a domestic supply. From my own knowledge, I know that lithopone is being used very largely there.

2557. The zinc-white you sell to the home market is the same as you sell to the foreign market?—Yes. We have various grades—one, two, and three.

2558. You, in common with other firms, are instituting research for substitutes for white lead?—Yes.

2559. Are you doing it jointly or separately?—Separately at the moment.

2560. Your particular firm is not working with any other firm?—No. We get together occasionally and exchange views. We have a federation of our own, but the matter has not been brought up officially yet.

2561. This is research on the part of your firm individually?—Yes.

2562. At the present moment you have nothing to offer as a substitute?—We have at the present moment on the market leadless paints composed of zinc and lithopone.

2563. (Mr. Gardner.) Could not you produce a zinc preparation for outside work which would stand quite as well as white lead?—I believe we could by manipulation.

2564. (Mr. Parsonage.) If zinc paint for outside work was mixed with mixing varnish, instead of raw linseed oil, would it not stand as well as white lead?—I am sure it would, but it would be much more expensive.

2565. It is a question of mixing with regard to its durability?—Yes.

2566. (Mr. Fell.) Have any of your zinc paints been used for carriage work?—In the form of enamels, yes.

2567. For ordinary motor cars or tramcars or anything of the sort?—Yes. We have supplied them in the form of enamels ready for use and also in Japan gold size.

2568. Not with regard to priming up?—No.

2569. Could you say where you have supplied these zinc paints?—I can only call to mind that it has been supplied in the form of enamel for ceilings and for decorative work.

2570. But not for outside work?—Never for outside work, as far as I know, or for filling up or first-coat work. That, as far as I know, has always been in lead.

2571. (Mr. Mason.) Would the addition of copal varnish to your zinc, so as to make it equal to lead, raise the cost of the paint to more than lead paint?—Yes.

2572. Would the cost of such paint as is supplied to the Office of Works be more expensive than lead paint?—As a matter of cost, yes; it would be more costly to produce.

2573. (Chairman.) They say not?—They are not manufacturers.

2574. But they know what they pay for it?—You have to take the question of competition into consideration.

2575. If I was asked whether zinc costs more than another article, I should judge of that by the price I was asked to pay, and if these people tell us that after four years' experience with a certain formula which has been used for four years it has cost no more for zinc than for lead, I should say that was conclusive?—They are in the peculiar position that they can always make their own price in the open market.

2576. (Mr. Mason.) Would not the contractor who put the paint on suffer?—Would it not have to come out of his pocket?—As a matter of fact it would cost more to produce, but if there was a universal demand for it we should find that there would be a universal price and it would come down to pretty near the price of ordinary paint.

2577. (Mr. Kinggate.) I believe you specially cater for the coach trade?—Yes, we make a speciality of coach colour.

2578. Have you applied the Masury self-bound process to zinc-white?—No.

2579. You have not experimented with regard to zinc-white in that respect?—No, not unless it is asked for. We have never made a speciality of it in preference to lead.

2580. You have never made Masury?—No.

2581. There is a difficulty with zinc-white as to drying?—No difficulty, but it takes longer time than lead.

2582. Coach painting, as you know, is entirely different from house painting?—I do not think with zinc alone you would get the hard undercoat, but combined with siliceous filling up ochre it is known to answer.

2583. With the Masury paint?—No; the finishing coat would be all right, but the undercoats, no.

29 March 1911.]

Mr. J. W. GARSON.

[Continued.]

2584. I am talking about building up from the filling, not from the priming?—Then zinc could be used.

2585. Building up with zinc?—Then zinc could be used satisfactorily.

2586. With the Masury patent?—Yes.

2587. (Mr. Gardner.) You supply in pulp?—We supply in all forms.

The witness withdrew.

Mr. WILLIAM A. HUMFREY examined.

2588. (Chairman.) Are you works manager of the Brimsdown Lead Company, Limited?—Yes.

2589. What does your firm manufacture?—Lead products of various kinds. The main product is white lead, the other products being more or less subsidiary to white lead.

2590. I think that you have a special process. Would you describe, very briefly, please, in what way it differs from others?—Our process consists of oxidising metallic lead in furnaces and after certain intermediate processes, converting that oxide into a basic carbonate, or white lead, while in suspension, in liquid, the white lead being afterwards filter-pressed and ground in oil in the usual way. The more general process is one in which metallic lead is cast into gratings or wickets, and corroded in stacks with spent tan and acetic acid.

2591. Will you tell us the main uses of your products?—Our use is almost entirely for painting; very little for anything else.

2592. House painting and coach painting?—I should say both.

2593. Do you handle any substitutes for lead paint?—None whatever.

2594. Should the use of lead paints be restricted or prohibited in this country at any time, would this mean serious loss of business for your firm?—It would mean practically the extinction of our firm.

2595. Have you any suggestions you would like to put before us as to precautions—short of providing substitutes for lead paints—which could be relied upon to abolish lead poisoning amongst both house painters and coach painters?—In answering that question I cannot speak as a painting expert. Being only a white lead manufacturer, my knowledge of the painting trade in its technical details is very limited, but I can speak as to the precautions which should be adopted in the handling of white lead, and which have met with some considerable success, and some of which might very well be carried out in a modified form by the painting trade, I think.

2596. What are they?—It appears to us that the first thing in the prevention of lead poisoning is the education of the workmen, and we have devoted considerable attention to that; that is to say, in taking on a new man, we first of all warn him in unmeasured terms as to the poisonous nature of the product he is going to handle, and then for some time keep him under inspection with further warnings, and watch whether he is negligent or whether he takes any notice of the warnings given to him.

2597. Who is going to do the watching?—In our case the foreman in the factory does it to some extent, and we also have one man who acts as inspector and takes general note.

2598. That applies to your own works?—That applies to our own works.

2599. But what would you suggest should be done where a man employs, say, 500 workmen, and they are scattered all over the country on different jobs?—I suppose such an inspection would be impossible in that case.

2600. That is exactly what we feel?—But I should think that in the trade generally there must be many instances where the men are not scattered; for instance, in large painting works.

2601. What some of us feel is, that we have to contend with a very serious and insidious evil which results in a very large number of deaths, and a still larger number of attacks of lead poisoning. Now we have been called together to find a remedy for that evil. Either we must prohibit the use of lead or we

must introduce such precautions as will check the inroads of this terrible evil. You have rather implied that with regard to house painting no precautions would be possible? No. May I correct that? I said that inspection of the men would be impossible in that case.

2602. How would you introduce precautions in the case that I cited of a man with 500 workmen scattered in threes and fours all over the place?—My own impression of the way in which painting is carried out by men working in twos and threes is that there are several things wanting, such for instance, as washing appliances. It does not form a regular part of a painter's kit always to have soap with him. He probably takes his meals with him, and has a very haphazard, if any, kind of wash at all before his meals, if he is on an out job. He, as a rule, is not an extremely cleanly person. He gets paint very much round his finger nails, and eats part of his food with his fingers. Naturally he holds his bread with his hand. That is one of the gravest risks painters suffer from on those small outlying jobs.

2603. Do not you think that with the lamentable state of affairs that I have depicted, if a substitute is found for lead, the Home Office ought to insist on its being applied?—I think that if a complete substitute for lead was found it ought to be applied.

2604. Notwithstanding the fact that it would do grievous injury to certain lead manufacturers?—That is a matter of very considerable import. If, as well as introducing a substitute, you also imply prohibiting the use of white lead, it would naturally create another evil by the harm it would do to those already engaged in the business.

2605. But it would be an evil that could be overcome by finding other employment, whereas the evil which exists to-day of men being poisoned would cease?—It is a matter on which I could not express an opinion without having all the details before me.

2606. We have evidence before us from the Office of Works that they have been using almost exclusively for the last four years zinc paints both for internal and exterior work with perfect satisfaction?—May I remark on that that the Office of Works is a branch of, shall I say, the Government Service (I do not know the right term to use exactly) which I have not any knowledge of. But we have some considerable acquaintance with both the Admiralty and the War Office, both of which branches of the Service are very large users of white lead still, and we feel in this way, we are in the position of simply supplying a demand. I take those two branches of the Service as being together probably the largest users of white lead in the world. Their need for white lead is shown by the fact of their buying it, and if they found that they could use a substitute, nothing that we could argue as regards the merits of white lead would be of any use.

2607. Supposing this inquiry results—of course I cannot say how it will result—in the Committee recommending the prohibition of the use of lead or greatly restricting the use of it, would that act as a stimulus to the whole trade to find a substitute? They would be obliged to use something else than lead, and then your firm and others in your position would suffer a certain amount of injury?—Yes; it would be an absolute evil to us.

2608. I suppose you realise, do you not, that this question of lead poisoning has been receiving very considerable attention in all foreign countries?—I have read that.

2609. In France, for instance, a law was passed in 1909 for prohibiting the use of white lead entirely in five years' time, both for interior and exterior work?—I believe that is so.

29 March 1911.]

Mr. WILLIAM A. HUMFREY.

[Continued.]

2610. In countries like Germany and Belgium the use of white lead for house painting has been strictly regulated, and in Austria it was prohibited in 1909 with regard to interior work. I only mention those facts to you because it is impossible in these days for England to be behind foreign countries in protecting workmen. You appreciate that, do you not?—I appreciate that. My own opinion on that point coincides more with the practice in the United States, where the use of white lead is much more confined to places where it is necessary and where it is suitable on account of its peculiar merits, and other paints are used where they are advisable and necessary, and not as in this country where white lead is used almost universally without any consideration of the merits of other pigments. There is no prohibition in the United States as far as I know.

2611. (*Sir Godfrey Baring.*) How many men do you employ on an average?—About 120.

2612. (*Dr. Collis.*) You mentioned the United States. You said that there was no prohibition?—So far as I know there is not.

2613. You are aware that factory laws in the United States are practically non-existent?—I know that they are much easier. I was under the impression that they varied in the different States very much.

2614. They vary in the different States; there is no uniformity; so we can hardly look to the United States as being an example to us in this respect as they are in other ways, perhaps?—I meant not so much as an example but as a reasonable way of treating pigments, instead of taking it that any one pigment can be used as a substitute or a universal paint or that you can wipe out any one.

2615. The United States have not collected any statistics of lead poisoning which occurs in houses or in factories where white lead is made. It may be that they are in the same position as they found they were when they came to look into the question of phosphorus?—The Chairman was referring to countries in which white lead was prohibited entirely or partially.

2616. The United States have made no inquiry whatever into the circumstances of the case. That is the only point I wish to bring out?—Why I mentioned the United States was that, as there is no country that I am aware of where white lead has been entirely prohibited for all purposes, one has had no experience of what the effect of entire prohibition is; and I think that the reasonable way of dealing with the matter is what has become naturally a system in the United States, of not using it unless it is necessary.

2617. I follow your point. I do not know whether it is necessary to question you further on the point of the difficulty of enforcing regulations on workpeople. You have already allowed that the difficulties are considerable?—I have allowed that they are considerable as far as inspection goes. I am quite of the opinion that other regulations might be enforced. I have not in my mind any exact regulations that are enforced in the painting trade, if any, on the working painter.

There are certain voluntary precautions, some of which we take, such as the provision of milk, the provision of sulphur tablets, the provision of medical advice and attendance.

2618. The medical examination is not voluntary?—No, that is not voluntary (that was my mistake), but the other two I mentioned are. They certainly have very beneficial effects. Then there is the selection by the employer of his men and knowledge of workmen. It is possible even with scattered workmen. They must be under supervision at some time.

2619. From your own experience of the past, even with that selection, you know that cases of lead poisoning have occurred in your own works, and that it took a considerable period for you to get the protection which you desired, and that elimination, on which you are now placing some stress, of the susceptible workpeople, so that you have now only a few cases?—Yes.

2620. You had that trouble even when it was within the four walls of your factory?—Yes.

2621. However strict the regulations, do you think that any such system could be applicable to house painters?—I do not think to such a degree, or with such ease, as within the four walls of a factory.

2622. (*Mr. Kinggate.*) How many cases of lead poisoning have occurred in your works during the last five years; how many cases of death and how many cases of illness?—I have no reliable record beyond three years—from the latter part of 1907. Practically the reliable records date from the time of the Compensation Act, and the number of cases that I have a note of here (which includes the whole of the cases known as "plumbism") were 17 in 1908, 15 in 1909, and 7 in 1910.\*

2623. Those were cases of illness?—Yes.

2624. What is the number of deaths?—There was one death in 1908, included in the 17 cases mentioned in previous reply.

\* The following addendum to this answer was forwarded by the witness in a letter dated 28th April 1911:—

"It is of considerable importance to emphasise the fact that no single case of lead poisoning has taken place amongst any of our workers who handle white lead in oil. Every case that has occurred in our factory can be clearly shown to be due to work in lead products other than lead in oil, and this fact and condition of affairs is borne out by the whole of my previous experience of over 20 years in the manufacture of lead products.

"As the condition in which lead is supplied to the painter is almost universally as an oil paste or paint, and in view of the fact that he (the painter) handles such a comparatively small quantity of white lead as compared with the actual worker in a white-lead factory, and further has every opportunity of doing his work with much more care and nicety than the factory hand, it does not appear to me that with ordinary personal cleanliness such handling of the oil paint and the application of the same to surfaces can really be responsible for 'plumbism' amongst painters.

"I am of opinion that the real cause is through dust in such operations as cleaning down, or rubbing off, in the dry, and with reasonable precautions in this work the total risk to a working painter should be very small."

The witness withdrew.

## FOURTH DAY.

Wednesday, 5th April 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

LORD HENRY BENTINCK, M.P.  
 SIR GODFREY BARING, Bart., M.P.  
 MR. E. L. COLLIS, M.B.  
 MR. F. G. RICE.  
 MR. W. G. SUTHERLAND.

MR. A. GARDNER.  
 MR. J. PARSONAGE.

E. A. R. WERNER } (*Acting*  
 R. U. SHAXBY } *Secretaries*).

Mr. J. PARSONAGE (a member of the Committee) examined.

2625. (*Chairman*.) You represent the National Amalgamated Society of Operative Painters, and you are a member of the present Home Office Committee?—Yes.

2626. What practical experience have you had in the house painting trade?—I was apprenticed to the trade. I have been in it practically all my life—35 years as a painter.

2627. Have you known many cases of lead poisoning among house painters?—I have known a great many cases.

2628. Can you give us the number of members in your society, and details of the lead poisoning cases which have come to your knowledge in connection with those members?—The average number of members of our society has varied from 15,000 to 18,000. I have tabulated particulars with regard to the numbers in our society. We have had a large number of deaths, and a still larger number of cases of blindness and total paralysis due to lead poisoning.

2629. What about attacks of lead poisoning which are not fatal or accompanied by blindness or total paralysis?—Such cases are extremely numerous. They are too numerous for us to keep any record or account of. In fact the funds of our society would be altogether insufficient to allow us to make any payment except in cases of death or total paralysis.

2630. Can you give us full details of the deaths and the number of cases of lead poisoning of all kinds?—I am only prepared to speak to-day of the very large number of cases which have come before my notice—deaths, cases of blindness, paralysis, and other cases of lead poisoning, which I have referred to. I can also testify to the excessive amount of Bright's disease which exists among house painters.

2631. Can you supply us with actual numbers and full statistics?—I can substantiate all my statements by actual figures; I have a number of them, but I have forwarded all the detailed information regarding these cases to Dr. Collis, and he has undertaken to sift them thoroughly, and present them to the Committee in a statistical form.

2632. Do painters often follow occupations other than painting at certain periods of the year, and thus minimise the risks of contracting lead poisoning?—No; I should say in very exceptional cases does a painter take up any other occupation except it is at seaside resorts, that is a painter who has been brought up to the trade as a painter.

2633. (*Lord Henry Bentinck*.) He paints at the seaside?—He follows his occupation of painter nearly all the year round.

2634. (*Chairman*.) Can you tell us how much of his time is occupied at full work in the course of a year?—It varies. I could not say what the average time is. I can speak from my own case.

2635. Would you say that the men are fully employed all the year round?—No, they are not fully employed all the year round.

2636. You cannot give us any idea as to the time that they are employed?—A painter may lose from six to eight weeks in the course of the year.

2637. Now what in your opinion is the chief cause of lead poisoning?—I should say the chief cause is the dry rubbing down with sandpaper. I would put that first.

2638. What do you mean by dry rubbing down?—The process of smoothing the wood or other work which is about to be painted or repainted.

2639. What methods of rubbing down are in common use?—The wet method, which consists of rubbing with pumice stone and water, and the dry method, which consists of rubbing with sandpaper.

2640. Which process is most common?—The dry method by far.

2641. What percentage of the whole work would be done dry?—At least 75 per cent.

2642. Is this method applied to newly painted surfaces on which the paint is already dried?—Yes.

2643. For what purposes is the wet method used?—It is applied almost exclusively to the smoothing of old painted wood before new paint is applied.

2644. Why is it used for this purpose?—Because the old paint is usually very hard, and the sandpaper would not touch it.

2645. Is the wet process much less dangerous than the dry?—Yes; it involves comparatively little danger.

2646. I will ask you then more particularly regarding the dry process. At what stage in the work of painting is it employed?—In painting interior work the surfaces are first washed, and woodwork is either rubbed down with pumice stone and water or dry with sandpaper. The latter is most general now, even before the first coat of fresh paint is applied to old work.

2647. Is this then where the principal danger arises?—No; the most dangerous sandpapering work takes place after the first coat is applied and dried.

2648. Will you describe fully the operations which are gone through before the second or further coat is applied to a surface newly-painted?—The painter carefully rubs down the newly-painted work when dry with sandpaper in order to remove all particles of grit from the newly-dried paint.

2649. Does this cause much dust in the air?—Yes, the dust is dry, and, even though it is formed of white lead particles it is still light enough to float for a short time in the air which the painter is breathing.

2650. Is there a sufficient quantity of it to be visible on surrounding objects?—Yes; it covers his clothing, it settles on every ledge of the room in which the work is being executed, gets into the grain of the wood, and into each joint of the floor boards.

2651. Is it easy to collect and get rid of this dust?—Even when the clothing has been taken off and shaken, and when the floor has been carefully swept, the fine dust is still to be seen; each waft of fresh air from the door or window stirs up small particles of it, and thus endangers the health of the painters working in the room.

2652. How rapidly does the dust collect on the floor?—It collects so rapidly that if a painter keeps his feet in one place for a few minutes when rubbing a door, and afterwards steps away from the place on

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

which he has been standing, he sees on the floor a rough outline of his boot soles, caused by the white lead particles having fallen all round his boots when he was remaining still.

2653. Do I understand that this dusty process is not generally replaced by a wet process?—With one exception, the wet method is never applied to newly-painted surfaces when such are about to be repainted, where ordinary paint has been used.

2654. Has it not been stated from time to time that the wet process is applied in place of this dangerous dry rubbing?—Such a statement in connection with work where ordinary paint has been used would be quite ridiculous. No painter who values his reputation as a craftsman would dare to assert, in a meeting of practical painters, that it is in use; he would be laughed at, and any journeyman painter attempting to apply this process under the circumstances above mentioned would run the risk of being discharged for incompetency.

2655. You make that statement after considerable experience of the painting trade?—Yes. I have worked at the painting trade for over 30 years, and never during those years have I ever seen or heard of that process being applied in the ordinary way except to special work.

2656. You qualified one of your answers by saying that with one exception the wet process is not used. Will you explain this?—Yes. On a first-class job, where it is desirable that work should be finished with a high gloss, as in enamelling and varnishing, or work for hand polishing, which is extremely rare. The work in such cases may be prepared with ground pumice and felt.

2657. How is the wood or other work prepared for such a job?—Where the wood or other work is indented, cracked, or very rough, a coat of filling or stopping is applied.

2658. How is the filling made?—The filling can be made in various ways—with Japan gold size and white ead, or with ground slate mixed with some suitable vegetable.

2659. How is it applied?—This is applied in the form of a stiff paste, with either knife or brush, to the rough surface of the woodwork. It is generally applied with a broad knife, the painter taking the mixed material off a board. He holds the board in his hand. It is almost impossible for a painter to avoid getting this filling on his hands.

2660. Does this paste dry hard?—Owing to the nature of its ingredients this paste dries very hard—very much harder than the ordinary paint.

2661. Is it then rubbed down wet?—When dry the painter rubs this filling sometimes with pumice stone and water, but often with sandpaper. Of the two I should say more often with sandpaper.

2662. What is the object of the rubbing in this case?—In rubbing he has two ends in view—first, smoothness; second, the removal of as much of the filling as possible, consistent with the acquiring of a smooth surface, as the filling has no value except for the purpose for which it is definitely used.

2663. You have already told us that pumice stone and water are also used sometimes for rubbing down old paint. Why is it used for that purpose and for rubbing down filling in good jobs?—A painted surface rarely requires re-painting in less than three years. During the three years the paint has become very hard indeed, and all evidence of oil has become exhausted. In the mixing of filling little or no oil is used (usually none), therefore the filling, like the old paint, becomes hard and brittle. The brittle surface is most suitable for the application of pumice stone.

2664. (Mr. Sutherland.) Are you referring in that answer to paint or to filling?—I am referring to both the old paint and the filling.

2665. (Chairman.) The amount of oil used then is the important distinction between filling and old paint and ordinary newly dried paint?—Yes, oil, absent in the first two cases, is the most valuable medium with which paint can be mixed; one of its chief characteristics is its slow drying quality, which, within a certain limit, is, in itself, very valuable, as slowly drying or

slowly hardening paints are more durable than paints in which the drying quality is forced or rapid.

2666. How long is it before a coat of ordinary paint is ready for a further coat?—It depends on the mixture of the paint, the ingredients, and the vehicle used in them, but it is ready at the end of 24 hours' drying. But, though then dry, the hardening process would continue for some days, in fact long after the painter had completed his job.

2667. Is it not possible to rub such paint with pumice stone and water in between coats?—To rub such paint with pumice stone and water at any time during the hardening process would be very unwise, as the painter in doing so would run the serious risk of tearing the surface of the paint, thus doing serious damage.

2668. Could the painter overcome this difficulty by exercising great care?—It would be possible though it would be extremely difficult.

2669. Would it involve further difficulties?—Yes. The soft paint would get into the pores of the pumice stone and "clagg" it; in other words, hinder it from readily passing over the painted work, thus defeating the end which the painter had in view.

2670. Does this difficulty not arise with sandpaper?—In many cases sandpaper will "clagg," but not so soon as pumice stone. Sandpaper is the very best material known for the purpose now under discussion.

2671. Would it not be possible to insist on the wet process being used more generally?—We have not the least desire to see its use restricted. To seek to insist upon the wet process being substituted for the dry would be highly impracticable. It is not the rubbing which is at fault, but the material which is rubbed.

2672. You have now given us details regarding what you feel to be the most dangerous of the house-painting processes. What do you consider the second most dangerous process?—The painting of ceilings which have been covered with relief decoration, moulded or raised designs.

2673. Is white lead much used for such work?—As such ceilings are invariably finished in light colours (either white or cream) white lead is the chief material used.

2674. How many coats are generally used on such work?—This class of work (for ceilings) usually gets two coats of oil paint and one coat of flattening, but as the flattening process is now being displaced in many cases by the use of non-poisonous paints, we are concerned mainly with the ordinary painting in oil colours of these ceilings.

2675. Does much splashing arise from this operation?—In the painting of relief decorations (raised surfaces), owing to the fact that the paint has to be pressed with the paint brush into the background of the ornamental work, considerable splashing takes place, the splashes being very small in size.

2676. Does lead paint get splashed on to the face?—The painter must necessarily stand directly underneath the material which he is painting, having his face upturned; it necessarily follows that he catches on his face, and on his clothing, a continuous shower of very fine paint splashes; some of these splashes are on his lips, and, therefore, come very closely into contact with his saliva. The bitter taste of the paint is present shortly after commencing the process, and he is conscious of the presence of paint on the inner side of his lips for some time after finishing such work.

2677. Is the process called "stippling" similar to this in all respects?—Yes, it is. The paint is first applied with the ordinary paint brush, and then there is a square dry brush which is not put in the paint at all—it would be perhaps 9 inches square—and that is to hit the whole of the paint into the ornament, and the splashes, of course, fall down from that.

2678. (Mr. Rice.) Is stippling equally as dangerous as cutting into the ornaments of the ceiling?—I should say it is the more dangerous, because probably more splashes and drops fall from the stippling.

2679. (Mr. Sutherland.) Not from the stippling?—Yes, I should say it is so. It is a matter of opinion. Perhaps I should say that one splashes equally as much

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

as the other—that there is as much splashing from the stippler as from rubbing in with the brush.

2680. (*Chairman.*) Could a man possibly wear a respirator when doing such work?—The wearing of a respirator would be almost an impossibility, for the following reasons: To carry out the process he usually has to stand on a plank, the two ends of which rest upon trestles or step-ladders, there being no support to the middle. The plank, therefore, oscillates while the painter is at work; the painter must exercise care to maintain his balance. In his left hand he holds the vessel containing his paint; his right hand is used to manipulate the paint; his face must be upturned to enable him to see his work. To further encumber the painter with a respirator under those circumstances would be an act of cruelty; not only that, but the suppleness of his neck would be lessened, thus making it difficult for him to move his head. I am of opinion that any unusual restriction of the moving of the neck muscles would positively lessen his power to maintain his balance on the plank on which he is standing.

2681. Apart from that, have you ever seen a respirator that was comfortable to wear?—Never. Even if the employer was compelled to provide respirators, we feel that he would have the utmost difficulty in compelling his workmen to use them.

2682. Would it be possible to secure a proper, clean place for keeping respirators?—When not in use these articles must, of course, be kept somewhere; if on the job where the painters are at work (certainly the likeliest place), then they will be kept in the room which is being painted, where the paint is stored, and where bad air is ever present. Under these circumstances I readily say that I would rather run all the risks which a painter usually runs of contracting lead poisoning than adopt such preventives. The respirators would most probably be kept in the box of the man who was in charge of the job, where he would keep a number of his brushes and probably the stipplers too, and they would smell very strongly of paint.

2683. Can anything be done to introduce ventilation which will remove the danger? I mean by that, exhaust fans and the like?—I should say not. In a factory specially constructed, or adapted, for the carrying on of any process in which white lead is introduced it is quite possible to provide the necessary air-shafts and air-currents, and thus furnish a maximum of fresh air, or to adopt some method of suction by which poisonous substances may be removed; but it must be remembered that a living room in a house is constructed for quite other purposes than that of providing prevention against lead poisoning. Even the ordinary method adopted by a family to purify rooms, that of throwing open doors and windows, cannot always be adopted by a painter when paint is wet. This is more particularly the case in large towns, where dust and soot would positively ruin the work in hand. I wish to impress the fact that the successful carrying out of a painting job positively necessitates the closing of the doors and windows when paint is wet.

2684. What hours do the men work in such confined rooms?—The hours generally would be from 50 to 56 in town work, but in the country they generally work from 66 to 70 hours per week. They are not at painting all that time.

2685. Have the men ever instituted any suggestions that the hours of labour should be limited?—Yes, frequently, and the hours have been reduced considerably. The hours have been reduced these last few years a good deal.

2686. The Committee which sat on the Earthenware and China Inquiry unanimously—employers and employees—decided that the hours of labour in certain processes should be limited to 48, because of the grave dangers which ensue from breathing lead dust?—The painter who goes away into the country requires to work long hours, or it would not pay him to go, having his home to keep in the town, and to pay for himself in the country as well.

2687. All the medical evidence at our late inquiry showed that the dangers of inhaling lead dust were so great, and that they impaired the constitution to such

a high degree, that it was absolutely essential to limit the hours to a certain number.

(*Lord Henry Bentinck.*) Are you counting the travelling to and fro in the 70 hours?—No.

2688. Actual painting?—I am counting from the time he arrives on the job.

2689. (*Chairman.*) My question was, What hours do the men work in such confined rooms? Do you consider that lead poisoning can be contracted by breathing contaminated air?—Yes, I do consider that it can be contracted by breathing the fumes from the paint when it is being used and when it is wet in the room. I could not enter into any system of analysis to support that contention, but as painters' work necessarily varies in some degree, even when working in one room, there is no means of demonstrating that breathing the fumes arising from the process of painting has, in any one case which we know of, caused lead poisoning, but I positively believe that fumes arising from the lead do cause lead poisoning.

2690. That is what Dr. Baly said?—Dr. Baly rather supported my idea, but I have always had that opinion, and I think that 99 per cent. of painters would hold that view.

2691. Is a painter frequently sensible of the taste of paint in his mouth?—When a painter is working in a room in which large spaces of ceiling, walls, and woodwork are being covered with lead paint he becomes conscious as the day advances of having a very bitter taste in his mouth; if he thoughtlessly licks his lips the bitterness becomes intensified. I wish to point out that it is not necessary for him to have splashes of paint on his lips to enable him to realise the bitter taste. It is a somewhat difficult matter to account for this, but I am certain that you can taste dust.

2692. Do you believe that the mixture of white lead, oil, and turpentine gives off different fumes from those which arise from these three ingredients separately?—Yes. If a keg of white lead stood in the middle of a room with the lid taken off the keg nobody could smell the lead. If a keg of linseed oil stood in the room there would not be an objectionable scent from that. A keg of turpentine would cause a strong but harmless scent. Now break up some of the lead in portions of oil and turpentine, then all persons who stayed for some time in the room would be aware of a very offensive scent. Some would become ill in the presence of it. As the day advanced those staying in the room, even though they did not touch the paint, would begin to taste the paint in their saliva. Our theory is that the oil and turpentine release a certain quality in the lead which has hitherto lain dormant. The air becomes charged with a poisonous substance which is dissolved by the saliva, and thus sets up lead poisoning.

2693. Can you tell us anything of the possible ill-effects arising from the burning off of old paint with a spirit or charcoal burner?—When paint has been removed by burning off with a blow lamp the surface of the work and all mouldings, &c., has to be sand-papered. This is very dangerous, owing to the dust which comes from the rubbing down.

2694. How and where are the colours usually mixed?—On ordinary jobs, the man in charge of the job generally selects the largest room, and the paint is usually mixed in that room. He has a bench fixed in the middle of the room.

2695. Is there much danger of its being inhaled in this operation?—There is not so much danger; not much dust arises from that. The lead is always in paste form. But I have seen many cases of men, who usually are kept to break up the lead in the paint shop, who have suffered from contracted muscles and dropped hands, as we call them, more than the painter who is ordinarily using the brush. How they got that I could not explain, but I have known the man that mixes up the lead to suffer from dropped hands.

2695a. (*Lord Henry Bentinck.*) Is the lead in the form of paste?—Yes. The lead is always supplied in paste form.

2696. (*Chairman.*) Is it a damp paste?—It is very stiff. It is ground with oil. He will take it out with a large knife and have a stick and break it up.

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

2697. (*Mr. Sutherland.*) Not with his hands?—He will never break it up with his hands, but he will get the lead on his hands.

2698. (*Chairman.*) Is this a special job? Do men continuously work on this one operation?—Not generally. In large building firms the man in charge will have a labourer with him who will do this work.

2699. (*Sir Godfrey Baring.*) And do nothing else?—And do nothing else. There is no certainty that one individual will continue to do it.

2700. (*Mr. Bice.*) Is he a colourman?—Yes.

2701. He would be a labourer?—No; in many cases he will be a painter, but on building jobs the colourman will have a labourer to assist him, and then the colourman will put the finishing preparation to the paint.

2702. Who would suffer from dropped hands—the labourer or the colourman?—The colourman generally—the man who breaks up the paint. It is generally a painter who does that.

2703. (*Chairman.*) Is there any dust arising from the operation?—No, it is not dust. I cannot account for how they get dust.

2704. Do they get their hands much soiled?—They are bound to get the lead on their hands.

2705. Is there a very high percentage of lead in the dust; it is all lead, is it not?—It is all lead. The paste is genuine white lead.

2706. He gets a full dose very highly charged with poison?—Yes.

2707. (*Lord Henry Bentinck.*) Does the lead have a very strong smell?—Yes, there is a strong smell arising from the lead, and the man would be frequently leaning over the lid of the cask to get this very stiff stuff out with a knife. Then he puts it into a large "kettle," and he has a stick and breaks up the oil and turps into it to bring it up to the consistency required for use. It seems to affect the men in the muscles and in the hands more than generally.

(*Chairman.*) But that is impossible. It must go into the blood and affect the constitution.

2708. (*Dr. Collis.*) After how long at the work?—It would take some years, I dare say, to bring that about.

2709. (*Chairman.*) The most chronic form of lead poisoning is what is called "wrist drop"?—I know a case of a man, as healthy-looking a man as you would ever see, two years ago in London, who died in three days from lead poisoning. It was positively proved that it was lead poisoning. He was working night and day to get the job finished.

2710. Can you name any other processes in which there is a grave risk of the painter inhaling dust or fumes?—There is great risk from the dust that arises from scraping off old paint. Sometimes the paint is very old and brittle, and it can be scraped off dry, and that has very frequently caused lead poisoning. I consider that that is very dangerous.

2711. Do you think then that the provision and use of washing conveniences is important?—Yes, I do.

2712. Including hot water?—Yes.

2713. Is this always practicable?—I cannot see how it would be practicable to insist on such regulations being enforced. For instance, when the exterior of a house only is being painted the men are not expected to go inside for any purpose; and even inside, when a particular room, such as a drawing room, is being painted, it is not uncommon, particularly in London, for the men to have to go up a ladder to the window of the room they are working in, and to go down that way. On large building jobs particularly, or jobs where there are a large number of men, the men are not supposed to leave their work until the whistle blows for meals. They all rush to the paint shop and they are all wanting to wash their hands, and there is only one pail of water probably. That will become almost as thick as soup. They have to get out and get back again in half an hour.

2714. Is it possible for a lot of men like that to clean their hands properly in one pail of water?—It is impossible. Sometimes they try to get away a minute or two before the time quietly without being seen and wash their hands. A painter generally carries his own piece of soap with him. It would not do for them to

rely on finding soap provided at the job by the firm or the man in charge.

2715. (*Mr. Sutherland.*) You mean in a new building?—I am speaking generally.

2716. (*Chairman.*) Do painters usually wear overalls whilst at work?—The workman wears, generally, a white blouse or apron, or white jacket.

2717. How often are these washed?—They are usually cleaned every week.

2718. Where are they kept?—The workman will carry them with him in his bag with his tools, and on leaving off work for the day leave them in the room or place where the painter is mixed generally. That is where the man in charge of the job has his bench, and the painter's coat is usually hung up in this room during the day.

2719. There is, I suppose, some danger of dust arising from a dry overall that has been worn on a previous day, and this dust might easily be breathed?—Yes; the dust will probably remain. I have seen the painter many a time take off his blouse, take it outside and shake it when he is rubbing down a lot of work and shake the dust out of it.

2720. That is a good plan. I may tell you that in the earthenware trade we have recommended insisting on the men wearing an apron that can be washed every day, because it was demonstrated beyond question to me and to the Committee that the accumulation of dust that collected on the overall was a tremendous source of danger. One puff and a man breathed the dust immediately. With a view to meeting that we combined with overalls, cleaned once a week, a sort of mackintosh apron in front, that could be sponged down every day, so that there should be no dust there at all?—Yes.

2721. Is food always kept and eaten away from any possible contact with lead?—No. It is a common practice in large towns, especially in London, for the painter to carry his food with him from home, generally in his coat pocket, which hangs in the paint shop all day, and when he is able to make tea on the job the food is generally eaten in the paint shop.

2722. There, again, I may mention that we have recommended strictly prohibiting in the earthenware trade any meals whatsoever of any sort or kind, or any food being taken, in any place where lead dust arises. That is an absolutely cardinal law?—The food will positively taste of the paint. You can taste it in the bread, and smell paint in it.

2723. Is it not always practicable to arrange for a meal room to be provided so that no food should be brought into a place where painting work is being done?—No. They may possibly be doing only one room or two rooms, and all the rooms that are being done may be under paint at the same time, and unless the man went out he would have to sit in these rooms to eat his food.

2724. Do you consider that all the evils arising from eating with unwashed hands and from dirty overalls and the like are necessarily small in comparison with the dust and spray arising in the course of the man's actual work?—Yes, I do consider that they are much smaller than the dangers arising from the dust, because the painter himself tries in every way possible to keep himself clean, and particularly to keep his hands clean.

2725. How can the evils arising from such dust and spray be overcome?—I cannot see how it can possibly be overcome so long as the evil is in the material used, and it would only be by the prohibition of the material that it could be done away with.

2726. Is it quite impossible to apply exhaust apparatus for the removal of such dust and spray?—I should say it is quite impossible in the ordinary painter's work—in ordinary house work.

2727. Now, you have told us that it is not practicable in all cases to replace the dusty sandpapering by a wet method of rubbing down?—Yes.

2728. In cases where it is possible to do all the rubbing down wet, would this remove all the danger attendant on the use of lead paints?—No, it would not remove the danger entirely, but would greatly reduce it, but I never knew a job where it was possible to do

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

all the rubbing down wet. I have never heard of a job where it would be possible to do it; it is an impossibility.

2729. (*Lord Henry Bentinck.*) Why? Is it not merely a question of time?—No. You may rub down a newly painted surface after it is first painted, with pumice stone and water, but you would simply be removing what you had just applied.

2730. It all depends on the time you give it to dry, surely. If you gave it an extra 24 hours that would do, would it not?—No, it would not. It would "clagg" in a fortnight afterwards. Directly you applied the pumice stone and water you would take off the new paint, and would simply be doing damage.

2731. (*Sir Godfrey Baring.*) It is absolutely impossible, in fact?—It is absolutely impossible in the ordinary way to rub down freshly painted work with pumice stone and water.

2732. (*Chairman.*) Could the painting processes which chiefly give rise to spray, such as stippling work, be prohibited, or at least so restricted as to remove the danger?—Well, this work could be done by non-poisonous paint; in fact, the patent distemper paints that have been introduced in these last few years are now largely used instead of lead paints for ceilings. That is the only way in which the danger could be prevented, by substituting a non-poisonous material, and in no other way.

2733. (*Lord Henry Bentinck.*) Do the distempers contain non-poisonous material?—The distempers contain no lead.

2734. (*Sir Godfrey Baring.*) Are the results as good with those distempers?—Yes, but they have not the durability, because they could not be washed again. One or two could, but the ordinary distemper could not.

2735. (*Mr. Rice.*) Do you call the ordinary distemper a non-poisonous paint?—No.

2736. (*Mr. Sutherland.*) You are not suggesting substituting the ordinary distemper for paint for ceilings?—No.

2737. You are speaking of some of the washable distempers?—Yes, I am speaking of some of the washable distempers. They claim to be washable distempers, but you cannot see a decent job after one of them has been washed.

2738. (*Chairman.*) You may probably be aware that in all industries where the use of lead is allowed by the Home Office a periodical medical examination is insisted upon?—Yes.

2739. And if at the end of this inquiry the Committee recommend allowing lead to be used in this industry in the future, such a system of medical examination should be employed in this industry?—Yes.

2740. Do you think that that would be practicable in your case?—I do not think it would. I think there would be so many painters rejected that really I do not know what would happen, for I believe that more than 50 per cent. of the painters would show traces of lead poisoning, and if they were cast on one side I do not know where they would find men to do the work.

2741. That is only your own opinion?—No, it is not only my own opinion. A little time ago I had to complain of a surgeon giving certificates. In February of this year I had a claim come in for a man suffering from paralysis, and he was certified to be suffering from chronic lead poisoning. He was only admitted into the society at the beginning of December last year. I wrote to the doctor and asked him how he came to pass a man who must have shown signs of lead poisoning at that time, and his reply was that if he had to reject all the painters who came that showed any trace of lead poisoning he would reject 90 per cent. of those that came to him.

(*Mr. Sutherland.*) That is an *ex-parte* statement.

2742. (*Chairman.*) Would he give evidence to that effect if he was called by the Committee?—That I could not say. I have not asked him that. I wrote objecting to his passing this man, and that was his reply.

2743. (*Chairman.*) We had better take his name and ask him to come and give evidence?—He is an

ordinary medical practitioner. He is not a specialist in lead, and that may have been his excuse for passing these men. But I believe myself the more than 50 per cent. of them would show traces of lead poisoning.

2744. (*Lord Henry Bentinck.*) They told me in Nottingham that they were not troubled very much with lead poisoning, because they kept themselves very clean?—I could bring you some newspaper cuttings referring to inquests held recently on our men who died from lead poisoning in Nottingham. I would like to answer a little further with regard to Nottingham. Nottingham is exceptionally favoured in one respect, that they employ more genuine painters in Nottingham than they do in any town in England. If a painter there goes to ask for a job the employer himself asks him if he is a painter, and if he is a member of the Painters' Society, and if he is not he tells him that he will have to become a member the first week or he cannot be employed. That ensures that he has men who have been brought up to the trade.

2745. Yes, that is what they told me?—That is why. The employer himself insists upon having a man who has learnt his trade and is a member of the trade union.

2746. (*Chairman.*) Does that imply that the men are more careful?—Certainly.

2747. How would you get over the difficulty that you have put before us of the impossibility of preventing men contracting lead poisoning from the spray and dust?—The difficulty could not be got over except by doing away with poisonous material.

2748. You rather inferred, I think, that the Nottingham men, being men of greater experience, were more immune because of their cleanliness?—I say that there would be less danger there because they ensure that they get good men—more particularly there than in any other place.

2749. But the very best man in the world would not be free?—He would not; but my contention is that thousands of men come casually into the trade in London, and they do not know the risks they are running, and they are more careless. A painter who has served an apprenticeship to the trade knows the risk he is running, and he is careful. I do not think that there is a more cleanly man than the painter as a painter.

2750. Is much compensation for lead poisoning claimed under the Workmen's Compensation Act?—We have a great many cases. We have cases every week. I have two cases here that came in yesterday. In one of these cases the man has received compensation for two years exactly, and at this time the insurance company are making application to reduce the payment. He has received a pound a week for two years. This is a Manchester case.

2751. Has your society paid much money to members?—Yes, in sick benefit to our members, and we only pay for total paralysis from lead poisoning. Dr. Collis has all the information. The compensation that we recover from employers on behalf of our members we keep no record of. I know up to thousands of pounds were recovered last year, but that would not be a tenth part of the amount that is recovered in the courts by painters from employers under the Workmen's Compensation Act. Hundreds of cases get paid without going into court at all. The cases that are taken into court are the only cases we get any knowledge of, because the men have to apply to our head office for legal assistance, and that is always at once given.

2752. (*Lord Henry Bentinck.*) You keep no record of those cases where compensation is given without any legal proceedings?—No, no record whatever of those where the insurance company will pay without it going into court.

2753. (*Chairman.*) Do you find men reluctant to claim compensation?—Yes, and that is becoming more general. I have a witness to-day who will be able to give you specific instances of insurance companies preventing men getting work again at their trade after receiving compensation, and the men prefer, in slight

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

cases, rather than run the risk of losing their employment and being prevented from getting a job, to go on our ordinary sick benefit.

2754. Have you known men affected by other diseases which are intensified by the fact of their having lead in their system?—Yes.

2755. Even if they do not actually claim to be lead poisoned?—Yes. The majority of our cases are diseases that follow on or are consequent on lead poisoning.

2756. To sum up, then, so far as the methods of painting in vogue to-day are concerned, do you assert that it is impossible to stamp out the evil of lead poisoning without replacing the lead by some non-poisonous substance?—Yes, positively; it could not be.

2757. Have you yourself had experience in the use of non-poisonous substitutes for white lead?—No, I have had no experience of any value in the use of them. I have only seen experiments, but I can say nothing personally as to their durability.

2758. Have you formed any opinion as to their practicability for general use?—Yes, I have come to the conclusion that there are substitutes which could be used for white lead, and which could reliably take the place of lead.

2759. We have heard some suggestions of a reluctance on the part of some painters to adapt their methods of work to the peculiar requirements of zinc and other leadless paints. Did you find any difficulty in using such paints?—As I say, I have not used them, but I believe that the painter would readily adapt himself to the methods, as I consider that the principal thing is the proper mixing of the material.

2760. Do you think that such difficulties are not insuperable?—Certainly they are not.

2761. (*Sir Godfrey Baring.*) With regard to slack periods, I suppose there is a time in the year when painters are very slack indeed?—Yes, in the winter time generally.

2762. Is it your experience that they do not try to get any other employment during that time? I mean are they content to stand off?—They are not content to stand off. They are out every day looking for work. I might explain that my society pay unemployed benefit. Even last winter we paid out over 30,000l. to our members in unemployed benefit. But a condition of their obtaining that benefit is that they look for work every day.

2763. But as a matter of practice few of them obtain other work. Is that your experience? If a man is a regular painter he does not readily obtain other work during slack periods?—No, he does not. It generally depends on the man's ability as to the quantity of work he gets in the slack time.

2764. As regards cleaning, as far as your experience goes, would there be an objection by the foreman or by the employer to a man knocking off five minutes before meal times to wash himself in the employer's time?—Yes, he would get the snook if he was caught.

2765. You say that definitely?—Yes, I say so. I would qualify that by saying that purely painters' firms do allow time a little more than builders' shops, but on large jobs under large firms they are strict to time, and a man must wash in his own time.

2766. (*Lord Henry Bentinck.*) You said that they had to wash in the paint shop. The paint shop is the room in the house which they are painting, where the paints are?—Yes; that is generally where they would wash their hands. The paint is generally kept on the end of the bench where the foreman or man in charge of the job mixes up his paint. The soap is generally on the end of the bench.

2767. Would it be possible to have a legal provision to enforce the supply of so many pails for so many men on this class of job? Could you insist on that?—I cannot see how it would be possible to enforce that at all. The pails may not be required. There may be only one pail on the job if it is simply a painting job.

2768. But suppose that Parliament should lay it down that contractors' men should have so many pails, do you think it would be possible to enforce that?—I do

not think it would be possible to enforce a condition of that kind.

2769. Why not? If you had the right of objecting because there were not enough pails—the employer would be forced to provide them, would he not?—Yes, but I do not know how it would be carried out at all. There is so much difference in the size of a job; there may be half a dozen men on the job one day, and they may send another half dozen the next day, and they may be there for a day or two and then be drafted away again.

2770. Those men drafted away would not be in charge of the chargeman?—No.

2771. They would be on their own?—Yes, they would be workmen.

2772. Under the foreman?—Yes, under the foreman.

2773. Would it not be possible to ensure that the foreman provided the pails. If they have 20 men, they should have, I suppose, about four pails?—No. I have seen jobs where there have been 40 and 50 men and only one pail of water.

2774. But my point is, would it not be possible to make it a law that so many pails should be provided. If there were 40 men, there should be five pails, say. Would it not be possible to carry that provision out?—No, I do not think it would be possible. The pails would be used on the job for the purposes of doing the work, and when they were required for the men they would be found to be filled with distemper or some other material, and could not be used.

2775. If it was a legal provision that so many pails should be provided, the men could insist that those pails should be kept for their own purposes, could they not? They would not be so helpless as all that, surely?—You would require inspectors to go round. That would be the only way. It would not be fair to put it on to the workman to lodge the complaint.

2776. I see your point.

(*Mr. Gardner.*) I will give you an instance of why it would not work. Take a large house or a job near the painter's own workshop. There may not be a hurry. He uses that job as a "hospital." That is a trade term. One day you might have 20 men on the job, and the next day you might have none. The employer might send up a squad of men in the morning, and withdraw them again at breakfast-time. It is simply treated as a stand-by. If he has a big outside job on, and there comes a wet day, he would say, "You men had better go round to so-and-so's job."

2777. (*Lord Henry Bentinck.*) But the chargeman could carry the pail round with him, I should have thought?—I should like to see him do it.

2778. (*Sir Godfrey Baring.*) Is it your experience that on some jobs it is perfectly impossible to provide hot water?—Yes.

2779. In empty houses in towns?—Yes.

2780. We had evidence from the first witness, a gentleman from Newcastle, Mr. Laidler, that when there was no possibility of finding a fire in an empty house it was usual to send someone round with coals and wood to make a fire to heat the water?—That is when they require the wood and coals for the purpose of melting size or what is required for carrying on the work, but not for the purpose of providing hot water for the men, not for the men's convenience.

2781. You have never seen that done for the men's convenience?—No, I have never seen it done for the men's convenience.

2782. Speaking generally, is it your experience that men are ready to take full advantage of every kind of method for cleaning themselves that is provided?—Yes, they do.

2783. A good painter is anxious to keep himself clean?—He is, and he usually carries a piece of soap himself, and if he sees an opportunity of getting away a minute or two before time and washing his hands he does it; but he must not be seen doing it too often or he will be discharged.

2784. (*Dr. Collis.*) Have you ever seen paint applied with an aerograph?—No; is that a spraying machine?

2785. Yes. Have you ever seen paint applied with a spraying machine?—No. I have heard of them. We forbid our men to work with them.

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

2786. I wanted to know whether you thought that the spray caused by the splashing of the stippling was as fine as that produced by the aerograph; but you have not seen it used?—No, I have not seen it used.

2787. With respect to the question of respirators, I think you recall Dr. Baly's evidence that it is possible that vapour comes off from drying lead paint?—Yes.

2788. You know, of course, or may I suggest it to you, that any form of respirator, which is, after all, only a mechanical filter, will not stop vapour or gas?—It will not stop it.

2789. It will only stop dust?—Yes, it will only stop dust.

2790. You agree then that if Dr. Baly's suggestion proves to be a fact, that lead mixed with oil gives off a vapour, no respirator would be of any value?—Yes.

2791. Have you ever yourself worked with zinc paints knowing you were working with zinc paints?—No.

2792. Have you never worked with zinc paints at all?—Oh, yes, I have used zinc white.

2793. Can you tell me, when you were using zinc paints did you notice the same taste as you did when you were using a lead paint?—No.

2794. In what way does it differ?—I did not notice any particular taste in using zinc, but in using lead there is always a bitter-sweet taste.

2795. And that is distinctly absent when you are using a zinc paint?—Yes, it is.

2796. I think you also stated—I wish to have the matter certain—that the stiff paste as it comes in a paint pot also has the same smell?—The paste lead has a peculiar smell in the keg, but it is a smell peculiar to itself different from when it is mixed with the vehicle for applying it for use.

2797. One point as regards the medical examination. You instanced a doctor who stated that it would be impossible to pass any people as painters if he refused all in whom he saw traces of lead. You are aware, I presume, that it is possible to detect traces of lead absorption in the human body without the individual who shows those symptoms having lead poisoning?—Yes.

2798. So that it is possible that this doctor was speaking of such cases, showing, we will say, a light blue line, when he made this statement that all painters would have to be refused?—No, he did not say that all painters would have to be refused.

2799. The greater proportion?—Yes. I have his letter here.

2800. The greater proportion; that will be sufficient?—In fact, he said that this man did not show signs of chronic lead poisoning at the time he passed him, but he would show a trace of lead absorption.

2801. As a matter of fact, in medical examinations conducted in lead trades we do not expect medical men, perhaps you are aware, to refuse men who show such slight traces?—No.

2802. So that the wholesale rejection and bringing to an end of the whole of the painting trade by the doctors rejecting all the men submitted to them would not really occur?—It would not if they were only going to reject the severe cases, but if they were going to reject every man who showed a trace I do not know where we should be.

2803. Personally, I do not think that this would be a reason for rejecting the medical side of the suggested precautions. They have to be used in the other trades, and we have not found that trade is suspended in consequence. It rights itself?—Yes.

2804. Can you suggest any way in which, if it were insisted upon, such medical examination could be carried out; where, for instance?—I could not say what would be the best way, because a man is so often changing his employment from one firm to another.

2805. Do you think it would be possible for a painter to be treated as the stonemason in Holland (I think I am correct in stating), having to get a trade certificate, which has to be submitted to a doctor periodically for his signature?—Where does he get the certificate?

2806. From a doctor. It is supplied by the State, and he has to get it countersigned periodically during

the course of his life's history. It is a trade-health certificate. There are certain supervisions, and up to 21 he gets dismissed from his trade entirely if his health breaks down. After 21 they watch his health. They consider he has learnt his trade then and they cannot turn him out. Later on it acts in his own interests as telling him how he is. He gets examined for nothing. Do you think that if such a trade-health certificate was kept by painters it would be possible to catch them when they did not go and submit themselves to medical examination?—I do not think it would; I do not think so at all.

2807. Because they are scattered so much about at their work?—Yes.

2808. It would really be impossible to find a man always who had submitted himself to medical examination?—Yes.

2809. Do you think it is likely that a man would submit himself, if he was feeling a little ill, and wished to earn full wages, for medical examination, thereby running the risk of being put on half wages?—Not unless the law was altered with regard to compensation so that he would not suffer in any way by submitting himself to medical examination: under present conditions he certainly would not submit himself.

2810. You think he would voluntarily withhold himself from such examination, and it would be practically impossible to catch him?—Yes.

2811. Those are the real difficulties, from my point of view, on the medical question. With reference to Nottingham painters, you consider that one reason why painters there do not suffer so much from lead poisoning is that they are all apprenticed?—I consider generally that the painter who has been apprenticed to the trade as a painter does not suffer so much as the man who casually comes into the trade, as unfortunately many of them do, especially in London.

2812. Your suggestion is that the men who have been long in the trade do not suffer so much from lead poisoning as men who have come into it recently?—That is so.

2813. You have suggested that cleanliness is one of the reasons?—Yes.

2814. May I draw your attention to the answer to Question 277, asked of Dr. Legge when he was examined: "My colleague, Dr. Collis, has brought out "the fact that attacks of lead poisoning are commonest "in the first and second years of employment"?—I remember that.

2815. The point that I would suggest on that is not absolutely a proven one, but perhaps you might agree that men, by prolonged exposure, get a certain immunity, apart from washing?—That is a statement by Dr. Legge that I agree with. I asked Dr. Legge about it at the time. I am referring to men who come into the trade, and, not having been brought up to the trade, they do not know the risk and danger they are running, and they do not take the precautions that a painter does.

2816. I understood that was your point of view, but I wanted to see whether you would possibly agree with another point of view or explanation of the same phenomenon, namely, that a man who is long exposed to lead gets a certain immunity to the influence of lead. I suggest to you that there is medical evidence to support that. I wish to bring the point out because I think too much reliance is being placed upon the possibility of providing for the house painter, washing accommodation and means for cleanliness. Personally I think we can hardly touch the question of lead poisoning in that way, and I only wish to know from you whether you would be inclined to agree that there is this other method of explaining the phenomenon?—Well, I think it all depends on a man's constitution. I have known the most cleanly and careful men suffer continually from lead poisoning. I have had lead poisoning myself. I had it for three months. I attended Westminster Hospital for three months, and I was always extremely careful and extremely temperate in every way. But my constitution rendered me more liable to it, and I do not think there are any

15 April 1911.]

MR. J. PARSONAGE.

[Continued.]

two men alike in that way. So far as cleanliness is concerned, I believe that any man is liable to take it, however cleanly he is.

2817. That is the point I wish to make clear, that so far as cleanliness is concerned any man is liable to take it?—Any man is liable to take it.

(Dr. Collis.) With that I myself practically agree.

2818. (Mr. Sutherland.) I would like to clear up the point raised by Lord Henry Bentinck and Sir Godfrey Baring about the provision of washing accommodation. In the rules between your men and the employers, in some cases I know that it is so; is it not generally a rule that provision shall be made for hot water for meals?—No, it is not.

2819. It is in Manchester?—Possibly, but every town makes its own working rules.

2820. But what obtains in Manchester can surely obtain elsewhere. It is so in Southport?—I know it is so in Manchester, but it certainly is not followed out; I would not like to say that it is. I do not think it is in their rules that hot water shall be provided.

2821. Yes. When the arbitration was before Mr. Hudson it was a point that was made a good deal of, and it was included in the working rules. Wherever there is water for the purposes of carrying on a job there is also the convenience for getting it hot, is there not?—There generally is.

2822. Speaking broadly?—Except in empty houses and those kinds of places.

2823. Even in empty houses if it is a job of any importance the employer sends coal and wood?—Yes.

2824. Fuel for fires?—Yes, for the purpose of heating the size.

2825. But it is there for the men to use for their own purposes, for making hot water for their meals and for washing purposes?—They do not generally get hot water unless in the winter time they want it, because cold water is too cold.

2826. They get hot water for their breakfast and for their dinner?—Yes, for making their tea.

2827. Then if they can get it then they can get it for washing purposes?—They would not be allowed to get it.

2828. It is no good making the case difficult, is it?—No; I am not trying to make it difficult.

2829. Because in the great majority of cases there may be occasionally a case where through some extraordinary cause the difficulty of getting hot water does exist you cannot accept that as a working rule at all. How do you account for this, that in Scotland, where there is just as much lead, probably more lead, used per man, per operative painter, than in England, and where the work is thoroughly done, lead poisoning is a very much smaller element of disease in painters than it is in England?—If the cases are so much smaller there I cannot account for it.

2830. They are very much smaller?—If you take the population of London and the population of Scotland—

2831. I am taking the percentages. They are very much smaller?—Have you any statistics to show that?

2832. Dr. Legge's statement in this report, that Scotland is practically immune from it, and he attributes it to the stone buildings. But I do not agree with him there?—Even admitting that, I think I can explain it. If you take the percentage you must take the radius where you get the percentage from. In London there are 6,000,000 people within a radius of 12 miles. You will not get 6,000,000 of people within a radius of 50 or 100 miles in Scotland.

2833. But if lead and oil and turps are poisonous in London, the same things must be poisonous in Scotland, and if they are not, why are they not?—We will take a large hotel in London that is being painted. You will get 100 painters on it, and they are all confined in the rooms of the hotel, and the windows must not be opened or the paint will never dry. The window is painted first and closed up. The paint would never dry if there was a draught of air. In Scotland you would go a long way to get 100 painters; they would be scattered.

2834. But there are big hotels in Scotland, the North British Hotel, for instance; and they are under

pressure just the same?—In spite of what you say, I would say that the percentage of lead poisoning cases in Glasgow is as large as it is in London. But you are taking Scotland generally.

2835. Yes?—Take the area of the South of England. There are very few lead-poisoning cases in the South of England in the agricultural districts, Wiltshire, Berkshire, and all through there. I would compare that with Scotland. I do not think it fair to compare London or Manchester with 7,000,000 of people within a radius of 20 miles. You cannot compare London with great open country like Scotland.

2836. But, speaking generally, these men are amongst the best-trained men in the business, are they not?—Yes.

2837. Scotch operative painters are well trained?—Yes.

2838. They use lead very extensively?—Many of them come to London and get lead poisoning.

2839. The conditions of a lot of Scottish painting where they go to gentlemen's mansions are just the same here in England, and why is there a difference? They are out in the open country?—I do not know whether the Scotch are hardier or what it is. I have known men go from London to country jobs in Scotland and be sent home to London with lead poisoning. I have known four men sent back from one large job.

2840. From Scotland?—Yes.

2841. (Chairman.) Is there as much lightly-tinted painting done in Scotland as there is in England?—I could not say, but I believe that in Glasgow it is generally white lead. The more confined the space the more likely they are to get lead poisoning.

2842. (Dr. Collis.) Dr. Legge's figures are these; in the whole of Scotland only 20 cases, 12 of which were in Glasgow?—There you are.

2843. That is an important point. That is the point that you were making. All the figures here given are absolutely voluntary notifications, and it entirely depends on the doctors as to whether they happen to notify them. I cannot find that Dr. Legge gave us the deaths which occurred in Scotland, which are absolute figures. These voluntary figures really cannot be taken as much to go on, but for what they are worth, the 12 in Glasgow bear on the point that you were making?—Yes.

2844. (Mr. Sutherland.) Then with reference to the dust in rubbing down. It would have to be a very severe rubbing down, and a very special case that would cover a man with dust, and leave the marks of his feet surrounded by white where he had stood?—No; in my experience it is not so. It has been my own experience many many times that I have glass-papered a door down, and after I have dusted the door down I have swept the dust up, and there has been a considerable amount of it, and I have thrown it in the fireplace. The white dust which lies about would positively show your footmarks.

2845. Cannot you rub down with sandpaper and a little turpentine?—No.

2846. It is done?—It could not be done in ordinary cases.

2847. It could not be done with water, as a witness suggested last week, but you can do it with turpentine?—You agree that it could not be done with water.

2848. Quite?—It could not be done with turpentine either, I think, because you would be softening the paint again.

2849. You suggested that there was equal danger with regard to stippling. Does not the danger arise when you are applying the paint on to the broken surface of a ceiling and not from the distributing which the stippler does?—The man will get his hand and arm completely covered when he is using the stippler, even more than a man who is laying it on.

2850. Has not the coming of washable distempers like Duresco and other things very largely superseded the painting of ceilings with poisonous material by the application of a material that is not poisonous, and which is put on with a large brush? It has done so in the Manchester district?—I admit that it has come more into use.

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

2851. Very much more?—Yes, very much more, and it is coming more into use for ceilings.

2852. So the danger is diminishing?—It is diminishing, but it will never be entirely done away with. There are many places where they would never think of using washable distempers—where there is more heat.

2853. For ceilings?—Yes.

2854. It is perfectly sound in that respect. Now with regard to the closing up of the rooms, that is only done when the process of flattening is on, and after that the windows are opened?—No, you could not paint rooms in London if you had open windows.

2855. After you had painted them you could?—No.

2856. Why not?—Because the draught would not allow the paint to dry. You would have wet patches wherever the paint caught it, and the soot coming in would cover the paint. You must keep the room closed, and the window is the first thing painted when a painter starts in a room.

2857. You do not think that the use of a respirator is possible?—No.

2858. Do you think that the men would not submit to them?—Even if the men submitted to them, where would they be kept? They would be kept in the box where the foreman painter kept his stipplers and all that.

2859. Each man would keep his own respirator?—If he kept his own respirator he would keep it in his box where he kept his blouse and apron with paint all over them. The finest thing out to give a man lead poisoning would be to give him a respirator.

2860. You think that there is danger from the odour or vapour given off from the paint?—That has always been my opinion. It is only an opinion. I have no means of proving it except from experience.

2861. Did you think there was any danger from dust before Dr. Legge stated it?—Most decidedly. I have always known that the principal danger is from dust. Every painter should know that.

2862. Your information results from your experience as secretary of your trade union, I take it. Is it your own experience?—It is my personal experience as a working painter. I have worked at the trade for 35 years.

2863. I understood you to say that you represent 15,000 to 18,000 members of the trade union?—Yes, I am the general secretary of the trade union at the present time.

2864. Have you any experience of men outside the union?—Yes; for 28 years I worked in the West End of London for the principal decorating firms, so that I have a very large experience of non-society men.

2865. When you say that it is very exceptional for painters to take other occupations you not only refer to members of your own society but to non-society men as well?—I am referring to painters, whether non-society men or society men. I mean men who are painters. I am not referring to the men who are introduced as painters generally, in the West End of London—particularly, by building firms upon places like the outside of Regent Street to do outside work in the spring of the year, where they manufacture scores of painters, unfortunately. Those are the men who will take lead poisoning quicker.

2866. (Mr. Rice.) Do you seriously say that painters are manufactured?—I do not say that they are painters, but they are employed by builders to do painters' work.

2867. They themselves claim to be painters?—I suppose they do.

2868. You rather suggest by your evidence that builders go out into the street and find men and say, "Come and be painters." Is it not a fact that these men apply for work as painters, and they are put on as painters?—Yes.

2869. And paid the trade union rate?—No. What is the trade union rate, if I might ask the question?

2870. The trade union rate of wages for painters is 8½d. an hour?—May I ask whether your firm would pay the trade union rate to all the painters they employ?

2871. We pay 8½d. an hour to every painter and 7d. an hour to every labourer?—Whom do you term a painter?

2872. A man who paints?—Would you pay that to every man who uses a paint brush?

2873. We should pay that money to every man who was a qualified painter in our foremen's opinion?—One foreman's opinion.

2874. We have several foremen; I mean, men employed as painters. Do you distinguish between painters and painters' labourers?—My distinction is between a painter and a man who uses a paint brush and applies paint. Now to every one of those men would you pay the standard rate of wages?

2875. Yes, 8½d. an hour?—To every man who uses a paint brush, whatever he uses it for?

2876. I do not say to every man who uses a paint brush, whatever he uses it for, because I can conceive of a painter's labourer smearing on a bit of paint for some purpose who would not be put to what we call painting?—How is it, then, that the Master Builders' Association in London refused to sign the workmen's rules?

2877. I am not going to enter into that discussion. It is not a proper question to ask me.

(Chairman.) It is not material.

2878. (Mr. Rice.) I am quite willing to give any experience of my own firm, but I cannot discuss any questions with you with regard to why London master builders refused to have any rules with regard to the painters in London. That is not a fair question to ask me?—I asked your permission to put questions to you.

2879. Now your experience is founded on society and non-society men, and when you say it is very exceptional for painters to take other occupations you refer to all men working as painters?—No. I refer to men who have learnt their trade as painters, and those are the men that I term painters.

2880. Does the information about the deaths, blindness, Bright's disease, and paralysis only refer to those men who have learnt their trade as painters?—So far as I am concerned, it only refers to men in my society.

2881. We have two classes of evidence—your own experience on the one hand, and your information from your society on the other?—The information with regard to the number of deaths and disease and all that must necessarily be from members of my own society. If you could possibly get statistics with regard to men outside you would find, I should say, that the condition of things would be ten times worse.

2882. We have not your statistics yet. We shall get those, I take it?

(Chairman.) Those will be all compiled and brought out very clearly later on.

2883. (Mr. Rice.) The chief cause of disease, you say, is the dry rubbing down?—I have always put that down as being the most dangerous in my opinion because of the dust.

2884. You say that 75 per cent. of the work done is dry rubbing down?—Yes.

2885. And the wet process involves comparatively little danger?—Yes.

2886. Are you familiar with the specification of the London County Council for their painting work?—No, I am not familiar with that. I have mainly worked for the principal decorating firms in the West End of London.

2887. Are you aware that the London County Council specify wet rubbing down, and insist upon it being done?—I should say that they do nothing of the kind. After the first coat do you mean?

2888. I mean in their painting work. Take the outsides of county council schools, for instance. They are all rubbed down with water, and no glasspaper is used at all?—Before any paint is put on?

2889. Yes. With two coats of paint there is not much rubbing down wanted, as you know?—I know that. I know the way in which council schools are done.

2890. I also know that they are done in the most expensive and most excellent way possible. I only say

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

that to correct any impression that council school work is scamped?—I know as a fact that it is allowed by the Council that a man may be taken on as a labourer on school work, and he is paid the labourer's rate of 7*d.* an hour, and the same man is put on to do painting. The only stipulation made by the County Council is that he must be paid the painter's rate when he does the painting. They do not mind whether he is a labourer or painter as long as he is paid the rate.

2891. I agree, but that does not concern the County Council; that is a matter of the arrangement of the work?—That is the County Council regulation, that the labourer shall be allowed to do the painting, and we have fought against it all along. The same man who washes and rubs off the dirt and so on, whether he is qualified or not, is allowed to do the painting, because school work is generally rough work.

2892. That is irrelevant to my question. You say that 75 per cent. of the work is done dry, and I only want to point out to you that there are instances of public bodies who insist on the work being rubbed down wet?—I grant that readily, before the work is painted, but after the first coat is applied it is dry rubbing, either by the London County Council or anybody else. It is not rubbed down wet except it is old work. With regard to the council school work, it is broad work generally painted with dark colours in the dado. The labourer goes round it with a piece of pumice stone, washes it down, and takes off the big lumps, and there it is. That is not rubbing down, as you would term rubbing down generally.

2893. But will you explain to the Committee the actual practice? We do not want to imagine cases. Now, wet rubbing down leaves a lot of water on the floor?—Yes.

2894. Assuming that there is a little rubbing down required after the first coat, there is plenty of water to lessen the dust. I do not say that no dust comes from it, that is not my point; but I ask you to explain to the Committee the actual condition of things. When the labourer has done the surface all over and the paint is applied to the work there is plenty of water on the floor?—On the floor?

2895. No doubt there is?—How is it possible for him to paint when the water is lying on the floor?

2896. He would dust up the edge. I want the Committee to see the actual conditions of work?—He would certainly clean up the water from the floor before he commenced to use any paint.

2897. But there would be water about the floor?—No.

2898. Your answer is, No?—Yes, I say there would be none.

2899. Now with regard to sandpapering; if so much dust is caused a quantity of sandpaper must be used on the job?—Yes.

2900. You have worked on jobs?—Yes.

2901. Have you seen sandpaper arriving in huge quantities?—Yes.

2902. You have seen huge quantities of sandpaper arriving?—It all depends on what you term huge quantities.

2903. If you have so much dust that ladies go about with their heads covered there must be a considerable amount of glasspaper used?—Yes.

2904. How much glasspaper, for instance, would be sent for 30 painters for a month's work. You have worked with 30?—Yes. I could not say exactly. You may use a dozen quires. It depends on the job. In a private house, do you mean?

2905. Take for instance an hotel. There would not be 30 in a private house for a month?—No.

2906. You have no information as to how much would be used?—I do not know the quantity. I do not know whether you exactly understand. I am a practical painter, and I can tell you that I have been foreman for a large firm in the West End of London and carried out very large jobs in the West End of London myself.

2907. I only want to point out to you that it seems very surprising that there is so much dust about unless there is a considerable amount of glasspaper sent?—

There would be a considerable amount, but how much glasspaper would you require to rub down a door?

2908. That is what I am asking you. What have you seen sent for 30 men for a month's job?—I cannot say definitely.

2909. Not so much as I think you want to suggest?—It is not a question of the quantity of sandpaper.

2910. You think wearing respirators almost an impossibility?—Yes.

2911. You do not think it possible that a respirator could be carried about in a man's pocket as I carry my spectacles. If there is a desire for the painter to be cleanly, should he not carry his own respirator?—I do not understand much about respirators. I thought that he would probably put it in his bag. If he carried it inside his pocket he would require a leather case to keep it in.

2912. He could take the same care of his respirator as I take of my spectacles?—I do not think it is practicable.

2913. But you do not think it is an impossibility?—No. You wipe the spectacles every time you put them on.

2914. Yes. I do not want to wear dirty glasses. I want to see out of them?—A man would not want to wear a dirty respirator.

2915. In view of the limitation of the number of hours, is it customary for a workman to work 60 or 70 hours?—It is 66 in the country—it used to be 70. It is generally 66 now.

2916. In London it is 50?—And 56.

2917. Ten hours a day?—Ten hours a day is the general rule in the decorating firms in the West End of London. It is customary for builders to work for 50 hours a week. Other firms work for 10 hours a day, if it is a purely painting firm or a large firm like Maple's.

2918. Do you think that master builders and master painters are responsible for the deplorable conditions under which the painters work?—No, I do not. I do not say that either side is responsible. I would say that the competition for work would prevent their observing these regulations. It is the competitive system that forces the employer to get as much as he can, and not to give any more facilities to the workmen than he can help.

2919. Do you think that the employers give a fair amount of facilities considering the competition you have mentioned?—No.

2920. In what way do they not?—Especially building firms. They expect a man to remain at his job on a building until the foreman blows the whistle. Is that not so?

2921. Yes?—He has to come to the paint shop from perhaps the top of the building. He will find only one or two pails of water with 30 or 40 men on the job. He has to go to a coffee shop and be back again in half an hour.

2922. For breakfast?—Yes.

2923. He has an hour for dinner?—He has an hour for dinner, and he washes his hands quietly before that time if he has an opportunity. But on a building job he would be very soon discharged if he was caught before the whistle blew. This is a fact, is it not?

2924. I quite agree. To sum up, as our Chairman says, you do not think that employers are responsible for the deplorable conditions under which you say the men work. Could you answer yes or no?—If I had to say definitely yes or no, without being allowed to qualify it in any way, I should say yes. I would say I would put the blame more on the employer than on the workmen. It is a fact that they could give more facilities even under the present system of competition than they will do. Mr. Rice will admit that his own firm would not allow a man a minute before the whistle blew, and other firms will not. I know one exception. I have known a decorating firm to allow a man to wash his hands in their time.

2925. (Lord Henry Bentinck.) You think that employers could do a great deal more than they do?—They mostly could do a great deal more than they do.

2926. (Mr. Rice.) You are not speaking of individual employers, but you are speaking of the custom of the

5 April 1911.]

Mr. J. PARSONAGE.

[Continued.]

trade?—Certainly. I would not think of selecting individual employers. It is more usual in building firms than in decorating firms for the men not to be allowed to go to wash until the whistle blows.

2927. You know it is usual for building firms to provide a mess room?—Yes; it is more usual than for the others.

2928. And to provide a mess labourer?—Yes.

2929. The mess labourer has a fire provided for the men?—Yes.

2930. And the men have seats in the mess room to sit down upon?—Yes.

2931. And a table as a rule is provided?—Yes.

2932. There is a mess labourer who cooks the meals. It is the custom, is it not?—There will be a labourer who will heat the men's cans for their breakfast, but in London I do not think that it is the general custom for them to cook the men's meals on building jobs.

2933. You have been on building jobs, I take it?—Yes, but my experience there has been little compared with the other.

2934. But you have been on building jobs?—Yes.

2935. And you have been in mess rooms?—Yes. At Buckingham Palace there was a large mess room built out on the terrace for the men.

2936. You admit the existence of mess rooms?—Yes, but not generally. On large building jobs there are mess rooms.

2937. And a fire for cooking meals is provided by the employer?—Not for cooking meals but for heating the men's bottles.

2938. The same fire could be used for heating water?—It could be used for heating water, of course.

2939. Have you known cases where men have been refused hot water?—It is in very very few cases that I have known hot water provided.

2940. But have you ever known it refused? If the foreman painter were to say to the general foreman, "My painters ought to have hot water to wash their hands," have you ever known a case where it has been refused?—It is very little used.

2941. Have you ever known it refused?—I have not known it asked for definitely in that way, because it is a thing that is not recognised on a building job to ask for hot water. The labourer will get hot water in preference to cold for the men if it is to be had, but I have not known it stated that there must be hot water provided for the men.

2942. I am not asking about that, but have you ever known it to be refused?—Not where it can be got.

2943. The foreman painters are generally trade union men, are they not?—There are many who are not.

2944. There are some?—Yes.

2945. They would probably be in sympathy with the men?—Yes.

2946. They probably would see that some facility should be given for washing?—Yes.

2947. Have you had complaints from those foremen that the employers have refused facilities?—Yes, I have been in charge of work myself where my employer would not allow it.

2948. That is years ago, I take it?—Not so many years ago.

2949. That is the only instance?—No. The instances are far too numerous to recall or mention.

The witness withdrew.

Mr. WILLIAM PICKLES, examined.

2950. (Chairman.) What practical experience have you had in the house painting trade?—About 32 years, directly working at the trade.

2951. What branch of the National Society of Operative House and Ship Painters are you connected with?—I am under-secretary now. The particular branch that I have been most concerned with is the Huddersfield branch.

2952. Have you had any experience of lead poisoning among the members of your branch?—Yes, both from amongst my own workmates and through being an executive member of the National Society of Painters.

2953. Have you devoted yourself to studying the dangers to which painters are exposed and have you published papers on this subject?—I have written one article in the "Journal of Decorative Art"; I have written in the quarterly circulars connected with my own trade union, and lectured amongst the branches of which painters are members, on the question of lead and relative questions.

2954. Will you name the principal causes which in your opinion contribute mainly to the prevalence of lead poisoning among house painters?—I regard the chief cause as being dry rubbing, that is the rubbing of paint that has been applied and has dried. It is then rubbed with sandpaper before another coat is placed upon it.

2955. Do you regard stippling also as a source of considerable danger?—The stippling is merely a name for a process. What you may be using when you are stippling may be good or bad, but I take it that you refer to poisonous substances and probably to flattening, though not necessarily so. I would try to put my answer to your question in this way: when one is flattening a ceiling or painting a ceiling in oil, the ceiling has previously been papered with a raised paper, known in the trade as relief paper because of the fact that the ornaments stand out. In such cases there is brushing in of the colour and afterwards stippling, both of which are processes which splash; but the former, the brushing in, the more than the latter. The splashes fall on the painter, who must necessarily stand underneath. That applies more directly to

ceilings, because he does not stand underneath walls to work.

2956. As regards the dangerous process of dry sandpapering between the application of one coat of paint and the next, is it quite impossible to dispense with this and replace it by wet rubbing with pumice stone and water?—It would be very highly impracticable. The workman would endanger the work upon which he employs such a process, and no practical workman would think of doing such a thing as that.

2957. Filling coats and also old hard paint work are sometimes rubbed down wet, I believe. Why cannot this method be applied to newly painted work between the coats?—Because of the hardness of the substance you are coating. One need not point out the fact that old paint gets very, very hard during the years of wear. Filling is mixed in such a manner as to cause quick and hard setting, and the hard brittle surface can be rubbed down with pumice stone and water just as with sandpaper; in fact, the hardest of these substances would not be touched by the cutting of the sandpaper, and you require something like pumice stone to do the work with.

2958. Is it because sandpapering is cheaper?—No. The price of the work need not be considered; it has no effect on the question under consideration.

2959. Would the pumice stone and water method tend to destroy the film of newly dried paint which has not had time enough to harden completely?—You mean the paint itself by the word film, probably?

2960. Yes?—I would not expect that a man would try to do that. It would tear the paint as the pumice stone passed over it; it would damage it.

2961. Would the newly dried paint clog the pumice stone very quickly and so render it useless?—That would be one of the first effects; that would be an additional danger. The first danger would be that of tearing the paint, and the clogging would make it highly impracticable for the workman to employ such a process.

2962. Next as to the danger of stippling. When you are painting ceilings with moulded or relief work to what extent does the painter inhale fumes or spray? What is the particular danger that he encounters then?

u 7790

F 3.

5 April 1911.]

MR. WILLIAM PICKLES.

[Continued.]

—In addition to the fumes, which is one of the chief dangers, there is the fact that the paint is falling on his face and necessarily on his lips. The saliva tends to act as a solvent, and he feels the result of it in his mouth in the bitter taste.

2963. Can you tell us anything of the danger arising from the burning off of old paint with a spirit or charcoal lamp?—The painter becomes conscious of heaviness in the head on such occasions. Whether that arises from the fumes of the material he is burning, or whether lead is the chief cause is a matter upon which I have not any strong opinion. The fact that the painter feels the inconvenience is one of which I am aware.

2964. Sandpapering very generally follows this operation, I understand?—It must necessarily do so.

2965. Is not that dangerous?—The dust must necessarily be breathed by the painter. It is one of the dangers; but I should not put it in the foreground as one of the chief dangers.

2966. How are colours generally mixed?—That depends on the size of the job and the number of rooms to be painted. If a painter was only painting this room in this building he would have all his things in the room. If he was painting every room in the building he would have one cistern in which to keep the paints; and he would mix them in that particular room.

2967. Where does he keep the colours when he is painting the outside of a building?—In the gardener's tool house, or anywhere where he can get a place.

2968. Supposing it is a town and there is no such accommodation?—I have not worked in a city. I have worked in a town with 100,000 people nearly all my life. When we are on the outside of a house we take any outhouse we can get at our disposal.

2969. But supposing there were none?—I have not had any case where we could not find a place of some description. I not having worked in a large city, where there are restrictions with regard to building, the answer to a question like that would come better from a man who had worked in a city.

2970. Is there much danger of the workmen breathing dust in the operation of mixing colours?—No, not from mixing, because the lead has been ground in oil beforehand. He gets no dust in that case but only the smell of the paint.

2971. Can you name any other process in which there is grave risk of the painter inhaling dust or fumes?—In every process in which he is using white lead (supposing that it is a wall or woodwork) there is the danger. He must necessarily be inhaling the stench from the material which he is using, whatever he may be covering with it. In the case of ceilings his head or face is upturned, and he catches more than.

2972. You think the danger is in the fumes only?—Yes, in such cases.

2973. The paint gets on to his hands and clothes, and is not that a source of danger?—Yes. I had not that in my mind just for the moment. My point was rather on the question of application for the time being.

2974. The paint drops on the floor and dries and creates dust, does it not?—Yes. If he is a clean workman he will have a rag and remove it. If you want me to continue in respect of the question of the clothes, I would like to.

2975. Yes, go on?—You mentioned the hands. A painter necessarily must get his hands daubed with the paint. If there was a sore on them naturally he would run some risk. Painters usually try by wearing a finger, cut from an old glove, to ward off such dangers, but anyhow the fact that he must necessarily handle paint during the day brings him within the scope of danger while his hands are dirty. They are only washed at meal times and the close of the day, and unfortunately not always at meal times.

2976. Do you think that the provision of washing conveniences and the regular cleansing of the hands is important?—It is very, very important. It is highly important.

2977. Should hot water always be available?—Hot water is very rarely available.

2978. But I asked you, should hot water always be available?—Hot water is desirable—yes.

2979. Is this generally practicable?—Naturally to have a fire and a pan is an easy matter.

2980. For example, if you are painting the outside only of a house, are you allowed to go inside to wash?—No.

2981. How would you provide the hot water in that case?—We should have to ask for hot water, get a pail and carry it outside.

2982. You have no experience in painting the outside of a house in a large town. How would the men get the hot water, and where would they wash their hands if they were painting the outside of a house in a town?—In a large town I am afraid it would be difficult. I mention the fact that my experience has been in a small one, where we do not run the same risks.

2983. Is food often kept in the pocket of a working coat and eaten in a place where paints are being used?—That is quite the rule.

2984. Is it frequently impracticable to have the use of a separate place as a mess room?—I do not suppose that anybody would allow us to have that. I have never known such a case. For example, when you are painting only one room in a house you must use that room for all purposes.

2985. For meals too?—Yes.

2986. Do you generally wear overalls while at work?—Yes.

2987. How are they kept clean?—They are washed once a week.

2988. You frequently have to carry them in your tool bag, I believe?—Always.

2989. There is no doubt some dust from a dry soiled overall, and you would be likely to breathe this, would you not?—Yes, necessarily, as the week gets advanced.

2990. I have asked you questions about all such precautions as washing, mess rooms, overalls, and the like, because they are carefully insisted on in the pottery and other trades where there is a risk of contact with lead; but they would be difficult to carry out fully in house-painting, would they not?—Very difficult.

2991. Do you, however, consider that all the evils arising from eating with unwashed hands and from dirty overalls and the like are necessarily small in comparison with the dust and fumes arising in the course of the man's actual work?—I should put it in about the third position of order of danger.

2992. The other two being what?—Of the other two the first being dry rubbing, and secondly the association with the wet paint in the day's work.

2993. How can the evils arising from such dust and fumes be overcome?—They cannot be very well overcome.

2994. Is it quite impossible to apply an exhaust apparatus for the removal of the dust?—I do not see how it could be applied in a place that had been constructed for living purposes—a place other than a factory.

2995. You have told us that it is not practicable in all cases to replace the dusty sand papering by a wet method of rubbing down?—Yes, I explained carefully the technical conditions.

2996. In cases where it is possible to do all the rubbing down wet would this remove all the danger attendant on the use of lead paints?—Yes, in relation to that process.

2997. Is it possible to remove all the danger, do you say?—No. I say in relation to that process only.

2998. But I want you to answer the question and only the question. I am not asking anything else. I want to know whether it would remove all the danger?—No, it would not.

2999. You said it would at first?—I said only in relation to the one process.

5 April 1911.]

MR. WILLIAM PROKLER.

[Continued.]

3000. In cases where it is possible to do all the rubbing down, wet would this remove all the danger attendant on the use of lead paint?—Oh dear no.

3001. Taking that one process, what do you say?—I am trying to make it quite clear. I agree that with that one process there is no danger connected with it.

3002. That is what I wanted. In that case there would be a certain amount of dripping on to the floor?—Yes, but I would not attach much importance to that.

3003. But would not that dry and become dusty as the men walked about?—Usually a man has a brush and a pail of water by him, and if he is a clean workman he will take up the material from the floor and rinse the brush in the pail.

3004. You understand that in all industries where the use of lead is allowed, a periodical medical examination is insisted upon. Could this be applied in the house-painting trade?—Yes. In such a case, though the examination would be beneficial, if the fact became known that the man suffered from lead-poisoning it would be detrimental to his chance of getting work afterwards.

3005. How would you suggest that the men should be examined?—By a doctor, say, in each quarter of the year.

3006. Once a month?—I should have no objection to that, but I am merely saying at least once each quarter in the year.

3007. Then do you assert that it is impossible to stamp out the evil of lead-poisoning without replacing the lead by some non-poisonous substitutes?—Yes.

3008. Have you had any experience yourself of the use of non-poisonous substitutes for white lead?—Yes, I have used such substitutes.

3009. Have you formed any opinion as to their practicability for general use?—I am strongly of opinion that they can be used and that we can abolish the use of white lead absolutely.

3010. We have heard some suggestion of reluctance on the part of the painters to adapt their method of work to the peculiar requirements of zinc or other leadless paints. Do you find any difficulty in using such paints?—I find that when one speaks to a painter about these processes he is rather inclined to stick conservatively to the older system, but that can be gradually overcome.

3011. You think that the difficulty is not insuperable?—I do decidedly.

3012. Have you made any experiments with substitutes for white lead?—I have.

3013. Do you consider that it would be possible to prohibit the use of lead for all house-painting work?—Yes.

3014. Or at least to restrict it to not more than five per cent.?—I should prefer its total abolition.

3015. (Lord Henry Bentinck.) You have no experience, I suppose, as to the durability of zinc oxide paints?—Yes, I have painted rooms in my own house and kept them under view daily, and at the end of two years' time (that is the time that my experiments extended over in my own house) I found them to be in good condition. The paint had stood well.

3016. Were they in as good condition as if the paint had been lead paint?—Quite.

3017. Have you had any experience of this with regard to outside work?—I painted the outside of my own house for the same purpose. The difficulty was to know any difference in two years' time between the lead paint and the other kind.

3018. You noticed no difference?—I noticed no difference.

3019. Has anybody else you are acquainted with carried on the same experiment?—One firm in the same town carried out a job, a pretty good-sized job, for the corporation, of which I was then a member, which job I had partly under my care as a member of a certain committee. That gave me satisfaction. It was the painting of the inside of a wooden pavilion which was in very bad condition.

3020. Where is your house—in Huddersfield?—Yes.

3021. It is a rough climate. I suppose?—Yes. It is an industrial centre.

3022. There is plenty of rain and smut, too, I suppose?—Yes.

(Mr. Sutherland.) It is a very clean industrial town.

3023. (Lord Henry Bentinck.) But still it is the north country and it is wet. That is a good test I should think?—Yes.

3024. (Mr. Sutherland.) You do not attach great seriousness to the process of stippling as a danger?—Not to the process. It is the material the man uses that I attach importance to.

3025. And you do not think that it spreads or sprays the paint so much as the actual painting?—No, not by any means.

3026. You think that dry sandpapering is a fruitful source?—I do—the most fruitful.

3027. You made the point that in rubbing down the door by the wet process the man would wipe up the floor if he were a good workman?—He would wipe up the wet.

3028. And the material that he had rubbed off the door?—Yes.

3029. Do you think that much splashing comes on the man when stippling a ceiling?—Yes, but I should think that more came on to the man who was brushing the ceiling.

3030. Do you think that sufficient would come on him to get into his system through the saliva?—In the stippling or the brushing?

3031. In either or both?—In both, but more in the brushing.

3032. The same men do the two processes at one time or another?—Yes.

3033. Do you think that we could abolish the burning off with lumps and substitute solvents entirely?—We could, but I think it would not be desirable to do it.

3034. Would you think there is much danger in connection with the use of the burning-off lump?—Yes, but not so great as in the other processes which I have mentioned.

3035. Have you found any difficulty in your experience in getting hot water on a job?—Yes.

3036. For meals?—Yes.

3037. What kind of job was it where you had the difficulty?—In cases where we work in a room, and they compel us to enter the room by a ladder and insist that we must not go near the domestic part of the house. In those cases one cannot get hot water.

3038. That is not normal, is it?—In my case, no; but I should like to say that we work under very favourable conditions in our town.

3039. If you are working at a house where the people are in possession it is usual for you to get facilities from the servants, is it not?—In a limited sense, yes.

3040. Sufficient to enable you to get hot water for meals, and, if necessary, for washing?—Yes, generally, but there are exceptions.

3041. If the house is empty you can provide your own?—Yes.

3042. There is no difficulty on that score?—Not with us. Might I answer that by saying what I find in comparing notes with colleagues who work elsewhere in larger towns?

3043. I am only asking you your own experience?—If I answer yes or no it is not a good answer. I find usually that the larger the job, the larger the town, the greater the difficulty.

3044. Are you speaking of domestic work?—Yes, I mean by that, where there is an enormous number of painters working on a job there is a tendency for the employer to insist that they work to the last minute.

3045. What do you call enormous number?—20, 30, 40, and upwards.

3046. I should call that a good number, but not an enormous number. Does not the foreman always tell off the apprentices to get hot water for the men?—Usually for their breakfast, yes.

3047. For meals generally?—That applies merely to the scalding of tea and other liquids.

5 April 1911.]

Mr. WILLIAM PICKLES.

[Continued.]

3048. There is always hot water available for the purposes of the business?—Yes, usually.

3049. For the melting of size and the operations that are being carried on. That can be managed?—Yes.

3050. If it is available for one purpose it is available for the other. The men insist on it. Why cannot they get it for washing?—The two points to note are that you must have the necessary water, soap, and towels, and time to do it. You do not always have that.

3051. What would you call time to do it?—I think that a man might leave off, say, five or seven minutes earlier to do that kind of thing.

3052. That would only apply where there is a short break. You would not ask for that in the dinner hour?—But why not, if it is necessary to remove the paint from your hands.

3052A. But the man is paid for working up to the time of the hour that he is allowed for dinner. Surely in the interests of his own health he can spare sufficient time to clean his hands?—But if there is a limited supply of washing facilities and a large number of men, it becomes a rather serious matter. I agree so far as to say that he ought to do it, but my desire is to encourage him to do it. The more you discourage him the less he does it.

3053. You agree that he ought to do it?—Yes, I agree that he ought to do it.

3054. You agree that it is his duty to do it?—He ought to do it.

3055. (*Lord Henry Bentinck.*) But it is not the duty of the employer to give him facilities for doing it?—(*Mr. Sutherland.*) I believe that it is in our district. They give facilities for it, but within the compass of an hour the man has sufficient time to have his meal and wash his hands.

(*Lord Henry Bentinck.*) I should think that within the compass of 50 to 60 hours a week the employer would have time to allow for washing.

3056. (*Mr. Sutherland.*) It becomes in some cases a very big drain on the job. (*To the witness.*) The clothes are washed each week in the case of decent men?—Yes.

3057. Is there any danger of a spot of paint which he gets on his clothes drying and becoming dangerous towards the end of the week?—If the paint was splashed on his clothes it would powder by the rubbing process.

3058. By when?—Towards the end of the week if he got it on in the middle of the week. There would be danger because of the powder on his clothes.

3059. What experience have you had of non-poisonous paint?—I purchased about 50 or 60 pounds of non-poisonous paint last year to use mainly for experimental purposes. I have used it in this manner; I have had three rooms to finish with enamel. I have painted one room with white lead, one room with one kind of substitute, and another with another, to see which was the best job when I had finished.

3060. Did that prove satisfactory?—I preferred the non-poisonous to the white lead because I could get a whiter finish.

3061. Have you had any experience whatever of it for the outside of buildings?—Mainly in relation to my own house, but not so wide an experience as would justify me in speaking at length upon it.

The witness withdrew.

Mr. J. WALSH, examined.

3085. (*Chairman.*) What practical experience have you had in the house-painting trade?—I have been a painter since I was fifteen years of age, and am now thirty-six, practically twenty years.

3086. Have you had any experience of lead poisoning among the members of your branch?—Yes.

3087. Will you name the principal causes which in your opinion contribute mainly to the prevalence of lead poisoning among house painters?—Chiefly in

3062. You think the only remedy for lead poisoning would be the total abolition of lead?—I can see no means of adopting preventive methods which would be satisfactory, and therefore abolition is the only thing.

3063. Do you think that cleanly habits would mitigate it?—Decidedly, but you know that it is not necessarily the dirty workman who gets lead poisoning.

3064. Do you think that some men are exceptionally susceptible to it?—Yes. I am.

3065. That would point to their having selected the wrong trade?—That is highly probable, but they had been committed to the trade long before the susceptibility began to manifest itself.

3066. You are susceptible to it personally?—Yes.

3067. Your susceptibility has not been affected or diminished by cleanly habits?—No, by no means, nor temperate habits either.

3068. (*Mr. Rice.*) You said it is customary for painters to carry food in their pockets?—Yes.

3069. By whose orders do they carry food in their pockets?—It is the only convenient vehicle they can carry it in.

3070. That is not an instruction from the employer?—Not by any means.

3071. You said it is difficult to have clean overalls?—No, I did not say difficult—pardon me. I said we do it once a week.

3072. I have a note here that you said it was difficult to have clean overalls?—No, I did not mention that.

3073. It is not difficult?—No.

3074. Do you think if they have dirty overalls it is the men's own fault?—No. It is the fault of the process largely.

3075. But if a man has more than a week's dirt on his overalls it is his own fault?—I agree to that.

3076. You have had experience in all classes of work, have you not?—Yes, I have had experience in all classes, though I specialise in graining.

3077. You are really a grainer?—Largely so.

3078. Do you work for yourself?—For about 18 months I have worked for myself, but 30 years of my life has been spent as a journeyman.

3079. Have you been with many firms?—About four.

3080. Large firms?—Firms that in the main would employ say 20 or 30 men. The last firm I worked for for 11 years. Their average would be over that.

3081. In your town, Huddersfield, you have not had any difficulty in getting hot water, if you have asked for it?—It is a most unusual thing; we have occasionally.

3082. Generally people are sympathetic and tell you you can have it?—Yes.

3083. Do I understand that it is the custom in your town to allow time for washing?—Yes; you can get it always in our town. I carefully pointed out that I find that in accordance with the numbers the difficulty becomes greater, and I have found that invariably in discussing this question with my colleagues.

3084. My point is whether hot water is ever refused you, if it is possible to get it if you ask for it?—You are refused permission to go to the place where you can get it in some cases, but that is not the rule.

preparing the work for the next coat of paint, sandpapering or glasspapering. Also I think a lot of it arises from dry scraping of the old paint.

3088. As regards the dangerous process of dry sandpapering between the application of one coat of paint and the next, is it quite impossible to dispense with this and replace it by wet rubbing with pumice, stone and water?—I think so—when you consider that most of the work is done in a hurry and it is the simplest and easiest way to produce a very level surface.

5 April 1911.]

Mr. J. WALSH.

[Continued.]

3089. Would the pumice stone and water method tend to destroy the film of newly dried paint which has not had time to harden completely?—Yes, I am positive of that.

3090. Now next as to the spray from the brush. When you are painting ceilings with moulded or relief work and when you are doing stippling, to what extent does the painter inhale such spray?—He cannot help inhaling quite a lot of it, because as a rule it is mixed rather thinly in order to get into the crevices of the relief material, and in stippling, the stippler being a short haired brush, the hairs, generally between two and three inches long, throw the paint out all over his face and hands, and I do not see how he can avoid it.

3091. Can you tell us anything of the danger arising from the burning off of old paint with a spirit or charcoal lamp?—Yes. I think that a man must absorb quite an amount of old lead into his lungs. He is bound to be close to the lamp, and the draught round the work blows it on to him. I know from practical experience that after a long day at burning-off a man feels about fixed up.

3092. Does sandpapering generally follow this operation?—Yes; sometimes the wet process is adopted.

3093. Is sandpapering very dangerous?—Yes, because there is always a certain amount of old dry paint left after the lamp has gone over it.

3094. How are your colours generally mixed?—There is generally a place set apart on each job that they call the paint shop. It may be a corner in a room simply. The mixing is generally done on a bench.

3095. How does the danger arise in this work of mixing paint?—My own opinion is that it is largely from the fumes arising from the mixing of the paint with oil and turpentine.

3096. Can you name any other processes in which there is a grave risk of the painter inhaling dust or fumes?—I have already mentioned dry-scraping, and it is quite possible that a man might absorb a little through the wet process. He might absorb a little—not inhale it—by the use of sodas or sugar soaps for softening the paint, and that drying on his fingers or on his clothes might get into the body.

3097. There are no doubt many processes in which the painter cannot avoid getting his hands soiled with the paint or stopping material?—I do not know that that would altogether make much difference.

3098. But it does get on his hands?—He might avoid it.

3099. Do you think that washing conveniences are very necessary?—Undoubtedly.

3100. And that hot water should always be available?—Yes, if it is possible, but there is the difficulty that you cannot always get it.

3101. It is not always practicable, you say?—No, it is not.

3102. Mr. Parsonage has given us evidence on the main questions of this Inquiry. I suppose you generally accord with his views?

(Mr. Parsonage.) I have not had much to say to the witness because I desired him to give his own opinions. I do not often see him.

3103. (Chairman.) If you are painting the outside of a house, are you allowed to go inside to wash?—As a rule they do not care about it. There is a mistaken notion that the man who does the painting outside is a different type of animal altogether from the man who does the work inside.

3104. Is food often kept in the pocket of a working coat and eaten in a place where paints are being used?—Very often you cannot avoid it. If you are doing only one room in a house, you certainly do not like to put the people to any inconvenience.

3105. Is it frequently impracticable to have the use of a separate place as a mess room?—Yes, very often.

3106. When you are painting one room in a house?—Yes. I am working at a house at present where there is a large family. They can only give us one room at a time, and we are forced to get our food in the same room.

3107. Do you usually wear overalls while at work?—Yes.

3108. How do you keep them clean?—They are washed each week. We have an alternate suit.

3109. You frequently have to carry them in your tool bag, I suppose?—Yes.

3110. There is no doubt some dust from a dry soiled overall. Would you be likely to breathe it at any time?—Yes, you cannot very well avoid it. You take your overalls off at night and shake them then or shake them the next morning.

3111. How can the evils arising from such dust and spray as you have told us about be overcome?—The only real way, in my opinion, of overcoming it is to abolish white lead altogether.

3112. Is it impossible, in your opinion, to apply exhaust apparatus for the removal of such dust and spray?—No, I am afraid not.

3113. Is it impossible?—I am afraid it would be most impracticable.

3114. You have told us that it is not practicable in all cases to replace the dusty sandpapering by a wet method of rubbing down?—No, not when you have to follow the work up so soon as you have to do to-day.

3115. Would it be a good thing to have periodical medical examination by a surgeon with powers to suspend men who were afflicted with lead poisoning in its early stages?—I do not know what good that would do. My own opinion is that almost every painter has more or less lead in his system.

3116. Is much compensation for lead poisoning claimed under the Workmen's Compensation Act?—There is very little, I think, compared with the lead poisoning that is actually taking place, because men are almost terrified in many instances against taking advantage of the Act. They are afraid of losing their employment.

3117. You are interested, I understand, in ship painting?—Yes.

3118. Are the conditions similar when men are painting state rooms and other internal parts of a ship?—That is a portion of our trade that I do sincerely hope that some little attention will be paid to, because there are hundreds of house painters who have served their apprenticeship to house painting who work on the liners in the various seaports during the winter months when the boats are lying up, and the whole of the work, almost without exception, is rubbed down with glasspaper or sandpaper. There is no possible means of ventilation—that is by the air being continually changed. The usual means of ventilation, the port holes, are closed.

3119. Men working in ships come under the Factory Act to-day?—The difficulty is that the men I have in mind are not men who usually follow ship painting, but men who are taken on to do a particular class of work—state rooms and that sort of thing.

3120. Directly a man is taken on to do work in the state room of a ship he *ipso facto* comes under the Factory Act, and so he is protected?—The trouble is that he is far less protected than a house painter is at house work.

3121. (Mr. Parsonage.) The Factory Act is not carried out then?—No, not at all. I can honestly say that there are no means of washing hands or that sort of thing, and even if the washing of hands were carried out it would be of very little use. A man working in state rooms is eating dry lead.

3122. (Chairman.) Do I understand that some of your men periodically work in the state rooms of ships, and the clauses of the Factory Act are not put into force?—No, they are not. At the various periods when I have worked on ship work I have never seen a factory inspector looking over our work.

3123. (Mr. Sutherland.) How do you know that the men are terrified to make claims under the Workmen's Compensation Act?—I could specify one particular case if that would have any bearing. A man claimed compensation from a firm and got it, of course, through the insurance company, and, after getting a weekly amount, he settled for a lump sum on the understanding that it was not to interfere with his livelihood. On applying again to the same shop he was advised by his

5 April 1911.]

Mr. J. WALSH.

[Continued.]

employer that he had very good chances of employment, and that it would be much better if he went and worked somewhere else for a little while, as the extra premium demanded of him by the insurance company was an item to be considered. He went to work at another place, and on the second day of his employment he was asked to sign a paper. This paper he at first refused to sign, but the foreman told him it would make very little difference to him. This paper was to the effect that he had received compensation for lead poisoning. An hour after he had signed it he was discharged.

3124. After he had signed the paper?—Yes, after he had signed the paper. Of course, it was common knowledge that this man had received compensation. That I know is the absolute truth.

3125. Did he succeed in getting work elsewhere?—Very intermittently. The man has had to practically live on ship work, work which any man who values his health tries to get away from.

3126. Did he settle his compensation claim through the courts?—No, not through the courts; outside the courts.

3127. (Mr. Parsonage.) He received 16s. 5d. compensation?—Yes, for about eight months.

3128. (Mr. Sutherland.) Was he well then?—He was getting pretty well. He felt that he would, in a short time, be able to resume employment, and he settled for 50l. This man's experience, of course, has warned quite a number of men, who feel that they would like to claim compensation, from claiming it. That is the only circumstance I know of, but there may be others.

3129. (Mr. Parsonage.) There is a particular case in my Annual Report this year, for instance, where the courts said that if the insurance companies were going to do this they would take that into consideration in deciding the case, and award heavier damages to the man; and they are doing so all round the country, because it is preventing a man from reporting himself?—I can give you this man's name, because he has suffered so much that he feels he cannot be any further injured.

3130. Have you had some experience in the use of a non-poisonous substitute for white lead?—Yes.

3131. We had a Professor Baly here last week, from the Muspratt Laboratory, Liverpool University. Have you worked on that building?—Yes.

3132. Are all the paints used there absolutely non-poisonous?—Absolutely non-poisonous, that is to say, as far as we know they are non-poisonous; zinc white and Charlton white.

3133. The material is tested by a professor of chemistry there before it is used?—Yes. Each time I have worked on the job the professor in charge of the laboratory has taken samples of the zinc white; and when they used Charlton white he took samples of that—samples of the driers and samples of the oil.

3134. Did he examine it each time before it was used on the work?—Yes.

3135. Were you personally employed in this work?—Yes.

3136. How long is it that this has been used? I want to find out the durability of it?—Charlton white was first used about three years ago, and it was used on the raw plaster, but this laboratory had been in use for four or five years before the walls were painted. I know there were some tremendous chemical experiments—of course I do not understand the nature of them—carried out in this building, so the plaster would be saturated with chemical fumes, and the chemical experiments have been carried on since, but the white remains pure white. Last year, in September, I worked on the same job, and the room was being painted again for the first time then. The work can be seen there at any time.

3137. In your opinion, is it in better condition, and is it a better white than white lead?—Yes, I am positive of it.

3138. I understand this is interior work, where chemical experiments are carried on?—Yes. Of course I have not any knowledge of science, but I do not think any material can be put to any severer test than

it has been at this laboratory. There being a large amount of it obtained to do the work there, a lot of it was left at the shop, and it has been used on several occasions. My own opinion of it is that it is far better than lead—that is Charlton white and zinc white.

3139. Is the General Post Office all done with non-poisonous paint?—That is painted with non-poisonous materials, but it is not zinc white. I mean to say it does not come in bulk like zinc white does. The paints they use are Gay's Patent and Etruscan. I do not know the makers of the Etruscan, but it comes in bottles, ready made.

3140. With regard to the mixing of the ordinary zinc white, have you had experience in mixing that when it comes in paste form, the same as white lead generally comes on to a job?—Yes.

3141. With your own knowledge and experience, you have used it in the ordinary way?—Yes.

3142. And you know the quantities for mixing it and all that?—Yes.

3143. In your opinion, when the paint is properly mixed, would there be any difficulty in the painter applying it to the work?—No. It is just like all new things. A man wants to approach it with sympathy and with brains, and he wants to apply himself to something new. At the first go off, he mixes it as he has been mixing white lead, and it does not turn out a success with him, but it can be made a success. It only needs to be approached in the right spirit.

3144. (Mr. Sutherland.) Are you speaking of zinc white now?—Yes.

3145. (Mr. Parsonage.) If the manufacturers sent out this, you would get proper quantities, or the necessary oil to mix with it, and also they would send out a special drier that would be different to lead drier?—I will just briefly give you my own experience. The thing can be used with the ordinary materials, that is the thinners, that we use to-day, if the man will only take the trouble to think out what he is doing. The average man gets hold of, say, a drum of zinc white, and starts to let it down with turpentine in the usual way, and he begins to get it down, but, if he would only think it out a little, something else is necessary, either a little varnish or a little Japan gold size, and that makes the thing workable.

3146. When it became well known what was the proper thing to mix this with, the painter would not mind using it?—That is so, and I think when it became more popular the manufacturers of zinc white would make it almost ready for use, in the same way as white lead is made. I may say that we have used it on occasions for all classes of work, for woodwork and for ordinary flitting, friezes and ceilings, and that sort of thing, and it is far better—that is, once you understand how to mix it and use it. Of course, most men just get hold of it, and they find it works a bit sharp, and they do not make any attempt to alter it properly.

3147. That is a matter of experience?—That is all.

3148. But it would easily come into use?—Yes.

3149. In your opinion, these materials could be introduced and used commercially in the place of white lead generally?—Yes, in my opinion it is just the want of thought and sympathy.

3150. Leaving out specialties, like Charlton white or Gay's patent, or those kind of things, if a standard commercial quality, to take the place of what is termed general white lead now, were introduced on to the market, it would be equally as good as or better than white lead?—Yes, that I am confident of. The reason that white lead has lasted so long is that everybody takes white lead for granted.

3151. (Mr. Gardener.) I think you have worked a good deal in ship work?—Yes.

3152. Have you used much zinc white in ship work?—Very little. It has only been used for finishing coilings on account of its whiteness.

3153. (Mr. Parsonage.) Supposing that it was decided to recommend the abolition of white lead, how long would you propose to allow for white lead to be entirely done away with so that other substitutes could

5 April 1911.]

Mr. J. WALSH.

[Continued.]

be properly introduced and brought on?—I do not know. The employer that I usually work for, quite fell into the use of it right away. He does not use it always. Of course we use white lead nearly always now, but he is quite ready to be adapted to zinc-white.

3154. (Mr. Sutherland.) Who is your employer?—Mr. Cubley.

3155. (Mr. Gardener.) Have you used zinc-white outside?—It was used on one job, and it was a failure. I readily admit that.

The witness withdrew.

Mr. FREDERICK WILSON examined.

3158. (Chairman.) Do you live at 3, Tanfield Terrace, Birkby, Huddersfield?—Yes.

3159. What practical experience have you had in the house-painting trade?—Twenty-four years' experience with one firm.

3160. What branch of the National Society of Operative House and Ship Painters are you connected with?—The Huddersfield branch.

3161. Are you speaking for yourself now or for the men you represent?—I am speaking for myself, from my experience in the firm I am employed by.

3162. Have you had any experience of lead poisoning among the members of your branch?—To tell the candid truth, I have had trouble myself.

3163. But have you had any experience of lead poisoning among the members of your branch?—Yes.

3164. Will you name the principal causes which, in your opinion, contribute mainly to the prevalence of lead poisoning among house painters?—My experience in the trade (and I have vast experience for a young man) is that it is the rubbing process in the preparation work.

3165. As regards the dangerous process of dry rubbing and sandpapering between the application of one coat of paint and the next, is it impossible to dispense with this and replace it by wet rubbing with pumice stone and water?—No, it is not possible.

3166. Would the pumice stone and water method tend to destroy the film of newly dried paint which has not had time enough to harden completely?—Yes, it would be detrimental to the work he was carrying out.

3167. Then as to the spray from the brush, when you are painting ceilings with moulded or relief work, and when you are doing stippling, to what extent does the painter risk the inhalation of lead paint?—The worst of it is that when you are laying it on raised materials there is a certain amount of splash comes from the brush as it spreads out. You hold your head off, but you cannot avoid it. It covers your face and lips and everything. Then with regard to stippling, when you are going across the ceiling and back it sprinkles it so fine that you cannot see it, but you inhale it, and it drops on to your lips, and you naturally feel the taste of this lead.

3168. Can you tell us anything of the danger arising from the burning off of old paint with a spirit or charcoal lamp?—Ours is a firm who do a lot of burning off, to secure a good finish to the work, so that there will be no bad coating underneath, and nearly every man I come across has complained to me on the job about it. I have even had to stop a set of men and put another set of men on because the burning-off has been so bad. They have all suffered and have not felt well after this burning-off process.

3169. (Mr. Sutherland.) Is that with the lamps?—Yes.

3170. (Chairman.) Does sandpapering very generally follow this operation?—Yes.

3171. Is not that very dangerous?—There is a lot of dust and old paint and so on, and it is awful.

3172. Where are colours usually mixed?—We have a bench in every job we do.

3173. Is it usually in one of the rooms?—Yes, in one room which is convenient to the job we are carrying out.

3174. How does the danger arise in the work of mixing colours?—Of course some people may think it

3156. Was that due to mishandling?—I think so through not thoroughly understanding it. It turned black after it had been applied for some time.

3157. (Mr. Parsonage.) If it was mixed with varnish or boiled oil, do you not think it would stand?—Yes, I cannot see myself why it should not.

(Chairman.) I do not see the use of asking these questions, because we cannot use this evidence. We must have the actual experience of the people who have tried it and tested it.

is a dirty man, but I pride myself on being a very clean man.

3175. That is not the point. How does the danger arise in the work of mixing colours?—I think with continually working amongst it, with your hands touching the cans, and so on, and boxing one can, and mixing these colours, and handling the can, and always being over it; you cannot get it from the pure lead, as it is, but as soon as you commence to mix it with turpentine and oil the fumes are a lot stronger. You will find in working in people's houses that people who never touch the lead complain that the smell, and so on, makes them feel ill.

3176. Do you think the danger arises from the fumes when it is mixed with turpentine and oils?—Yes. The fumes do not do a man any good. I think it tends against his health.

3177. Have you known of cases of particular men receiving injuries from it?—Yes, if they do the work.

3178. Have you known many of them?—Yes, men I have tackled—but I have done most of the jobs; I do nearly all the mixing.

3179. Does it affect you?—Yes, it affects me very much.

3179A. In what way does it affect you?—I have had five doctors that I could refer you to if you wish, and it has always been lead poisoning.

3180. From this particular operation of mixing?—Yes, the mixing.

3181. Is your work confined principally to mixing?—Yes, in charge of jobs, mixing all the stuff for the other men.

3182. Do you get any of this mixed stuff on to your hands?—As I tell you, I am very careful indeed.

3183. Do you wash your hands immediately after you have mixed this lead with the oil?—Many times a day I go to the wash basin or bucket, with the soap, and wash my hands, particularly if I have been doing a big mixing job.

3184. Do you wash your hands immediately after?—Yes, I do, because I have been warned for years on that point, for the good of my own health.

3185. Do you think it necessary to have hot water?—It is not always handy to have it.

3186. But do you think hot water is better?—Yes, you get a better effect. Of course we use soft soap, which is very searching stuff.

3187. How can the evils arising from such dust and spray as you have told us of be overcome?—I will tell you one way in which I think it can be overcome. I have a privilege which few men enjoy. I am very pleased to say I work for an employer who is very much in favour of this idea of doing away with the white lead, and we have used, this last five years, more non-poisonous paint than I dare say 20 firms you could name. I have had the privilege of experimenting for years on panels alone, and trying it with three or four different pigments that we have used, and I find they are all right, and I find as years go on that I am improving in health every day.

3188. Does your employer know that you are coming up to give evidence to-day?—Yes, I have had to ask off from the work.

3189. Did he know that you were going to make that statement?—I do not think he does know, because he has left everything to me.

3190. (Mr. Parsonage.) Would he object to you making that statement?—Not in the least. What I

5 April 1911.]

Mr. FREDERICK WILSON.

[Continued.]

say here I am perfectly justified in saying and anybody can write to him.

3191. (*Chairman.*) Do you believe it is impossible to stamp out the evil of lead poisoning without replacing the lead by some non-poisonous substance?—I believe it can be stamped out.

3192. Do you believe that it can only be stamped out if lead is prohibited?—If lead is prohibited altogether.

3193. (*Lord Henry Bentinck.*) Can you give any reason why mixing should be so unhealthy?—My reason is that when a man is continually over the mixing bench he is inhaling those fumes and disagreeable smells which arise from the paint.

3194. Do you consider that the unhealthiness is caused by the fumes more than anything else?—I think so, as far as I can tell.

3195. (*Dr. Collis.*) How many attacks have you had that you have attributed to lead?—I should say about 10.

3196. Are you chiefly occupied in mixing?—Yes.

3197. Can you remember whether any single one of those attacks has followed when you have been doing mixing only, and have not been doing any other work whatever?—It is rather a peculiar question for me to answer.

3198. It is a difficult one, possibly?—I am not engaged mixing all the day through.

3199. That is the point I want?—I sometimes break off and do a little papering and other work.

3200. But do you do painting?—Yes, I do a little painting as well. I may tackle the door of a room and carry it through myself. I could not say definitely that it has all arisen from the mixing.

3201. I only want to know if at any time you have been doing mixing only and not any other painting work?—My biggest work is mixing.

3202. I understand you have used a large amount of non-poisonous paints?—Yes.

3203. You have mixed those?—Yes.

3204. What is your experience in mixing those, as regards the smell of which you speak which comes off them during the mixing?—I find I have no difficulty whatever. We are using them now on nearly every job; in fact I commenced a job on Monday. A keg of zinc white was sent on to the job, and there was never a mention about any lead. As I tell you, my health is getting better every year.

3205. If you were given two sets of paints of which you knew absolutely nothing as to what they were, and you had to mix those paints ready for use, could you tell which was lead and which was not?—Yes, I could tell it was zinc white or Charlton white or Dixon's.

3206. (*Lord Henry Bentinck.*) Does your employer use this zinc on outside jobs as readily as he does on inside ones?—No, not on outside work.

3207. He does not use it at all on outside work?—Yes, if it is going to be enamelled with china gloss enamel on the outside work he will use it.

3208. What do you mean by "if it is going to be enamelled with china gloss on the outside"?—If he specified a job to be enamelled with china gloss. If he was going to paint the outside of that window, and he was going to have a gloss surface on, he would have no hesitation in using it.

3209. If he was going to paint one of the London houses with white paint, would he?—The china gloss would answer all the effects of washing and everything else.

3210. It is a preservative?—It is an enamel.

3211. Would it add greatly to the expense?—Yes, it is a fair expense. As regards conversations I have had with my employer, he has said that if they made this non-poisonous lead universal and abolished white lead altogether, he is with us to abolish it and use nothing else.

3212. Would he use white enamel and varnish on the top of it?—Yes, and for the outside too.

3213. (*Mr. Sutherland.*) Which is your firm?—Messrs. Lunn and Cardno.

3214. How long is it since you had an attack of lead poisoning?—About three years ago, a severe attack.

3215. Is it since then that you have been using these zinc and non-poisonous paints?—Yes.

3216. Before that, or within the last three or four years?—The last three or four years I have used a lot.

3217. You said that you thought the principal cause of lead poisoning was rubbing down?—Yes.

3218. But still you say that so far as you are personally concerned it is the mixing?—Years ago I was not in the position that I have been in this last eight or nine years. Years ago I used to be mostly employed in rubbing down and doing the work generally myself, and I was at my worst then. I did my own mixing, practically. I did minor jobs, and did my own mixing paint, and everything, and preparing all the lot.

3219. But ordinary painting work, moderately cheap work, does not have much rubbing down, does it?—On a cheap job you cannot spend the amount of time.

3220. It does not get much rubbing down?—No.

3221. Whatever rubbing down there is, is just the dry rubbing with pumice stone, just to give a pretence of rubbing?—Yes.

3222. So that with cheap work it would not give much trouble with sandpapering?—No.

3223. Have you much complaint on the part of customers from the smell? You said that customers complained in your experience?—Yes, I went to a certain doctor's place, and he said I shall have to go away. We were doing all the burning off on a staircase. It was not in a room.

3224. Is that a very unpleasant process?—Yes.

3225. Turpentine will, if it is used, upset people sometimes?—Yes.

3226. With some people it is a restorative or a stimulant?—Yes.

3227. And tar is a stimulant with some people?—Yes.

3228. So that that is really a personal idiosyncrasy, is it not?—Yes.

3229. You say you mix a lot of paint?—Yes.

3230. And you wash your hands frequently?—Yes.

3231. So there is no danger comes through negligence on your part?—No. I am very pleased to say that they allow all of us to wash, everybody on the job, and there is boiling water and a lump of soft soap, or something, to wash your hands in before you have a meal.

3232. (*Mr. Parsonage.*) That probably only applies to that particular place?—To our shop in particular.

3233. (*Chairman.*) How many men use this one bucket of water which you have described?—If there are 12 men on the job they will all dive into it. They do not allow us to use the lavatory in a private house as a rule.

3234. What is the state of the last man's hands when he puts his hands into that water?—The last man will not be as clean as the first man; that is evident.

3235. And do you all use the same towel?—Yes, we do not get so very many fresh towels.

3236. (*Mr. Sutherland.*) Do you not carry your own towels?—No.

3237. Do you not think you should, as clean men?—It would be better, no doubt, if we did.

3238. Do you not think that all the men should each carry a towel?—It would be very difficult, sometimes, to put all these things into your bag. I carry a bag, and sometimes I cannot get my jacket that I work in, in the bag.

3239. Do you carry your food in your pocket?—No. I am placed so that I get home to nearly all my meals, unless I am working out of town.

3240. But even then, you do not carry your food in your pocket, do you?—No.

3241. Do you put it in a bag or basket?—No.

3242. Do you leave it at your lodgings?—Yes. I do not believe in having any food in the room where I am working. If I took it with me I should ask for it to be put in the cellar, if they would allow me.

3243. Have you any facilities on a job for getting hot water for washing?—Sometimes.

3244. But generally speaking?—I think if you ask people properly they will not object to it.

5 April 1911.]

Mr. FREDERICK WILSON.

[Continued.]

3245. (*Mr. Parsonage.*) With regard to durability of non-poisonous paints, how long is it since you first used these?—I should say five years ago.

3246. And you would think that it stands quite as well as the lead?—As far as I can gather. We have had tests made on the jobs that we go back to, and we have never had any complaint. I have done panels, and they are all in our shop to-day, and they have been exposed to the weather, and to the light, and so on, on the window side of the room. The panels have been done with four or five different materials, and if you did not know which was which you could not tell the difference in the materials; I am quite sure of that.

3247. (*Lord Henry Bentinck.*) Is the competition keen in Huddersfield among the painters?—Yes, it is very keen.

3248. Do you think your employer loses one job because he does not use white lead?—I could not tell you.

3249. (*Mr. Sutherland.*) He does use white lead, does he not?—Yes.

3250. (*Chairman.*) You told us just now that you generally go home to lunch?—Yes, I am very fortunate.

3251. Do many men go home to lunch?—No.

3252. Where do they generally have their meals?—Sometimes in the kitchen of the house, or where they can get them, and sometimes in the outside places.

3253. Do they ever have their meals in the place they are working in?—Yes, sometimes they cannot help it.

The witness withdrew.

Mr. FRANK LOWE examined.

3254. (*Chairman.*) Do you live at 81, Radnor Street, Hulme, Manchester?—Yes.

3255. What practical experience have you had in the house-painting trade?—I have been in the trade a matter of 33 years.

3256. What branch of the National Society of Operative House and Ship Painters are you connected with?—I am connected with the Manchester No. 1 Branch as a member, and I am organiser for the Manchester district.

3257. Have you had any experience of lead poisoning among the members of your branch?—Yes, in the Manchester district I have had 30 cases come under my notice.

3258. In what period?—Since the Compensation Acts have taken effect in reference to lead poisoning—since it has been brought in as an accident.

3259. That is since 1907?—July 1907 the Act was brought into force.

3260. Have those cases that you have referred to been fatal cases?—In some cases they have been fatal.

3261. What state of severity have the others been in?—We have had five deaths out of 30.

3262. Have the other 25 been serious cases?—Serious cases. Some have received compensation and been bought out; that is, they have received a lump sum and they have gone back to the trade and have again contracted lead poisoning.

3263. What, in your opinion, are the principal causes which contribute mainly to the prevalence of lead poisoning among house painters?—One of the principal causes is the rubbing down with glasspaper of the preparatory coats of white lead, and, again, the rubbing down with glasspaper of what we call hard filling or stopping, which is white lead. Bruises in the woodwork and uneven surfaces are filled with a hard filling of white lead and gold size, and in rubbing it down the dust from that is, in my opinion, one of the principal causes of lead poisoning.

3264. Do you believe that there is any injury caused from the fumes?—Yes, I do. One of the principal items, I consider, in my experience as a painter, is embossed ceiling work, which is flatted, and in the process of flattening you use purely a spirit colour, nothing but lead, turpentine, and a flattening with a gold size or varnish. With regard to the process of putting the colour on, it is laid on by one set of men, and stippled by another, with a large stippler. With regard to the man who is stippling, his head is always in that position, and his hands up there (*illustrating*), and his face and hands are covered with a fine spray of particles of lead. I have examined men when they have finished the process, and I have found that their faces were covered with miniature spots or specks of lead; and I have found the teeth and gums covered with lead. From the inquiries I have made and records I have taken, with regard to the principal persons who have suffered from lead poisoning, I have only found one man in the whole of my experience with a heavy moustache: he is the only one who is suffering to-day

from lead poisoning. The principal cases of lead poisoning that I have discovered have been men with either a slight moustache or no moustache at all. I have taken these statistics as I have gone along, and I have put it down that those men who are clean shaven find particles of lead getting on to the teeth and gums and the saliva of the mouth dissolves it, and they take it into their system in that way. When you see a man with a heavy moustache, after a day's flattening work, you find it is actually saturated, and soap and water have to be applied to remove it from the moustache. I have experienced that myself.

3265. As regards the dangerous process of dry sandpapering between the application of one coat of paint and the next, it is impossible to dispense with this and replace it by wet rubbing with pumice stone and water?—The process of wet rubbing is not in practice to-day in any painter's shop in the city of Manchester. Some 20 years ago they used to rub down, at one time, towards the finish of the coats, with ground pumice stone and felt as a finish, but those days have gone.

3266. Would the pumice stone and water method tend to destroy the film of newly dried paint which has not had time to harden completely?—It would be impossible to rub it down with pumice stone and water in the ordinary way, without it was ground pumice stone and felt, and then the colour would have to be hard drying colour all the time.

3267. Would not the newly dried paint clog the pumice stone very quickly and so render it useless?—Yes, you could not use it. It would tear it to pieces.

3268. Can you tell us anything of the danger arising from the burning off of old paint with a spirit or charcoal lamp?—Yes; the danger of burning off with a spirit or charcoal lamp is that the flame of the lamp close on to the work softens the old material, and the man applies a scraper to get it off, and all the while his head is over it, and therefore he is inhaling the fumes of the burnt material, oil and lead, the whole of the time he is doing that process.

3269. Sandpapering very generally follows this operation, I understand?—Yes.

3270. Is not that very dangerous?—It is.

3271. Do you know anything about mixing colours?—Yes, I was a mixer.

3272. How does the danger arise in the work of mixing colours?—The danger arises from the mixer standing over the "kettles" he is using. If it is on a bench his head is over it all the time, and, of course, he is inhaling the fumes from that the whole of the time. Then, again, a mixer may not be burning off in the ordinary sense, but he is all the time getting what they call stook cans ready in his leisure time in the shop. He throws a dash of turpentine in it, sets fire to it, and then takes his palette knife and scrapes it round. Therefore, he is bringing out the dry lead from the sides of the cans, and he is inhaling that as well. That is why a good many of the mixers, not at actual work in burning off and flattening work, are hooked in their hands. The majority of our

5 April 1911.]

MR. FRANK LOWE.

[Continued.]

mixers are hooked in their hands, and I put that down to no other thing than the scraping out. You might find a man who is a mixer, the whole of his life, perhaps, not applying colour himself, or sandpapering in between coats. He stands with the can hot, with a sheet of paper over it, and he takes his knife and swirls round the whole of the loose lead in the can with the turpentine and there comes out a sheet of dust. I put that down as one of the principal reasons for the mixer having hooked hands.

3273. Do I understand that that process which you have described greatly increases the dangers to the mixer?—Yes, to the mixer. If the cans were pickled or burnt out with a slow process, there would not be that danger.

3274. Do you think that the provision of washing conveniences and the regular cleansing of the hands is important?—It is important.

3275. Is hot water always available?—It is not available—and very seldom cold water in the Manchester district. It has been made compulsory in our working rules that the employers should supply boiling water for meals. That had to be put in the rules because it was nearly impossible, in large centres of industry like Manchester, to get hot water.

3276. (Mr. Parsonage.) It is not for washing hands?—No, it is for meals.

3277. (Chairman.) With regard to your meals, where do the men generally have their dinners?—Taking it on the whole, on new property (and I cannot account for this), what we call the jerry property, where there are plenty of rooms, I have found the men actually having their meals in the lock-up where the paint is kept.

3278. Why do they use that room?—For the reason that the other rooms are not protected by closing them and locking them up. There is nothing compulsorily provided for the men to have their meals. They are scattered over a job the whole of the morning or afternoon, and they put their clothes in this lock-up, and when the place is not actually being used by the foreman it is locked up, so they do not run the risk of losing their clothes. Their food is there, as well, in that room.

3279. Do the men usually wear overalls while at work?—Yes, always a jacket and an apron; and sometimes trousers.

3280. How are they kept clean?—The men take them home weekly to be washed.

3281. Do you frequently have to carry them in your tool bag?—Yes.

3282. Is there any risk in that?—If the man puts his food in the tool bag there would be.

3283. Does he often do that?—In changing jobs he does.

3284. Why is he not more careful?—He simply packs the lot into one bag. I did not do it myself. I always had a bag for carrying my food, but I have seen men put food into the bag with their overalls.

3285. How can the evils arising from the dust and spray which you have described be overcome?—In the first place, the only way to overcome them is to absolutely prevent the use of white lead in the painting industry.

3286. Have you yourself had any experience in the use of non-poisonous substitutes for white lead?—Yes, where I served my time. I served my time in New York.

3287. Have you formed any opinion as to their practicability for general use?—Yes, zinc-white is just as good as the white lead. There is a slight prejudice against it, but it is simply because the workers do not seem to understand the use of it.

3288. Do the workmen that you represent find any difficulty in using such paints?—They find no difficulty in it. They use it successfully in Manchester.

3289. (Dr. Collis.) Did I understand you to say that there is a definite smell given off when you are mixing lead paints?—Yes.

3290. You spoke also of fumes coming off when you are burning old paint off?—Yes, there are.

3291. Is there any similarity in taste or smell between those fumes and what you get when you are mixing paint?—They are about the same.

3292. You think they are about the same?—They are. When you come to burn paint, you get almost the same fumes from the burnt paint.

3293. Have you ever had to burn off leadless paints, zinc paints?—I have never burnt any off myself.

3294. There is one point I want to get quite clear in my mind with regard to the cleaning of the cans. Do I understand you to say that you put turpentine into the can and set it alight?—Yes.

3295. Where would the man be after he set it alight?—He would be just by it, waiting till it goes out, and then running a knife round the can.

3296. Could he not stand a yard away?—He could if he liked, but he has to stand close to it, because he keeps revolving the can to stir it.

3297. So he must be close to it?—Yes.

3298. Have you done this process yourself?—Yes.

3299. Have you noticed any taste or smell coming off from that?—Yes, there is a foul burnt smell.

3300. Is that anything like the smell that comes off in the mixing, or the fumes from burning off?—Yes, it is exactly the same; the fume of the lead is there.

3301. I want to get it from you whether you recognise the smell?—Yes, it is exactly the same smell.

3302. Then afterwards do you turn out the dust and shake it aside?—Yes, we turn out the dust.

3303. (Mr. Sutherland.) Do you say that rubbing down by the wet process is absolutely obsolete in Manchester?—Yes, except in the first commencement of preparation on a job.

3304. That is the rubbing down of old work?—Yes.

3305. How long is it since you actually worked at the trade?—Twelve years.

3306. In reference to the case that Dr. Collis has spoken of, the burning out of cans, have you ever known that affect anybody?—I have known men complain of the fumes.

3307. But it is a common practice, is it not?—It is a common practice in the trade to burn them out.

3308. It is an everyday operation, is it not?—Yes, it is, among the trade.

3309. Your reply seemed to show that the mixer did it; it is not necessarily associated with the mixer, is it?—He generally does it.

3310. Whom do you call the mixer?—The man in charge.

3311. The foreman?—Yes.

3312. The foreman would not clean out the cans, would he?—He does it.

3313. He may clean out a can now and again, but would he not set a boy to clean out the cans?—It just depends upon whether the boy is there or not. Boys are not very plentiful in the trade.

3314. Then he would set a labourer to clean it out, would he not?—Labourers are not very plentiful in the trade at Manchester. You might have a labourer on a large job, with 500 men, or something like that.

3315. You think a moultache prevents the danger, do you?—Yes, I do. It prevents it getting into the mouth, at any rate.

3316. You were asked whether rubbing down with pumice stone and water would be permissible on new work, and you said "No"?—No, except with hard material.

3317. But rubbing down with pumice stone and water and felt is done in the best work to-day?—There is no felt used in the Manchester trade to-day.

3318. You must not tell me that, because I know there is?—I have a decent experience.

3319. On what you call the jerry work, the cheap work, there would be no rubbing down with anything, would there?—Sandpaper.

3320. How much?—They do it.

3321. It would be a pretence of it, would it not?—They generally do the doors.

3322. But that would not be much, would it, because they want to leave the paint on?—They want to get smooth surfaces.

3323. They do not get smooth surfaces on jerry-built jobs, do they?—You can class most jobs as that now.

5 April 1911.]

Mr. FRANK LOWE.

[Continued.]

3324. There are plenty of good jobs, but with jerry jobs they do not rub down with sandpaper to any extent, do they?—On all jobs there is some done.

3325. But that would not be enough to affect the health of the painter, would it?—There is some danger in it.

3326. If you are dealing with nice work, with varnish and enamel, you rub down; but on cheap or jerry work you do not get the rubbing down that would produce dust which causes the poisoning?—I am not in a position to say how much dust would cause the poisoning, but what I am going to say is that on all jobs, let them be rough or good jobs, a certain amount of preparatory work is done.

3327. It is done with lump pumice stone on cheap work more than anything else, is it not?—It is done with sandpaper, in my experience.

3328. What I want to establish is, that the jerry work forms a very large proportion of painters' work. You know the large proportion of jerry property that is put up, and therefore there must be a large proportion of jerry painting. My contention is that rubbing down there is a negligible quantity; it is more honoured in the breach than in the observance?—But still it is done.

3329. Very likely, but is there anything in that that would seriously prejudice the health of the painter?—The majority of lead poisoning cases that I have dealt with up to now have originated in the best shops. I have not had many from what you call the jerry property—perhaps 3 out of 30.

3330. (Mr. Parsonage.) The better the work the more the danger?—The better the work the greater the danger.

3331. (Mr. Sutherland.) A man does not, when he is burning off with a lamp, hold his head over the lamp, does he?—The lamp is in one hand and the knife is in the other, and they are both close together, and there is only the length of his arm to keep him away from it at any time.

3332. He could not keep his head over the lamp or he would get it scorched, would he not?—He must be in that position. He cannot get the lamp far enough away from him to avoid the fumes. He is all the time on top of his work. There is only the length of his arms.

3333. You could rub down with pumice stone after using the lamp, could you not?—It is not quick enough.

3334. Could you not rub down with pumice stone and water just as quickly?—No. They do not do it, and for this reason, that the pumice stone would have to be shaped for the moulds, and with regard to the rubbing down and burning off of the jerry property, they simply tear it to pieces with sandpaper.

3335. (Mr. Parsonage.) If the paint is burnt off clean, you could not put water on it, because the water would get into the grain of the wood, would it not?—Yes, in some cases it would.

3336. In some cases you could, but generally you must use glasspaper. Is not that so?—Yes.

3337. (Mr. Sutherland.) Now about the washing conveniences. There is invariably water on the job, is there not?—Yes, you can generally find water of some description.

3338. And the working rules provide that hot water must be given for meals?—Yes; and that had to become compulsory.

3339. These rules were mutually agreed upon, were they not?—Yes; the Arbitrator decided them.

3340. But there is no compulsion on one side or the other: it is mutual agreement?—Yes.

3341. If they can get hot water for meals they can get hot water for washing, if they want it, can they not?—It just depends. If the employers were to make that part of the conditions when they took the work, they could get it, but if the men went and asked for a kettle of hot water, without there was a hot water tap, they might not get it. If there was a hot water tap in the house they would not object to giving you a bucket of hot water, but in these warehouses and offices and property of that sort there is no hot water tap.

3342. There is nothing to prevent the man from boiling it in a bucket on the fire, if he can get a fire, is there?—No, but take the large number of staircases that are done, where you are simply allowed to come in and go out, and you do not get near anything else.

3343. Do you mean warehouses?—Yes, and office property, which is a big item in Manchester.

3344. Where do you get the hot water for your meals, then?—They generally have to go to a restaurant and pay for that. They send a boy out to the restaurant, and he gets hot water and pays a halfpenny a can for it. You have experienced that on your time sheets, I know.

3345. What experience have you of zinc white?—At the commencement of my career the standard in America was 60 of zinc to 40 of lead. We used nothing else.

3346. But that would not be accepted as a non-poisonous paint?—No, it was not done for that purpose at all. The experience in Manchester with zinc is very limited. We have the Government stipulating that no lead shall be used upon their work, so far as the post offices are concerned; zinc is used there; and we have the Manchester School of Technology, each floor of it, and the whole of their work now is being done with zinc.

3347. Do you know what kind?—A firm in Liverpool supplies it. I do not know the name. It is guaranteed to be pure, and it stands the analyst's test.

3348. You say that the workmen find no difficulty in using it?—Not in using the material. We had 160 men in one department on this technical school last August, and the August before we had 280 men; 175 for the contractors, and the rest was made up from direct employment.

3349. That is on the School of Technology?—Yes.

3350. Do you know that the employer who did that contract was ignorant of the process of working zinc, and he lost a very heavy amount of money on it?—Yes, and I know the reason he lost it. I was one that appealed on his behalf. There were a lot of matchboarded ceilings, and the joints had to be caulked with cotton and filled up with zinc stopping, and then he tendered for a certain amount of machinery that he knew nothing about at all. He did not get underneath to see it.

3351. He lost it because the men were unfamiliar with the process, and could not get a satisfactory job to satisfy the clerk of the works?—I could tell you exactly why he lost it. He lost it because the man in charge of the job put the wrong men in the wrong places.

3352. I am asking this because you say that the workmen find no difficulty in using it?—No difficulty in using it.

3353. Is it not a fact that they do?—In my experience I have painted perhaps 80 or 90 figures with the zinc white, and I never had any difficulty myself. You can get just as decent a finish and just as quick or quicker than white lead.

3354. Have you any experience of it on outside work?—No. I have seen some work where it has been experimented with, and where it is fastened or varnished with gold size it stands just as well as other work.

3355. (Mr. Parsonage.) With regard to this school where they used all this zinc white, was there any other trouble with the contractor besides the material he was using?—Yes.

3356. Was there any trouble about the rate of wages he was paying?—Not on that occasion.

3357. But you had trouble with him?—Yes, trouble with non-society men—inferior men.

3358. Inferior men that he brought into Manchester?—Yes.

3359. He had to replace those men with others, had he not?—Yes.

3360. That would cause him a loss, apart from the materials, would it not?—On jobs when you have to take a large number of men on, when they know they are only on for that job, you do not get the same out of them as you would from a regular staff. He had a man on at the time who was not fit to organise the job, as I

5 April 1911.]

Mr. FRANK LOWE.

[Continued.]

told him at the time, and I tried to assist him at the time, because I realised that the employer was fair, and if we could help him we would do it. I suggested an alteration in the organisation of the job.

3361. It was not the material?—No, there was no difficulty of that sort. These other men have worked at the other school themselves and have applied this material, and there has been no difficulty with them in doing it. There is a difficulty when the man first starts breaking it up until he knows how to break it up; but there is no more difficulty with this material than with lead or anything else. There is difficulty with enamels until you get to know them.

3362. (Mr. Gardener.) Do you think that personal cleanliness has anything to do with lead poisoning?—I think it has a lot to do with it. There are three out of the 30 cases that I have here that I would expect to have lead poisoning.

3363. Why?—Because of their dirty habits. The others have been exceptionally clean men.

3364. You have 27 out of 30 exceptionally clean men?—Yes.

The witness withdrew.

Mr. HENRY ALEXANDER CAMPBELL examined.

3371. (Chairman.) Are you a master house-decorator?—I am.

3372. Where is your business?—Our office is 25, Newman Street, Oxford Street.

3373. How long have you been engaged in the painting trade?—I have been engaged in it about 35 years.

3374. Have you been an employer all that time?—Yes. I joined with my brother in business, after he had been established about 10 years, as a partner.

3375. Perhaps you can tell us about the number of men you employ?—Of course, it varies very much, but I have taken as an average about 60, generally, through the year, as near as I can tell. It goes up to 100 or 120, and sometimes it drops down to 20.

3376. Now, about lead poisoning or painters' colic, have you known any cases of it?—Some slight cases I have known, but nothing serious. In all my experience I have never had anyone die of it, and none of my regular men have ever suffered from it. Cases that have occurred have been casual.

3377. Do you mean that you have paid no compensation?—None whatever.

3378. Or that your men have not, to your knowledge, broken down on account of lead absorption?—That is what I mean.

3379. Have your men had occasional days of sickness due to lead?—Not that I know of, due to lead. Of course, they stop away at times, but they have never reported that it has been due to lead.

3380. How do you know that it is not due to lead?—I do not know that, when a man stays away for a day, unless he reports it to a foreman. Perhaps he says he was not feeling well, or it might be only laziness or disinclination.

3381. Do you have a periodical medical examination of your men?—No.

3382. Then is it possible that some of them may be suffering from the slower and more insidious forms of the poisoning. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—Yes, it is possible, but highly improbable.

3383. I have an impression from your answers that you hardly realise the magnitude of this lead poisoning evil. Do you know that the Registrar-General has recorded no less than 28½ definite deaths from lead poisoning amongst house painters in the last 10 years?—I have heard of it.

3384. And that his mortality figures show, for painters, a death rate considerably higher than the normal, from troubles which are the frequent effects of exposure to lead, such as Bright's disease and nervous diseases?—May I take it that that is connected with my part of the trade, that is, house painters and decorators?

3365. And yet you lay great stress on cleanliness as a preventative?—If a man is cleanly in his habits it will help him in his health in all senses.

3366. I understand you to say that your employers at Manchester supply you with hot water for meals. Did you ever know of an employer supplying you with coal in an empty house for providing hot water for washing purposes?—Yes, I have got it and charged it myself.

3367. Is it a customary thing?—It was principally to melt the size that he supplied the coal.

3368. (Mr. Parsonage.) Not specially for the men washing their hands?—No.

3369. (Mr. Gardener.) If you had no size on the job which required to be melted, would the employer supply you with coal to make hot water?—I do not think any employer would object to finding a reasonable amount of coal to boil water.

3370. In practice is it customary for them to do it?—No, it is not done as a custom.

3385. Yes?—I was not sure whether it was applying to coach building, and what I call the more risky forms of painting.

3386. You are not aware of that?—I am not.

3387. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever, in the last 10 years?—I do not.

3388. Do you realise that these cases, reported voluntarily, as I have said, are only a fraction of the whole, inasmuch as the Home Office have no legal right to pay for such reports, and have, therefore, been bound in the past to discourage reporting to some extent?—No, I do not know that.

3389. I am sure you will agree with me that all this sickness and death is very deplorable?—Very.

3390. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, I do. I have heard of it in France particularly.

3391. That the use of white lead has been prohibited to an appreciable extent abroad?—Yes, I have heard so.

3392. And that the work of painting has been most strictly regulated in several countries where the use of white lead is still allowed?—Yes, I have heard that it is—not in many countries, but in several countries I have heard that it is.

3393. Do you not think it is regrettable that this country should be behind other nations in this respect?—Of course, I think a certain amount of legislation is necessary.

3394. A good many small dangers attend the use of lead. For instance, the risk of contamination of food by unwashed hands?—Yes.

3395. Do you attach importance to personal cleanliness on the part of the men?—Very much importance.

3396. Do you consider lavatory accommodation essential?—Most essential.

3397. Including the supply of hot water for washing?—Yes.

3398. Is it generally practicable for the men to have hot water to wash in?—Very generally—in fact, mostly so. We take special care that it is so. They could scarcely carry on their work without a certain amount of hot water.

3399. For example, when the exterior of the house only is being painted, and the men are not expected to go inside for any purpose?—In any case they must have a collar, or some place where they can make hot water.

3400. But not necessarily?—They could not mix their paint and get on with their work without it.

3401. But they do that in a certain place away from their work, do they not?—I do not see how they could.

5 April 1911.]

MR. HENRY ALEXANDER CAMPBELL.

[Continued.]

My men are always instructed to take pails, and they would ask for a cellar or an area, and if they could not get anything else, they would take a few bricks and stack some wood and make a fire and make some hot water to wash in; that is, if they could not get access to a fire.

3402. Do you advocate definite rules regarding the wearing of overalls?—Yes.

3403. How can you ensure these being kept in a cleanly state?—If a painter was to come on any of my jobs on a Monday morning without a clean one he would be either sent back or discharged.

3404. If the workman has to take his overalls with him in his bag, will they not be in contact with his tools?—He does not carry his tools in his bag.

3405. The men who have been here to-day say they do?—If that refers to paint brushes and things I say no, certainly not.

3406. (*Mr. Parsonage.*) His own tools?—A painter has no tools except a putty knife, or something of that kind.

3407. Has he not?—No, his employer finds him in all tools.

3408. Does he find him with a broad knife and filling knives and a board?—With a board certainly. Painters very often have a knife of their own, a palette knife, when they are going to mix paint, but the ordinary painter does not need it.

3409. Do you provide a stripping knife and a broad knife, and so on?—Yes, with many of them, but ordinary painters would not want those, and they do not have knives which would convey very much white lead on to their overalls. Some of the painters have knives, but they do not have anything that would spoil the overalls by contact.

3410. Some of your men would carry a few fitches too, would they not?—They may do, but they are not their own, if they do.

3411. (*Chairman.*) Where can the overalls be kept from day to day when they are working continuously on one job?—The foreman has a box which he puts in a room, and if there is not room in the box they would hang them round the walls of a room that was not being used.

3412. Can you always provide a place for the painter to hang up his coat?—We have to ask for it.

3413. But can you always provide a place where there will be no risk of dust falling upon it?—It is nearly always arranged that one room shall be set apart till the last.

3414. Do you advocate also a rule regarding meal rooms, so that no man shall eat his food in the place where paint is being handled?—Most certainly.

3415. But the witnesses who have been here to-day on behalf of the men have told us that invariably they have to eat their meals in mixing shops and places where they are working?—It is not my experience. They cannot work for very good firms.

3416. Supposing a set of men are painting in one room, where are they to have their meals then?—If there is only one room, do you mean?

3417. Yes?—We should ask, on their behalf, that they should have another room.

3418. Who would ask?—I should ask the clients, through my manager or my foreman. If we are sent on country jobs a room is provided the whole time for the men to have their meals in—outside the house generally or in the kitchen—certainly not where the painting is going on.

3419. All these precautions, which I have enumerated, are insisted on for the mitigation of lead-poisoning risks in potteries. Would not it be exceedingly difficult, from your point of view, to carry them out in the house-painting trade?—I do not think so, if the foreman had proper instructions.

3420. Even supposing that is the case, such precautions would not deal with the most important risk, namely, the risk arising from dust and spray which the workman is inhaling during the whole of his working hours?—No, that would not affect that, but that is pre-supposing that the risk always exists to the workman. We contend that it does not so much.

3421. I will take you through the processes then. First, as regards the dry rubbing down with sandpaper.

I understand that this process is indispensable?—It is indispensable to a certain extent. We rub down principally with pumice stone and water all the old lead, and where there is rough joinery, or anything of that sort, we use glasspaper. Then if the work is not smooth enough we may allow a man to give it a coat of fine glasspaper, but in that case he is advised to use it with a little turpentine and moisten his glass paper.

3422. Is the dry method not applied invariably to newly-painted surfaces on which the paint is already dry?—No, I should not allow one of my men to use the glasspaper indiscriminately.

3423. Is the dry method not applied invariably to newly-painted surfaces between the coats?—To a very limited extent, or else he would take off what he has already put on: he must not do that. I say he might just take a little where he sees any slight roughness in the surface, but it would be very small. He certainly could not go with a large sheet of glass paper and rub that all down and cut off what he has just put on, or else we should be very great losers by it.

3424. I understand the wet process cannot be substituted for dry rubbing between the first and second coats when ordinary paint has been used? That is so, is it not?—Yes.

3425. It is only on high class work which has to be enamelled or varnished that the dry process can be dispensed with, is it not?—Yes, where they felt it down.

3426. But a fresh coat of paint which has dried, say, in 24 hours, but not yet thoroughly hardened, would be spoilt by wet pumice stone, would it not?—We should not pumice stone that; I have said so.

3427. That would be dry rubbed?—Yes.

3428. I suppose the pumice stone would clog?—Yes, it would spoil it.

3429. Where dry rubbing down with sandpaper is indispensable, how can you prevent the worker from breathing the lead dust?—For one thing, they are generally in rooms where the windows are open, and we contend that there is not a large quantity of dust, but what little dust there is can go out of the window.

3430. The workpeople who have been here to-day have told us that the windows are always closed under those circumstances?—In rubbing down, certainly not.

3431. (*Mr. Parsonage.*) When the paint is wet?—Yes, to dry the paint, but we are presuming that the paint must be, to a certain extent, dry, before they could commence rubbing down.

3432. (*Chairman.*) But you think that the mere fact of opening the windows would get rid of all the dust in the room?—All the dust that there is. I contend that there should not be much dust if the painter is doing his work in a proper manner.

3433. But there would be a certain amount of dust?—Yes.

3434. Let us take it that there is only a small amount of dust; how do you suppose that that could be obviated?—I say that if the glasspaper which he uses is moistened with turpentine that minimises it a good deal, because he uses his paper wet instead of dry, and that obviates the dust to a very great extent. Then, again, as regards what dust there is on the floor, we set a labourer to take it up. It would settle on the floor.

3435. But the Home Office have laid down in other industries that every particle of dust must be removed from the worker, either by exhaust draught or some other method?—Yes.

3436. Could that be applied to rubbing down in the case of house painting?—I am not prepared to answer that right away.

3437. At present you think it could not?—No, I scarcely see how it could be done.

3438. So that the amount of dust arising from this sandpapering could not be mitigated?—I say it can be mitigated by what I have said.

3439. But you have agreed that a certain amount must still remain?—Yes.

3440. And that the amount which still remains could not be removed?—No, I do not see how it could; it must be in the room, of course.

5 April 1911.]

Mr. HENRY ALEXANDER CAMPBELL.

[Continued.]

3441. We have been told by one of the witnesses that this dust covers his clothing as well as the floors and surrounding objects. How is it possible to save the workman from this very serious danger involved in breathing this dust?—Of course, I do not agree that there is enough dust to cover himself, or there ought not to be enough dust.

3442. The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

3443. This gives rise to splashes which must frequently fall even on the face of the worker. How can you deal with the spray which arises in this operation?—Of course a good painter would not splash very much if he is a man who understands his work.

3444. Supposing he is not as good a painter as you picture to us, what do you say then?—I should not care to go into a room and see a man splashing about like that.

3445. Do you mean to say that a good painter would make no splashes in the work?—I do not say that he would make none, but he should not make many; I should not like to see him make many.

3446. You said there was very little dust in the operation I was asking you about just now, and now you say there is very little splashing in the operation of painting the ceilings?—No.

3447. But there is a certain amount?—Yes, there must be a little.

3448. That falls on the face of the worker, I take it?—It may fall on his clothes, and that sort of thing.

3449. He has got his face looking up at the ceiling, has he not?—He is working with his arms a certain distance away from his face. I have not observed it, at all events.

3450. But when he is painting the ceiling he could not cover his face with his arm, or he would not see the ceiling, would he?—No, but he would have the brush a certain distance away.

3451. He would be working like this (*illustrating*) so that it fell on his face, would he not?—I have not found it so.

3452. You have never found it fall on his face?—I do not say I have never, but not often. It would not be much.

3453. But there would be a certain amount, would there not?—There might be a certain amount.

3454. Do you think that you could use an exhaust draught to catch the spray?—No, I do not think you could.

3455. Then there is no remedy to remove the evil?—I cannot think of one for the moment.

3456. You think there is no remedy for the evil of the spray which falls from the ceiling?—No, I cannot think of any for the moment.

3457. Precisely the same considerations apply to the process of stippling, do they not?—Yes.

3458. Do you have old paint burnt off with a spirit or charcoal burner?—No, I do not very often. It is often taken off with strong acid—a wet process.

3459. But do you ever have old paint burnt off with a spirit or charcoal lamp?—I have had one or two cases in years.

3460. But it is not the custom of the trade to work in that fashion?—It is the custom of a good many, but I think it is gradually being done away with.

3461. Suppose it is the custom in some cases, how can you prevent the worker from inhaling the fumes which arise from this process?—You cannot prevent it, I think, unless he wears a mask.

3462. Do you think that would be practicable?—No, I do not think so.

3463. Where and how do your men mix their colours?—They have a paint shop, a place set apart on every job, for mixing it. We send the raw materials and they mix it there on the job.

3464. Do you adopt any precautions to deal with the danger that arises when colours are handled dry?—We do not, but nearly all ours are sent out in oil.

3465. It appears from your evidence that there are certain indispensable processes in carrying out which a painter must necessarily inhale some dust, some spray or some fumes containing lead?—Yes.

3466. I want to ask you how these dangers can be met?—It is a difficult question to answer; I do not know that I can answer it right away.

3467. Is it possible to remove the danger entirely in any other way than by using a substitute for lead?—I suppose it is, but I cannot for the moment think of anything to absolutely do away with all possibility of danger.

3468. Various witnesses have told us about non-poisonous substitutes for lead as a paint base. Have you had any personal experience with such substitutes?—Yes.

3469. Have they been successful?—We do not care about using them entirely as a substitute, but we use them very often in conjunction with lead.

3470. The Office of Works and several other people who have been before us have succeeded in obtaining efficient non-lead paints. I suppose you agree that if an efficient substitute can be found the use of lead should be prohibited?—If we could all be put upon exactly the same basis; I mean if it is proved to be efficient, and if the architects and others would get in the habit of not specifying the use of lead, we should not object at all.

3471. Supposing this Committee were to recommend unanimously, or by a majority, the prohibition of lead entirely in this country, and it was to apply to every user of paint, would the master painters support that?—I think so. I should cordially recommend them to.

3472. You mean to say that putting them all on the same basis would remove any evil as regards that?—Yes, always providing that an efficient substitute can be found. I think you said it had been tried for four years.

3473. I did not say so, but you have probably heard that from outside?—I may be mistaken.

3474. Have you been in communication with anybody in connection with that? Who told you four years?—I thought you said so.

(*Mr. Sutherland.*) I think I am responsible for that.

3475. (*Chairman.*) You realise that if a free use of lead is allowed to continue the Home Office will have to insist on the most rigid observance of all precautionary measures, in the same way as in other industries, where the workers handle lead?—I should be very pleased if they did so.

3476. And you realise that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—That also we should be very glad to do, but the workmen would be the first to find fault with it.

3477. All this would involve an extremely complicated and elaborate code of regulations?—Yes, it would.

3478. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess rooms, washing accommodation, avoidance of dust, limitation of hours, and all other such matters?—Provided we are all put exactly upon the same level, and if it can be efficiently carried out, yes.

3479. Do you think it is possible to subject painting operations to systematic and thorough inspection?—I am afraid not. I cannot think that it is.

3480. Then in your view such precautions or such a code of regulations would become a dead letter?—I am afraid so. The distances are so far apart that periodical and constant inspection would be almost impossible.

3481. Then do you think, in view of your opinion, that the Home Office should institute a code of regulations which they could not put into operation?—No, I think they could only perhaps give penalties where it was found that men were not working according to the rules. We should be very glad of a code of efficient rules; I should like to put on every time sheet, for instance, that was sent out, instructions to the foreman, or a notice hung up in

5 April 1911.]

Mr. HENRY ALEXANDER CAMPBELL.

[Continued.]

every paint shop. I have thought a good deal about the best manner to do this. It is not like going to factories, because one would have to send notices of every job to the Home Office everywhere there was a bit of work going on. It would mean an immense amount of labour, I think, and it would open up such a vast prospect.

3482. But you do not think it would be best for the Home Office to make regulations in the case of using lead?—Yes, I see no objection to it.

3483. But from what you say yourself as to the immense amount of labour and the almost insuperable difficulties which would ensue if the code were introduced, and the almost impossibility of enforcing the rules, do you not think it would be much better for the Home Office to say, "The evil exists, we cannot remedy it, we shall prohibit the use of lead altogether"?—By all means I think so—in that case.

3484. (*Dr. Collis.*) Do you employ any people except painters, such as paper-hangers and plasterers?—Yes.

3485. Do you insure your men?—Yes.

3486. Do the insurance company ask you to pay any different premiums according to the employment of the men?—No, not ours. They take the average workmen all through—anybody connected with our trade.

3487. They take the painting trade as a whole?—Yes, they take the painting trade as a whole. We pay one universal rate.

3488. Do you know how that compares as regards any other industries, such as builders, for example?—Some contend that painters and decorators are more liable to injuries than builders.

3489. I want to know whether you know whether insurance companies ask a higher premium from your trade on behalf of your operatives than they do from builders for builders' operatives?—No, they do not from us. There are certain firms that pay higher rates than others. I think they take a firm according to the class of work they do.

3490. Do you know how much building masters pay?—No, not regularly. I believe they pay about 30s. I think that is about the rate, but I do not know.

3491. (*Mr. Sutherland.*) A jobbing builder is at a lower rate than a painter and a decorator. Is not that so?—Yes.

3492. And lead poisoning is a big element in the rate?—Yes, it is.

3493. (*Dr. Collis.*) That is the point I rather wanted to get out?—Yes, I can answer that.

3494. (*Mr. Sutherland.*) You do what we call a very high-class trade?—I believe so.

3495. You do a good decorative trade?—Yes, a good decorative trade.

3496. Do you see any reason why the hours of labour should be reduced because of the use of white lead, even supposing the Government do not prohibit it?—No.

3497. Do you attach any importance to a man working 10 or 12 hours? I am speaking of the average painter. Do you think a man is more immune from lead poisoning if he works 10 or 9 hours a day than if he works 11 hours?—Not a bit.

3498. The usual conditions of the man's employment and the surroundings are wholesome, are they not?—Yes, very, generally speaking, for a class of business such as we do.

3499. (*Mr. Parsonage.*) Would that apply to working in a theatre?—Yes.

3500. You do a good deal of that, do you not?—Yes, we do.

3501. (*Mr. Sutherland.*) For instance, in private houses the rooms are wholesome, fresh, and clean, are they not?—Quite, as a rule.

3502. There is no foul air in them?—No; there is ventilation, and the windows are kept open.

3503. The dust which would arise in an ordinary rubbing down is of a very minute character in quantity, is it not?—Yes.

3504. Do you generally provide washing arrangements, or do you see that they have facilities, such as

soap, and so on?—Yes, always; soap and towels are all provided and sent on to the job.

3505. Do your men complain of any lack of facilities in that respect?—No, I have never had them complain. The difficulty is to keep them up to the mark, and for the foreman to see that they use them.

3506. You were asked about tools. The man does not carry his tools, does he?—Not as a rule.

3507. They are sent on to the job, are they not?—Yes, and he hands them to the foreman, who puts them in the box at night.

3508. What he carries with him would be personal knives?—Yes, something that he fancies in the way of knives.

3509. Would he keep those in a clean condition?—Yes, or else he could not work with them.

3510. A clean man would not think of putting his knife away dirty, would he?—No.

3511. And any fitches, or anything of that sort, would also be put away clean, would they not?—Yes.

3512. So there would be no contamination in them?—No. If he did not clean them he could not use them; they would get hard.

3513. Have you any personal experience of any substitute of the same virtue as lead for general painting?—No, not quite.

3514. Do you know that most substitutes—zinc compounds—have to be specially mixed, and they are not mixed with the ready facility with which lead is?—Yes.

3515. And that lead has held its own against all competitors for the last 120 years?—Yes. We always like to put a basis of lead. We use zinc oxides, and others, afterwards.

3516. Do you feel that the decorating trade has no prejudices against these non-poisonous paints?—I do not think so, whatever.

3517. And that the consideration that they have is purely one of service to their customers?—Yes.

3518. And that if a paint with an equal value of protective qualities and facilities of application to lead were promulgated, the painting trade would accept it for their own interest, because it would reduce the cost of insurance?—Undoubtedly. We should be only too glad.

3519. Your men do not often take their meals in the paint shop, do they?—Scarcely ever.

3520. Except in occasional cases?—They may do, but very rarely.

3521. Do you use much of these paints, like Duresco, and water paints, for ceiling work and relief work?—Yes.

3522. Has that very largely supplanted the use of flitting for ceiling work?—Yes, very much.

3523. On the ground of cost and on the ground of quickness?—Yes, the majority of ceilings are done with those sort of things now.

3524. Do you think that anything like a general inspection of painters would be impossible?—I do not see how it could be carried out.

3525. You think it would clash with the privacy of your customers, and it would also involve an enormous staff of inspectors to follow it up?—Yes.

3526. (*Mr. Rice.*) In the course of carrying on your work I take it you have to visit your various works?—Yes.

3527. And do you sometimes go into the room where the rubbing down is carried on?—Very often; of course we must.

3528. Have you ever noticed the dust from rubbing down settling on the window ledges to any great extent?—Very slightly. A man has his dusting brush with him as a rule, and he just carefully brings it down on to the floor and puts it into a paper or duster or something. He collects it as he goes along very often.

3529. Have you ever had occasion to put your foot into the dust that has been caused by rubbing down?—No.

3530. So that when you made the next step you left the imprint of your foot in the lead dust?—No.

3531. With regard to the use of towels and water, which you generously supply your men with, do you

5 April 1911.]

Mr. HENRY ALEXANDER CAMPBELL.

[Continued.]

have any difficulty in getting the men to use them?—No. The men will go to a pail of water. If there is any difficulty in getting hot water the labourer will get pails of water, and you will find the men, when one o'clock comes, go and wash their hands.

3532. And when the dinner bell rings they go and wash their hands in the ordinary way?—Yes.

3533. You do not have any complaint from your foreman or men that there is none provided anywhere they go?—No. I have notes from three of my very experienced men and they would be glad to come down if they were required.

3534. (Chairman.) We would take any evidence that is available, of course?—They said they would come down and support all that I have said. They have given me their notes.

3535. Their notes alone will be no use, I am afraid?—They have signed them.

3536. (Mr. Rice.) Now, with regard to the amount of painting work done, there is the outside painting, where there is no rubbing down with glasspaper, or very little, where it is washed off by the wet process, and there is the inside work, where the rubbing down process with glasspaper is sometimes used?—Yes.

3537. Can you give me any idea of the proportion of the dry rubbing down process compared with the wet rubbing down?—It is infinitesimal as compared with the other. It would be very very small.

3538. Do you mean the water process would be small?—No, the dry process.

3539. The dry process would be very much smaller than the water process?—Yes. For instance, in here he would immediately commence to rub this paint work down with water and pumice stone, and when he has got his first coat on he might, as I say, have to take his glasspaper and smooth down any inequalities that there were.

3540. Would you be surprised to hear that 75 per cent. of the work is rubbed down by glasspaper?—It is not my experience.

3541. Can you tell me anything about the proportion?—No.

3542. Would you be surprised to hear that 75 per cent. of the work is rubbed down with glasspaper?—It would be a very large bill for glasspaper or sandpaper if they did.

3543. You would be surprised to hear it was 75 per cent.?—Yes.

3544. That is not in accordance with your experience, is it?—It is much less.

3545. (Chairman.) How much would you say?—Not more than 10 per cent., I should think. I should not really think more—without consideration.

3546. (Mr. Rice.) Is there a process known as felting down?—Yes.

3547. Do you do much of that?—That is only used principally for front doors, or where they want a very nice coach surface, as we call it. It is hardly used for any other surface.

3548. There are three processes of preparation, are there not? There is the dry process, which you say is about 10 per cent.; there is the wet process, and the felting?—Yes.

3549. (Chairman.) When you say 10 per cent. are you speaking of your own particular high-class business, or of painting generally in the trade?—I was speaking of my own business. I really cannot answer so much for the others, but I do not see that it would pay them to do it.

3550. (Mr. Rice.) On the question of the messroom, it is customary on all jobs of size to find a messroom for the men, is it not?—Yes.

3551. They are not bound to hang their overalls in that messroom, are they?—No, they would not hang them in the messroom; they are generally found a room for that purpose—a lock-up room.

3552. That is probably the same room where their brushes are kept?—Yes.

3553. The men will keep their brushes and overalls in the colour shop, will they not?—Yes.

3554. So there would be no need to put them in the messroom where their food is?—No.

3555. I understand it is customary for the men to bring their food in their pockets?—Occasionally.

3556. There is no need for the men to put that food in the colour shop?—No. It is very seldom they bring it in their pockets, now, I think. They generally go out and get it, or in the country, where they mess together, one acts as caterer, and they get on exceedingly well.

3557. (Mr. Parsonage.) They do not, in London, as a rule, bring their bread and butter, but they go out to the coffee-shop, do they not?—Yes. In London, of course, they might bring their bread and butter.

3558. (Mr. Rice.) With regard to the possible use of a substitute for white lead, do I understand you to say that the trade would have no objection whatever to any efficient substitute being found?—No, I think not, none whatever.

3559. In fact, they would rather welcome it, would they not?—Yes, I think so, because it would lessen our insurance.

3560. I know what your experience is, but from what you know of employers, are they not generally fairly careful of the health of the men?—Yes; they have to be. We do not want rickety men or men who are unable to work. It is best for us to keep our men up to a high standard of health.

3561. Have you had many cases of lead poisoning among you employees?—No, hardly any. We have paid no compensation, as I have told the Chairman, and as far as we know, although men stop away sometimes for a day or so, it has never been brought to our knowledge that it was from lead poisoning.

3562. Would you be surprised to hear that about 50 per cent. of your men have lead poisoning?—Yes, very much surprised.

3563. You would be surprised?—Yes.

3564. You do not think it is possible?—No, in fact my oldest foremen always contend that it is not so.

3565. (Mr. Parsonage.) With regard to lead poisoning cases, your foreman takes on the men?—My manager does, as a rule.

3566. Of course, he takes on the men for the time he wants them, and then they are discharged again; is not that so?—Yes.

3567. Probably in the winter you will not have half a dozen men on at all?—We very seldom go down so low as that, because we have to keep a nucleus.

3568. Of how many?—We keep always, perhaps, 20 men, who are, perhaps, foremen, and we have to find them work somehow or another, and draft them out.

3569. Is it as much as 20?—I will not say 20, perhaps 12, but I do not think we ever drop down to less than about 12 men.

3570. They are on in the winter time?—All the time. Absolutely I find them work, for maintenance, and different things. Even if we had not got a job, I should find them something to do, rather than let them go, because of the difficulty of replacing them.

3571. The other men, we will say, are men taken on casually as they come along, is not that so?—Not as they come along.

3572. Mr. Macdonald would generally take them on, I suppose?—He would know the men and have their addresses. They would not be casual strangers.

3573. With regard to men that he knew, who had worked for him before, he would give them the preference, naturally?—Yes.

3574. Many of these men would be working nine months in the year in the other shops?—Of course they may.

3575. And might they not easily have lead poisoning without it coming to your knowledge at all?—Yes.

3576. You say that you provide towels?—Yes.

3577. Do they not usually use the wash leather instead of a towel?—We do not want them to do that if we can help it. Towels are always provided by the foreman, but we do not want them to use the wash leathers. We cannot always guarantee that they do not use the wash leather, of course.

5 April 1911.]

Mr. HENRY ALEXANDER CAMPBELL.

[Continued.]

3578. With regard to the rubbing down, you say that 10 per cent. of it is dry?—It might be 10 per cent., I said.

3579. Then the 90 per cent. would be pumice stone and water?—Yes, I should think it would be. I do not know. I would like perhaps to amend that. I ought to give a little more consideration to that. But it is not so much more than 10 per cent. We have very little dry rubbing.

3580. You cannot use pumice stone and water on newly painted surfaces, can you?—No.

3581. The pumice stone and water is used on the hard paint before the first coat is applied?—Yes.

3582. After the first coat is put on and rubbed, between coats, it is always glasspaper?—Yes.

3583. And the work has got to have probably four coats of paint. Yet you say in face of that statement that 90 per cent. of it is wet rubbing?—Yes.

3584. How can you explain that. If a door has to have four coats, and it is rubbed down once with pumice stone and water and three times with sandpaper, how can you say that 90 per cent. of it is wet rubbing?—No, I suppose I shall have to amend that. I have not considered it.

3585. Supposing you put it 90 per cent. sandpaper and 10 per cent. pumice stone and water, would not that be nearer the mark?—Oh, dear no. It might be a third of it dry, but I should say not more, if I went as far as that. I would like to give that a little more consideration, because it is a point I have not studied sufficiently.

3586. I have never worked for your firm, but I can tell you of firms in the West End of London that I have worked for for 28 years every one of which you would know, who are equally as high class as your own. I am speaking from personal knowledge of many of your men. I understand you always pay the rates?—Yes.

3587. It is true that you always pay the standard rate of wages to all your men, and you generally get the best men, is it not?—It is more than the standard rate. We pay 9d., and the standard rate is 8½d.

3588. (Mr. Rice.) May I interpose. My question to Mr. Campbell was bearing in mind the outside work. Mr. Parsonage's question about a door is one thing, but what I pointed out was with regard to outside work?—(Witness.) I was thinking of that proportion when I answered.

3589. (Mr. Parsonage.) But I am talking about the work you generally do. You do not do so much outside work, do you?—No, we do not. Then, of course, that minimises it considerably, if you confine it to inside work.

3590. That would be so, but the great danger from lead poisoning is the interior work?—Yes.

3591. And in that work the proportion of dry rubbing to wet rubbing is far greater?—I do not think so, because we have particular work to do which must be thoroughly rubbed down first with pumice stone and water, and when that is once done the dry rubbing is not much between the coats.

3592. You say you fill it up and rub that down with glasspaper?—Yes.

3593. And between each coat, if you are going to work with enamel, you have always got to glasspaper it?—Yes, and then, as I say, we use a little turpentine with the glasspaper, so that that is not dry rubbing.

3594. You very seldom use turpentine in rubbing down with glasspaper, do you?—We give instructions to have it done.

3595. In my experience it is very seldom done. It is about as often done as felting down is done. You were speaking of the man keeping his coat in the lock-up room where the foreman keeps his brushes. That is the same room where he will keep his coat?—Yes.

3596. And he will keep his food in his coat pocket all day, sometimes, in the room where the paint is mixed? That is so, is it not?—I cannot say, I really do not know. He is not obliged to do it, but men may do it, of course.

3597. I have known many men that have worked for you that have suffered from lead poisoning, but I

cannot say that they have actually contracted it on your work?—We are liable if they have contracted it previously, as you know.

3598. I have had it this last year with several firms, and there have been several cases with Maple's of lead poisoning?—Yes, my idea about lead poisoning is that it has a great deal to do with the physique of the men; and that it is the man who comes on casually who is the man who gets it more easily.

3599. I quite agree that the man who is brought up to the trade and introduced into it and who understands the dangers is more likely to be careful?—Yes.

3600. But it is the man who is introduced at a cheap rate who is more liable to get it?—Yes, and perhaps the ordinary common house painter, who is only a house painter eight months in the year.

3601. We do not call them painters?—I should not call them painters either, but those are the men who would be given in as painters when they are counting up lead poisoning cases. I say they are not painters, the same as you do.

3602. (Mr. Rice.) But they are known as painters when they work, and they are taken on as painters?—Yes, of course; in times of great pressure there are a lot of men taken on as painters as long as they can hold a brush.

3603. (Mr. Parsonage.) That is so in London, and especially in the spring season, is it not?—Yes, that is so.

3604. Many men that work for you, and have worked for you for years, may have lead poisoning without it coming to your knowledge at all?—They may, if there is no complaint made.

3605. At the present time, in the spring season, you will have more men on than you will have at any other time of the year, will you not?—Yes.

3606. At other times, if your work drops off, they go somewhere else, and they come round again to see if you have anything; is that so?—Yes.

3607. So that they are always migrating from one shop to another?—That is so.

3608. So that, as a matter of fact, no individual employer could positively state as to the health of his men?—No, only the cases that come before him.

3609. (Mr. Gardner.) Are you a practical painter, that is to say, have you served your time at the trade and worked at the trade?—No, I have not.

3610. You have been asked about the technique of the job. Is what you have said purely from observation in going through the works?—Yes.

3611. You have not executed any work yourself, have you?—No, except at home, only as an amateur.

3612. In speaking of the work in your firm, do you know whether you use sharp or flattish colour, or oil colour in bringing up the work?—We use oil colour in bringing up the work—yes, we use mixed sharp colour. It is a question of time.

3613. Do you use principally mixed sharp?—Yes.

3614. I suppose you are aware that sharp colour is much more brittle than oil colour and flattish colour?—Yes.

3615. And there would be a great deal more dust, even with giving it a slight rub with sandpaper, than if it were flattish?—Yes.

3616. Are you of opinion that a man working nine hours, say, in a confined room, is as healthy as a man at the end of a day who has worked 12 hours. Which is the healthiest man at the end of the day?—The man who works nine hours, undoubtedly.

3617. Then you said you thought there was no special need for adjusting the hours of labour?—No, I find the great obstacle to that are the workmen themselves.

3618. That is a point as to the means of earning a living and the necessity of having a certain amount of money to keep their families and themselves, of course. I take it your establishment is one of the first-class establishments in London, and, therefore, you do not do much jobbing work, do you?—Yes, we do at times.

3619. Do you go out to do one or two rooms in a house?—No, not if you call that jobbing work.

5 April 1911.]

Mr. HENRY ALEXANDER CAMPBELL.

[Continued.]

3620. That is what I call jobbing work?—No, we do not do that.

3621. In supplying your men with brushes, you do not supply a man with a set of brushes, but all your brushes are sent to the job. Is not that so?—Yes.

3622. You remarked that a man never carried tools in his bag. I suppose that you would be astonished to learn that men in many districts carry dusters and carry a papering brush, and in many cases they carry oil brushes and varnishing brushes in their bags, and that they have specially brought up these brushes for special jobs?—Yes.

3623. Lead in past years has held its own in the trade, but was that not because zinc white was not known and properly understood?—I think it was, in past years, certainly.

3624. Then if zinc white was better known it could take the place of lead quite well, could it not?—I do not admit that—not at present.

3625. But if it was as well understood as lead, why should it not take the place of lead?—It takes three coats of zinc, in my opinion, to equal about two coats of lead.

3626. I suppose you would be surprised to learn that we have been told that two coats of zinc paint are equal to three coats of lead?—I am not surprised at anything you have been told.

3627. (Chairman.) The Board of Works told us that by practical demonstration?—We have not been able to prove it ourselves.

3628. Have you tried it?—We have tried it many times.

3629. (Mr. Gardner.) If that could be proved, would you not admit that zinc white could take the place of lead quite well?—If it could be proved, of course I would.

3630. (Chairman.) May I take it that if the Board of Works' evidence is accepted by the Committee you would fall in with it?—Certainly.

3631. (Mr. Sutherland.) Would you think that that would be sufficient evidence?—Not at present. I think we ought to go into it in a much larger manner before deciding on such evidence as that.

3632. The evidence is good, as far as it goes?—Yes, but I do not think it goes far enough.

3633. Would it satisfy the Institute of British Architects?—No, I do not think it would.

(Chairman.) The Institute of British Architects have demonstrated to us here beyond question that you can have a substitute for lead.

(Mr. Sutherland.) But the two witnesses were only giving their two individual opinions. They did not commit the Council or the Institute.

The witness withdrew.

Mr. H. VIGURS HARRIS examined.

3639. (Chairman.) Is your business at 70, George Street, Plymouth?—Yes.

3640. Are you a master house decorator?—Yes.

3641. How long have you been engaged in the painting trade?—I am the third generation in the business. I have been in it about 41 years; I think you can call it 40 years.

3642. Have you been an employer all the time?—Yes.

3643. Perhaps you can tell us how many men you employ?—Of course, in the painting trade it varies.

3644. Will you give me the variations?—Last year we had, men and boys, 64. I took May as being the highest and January this year as the lowest for the 12 months. We had 36 in January; that would mean an average of 50.

3645. Now, about lead poisoning or painters' colic, have you known any cases of it?—Yes, very few.

3646. I suppose you have paid a certain amount of compensation?—It is only lately that compensation has come in.

3647. Have you paid compensation since it has come in?—We had one case, the case of a man called Dawe. He came to us and I think he was with us about 10 days. He was working about 16 miles away

(Chairman.) I think you will find that they will. They had been selected with others to make the experiments.

3634-5. (Mr. Sutherland.) Yes, but it is only in a tentative state at present. (To the witness.) That would relieve the tension very much with regard to the master painters, if the Institute of British Architects said that, would it not?—Yes.

3636. (Chairman.) If the prohibition is ordered, they would all have to fall in with it, would they not?—Yes.

3637. You seem a little uncertain in your answer as to the percentage of men employed in dry rubbing and the percentage of men who are employed in wet rubbing with pumice stone and water. Perhaps it is because you have not had an opportunity of thinking it over, but you have ranged from 10 per cent. to 33 per cent. already. Would you like to give that further consideration and to communicate with the secretary as to what the result is with regard to the percentage of work?—Yes, I would like to think it over, because I have not given it consideration.

3638. Of course, you realise that it is very important?—Yes.\*

\* Under date 13th April 1911 the witness wrote as follows:—

I beg to enclose amended reply to the question left over last Wednesday, to which I have given my very close attention.

Enclosure:—

Question.—What is the proportion of the whole of the labour in preparation (per cent.) of dry rubbing down paint between coats with glasspaper, as against cleaning off with water and pumice stone to prepare for repainting?

Answer.—Taking the standard of repainting as two-coat work, I say 33½ per cent. at the outside, but probably less. (I consider two-coat work as the general standard, for in my view there is much more two-coat work done than three or four coats.)

There would be double the amount of lead got off the work from the wet preparation with pumice stone to what was got off in the dry rubbing down with glasspaper.

In three- and four-coat work the proportion would be of course somewhat higher; but would never, I am sure, exceed 50 per cent.

In my opinion this entirely begs the question whether any powder or any appreciable quantity is formed during the dry rubbing down between each coat.

In modern conditions, the time given for painting is such that each coat has never time to harden sufficiently to form a powder when rubbed down with the glasspaper, but, on the contrary, it mostly adheres to and fills up the glasspaper.

Then, again, there is not anything like so much lead taken off in the dry rubbing down process as there is in the wet preparation, when the paint is actually cut into.

in the country. He scarcely touched paint at all while he was with us. He was stripping rooms and washing off ceilings, and he suddenly developed lead poisoning. We paid compensation, but he had acquired the poisoning somewhere else, not in our shop, because he scarcely ever touched the paint while he was with us.

3648. How many cases have you known in the last five or six years?—That would occur to me as the only one. Within the last 20 years altogether I should think four in our shop.

3649. Have they been serious cases?—One was rather serious. He was advised to leave. Two of them occurred with storekeepers and two with operatives.

3650. Have your men, in addition to that, had occasional days of sickness due to lead?—Not that I know of.

3651. Have they broken down in health at all?—Almost the only thing that I can remember is that when influenza has been raging in the locality our men have fallen victims like other people, but I think on the whole the health of our men has been extremely good.

3652. Do you have a periodical medical examination of your men?—No.

5 April 1911.]

Mr. H. VIGORS HARRIS.

[Continued.]

3653. Is it possible that some of them may be suffering from the slower and more insidious forms of the poisoning?—I do not think so. I was suspicious of a boy during the last 18 months. He was very heavy and dull, and I wrote to his father, and I found out afterwards that what was making him dull was not any poisoning but that he had contracted a tremendous habit of cigarette smoking, and it was not lead poisoning at all. I really cannot say that we are much troubled with it, or have been.

3654. But do you recognise the magnitude of this lead poisoning evil in the country?—Yes, I recognise it since it has been spoken about in the Press, but I could not recognise it from our own experience.

3655. Do you know that the Registrar-General has recorded no less than 284 definite deaths from lead poisoning amongst house painters in the last 10 years?—No, I was not aware of it. I did not know the number. I knew it was larger than one would like to think.

3656. And that his mortality figures show for painters a death rate considerably higher than the normal from troubles which are the frequent effects of exposure to lead, such as Bright's disease and nervous diseases?—I should not admit it in our shop. I should simply say it has not happened in our shop.

3657. Do you also know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the same 10 years?—Yes, but I should say against that on the other side that it is just the same as this: my experience is that when a medical man says he does not know what is the matter with you he says you have a touch of influenza, and so with regard to any man who is in any way connected with the painting trade and has anything the matter with him it is at once suggested that he has lead poisoning. I think influenza and lead poisoning have been a god-send to medical men. I am not speaking from experience; now but from observation with regard to influenza, and our men tell us the same about the lead poisoning.

3658. Perhaps you would be surprised to hear that these cases, which are reported voluntarily, are only a fraction of the whole, inasmuch as the Home Office have no legal right to pay for such reports and are, therefore, bound to discourage reporting to some extent?—I have not misunderstood the magnitude of the evil. At home we have always been fighting against it. One of our apprentices was handling lead in the way of cementing lights and I said, "Do not let that boy go on with that, and see that he washes his hands every time he leaves off in sulphuric acid and water and, if necessary, drinks a little of it."

3659. I am sure you will agree with me that all this sickness and death is very deplorable?—Yes, very.

3660. Do you know that this lead poisoning evil has attracted the most careful attention in many foreign countries?—In France I know it has. I thought that the use of white lead in paint was practically forbidden in France.

3661. Do you know that the use of white lead has been prohibited to an appreciable extent abroad, and that the work of painting has been most strictly regulated in several countries where the use of white lead is still allowed, and do you not think it regrettable that this country should be behind other nations in this respect?—I should not like England to be behind in any humanitarian thing. I think any trade should suffer a good deal of difficulty rather than endanger the health of the operatives.

3662. I felt sure you would think so?—Quite.

3663. A great many small dangers attend the use of lead—for instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—I attach as much importance to that as anything. I have had interviews, with a view to your inquiry, with several of my older men, and they have always wound up by saying, "There is no danger to the health of the men at all if they would only keep clean, if they would only wash properly."

3664. Then you consider lavatory accommodation essential? It is essential from one point of view, but how can it be provided? We are not a factory.

3665. We will come to the difficulties presently. You have told us just now that your own men informed you that they consider that cleanliness is indispensable?—Yes.

3666. And as a corollary of that I ask you whether you consider lavatory accommodation to be essential?—Most certainly, but I do not know whether it would be used.

3667. That is not the point?—I quite agree with you that washing is essential.

3668. Including a supply of hot water for washing?—No, I should not have thought that was essential.

3669. You cannot get paint off your hands easily with cold water, can you?—Yes, I think so, if you wash and add a little petrol or turpentine.

3670. Have you tried it yourself?—I have not.

3671. Must it not be more easy to get paint off the hands in cold weather with hot water than with cold water?—Yes, naturally.

3672. Is it generally practicable for the men to have hot water to wash in?—No.

3673. For instance, I suppose when they are painting the exterior of a house the men are not allowed to go inside?—They would not be allowed in. Sometimes they ask for hot water for tea. When they go to some houses it is refused, as if it were a liberty to ask the thing; others are very very kind.

3674. Do you know, for instance, that even when painting the inside of some particular room it is not uncommon to require the men to enter by the window?—Certainly. We have not a great number of cases in our district like that, but it is so sometimes.

3675. Do you advocate definite rules regarding the wearing of overalls?—No. I rather insist upon it personally for what I call discipline. If a man is not properly clothed I tell him he is not fit to go to a nice house. I should not have thought overalls were imperative.

3676. The great evil with regard to lead poisoning is the dust which the men breathe. That is proved beyond question?—I must accept it if it is a statement of yours.

3677. You may accept it not from me only but from the evidence that I have taken on another committee on lead poisoning in potteries. There it was laid down beyond question that the great prevalent evil was the dust which was created?—Yes.

3678. As these men must create a certain amount of dust in their work, do you not think that a definite rule should be put forward regarding the wearing of overalls?—I should like the rule with regard to inside work, but I do not like a man being hampered with too many things when he is working on ladders.

3679. I have told you that the great prevalent evil is the dust which accumulates in the room and which settles on the men, on their clothes, and on their face and hands, and so on. If that is the case do you not think that it should be imperative that they should wear overalls, which they can take off and leave behind when the work is finished?—It would not occur to me now as imperative, I should not have thought it was so serious as you make out. You may be right, but from practical observation I should not have thought so.

3680. (Mr. Parionage.) Possibly the Chairman is referring to the ordinary white things that the painter wears—the jacket and apron.

(Witness.) I thought the Chairman meant the trousers. I should be very glad if it were made compulsory. I think it shows discipline.

3681. (Chairman.) How can you ensure that the overalls would be kept in a cleanly state?—You could not possibly ensure it unless the Government insisted on all employers providing jackets and aprons for the men; and also that they should wash them. I do not think you could be sure of the men doing it.

3682. Do you think that they ought to be washed frequently—at least once a week?—If a man comes with a dirty jacket or apron on Monday morning I speak to him at once.

G 4

5 April 1911.]

Mr. H. VIGURS HARRIS.

[Continued.]

3683. Do they often come with dirty overalls?—No, they do not.

3684. Then you do not have to speak to them very often, do you?—No, not very often. Perhaps it is fair to say that our shop is not a model shop, but it is not a dirty shop, and perhaps it is better than the average.

3685. You take personal care, probably, of your workpeople?—Yes, and I like the men too.

3686. My point is this. As I have told you, dust collects either on the men's clothes or on their overalls that they wear. If the men are allowed to take their overalls home with all the accumulated dust on them that is a source of danger. Do you not think that ought to be prevented?—Of course I must accept your dictum, but I should not have thought it was much source of danger.

3687. I think in the pottery trade it was found to be one of the great sources of danger?—It might be there.

3688. Because it collected the dust?—Except in a few cases, I do not consider that we have a very great deal of dust. In some cases we have.

3689. I will come to that in a moment. Then, with regard to meals, where do your workpeople have their meals?—A certain proportion of them have their meals at the houses where they are working, that is to say, if they are a mile and a half from their homes they would have it in that way. Sometimes they would have it in the room where they have been working. In many places they would be allowed to have it in the servants' hall, or, if there was an outhouse, they would rather go there than have it in the room.

3690. Do they ever have their meals in the place where the work is being done?—Constantly; as often in the room that they are working in as elsewhere.

3691. Is not that a great source of danger?—I should think it was not at all nice. When they are in our shop we have a separate room, our porter's cottage, where they go and have their meals.

3692. You have a separate mess room?—Yes, a separate mess room. But then, of course, most of the men are out. It does not apply to more than half a dozen.

3693. Do you mean that the difficulty of providing a mess room is insuperable?—Yes, only a very small proportion can avail themselves of it.

3694. Do the men who go out to work frequently have to take their meals in the rooms in which they perform their work?—Yes, very frequently. That would not be advisable, of course.

3695. Now, all these precautions which I have suggested (and all these rules are insisted on in other industries that are liable to lead poisoning with a view of mitigating the risks which the workers run), would it not be exceedingly difficult to carry them out faithfully in house painting operations?—I should say it would be difficult.

3696. Then, at the best, such precautions would not deal with the most important risk, namely, the risk arising from dust and spray which the workman can inhale during the whole of his working hours?—No, I think none of those you have suggested would deal with it.

3697. First, with regard to the dry rubbing down with sandpaper; I understand this process is indispensable?—It is indispensable, but I should have thought that the danger was a minimum from that cause in house painting, because what we rub down is nearly always oil coats or half-and-half coats. When we come to the finishing coats and flatting, it would powder a great deal more, but we very rarely do it except sometimes for getting up white enamel work, and where we have to use things for flatting. In the ordinary way the under coats have a large proportion of oil; in fact, we would rather flat upon a good oil wall than we would upon a dead wall.

3698. (Mr. Parsonage.) That is necessary, of course; to get a good effect?—Yes.

3699. (Chairman.) Is the dry rubbing down not applied invariably to newly painted surfaces on which the paint is already dry?—I suppose we would have to divide the work. I suppose the major part of the work

in England is cheap work, and there probably they might pass the glasspaper. I think you would find that with regard to two-thirds of the cheap work the men do not see a sheet of glasspaper from week end to week end, but on better work they would use glasspaper, and on the best work they would use pumice stone and water, and there would be no dust.

3700. Is there not a certain percentage of rubbing down which is done in a dry state?—On good work mostly, in getting up woodwork.

3701. I understand the wet process cannot be substituted for dry rubbing between the first and second coats when ordinary paint has been used?—No, you cannot use wet on that at all, because it would, of course, discharge the paint again.

3702. And you have told us it is only on high class work which is to be enamelled or varnished that the dry process can be dispensed with altogether. Is not that so?—No, I did not mean to convey that. I meant to say that on high class enamel work it would be more dangerous, that is to say, there would be more powder there, because it is essential for good enamelling work that you must use scarcely any oil at all; you must have it more flat work, and of course flat work requires more turpentine than oil, and there would be more dust in the high class woodwork.

3703. I suppose you will admit this, that in dry rubbing with sandpaper there is a certain amount of dust which ensues?—No, I should not admit it. I am prepared to accept it if you say it has been said in evidence, but it would never occur to me that there was, in rubbing down paintwork that was being nicely done, because in flatting we have a strong binder; we always put in a varnish to bind it, or else what we do one day would be lost when we rubbed it down two days after. It would powder too rapidly.

3704. Filling material dries very hard, and therefore can be rubbed down with pumice stone and water, can it not?—It depends what you use. Sometimes you have a distemper filling, and then you have glasspaper used. There are certain fillings now which scarcely want any rubbing down, but as a matter of fact we rub down filling with pumice stone and water.

3705. But a fresh coat of paint, which has dried within 24 hours, say, and not yet thoroughly hardened, would be spoilt by wet pumice stone and water, would it not?—It would.

3706. And would it not also tend to clog up the pumice stone?—It would.

3707. Where dry rubbing down with sandpaper is indispensable, how can you prevent the worker from breathing the lead dust?—I do not think you could prevent him breathing it at all, unless he had a mouth and nose mask.

3708. That would be very uncomfortable, would it not?—I do not think he could work properly with it, and I should not think it was feasible.

3709. Can you use an exhaust draught to remove the dust?—No, I should not say so. I should think that it would stir it up more.

3710. The amount of dust arising from this sandpapering, according to the evidence that we have before us, is very considerable. We have been told that it covers the man's clothing as well as the floors and surrounding objects. How is it possible to save the workman from the very serious danger involved in breathing this dust?—Are you referring to the ordinary rubbing down of paint work?

3711. Yes?—I have never seen such a case. I have seen it when we have been rubbing down filling, or scraping old paint, when we have not burnt it. When the glasspaper gets clogged, the man rubs two pieces together, and then I have seen the man rub dust off the paper.

3712. The amount of dust arising from the sandpapering is very considerable where the man is working. Would you agree to that?—No, I would not agree to that unless you qualify it. It is only when you are getting up woodwork very sharp. It may happen there, but that would not be in the South of England.

3713. Then would you say that that dust so created would cover his clothing as well as the floors

5 April 1911.]

Mr. H. VIGURS HARRIS.

[Continued.]

and surrounding objects?—If it covered the floor I think it must stand to reason that it would adhere to his clothing. I think it is a point in favour of the overalls. It would cling to woollen, of course, more.

3714. How is it possible to save the workman from the very serious danger involved in breathing this dust?—If I had to say what I really believe, I do not consider in our shop it is a serious danger.

3715. I am not asking about your shop just now. I only want you to tell us what is really in your own mind. I think you have admitted to the Committee now that there is a considerable amount of dust from this sandpapering and this particular process?—Yes.

3716. What I want to ask you is: How is it possible to save the workman from this particular dust?—I do not know that you can save him. For instance, suppose you had a veil, which might seem a very good suggestion, I think that it would be more injurious probably. I think that the mesh would get clogged. It would be a permanent source of danger, I fancy. I have here some remarks which one of our men made about a man who was in our employ for a number of years. He was subject to lead poisoning, and whenever he was doing any of this rubbing down he would put a cloth around his nostrils and over his mouth, but he is the only man I have known to do it.

3717. (Mr. Parsonage.) If there was no dust the man would not want to do that even, would he?—No.

3718. (Chairman.) The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—I take it you are referring to cornices, and so on.

3719. (Mr. Parsonage.) Anaglypta ceilings?—Yes, that is so.

3720. (Chairman.) This gives rise to splashes which must frequently fall even on the face of the worker. How can you deal with the spray which arises in this operation?—I should be inclined, on the spur of the moment, to say you cannot deal with it.

3721. Could you use an exhaust draught to catch the spray?—No, I think any use of an exhaust draught would aggravate the complaint. That is my feeling about it. It would just set it going all over the place.

3722. Then again we are confronted with the problem of how to save the worker from the grave danger involved in breathing this spray?—I should not have thought he did breathe it. I should have thought he got some of it on his face perhaps, but I must say that when our people are doing it there is very little of it. Some people will do it and they will not have any marks when they come off the scaffold.

3723. A witness told us that if he was working, as he described, with his face up to the ceiling and his arms above him, there would be a considerable amount?—I think a good sensible workman would do all he could to save himself. He would work more in this way (*illustrating*). As a rule with work like that we put our best men on it, and as a rule I do not notice it very much. Then, again, I suppose it does happen to a certain degree, and sometimes badly. Anyone who knows anything about house painting knows that some people will put as much on the floor as they will on the work.

3724. This Committee has been formed to suggest some practical alleviation of the evils which ensue. If all the workmen were practically machines that could be worked upon, no doubt we could recommend some regulations which could be carried out; but they are human beings, so that the difficulty is this, that we realise the danger exists and we have to sit here as practical men and suggest some remedy. It is no good our saying that some men are more careful than others. We know that this evil exists to an overwhelming amount, and we hope to get some suggestions from witnesses like you. Precisely the same considerations apply to the process of stippling, do they not?—

No, I should not think so. You would not get paint on the face through stippling.

3725. You do not think you would?—No, I do not.

3726. (Mr. Parsonage.) Would he get it on his hands?—No, I do not think so. The stippler only distributes; it does not send paint flying abroad. It rather prevents it flying.

3727. I suppose he would get paint on his hands, would he not?—No, he would not get the paint on his hands through stippling. All the splashing and the contact of lead with the clothes or with the face is with the putting on of the paint, not with the stippling.

3728. (Chairman.) Do you have old paint burnt off with a spirit or charcoal burner?—It is spirit now; of course, charcoal is out of date.

3729. How can you prevent the worker from inhaling the fumes which arise from this process?—You cannot prevent it, I should say.

3730. Do your men mix their colours in the paint shop?—A great number of people do not do it there, but I have it done in the paint shop, because then I have greater control over it. We send it out ready tinted with just a little alteration to be made on the job when I or my deputies go round. I prefer mixing it in store.

3731. Do you adopt any precautions to deal with the danger that arises when colours are handled dry?—No. I do not know what precautions you can adopt. There is only one thing I have had under consideration for some time, and that is that I have a row of three or four mills on a bench and a motor, so that we shall not have any breaking up by manual force, but it shall go straight into the mill and shall be run through the mill and be mixed in that way. That is the only precaution that I know that can be taken.

3732. It appears from your evidence that there are certain indispensable processes in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. How are these dangers to be met?—I suppose any straightforward person would say that if you meddle with poison you have to take the risks. There is no doubt that lead is a poisonous matter. It would be foolishness to say that it was not, but I should not have thought that it was as poisonous as your statistics give, from my own experience.

3733. You admit the evil exists but you can suggest no practical remedy?—No, except the enforcing of practical cleanliness, and if I am in one place and my men are on a staff perhaps 100 miles away, no one except the foreman can enforce it.

3734. This is the point. Is it possible to remove the danger entirely in any other way than by using a substitute for lead?—Of course it has been discussed for a long time.

3735. I am speaking now of these dangers which you admit exist, and I ask you, is it possible, under the circumstances, to remove the danger in any other way than by using a substitute for lead?—No, I do not think it is. On the spur of the moment I should not think so. If you deal with poison, and it has its legitimate effects, you must do away with the poison.

3736. Various witnesses have told us about non-poisonous substitutes for lead as a paint base. Have you had any personal experience with such substitutes?—Do you mean as a first coat or altogether?

3737. I am speaking generally?—I have had some experience of zinc and also of some of the materials that are now sent out by the enamel people as under-coatings, which I believe have a zinc basis.

3738. We have had a representative of the Office of Works here, as a witness, and several other people, who have succeeded in obtaining efficient non-lead paints. I suppose you agree that if an efficient substitute can be found, the use of lead should be prohibited?—I do not know that I agree with that, unless it could be very much limited. I think there are cases in which lead might be almost a necessity—for outside work, I mean.

3739. Would you go so far as to say that it should be limited?—Yes, very much limited.

5 April 1911.]

Mr. H. VIGURS HARRIS.

[Continued.]

3740. Would you say that it should be limited to this extent, that they should be permitted to use 5 per cent. of lead, a standard which the Home Office have treated, in one or two industries at least, as substantially free from danger?—I think 5 per cent. is a very low percentage, because suppose it is necessary to use it outside on exterior work; if you took a master painter's pigment bill, you would find that what runs away with colour tremendously is the outside painting. For instance, in a place like Plymouth there are a great number of stucco houses, a great quantity would be used on the stucco.

3741. What I mean is that no paint should contain more than 5 per cent. of lead. I may tell you that the Office of Works accepted that as their solution of the whole trouble. They said you could do it very well without any lead at all in a great many instances, but if it was decided not to allow more than 5 per cent. of lead to be used in any given paint they would accept that willingly?—I think it is quite possible that if you had more than 5 per cent. you would defeat your object, and people would not be immune from poisoning. I quite see that, but you are suggesting that no one should be allowed to use pure lead on a building, and I think that is rather a serious thing, as I say, because of climatic conditions.

3742. Of course we want to protect the trade as far as possible; but primarily our purpose of meeting is to protect the workpeople?—I do not see why you need protect the employers at all, because, if they are all put on a level, they cannot any of them use it, but if you say you are protecting the white lead manufacturers it would be different. It does not matter to me if we are all on a level.

3743. Instead of the precautions which I have enumerated against the evil which undoubtedly exists, would you welcome, if it were a general order to apply to the whole of the trade, the prohibition of lead?—I do not know that I can answer that, because, although I have had a long experience of zinc, for instance, I am not sure whether we could easily do without lead in every case.

3744. Now I want to put the converse point to you. I want you to realise that if the free use of lead is allowed to continue the Home Office will have to insist—they are bound to do it—on the most rigid observance of all the most precautionary measures that could be devised in the same way as in other industries where the workers handle lead?—I shall be very glad for every precaution to be taken that would save life if the precautions can be taken and the regulations administered.

3745. It may be necessary that the hours of labour would have to be reduced, as has been done in other dangerous trades?—In which case I think it would be distinctly for the advantage of the country that you should prohibit the use of lead, because I find that through the increased price of painting work not so much work is done at present, and houses are not painted as frequently as they used to be. I have noticed that rooms and houses that used to be done every five or six years run now for 10 or 12 years, and customers say, "We cannot stand the cost this year; we must wait a year or two." There is a considerable looking to the cost of things at present. I would much rather see lead prohibited than that there should be an arbitrary raising of the cost of the thing. I am not speaking of the workmen's wages being raised now; that is another point altogether.

3746. I will put another point to you. It would necessitate a minute examination of every worker perhaps once a month, at the expense of the employer, which is done also in other industries, and it would involve the most rigid factory inspection. It would further involve a complicated and most elaborate code of regulations. Would you be prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess rooms, washing accommodation, avoidance of dust, spray, and fumes, limitation of hours of labour, together with periodical medical examination?—I am an individualist with socialistic ideas, and I think the less hampered any business is with rules and regulations enforced by

an outside authority the better. It would be infinitely better for the painting trade to have white lead absolutely prohibited than to have administration which would be exceedingly difficult for the master painter to fall in with.

3747. Then it comes to this, that if, as I foreshadowed, it became necessary to introduce those regulations, you, as an employer, would prefer the abolition of lead?—I do not know personally about the regulations. I am not keen or sweet on white lead at all, personally; I am the other way about. In fact, I very much admire zinc painting, to speak plainly.

3748. But you were speaking just now very strongly and antagonistically against inflicting on the trade all these burdens?—Yes; I do not know how we should carry them out.

3749. Do I understand you to prefer the abolition of lead entirely to the strict regulations?—Yes, I much prefer it.

3750. (Dr. Collis.) You were speaking of the fact that the medical profession was rather inclined to notify or declare to be lead poisoning what might otherwise be a transient illness?—Yes, that is my experience. Whenever a foreman comes and says a man is suffering from lead poisoning I always say I should prefer him to see another doctor.

3751. Are you aware that in this industry a larger number of people than in any other industry die of Bright's disease?—No, I am ignorant on these points.

3752. A point occurs to me, that if lead poisoning is charged with certain transient illnesses which are not due to it, perhaps it is escaping the extra number of deaths from Bright's disease amongst the number of people employed in the painting trade?—If you say so I will accept it. I do not know it, but I can quite understand that it manifests itself in different ways.

3753. My point being, after all, that if lead bears the blame for a few transient illnesses, it escapes the blame for certain deaths?—Yes. May I just run over a few instances of my men? Here is one man, aged 60, who has been with our firm nearly 30 years, but has never had lead poisoning or colic, and never feels the bad effects except from the fumes of turpentine.

(Chairman.) I do not think it is necessary to give those details.

3754. (Mr. Sutherland.) You are past President of the National Association?—Yes.

3755. The National Association is not taking up any position antagonistic to the use of substitutes, is it?—My opinion is that if it were brought before the body of the National Association they would all begin to fume against it, and would all say that they only wished for what was the best. I mean to say they would have a prejudice against any change, but I do not think they are taking up any antagonistic position.

3756. They would simply want to be satisfied that what is substituted is equal to what is to be dispensed with?—That is so.

3757. That the substitute for lead would be as efficient?—That is so.

3758. Then there is the other question of the effect on the general public. We have not sufficient data at present that there is anything equal to the wearing capacity of white lead, and if by any precipitant action it was prohibited, and the cost of painting was increased, and the wearing qualities were diminished, it would impose a very heavy cost upon both public and private property owners?—I should think that we were further on than your suggestion seems to show. I have great confidence in zinc, and so had my father before me, for its durability, because we found that if we did, say, a staircase with zinc flatted and put a fair bit of varnish in it, for 20 years we could wash that staircase and it would come up as new paint.

3759. I am not speaking of interior work at all; I am speaking of exterior work, which represents a very large proportion of the painting trade?—Yes, half of it.

5 April 1911.]

Mr. H. VIGURS HARRIS.

[Continued.]

3760. Do you think that we have information enough to-day to put aside a valuable pigment like lead?—I think I shall have to tell the Chairman that our experiments have not reached this stage of absolute certainty, and the experiments are not limited to this country, but are going on in America, and so far the opinion in America is more in favour of lead, but it is not final.

3761. That does not meet my question. It must be either total abolition or nothing?

(Chairman.) Plus the regulations.

3761A. (Mr. Sutherland.) I think the regulations would break down from their own difficulty?—They may break down, but they would break down the employer with them, and I should be very much humiliated if I were hal up for evading the Act, which was propounded for the sake of saving the men. I do not think they could carry out those suggestions.

3762. I am not thinking of firms like your own, but I am thinking of the average master painter, who would probably never look at the regulations, he would set them aside. It would be difficult to enforce them, and it would land everybody in endless confusion. What I want to know is: Do you think that at the present stage we have got sufficient data to work upon to set aside white lead?—I think we have sufficient data for inside work, interior painting, and decoration. I am not quite clear about the exterior, but I would rather risk it than have these regulations.

3763. As to the dry rubbing down, do you think that in the process of dry rubbing down a man who was working on a door rubbing down would cover his clothes and his shoes so that when he stepped from where he was standing it would leave the impression of his feet?—I have not seen it like that. I should not have thought from one door you could do it.

3764. Can you imagine it?—No, not rubbing down paint. If you rub down filling, that is a different thing.

3765. I mean rubbing down paint—sharp colour even?—Supposing it was a third coating; I should not have thought it was possible.

(Chairman.) Did you mean that, Mr. Parsonage?

3766. (Mr. Parsonage.) I was referring to the work done in London (to the witness), where it is all sharp colour?—My answer is that the way we do our work, if it is sharp colour, there would be powdering.

(Chairman.) The witness ought to know that Mr. Parsonage, who was in the witness box this morning, gave us that suggestion.

3767. (Mr. Parsonage.) My experience is obtained in the West End of London, where we have to use all sharp colours, and we cannot use oil colour on account of the atmosphere. (To the witness.) I did not distinctly say what the thickness was. My statement was that if you were standing rubbing down the door, when you moved your feet away you would see the impression. There would not be the dust there that there was round where you were standing. I did not say that there was one-sixteenth of an inch of dust or any thickness of dust. You can understand that when you move your feet away there would be none there, and you would be able to see it on the floor, and you would dust it up with your duster on to a piece of glasspaper?—I do not think it would be so to the extent that you describe. We are not so sparse as some people are. I like to put a fair amount of varnish in the flattening, and then I do not think you find powdering.

3768. But if you follow up one fast colour with another, there would naturally be more powdering than you would get with the oil?—Yes, there would be a certain amount of powdering.

3769. It is one sharp coat on top of another that causes it?—Yes.

3770. (Mr. Sutherland.) What do you say with regard to taking meals in the paint shop and on the job?—I never allow that. I do not think it happens.

3771. It does sometimes, does it not?—It is a very serious thing.

3772. Do you think it would be poisonous?—No, I think it would be injurious.

3773. It might be nauseating and unpleasant, but do you think it would be injurious?—I think it might be.

3774. Do you think it is not practicable to get hot water?—Not always, but you can get it in a gentleman's house.

3775. Where do you have your paint shop?—Perhaps in a coal cellar.

3776. Not in the coal cellar, do you?—Yes, sometimes the coal cellar.

3777. Or the wood cellar?—A cellar, yes.

3778. An outbuilding. Very often the coach house is set aside for that?—Sometimes, yes.

3779. The doors are open and the men could have their meals there. It is not a hurtful process. Sometimes they have them in the stable, do they not?—I do not say you would detect anything, but I should think it was not good for a man's vitality.

3780. But generally provision is made that the men shall have their meals apart from the paint shop, is it not?—I consider that in working away from the shop, where the men must have their meals upon the job, half the time they have it in the room where they are working.

3781. If you are taking a house right through, that would not be the case, would it? There would be one room probably set aside and left to the last?—Yes, but unfortunately you do not have many houses to do right through. Nowadays it is generally two or three rooms which people can afford to have done at a time.

3782. Now, with regard to the filling and rubbing down. If the filling is done with the knife, like the French do it—stopped with the broad knife—it does not need much rubbing down, does it? Very often it is left as it is?—When that is done I find the men like to use the glasspaper, and I prefer them to use the pumice stone and water then.

3783. On the hard filling?—On the hard filling. It is a little more troublesome job to do, only they get it smoother and they get it level.

3784. You do not mix much dry lead, do you?—No, I do not think we use half a hundredweight of dry lead in the course of the year. The only thing we use it for is when we use American filling, which is a very fine and expensive filling to work. We use it for walls and woodwork, and coachmakers' filling, but then it is bound by japan very strongly. We could not rub down American filling and dry white lead with glasspaper, it must be water and pumice, or something like that.

3785. Have you had any experience of zinc paints for outside painting?—No, but I am going to give myself a good deal of experience, because I am utterly weary of the effect in our climate of white lead. It chulks and powders so easily.

3786. Can you give us any opinion upon that point?—No, but where I have used one-third of white lead and two-thirds of zinc it has stood very much better. I have done it in conservatories.

3787. Do you think that the use of lead necessitates the reduction of the hours of labour of painters? Do you think painters run any risk to health by the present hours of labour?—I do not think that would save them from poisoning at all. I think it would mean very little difference. The difficulty in the painting trade is this, that you would never exactly overcome it by working altogether through the masters, because customers employ a lot of men direct more than they used to, and we are faced with this difficulty sometimes—and when I find it out I discharge the man, even if he is an old man—that a man will work so many hours a day for me, and then he will go off and work for my customer or somebody else's customer so many hours in the evening.

3788. (Mr. Parsonage.) Is not that dealt with in the rules?—Yes, but you have not half the men in the union.

3789. But is it not the fact that in the rules between your society and our men in Plymouth it is provided that the men shall not take on work?—Yes, I think it is, but I have not had occasion to read the rules lately.

5 April 1911.]

Mr. H. VIGURS HARRIS.

[Continued.]

3790. In sandpapering work down, do you ever use turpentine with the sandpaper?—Scarcely ever.

3791. Very rarely?—Very rarely. I would say almost not at all is so rare.

3792. I would like to bring this point out, because it is a point that has been laid stress on by a previous employer who gave evidence this afternoon. He said, in the whole course of his experience he did not think he had seen turpentine used more than 20 times in the last 30 years. Would that agree with your experience?—The only occasion on which we use turpentine is in rubbing down with glasspaper.

3793. Do you use pumice stone and water?—Yes, a great deal.

3794. For rubbing down before it has its first coat?—Yes.

3795. After that can you use the pumice stone?—No, except on hard filling.

3796. The main rubbing down is really sandpapering, is it not?—Yes, glasspapering.

3797. What percentage would you put of sandpaper to pumice stone? Which would you consider was the most used, taking interior work?—I do not know, and I do not think ours is a typical shop either, because we use a great deal of both. I know it is rather a byword in the town, the amount of pumice stone we use.

3798. Do you use an exceptional amount of pumice stone?—I think we use an exceptional amount of pumice stone.

3799. But still, for inside work, you would agree that there was more glasspapering done in rubbing down than pumice stone?—I do not think the men are so many hours on the glasspapering as the pumice stone.

3800. But a door is rubbed over two or three times with sandpaper where it is never rubbed once with pumice stone. Is not that so?—That is so.

3801. (*Mr. Gardener.*) I take it you are a practical painter, and you have worked as a painter?—I have not worked as a painter. My son has, but I have not.

3802. Then your evidence is only the result of observation?—Yes, always being in it.

3803. You mentioned, with regard to the lead-poisoning cases that you had, two storekeepers who had suffered from lead poisoning?—Yes.

3804. What is the storekeeper; is he a shopman?—The front part of the store, the front bench, is a

The witness withdrew.

Mr. WILLIAM HENRY CANTRILL examined.

3817. (*Chairman.*) Are you a master house decorator?—Yes.

3818. Where is your business?—98 and 100, Oxford Road, Manchester.

3819. How long have you been in the painting trade?—Myself about 23 years.

3820. Have you been an employer all that time?—No; perhaps 18 or 19 years.

3821. Were you apprenticed to the trade?—Yes, as a student, not a bound apprentice.

3822. How many men do you employ?—Our numbers range from 15 to about 74, but the average comes to about 45.

3823. Perhaps you can tell us about the average yearly number of painters you employ?—It varies, 45 is the average.

3824. Now about lead poisoning or painters' colic. Have you known any cases of it?—Yes, several.

3825. Do you mean that you have paid a certain sum of compensation?—Yes, we have paid compensation in three cases.

3826. Have your men, besides that, had occasional days of sickness due to lead?—We have not had any other complaint than those three.

3827. Do you have a periodical medical examination of your men?—No.

3828. Is it possible that some of them may be suffering from the slower and more insidious forms of

mixing bench, and he is responsible for nearly all the mixing of the shop.

3805. Is that man a painter?—In these two cases he was not a painter.

3806. He is just a man you employ for colour mixing?—Yes.

3807. How would you account for him contracting lead poisoning?—I think that is by excessive contact with it.

3808. From the fumes arising from the paint he was mixing?—No.

3809. You think not?—No, I think, without knowing it, it gets about his person, however clean he is. The man I have now is very clean, and he always has sulphuric acid and water to wash in, and he drinks a certain amount too.

3810. Was the man who contracted poisoning uncleanly in his habits?—He was uncleanly to this extent, that the men would say that if Williams had not got a knife handy he would put his hand into the lead tub and take it up. Sooner or later that man was bound to have it, but I do not think it is normal.

3811. In working with the stippler you said you thought there would not be many spots thrown about?—I do not think so.

3812. In working with a stippler on a wall, have you not seen the end of the wall and the back of the stippler covered with spots?—I do not think I have noticed it in working. Generally when there is any stippling I am on the job, but I am very particular about the stippling.

3813. I have used a stippler very frequently, and I have found the back of my hand all covered with small spots often?—Possibly that was the result of your brushing or somebody else brushing after the stippling. With stippling the stippler generally follows the other man, I think.

3814. I do not believe in a man leaving a stippler to distribute the paint?—No, nor do I.

3815. The stippler should merely put the surface on, should he not?—Yes, but I do not think what you are complaining of on the back of your hand comes from the stippling process, but from the other man.

3816. You are going to experiment with zinc outside. Up to now you have just tried it as an admixture. You have not tried it by itself, or with refined boiled oil, have you?—Yes, I have. What I have done is this: I have given the first coat of lead, and then two coats of zinc. I should not like to speak dogmatically upon the result.

the poisoning?—It is not apparent; it might be; I have not observed any symptoms.

3829. But you know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—Certainly.

3830. I gather from your answers that you realise the magnitude of this lead poisoning evil?—Certainly.

3831. Do you know that the Registrar-General has recorded no less than 284 definite deaths from lead poisoning amongst house painters in the last 10 years?—I had not known it till yesterday, I think it was, when I heard it stated.

3832. And that his mortality figures show for painters a death rate considerably higher than the normal from troubles which are the frequent effects of exposure to lead, such as Bright's disease and nervous diseases, and that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—It is my conviction that things are ascribed to lead poisoning which are not really lead poisoning.

3833. I said that these were voluntarily reported by surgeons?—Undoubtedly they would be so.

3834. Do you realise that these cases, reported voluntarily, as I say, are only a fraction of the whole, inasmuch as the Home Office have no legal right to

5 April 1911.]

MR. WILLIAM HENRY CANTRILL.

[Continued.]

pay for such reports, and are, therefore, bound to discourage reporting to some extent?—Yes.

3835. I am sure you will agree with me that all this sickness and death is very deplorable?—Undoubtedly.

3836. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, I am aware of that.

3837. And that the use of white lead has been prohibited to an appreciable extent abroad?—Yes.

3838. And that the work of painting has been most strictly regulated in several countries where the use of white lead is still allowed?—Yes, I am read up in that pretty well.

3839. Do you not think it regrettable that this country should be behind other nations in this respect?—I think there should have been legislation before.

3840. A good many small dangers attend the use of lead. For instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—Undoubtedly.

3841. Then you consider lavatory accommodation essential?—Washing accommodation is certainly required.

3842. Including the supply of hot water for washing?—Yes.

3843. Is it generally practicable for the men to have hot water to wash in?—Yes.

3844. Can they always get it wherever they are working?—Pretty nearly always. It is very seldom you get a case where you cannot get hot water.

3845. For instance, when the exterior of the house only is being painted, and the men are not expected to go inside for any purpose, where are they to get the hot water?—They get the hot water for washing and for meals from the people belonging to the house.

3846. Supposing the people in the house will not supply it?—We should have to make some arrangement to have a stove for boiling the hot water for washing and for the meals.

3847. But you could not have a stove outside the house, could you?—We could put it in the yard.

3848. Supposing it is a London house with no yard, where would you put it then?—I have not experience of that class of house. My only experience of London painting has been interiors.

3849. The difficulty would almost be insuperable in the case I have cited, would it not?—There is always an area in a London house. They must have a place where they are to store their materials, unless they go backwards and forwards to the shop.

3850. Do you know that even when painting the inside of some particular room it is not uncommon to require the men to enter by the window so that they do not have access to any part of the house?—That is so.

3851. Do you advocate definite rules regarding the wearing of overalls?—Yes, they should all wear overalls.

3852. How can you ensure these being kept in a cleanly state?—They are supposed to have them clean once a week at least, or we want to know the reason.

3853. If the workman has to take his overalls with him in his bag, will they not come in contact with his tools?—Not with wet paint brushes. His other tools would be clean, such as knives, and that sort of thing.

3854. Where can the overalls be kept from day to day when working continuously on one job?—They are usually hung up wherever they hang up their clothes, in the room they use as a mess room.

3855. Can you always provide a place for the painter to hang up his coat where there will be no risk of dust falling upon it?—They make a place for themselves generally. They usually drive a nail into the wall or something.

3856. Where do the men generally have their meals?—As a rule in the kitchen or basement.

3857. But do they not frequently have them in the room in which they are working?—Not very often.

3858. Do they sometimes?—They do sometimes, when they are only doing one room.

3859. But in the case where they are only doing one room, they would have to have them in the room they

are working in, would they not?—Yes, if they are not working near enough home for them to go home to their meals.

3860. Then you cannot always provide a place quite free from the risk of contamination where the painter may leave his food during his working hours?—He always carries a bag for his food, but you could not guarantee that you could find a separate room.

3861. All these precautions which I have cited, and others as well, are insisted on for the mitigation of lead poisoning risks in potteries?—Yes.

3862. Would it not be exceedingly difficult to carry them out faithfully in connection with house-painting operations?—It would, except where the painting is done in workshops.

3863. Then at the best, such precautions would not deal with the most important risk, namely, the risk arising from dust and spray which the workman can inhale during the whole of his working hours?—No.

3864. First, as regards the dry rubbing down with sandpaper. I understand this process is indispensable?—Yes.

3865. Is the dry method not applied invariably to newly painted surfaces on which the paint is already dry?—Always between coats, yes.

3866. I understand that the wet process cannot be substituted for dry rubbing between the first and second coats, when ordinary paint has been used?—No, the wet rubbing would cause it to cord up, to rub up into little lumps. It is not practicable.

3867. Is it only on high class work which is to be enamelled or varnished that the dry process of rubbing down can be dispensed with?—It is done in all processes to a slight extent.

3868. But my point is this: is it only on high-class work which is to be enamelled or varnished that the dry process can be absolutely done away with?—Do I gather that it is in rubbing down varnish or rubbing down enamel which has been done already for a next coat, then the work is done in water, but otherwise it is done dry? Is that what you are referring to?

3869. Yes?—That is so.

3870. The filling material dries very hard, and, therefore, can be rubbed down with pumice stone and water, can it not?—Yes.

3871. But a fresh coat of paint which has dried, say, in 24 hours, but not yet thoroughly hardened, would be spoilt by wet pumice stone?—Yes, it would be.

3872. And it would also clog up the pumice, I suppose?—Yes.

3873. Where dry rubbing down with sandpaper is indispensable, how can you prevent the worker from breathing the lead dust?—There is practically no dust from it in rubbing down oil paint, but if they were rubbing down the filling which is made from white lead there would then be dust.

3874. We have had evidence to-day which shows that the dust arising from the sandpapering is very considerable. We have been told that it covers the man's clothes as well as the floors and surrounding objects. How is it possible to save the workman from the very serious danger involved in breathing this dust?—It would have to be a flattening paint, that is, paint which is made with turpentine alone. If it was paint with oil, that would be impossible.

3875. I am speaking of flattening paint?—If there was much glasspapering done on flattening you would get a dust.

3876. Could you use an exhaust draught to remove this lead dust?—It would have to be part and parcel of your rubbing down with glasspaper.

3877. It would not be practicable?—No, it would not be practicable.

3878. The next question I want to ask you is about the painting of ceilings having moulded or relief designs. In doing this work we are told that the brush has to be pushed into the background of the ornamental work; is that true?—Yes.

3879. This gives rise to splashes which must frequently fall even on the face of the worker?—Yes, it does.

5 April 1911.]

MR. WILLIAM HENRY CANTRILL.

[Continued.]

3880. How can you deal with the spray which arises in this operation?—It is a thing which is bound to occur. It could not be obviated.

3881. You cannot use an exhaust draught to catch the spray?—I think not.

3882. Then, again, we are confronted with the problem of how to save the worker from the grave danger involved in breathing this spray?—Of course, if he kept his mouth open he would be just as likely to take it in as not.

3883. He could not keep from it very well?—Not if there was much, but the amount of spray is very small.

3884. You admit that there is a certain amount of it?—Yes, there is a certain amount, because after you have been doing it you require to wash your face. It is all over little specks.

3885. Precisely the same considerations apply to the process of stippling, do they not?—No; there would be no splashing from stippling.

3886. Would you agree with this, that fine particles come from it?—No, I do not agree that anything comes from it. It attaches to the brush itself. As soon as the brush begins to get clogged you have to discard that brush and get a fresh one, if you are going to make a decent surface of it.

3887. Do you have old paint burnt off with a spirit or charcoal burner?—With spirit burners.

3888. How can you prevent the worker inhaling the fumes which arise from this process?—If he is working in a room, of course, he might get the fumes, but outside he would not be likely to get any fumes. If he uses a lamp inside he would get the fumes, but it is very unusual to use lamps inside, because of the unpleasant smell it makes about the building.

3889. We have been told by one witness, that the burning off outside has sometimes occasioned poisoning. Are you surprised to hear that?—Yes, I am surprised.

3890-1. It would depend which way the wind was blowing. It might blow right in a man's face?—Or he might be working in an alcove where the fumes were, so to speak, pocketed.

3892. Do you agree that there is danger outside?—It is very small.

3893. Where and how do your men mix their colours?—On the job always.

3894. Do you adopt any precautions to deal with the danger that arises when colours are handled dry?—We have no lead dry colours.

3895. But in mixing the turpentine and oil with the lead there are a certain amount of fumes which arise, are there not?—If it is demonstrated that the fumes from lead at an ordinary temperature are dangerous, then there would be some danger.

3896. It appears from your evidence, then, that there are certain indispensable processes in carrying out which the painter must necessarily inhale some dust, some spray or some fumes containing lead. How are those dangers to be met?—By dispensing with lead.

3897. Is it possible to remove the danger entirely in any other way than by using a substitute for lead?—I do not think so.

3898. Various witnesses have told us about non-poisonous substitutes for lead as a white base. Have you any personal experience with such substitutes?—We have used three or four manufactured articles which are all of a similar nature on analysis—whites.

3899. Have you used leadless white paint for exterior and interior work?—Both.

3900. Have the workmen applying these non-poisonous paints known what they were using?—No, they have not.

3901. Did they use them satisfactorily?—Quite.

3902. Have you had any complaints as to difficulties in working with the leadless paints?—Not with those that they have known nothing about.

3903. I think you have something to tell us about the painting classes at the Manchester Municipal School of Technology?—Yes.

3904. Have you used white lead there?—Not this year at all.

3905. Have the students found any difficulty in using the substitutes?—None whatever. There have been just the same difficulties that we have with white lead there, and that is the first difficulty that we have to get over with new painters, they will make the stuff too thin.

3906. Is the work as good as when white lead was used?—Better.

3907. Corroborating what you have told us, the Office of Works and several other people have succeeded in obtaining and using non-lead paints. I understand you agree that that is quite possible?—I think it is so, yes.

3908. Then you realise this, that if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures in the same way as in other industries where the workers handle lead?—We shall find difficulties in framing them.

3909. But if lead is used?—There should be some restriction I think.

3910. Do you realise also that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—The hours are not excessively long already, I think.

3911. Do you think also that this would involve an extremely complicated and elaborate code of regulations?—I am sure it would.

3912. Would you be fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation, avoidance of dust, limitation of hours and all other such matters?—It would be almost impossible to observe anything on that.

3913. (Mr. Sutherland.) Would you qualify that?—Yes. I think it would be absolutely impossible.

3914. (Chairman.) You would prefer as an alternative to that, the abolition of lead?—Yes, I would, absolutely.

3915. (Mr. Sutherland.) Does the term zinc oxide indicate a particular paint, or does it indicate simply a white paint in which zinc in indeterminate proportions is used?—I should say you would insist on the zinc oxide without any admixture.

3916. Would pure zinc oxide give you a permanent paint?—I think not.

3917. Then you would have to mix it with some other material to give it the permanency and to give it opacity?—The zinc would be too transparent, altogether.

3918. Then practically what the chairman calls non-lead paint represents any amount of different formulas, does it not?—Yes, either china-clays or something of that sort.

3919. And to establish a standard of leadless paint would mean co-operation between public bodies to get something that would be accepted?—Yes.

3920. For instance, if the Government prohibited white lead it would simply leave the profession, the builders, and the public, confronted with any kind of paint that was put on the market as leadless paint. An architect drafting a specification in the interests of his clients naturally wishes to get the best. How should we get it?—I think you want an inquiry to find which is the best and make it the standard.

3921. There is the Government's interest and the architects' interest representing their clients and the public interest representing permanency?—Yes.

3922. Have you had much experience of zinc paints for outside work?—Not a great deal.

3923. Have you had sufficient to really establish data upon it?—I think not.

3924. Do you think it would be an easy thing to establish a formula for leadless paints?—In a given period of about five years.

3925. I was going to ask you what term you think it would be necessary to give the public in order to transfer them from the use of lead paints to the use of leadless paints. You say you think five years?—Yes, I should think so. I think it would force the hands of the paint manufacturers or chemists and make them bring something forward.

5 April 1911.]

MR. WILLIAM HENRY CANTRILL.

[Continued.]

3926-7. Do you think it is desirable for this Committee or any other body, or this Committee, in conjunction with any representative body, to establish, on an adequate scale, something like tests of the physical properties of these leadless paints?—I think myself that a Committee should be formed to go into this matter.

3928. Do you know that the Dutch Government have just completed an inquiry which covered something like five or six years?—Yes.

3929. And that they took zinc paints and lead paints, and they seem to have tested them on all kinds of surfaces and position. Do you think that such a step is desirable for this Committee, or any other committee, before committing ourselves to a definite pledge or recommendation?—I should say it is necessary that you should have a committee about it, and not bar the use of lead immediately.

3930. You do not think there would be any objection on the part of the painting trade, given a satisfactory substitute for white lead?—I think not.

3931. Then a question was put to you about the fumes from the lamp. Do you think a worker works directly over the fumes of the lamp while burning off?—Not too unpleasantly near.

3932. Nor so near as to be dangerous?—No, he holds it at arm's length, except just in corners where he cannot.

3933. You think the objectionableness of the fumes would not be sufficient to endanger the health of the operative?—No.

3934. The interior work is not done with a lamp but done with solvents?—Yes.

3935. Do you give your men accommodation for hot water? You are bound to for meals, are you not?—Yes.

3936. But is there a difficulty in getting them hot water for washing their hands?—No, I do not think so. We find, as a rule, the customers themselves are only too pleased to find it.

3937. Do you think there is any danger in rubbing down?—No.

3938. Do you think the rubbing down is done to such an extent, and cuts off so much dust containing lead, that it becomes a danger to the health of the operative?—In our experience there is very little glass-papery done.

3939. And it would always be done, not so much to remove the surface of the paint, as to remove the little knits or rubs?—Yes.

3940. You do not think that the danger from the spray or dust, coming from stippling, is insignificant. It comes from the application of the paint?—Yes, it comes from the application of the paint. The man who is stippling always comes off worse than the man who is laying on the paint, because he stands a short way from the ends of the brush and he receives splashes from the brush, whereas the man who is putting it on gets none. It is not from the stippler, but from the man who is applying it, that he gets his splashes.

3941. The addition of lead poisoning to the Workmen's Compensation Act has added substantially to the rate of insurance, has it not?—Yes, undoubtedly.

3942. It rose, I think, from something like 25s. to 30s. per cent. last year?—Yes.

3943. (Chairman.) Why do you consider five years necessary as an experiment?—In Manchester the life of an average outside is five years.

3944. But you think the Home Office would allow that period in view of the evidence that they have got from the Board of Works who have been trying it for the last five years?—If they have given it the five years test I should think that is quite sufficient.

3945. (Mr. Sutherland.) I should like to ask you whether you do not think that climatic conditions are not an important factor in the question of the use of zinc-white for outside?—Yes.

3946. In a climate like France it is very different to a variable climate like we have here, where there is so much damp?—Yes. Even 10 or 12 miles out of Manchester you would find it lasted very much better than in Manchester itself.

3947. (Mr. Parsonage.) You have paid compensation for lead poisoning cases, have you not?—Yes, three cases.

3948. One has been on for a considerable time, has it not?—Yes.

3949. Four years, I think?—Yes, three or four years.

3950. Was that the case of Winterbottam?—That is the name.

3951. I think he is still drawing compensation, and he has been receiving it since 1907?—No, it has been settled recently, and he is back at work again, not with us, but, I believe, with his brother-in-law—but he is at the trade.

3952. (Mr. Gardner.) You said you had been 23 years in the trade and 18 years of those as an employer?—Yes.

3953. Then you said that you had been apprenticed as a student?—I was with my father.

3954. But you went out to work, did you not?—Yes, I went out to work and studied in the evening at the Art School, and took the winter terms at the Art School instead of working at the trade.

3955. Then we may take it that you are a practical painter having worked at the trade?—Yes.

3956. In speaking about the provision of hot water, of course, you are speaking of your Manchester experience, and not outside the Manchester area?—Yes; it is within the rules of the Union that it must be provided, and a place to get their food in.

3957. If dust and fumes are not the cause of lead poisoning what would you say was the cause of lead poisoning?—It is only my theory, but I think they can take it through the pores through dirty hands, and leaving it on during the night, through not properly washing themselves, just the same as they can by eating it.

3958. (Mr. Parsonage.) It is the fact that the doctors do not accept that, is it not?—The doctors do not accept that, but it is my opinion that you can get infection through the skin. In working with dirty handles of brushes I think it is just as dangerous as eating it.

3959. (Mr. Gardner.) I suppose unless he was a very careless workman who was working on that wall, say, he would not make those spots on the floor with the stippling?—No.

3960. How would you account for it if there were those spots when it was stippled?—It would make a great many small splashes from the edge of the brush.

3961. From the stippler?—No, not from the stippler. In laying it on it flicks from those small outside strands.

3962. How would you account for the man working with the stippler having the back of his hand covered with small spots if it was not coming from the stippler?—I do not know; I have not noticed it.

3963. Have you yourself stippled much?—Yes.

3964. And have you never noticed it?—No.

3965. (Mr. Parsonage.) That is an illustration of a stippler? (Sketch handed to the witness.)—We do not use that class of stippler, but I can quite understand him getting it, because he would be receiving it from the man who was brushing and not from his own brush.

The witness withdraw.

## FIFTH DAY.

Thursday, 27th April 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Mr. E. L. COLLIS, M.B.

Mr. F. G. RICE.

Mr. W. G. SUTHERLAND.

Mr. A. GARDNER.

Mr. J. PARSONAGE.

E. A. R. WEBBER

R. U. SHAXBY

} (*Acting Secretaries*).

Mr. J. PARSONAGE (a member of the Committee) recalled and further examined.

3966. (*Chairman*.) You are Secretary of the National Amalgamated Society of Operative House and Ship Painters and Decorators. I understand that you have handed to Dr. Collis various records in your possession showing particulars of the deaths which have occurred for a number of years among the members of your society?—Yes; in all I have handed to Dr. Collis records of 935 deaths which have occurred during the six years from 1905 to 1910, inclusive, among the members of my society.

3967. What is your average membership?—About 16,000, taken over the last six years.

3968. The title of your society includes both house and ship painters. How many members of your society do ship painting exclusively?—I could not say

definitely the number who do ship painting exclusively. I should think it is very small; I should not say more than 100. I could get the records from our branches in the shipbuilding districts.

3969. Perhaps you will do that?—Yes.

3970. Were the records compiled specially for the purpose of this inquiry? No; they were compiled without any reference to their being used for a purpose such as that of the present inquiry.

3971. How have they been collected during the years in question? Quarterly, for the purpose of insertion in our quarterly reports.

3972. May we rely upon their being absolutely trustworthy as far as your society is concerned?—Yes.

Mr. ARCHIBALD GARDNER (a member of the Committee) examined.

3973. (*Chairman*.) You are the Secretary of the Scottish Society of Operative House and Ship Painters. I understand that you have handed to Dr. Collis the various records in your possession showing particulars of the deaths which have occurred for a number of years among the members of your society?—Yes; I have handed to Dr. Collis records of 305 deaths which occurred during the 10 years 1901 to 1910, inclusive, among the members of the society.

3974. The title of your society includes both house and ship painters. How many members of your society do ship painting exclusively?—I have no accurate information as to how many men never work outside of a shipyard, but I should say from 50 to 75. I can get the accurate information as to that point, but I would not put it above 75 who never leave the shipyard.

3975. What is the average membership of your society?—Our average membership is a little over 3,000, say 3,240.

3976. Were the records compiled for the purpose of this inquiry?—No. They were compiled without any reference to that. They were compiled for the information of our members.

3977. How have they been collected during the years in question?—Quarterly from the branches. We get them in quarterly.

3978. May we rely upon their being absolutely trustworthy as far as your society is concerned?—Yes.

3979. (*Dr. Collis*.) Is there any difference between the way in which house painting is carried on in Scotland and in England which might make the Scottish workman more liable to accident?—No. There are differences in scaffolding outside work in some towns. We do not use the travelling cradle. It is all ladder work, with the exception that we use what is called a hanging scaffold, which is a much more dangerous form of scaffolding than the travelling cradle.

3980. Would they be more liable to falls with the hanging scaffold that you speak of?—Yes. There is no protection for the men.

3981. (*Mr. Sutherland*.) There is not a back board?—No; there is only a belly rope.

3982. What are these deaths? Do they include accidents?—Every case of death, no matter what the cause, including accident, has been sent on to Dr. Collis. They have all been copied from the certificates which we have in the office. We file all the Registrar General's certificates.

Mr. E. L. COLLIS, M.B. (a member of the Committee), examined.

3983. (*Chairman*.) You are a Medical Inspector of Factories at the Home Office, and a member of the present Committee?—Yes.

3984. You have received certain details from Mr. Parsonage and Mr. Gardner, members of the Committee, relating to deaths among house painters?—I have.

3985. Do the figures supplied by Mr. Parsonage relate to deaths among members of the National Amalgamated Society of Operative House and Ship Painters and Decorators during the years 1905 to 1910?—I understand that that is so.

3986. And those supplied by Mr. Gardner relate to deaths of members of the Scottish Society of Operative House and Ship Painters in the years 1901-1910?—Yes.

3987. These figures, as we have heard from Mr. Parsonage and Mr. Gardner, include a small proportion of ship-painters. Would this affect your deductions at all?—I think not.

3988. What are the respective numbers of deaths which have occurred in the two societies?—There have been 935 deaths during six years in the National Amalgamated Society of House and Ship Painters and Decorators among an average membership of 16,571; and 305 deaths in 10 years in the Scottish Society of House and Ship Painters among an average membership of 3,239.

3989. Then in all you have examined records of 1,240 deaths among the members of those two societies?—I have.

27 April 1911.]

MR. E. L. COLLIS, M.B.

[Continued.]

3990. The Registrar General at Somerset House in classifying the mortality figures according to occupations, deals with a class defined as "plumbers, painters, and glaziers." Do you consider that this class accurately represents house-painters taken by themselves?—No, but since house-painters form a large proportion of this class, the figures stated give some indication of the causes of death among house-painters.

3991. Have you studied the Supplement to the Registrar General's Report from this point of view?—I have.

3992. What are the main points of interest to this Inquiry which are brought out in the Supplement?—It is there stated\* that "in the main working time of life the comparative mortality is 1,114, or 11 per cent. above the standard. This excess is most marked under the headings 'Plumbism' and 'Bright's Disease.' But there is also a substantial excess in the mortality from phthisis and diseases of the nervous system . . . . It is noteworthy that the high fatality from plumbism and Bright's disease which occurred ten years ago has been maintained since that date, the mortality from plumbism being 22 in both periods, and that from Bright's disease being 72 in the first and 69 in the second of these periods respectively . . . . It is significant that the mortality from lead poisoning has remained practically constant ever since 1880-82."

3993. When you say 69, is that 69 deaths out of 1,000?—That is the comparative mortality figure.

3994. (Mr. Sutherland.) Does it mean 69 per 1,000?—No, not quite. You have the mortality from Bright's disease of all males taken as a certain number in every 1,000 deaths, and then you have the comparative mortality figure among painters, plumbers and glaziers in proportion to the 1,114 of that class. Comparative mortality figures always take the whole of the deaths in the general population as 1,000. The comparative mortality figure for Bright's disease for all occupied males is 32 as compared with 69 and 72 for the class we are dealing with.

3995. What is the 1,114?—All males being 1,000 it is 1,114 for the class he is dealing with, namely, plumbers, painters and glaziers. If you had a given general population, which would be somewhere about 60,000 to 70,000 of ordinary people, 1,000 would die; but if you took 60,000 to 70,000 plumbers, painters, and glaziers in the same period 1,114 would die.

3996. Why do you fix on 60,000 to 70,000?—It roughly gives you the number among whom 1,000 do die of the ordinary population.

3997. (Mr. Rice.) Suppose we said 11 per cent. more die?—That is his statement.

(Mr. Gardner.) The mortality is 11 per cent. higher amongst plumbers, painters and glaziers than it is amongst ordinary people.

3998. (Chairman.) Have you, in the course of your investigation of the figures supplied to you by the societies' representatives, given attention to the diseases mentioned in the Registrar General's Supplement as specially liable to affect lead-workers?—Yes, particularly from plumbism, Bright's disease and phthisis, but I have not attempted to deal with "nervous diseases" in this investigation, because I felt some uncertainty as to which diseases the Registrar General had included under that heading.

3999. Have you arranged the information in the form of statistical tables?—Yes, on the lines adopted by the Registrar General. I put in a table showing the details for the two societies taken together.

4000. What deductions can be drawn from these figures?—I have drawn up a second table to show the deductions which may fairly be drawn, namely, that in every 100 deaths which have occurred among the members of these societies, between 13 and 14 occur from causes attributable to lead.

4001. Does this mean that of every 100 painters who died, only between 86 and 87 would have died if

they had not come into contact with lead?—The study of the ages at death leads me to think that this is so, because if these three causes of death be removed from the total other causes, the age at death from these remaining causes then closely approximates the age at death of all males.

4002. Does the age at death of the members of these societies differ at all from that of the general population?—Yes. I have arranged additional columns on Table II. to show this point. In these columns the median age at death (which Bowley in his book "Elements of Statistics" regards as the most useful form of average) is shown to be eight years lower for house painters than for all males.

4003. Will you give us details of those figures, please?—For all ages the median age at death due to all causes is 56 to 57, to plumbism 48, to Bright's disease between 57 and 58, and to phthisis 39 to 40. In the class given by the Registrar General, plumbers, painters and glaziers, the median age at death due to all causes is 48 to 49, to plumbism 44, to Bright's disease between 50 and 51, phthisis 38 to 39. As calculated from the table made from the statistics of the two societies, the median age at death from all causes is 48 to 49, to plumbism between 45 and 46, to Bright's disease 49, and to phthisis between 38 and 39.

4004. The most important conclusion is that, from all causes, the median age at death is 48 to 49 amongst painters, as compared with 56 to 57 among the general population?—That is so, with regard to the male population.

4005. How do you explain this great lowering of the age at death among house painters?—By the fact that plumbism and phthisis, which the earlier columns of the table show to be more prevalent among house painters, cause a lower median age at death than that caused by all other diseases.

4006. Do you consider that the increased prevalence of these diseases is sufficient to account for such a great difference in the median age at death?—Yes, I do.

4007. Have you noted any marked difference between the causes of death occurring in the National Amalgamated Society of Operative House and Ship Painters and Decorators and those occurring in the Scottish Society?—Yes. In the Scottish Society the incidence of plumbism is decidedly lower, that of Bright's disease somewhat lower, but that of phthisis decidedly higher. The figures are very close to those given by the Registrar General for plumbers, painters and glaziers.

4008. Have you noted any other difference?—Yes. The mortality from accident, particularly from fracture of the skull, is higher among the Scottish Society.

4009. (Mr. Sutherland.) Is the mortality from general accident higher in Scotland?—The mortality from accident is higher, which is accounted for particularly by fractures of the skull. If the fracture of the skull were taken out you would have about the same.

4010. (Chairman.) Now you have summarised for us the results of your investigation into the mortality among house painters. Is there any other way of ascertaining the amount of ill-health caused by employment?—Yes, from statistics of invalidity, by which I mean sickness occurring during life, when such statistics are available.

4011. Do you consider this question of invalidity important as a test of the danger of an industry?—Yes, it probably gives even more accurate information than the mortality figures.

4012. Why do you think so?—Because this point has been established in two separate reports, from which, if you will allow me, I will quote extracts. The careful investigation made, for actuarial purposes, by the Manchester Unity of Oddfellows, states: "On a broad view of the facts, therefore, it appears that as between the elements of geographical situation and occupation the former should be chiefly considered

\* Supplement to the Sixty-fifth Annual Report of the Registrar General of Births, Deaths, and Marriages in England and Wales. Wyman and Sons, 1908 [Ct. 2619]. Price 1s. 10d. p. lxxix-x.

† See Appendix XI., Table A. ‡ See Appendix XI., Table B.

27 April 1911.]

Mr. E. L. COLLIS, M.P.

[Continued.]

"in the formation of monetary tables depending on 'mortality.' When referring to invalidity this Report says: \* 'It will be seen . . . that the proportion of members sick during any year varies with the occupation, and that the differences in the 'risk of 'incapacity,' as it may be termed, in the several occupation groups, are remarkably regular at nearly 'all periods of life.' The Second Report is one issued in 1854 by the Registrar of Friendly Societies. It is there pointed out that 'it was established that 'locality had not very much to do with the average amount of demand which was likely to be made on 'the funds of a friendly society. The only real practical difference in the distribution of sickness that could be discovered was seen to turn on the amount of physical force called out by the occupation of the contributors.' These two Reports, issued with 50 years interval between them, bringing out independently exactly the same points, are, I think, somewhat remarkable.

4013. Are you aware of any general statistics of invalidity among painters?—Yes. The report already quoted of the Registrar General of Friendly Societies states:† "There were four highly exceptional cases which were susceptible of classification with any other calling . . . These cases consist of the mariners, the miners and colliers, the painters, and the railway servants." And he gives figures to support the statement.

4014. What do these figures show?—The tables given have been reproduced in curves by Mr. Shaxby and show that, although painters are not liable to accident-sickness to the same extent as the other three classes specified, yet the contribution required from the painters stands second, and is only exceeded by that required from miners and colliers.

4015. Do you think that these figures in any way represent the present condition of the health of painters?—Probably, because, although this inquiry has not been repeated, excessive invalidity among painters has been brought to light in recent years by the premiums required to insure employers against sickness among their workpeople.

4016. Against what risks do employers now have to insure their workpeople?—The Workmen's Compensation Act of 1897 made employers liable for sickness due to accident. The later Act of 1906 added sickness due to certain diseases caused by occupation, of which lead poisoning is one, and since this Act became operative insurance rates for painters have increased, presumably to cover risks due to lead poisoning while they have somewhat decreased during the same period for most other occupations.

4017. Upon what figures do you base this conclusion?—The investigation published in the United States, in their "Bulletin of Labour" of 1910, which was issued from Washington, in which figures are given showing, for all the principal civilised countries, the insurance rates charged in the various occupations.

4018. How do the rates for painters in this country compare with those of other countries?—The report shows that the increase of rates for painters which has taken place since 1907, has not occurred in countries where lead poisoning is not the subject of compensation.

4019. Next to coal-mining, in which the death-rate, owing to accidents, is very excessive, you consider that the house-painter's occupation is one of the most dangerous occupations in the country?—As far as information from the invalidity tables can help us, this point of view seems to be established.

4020. (Mr. Sutherland.) Does the United States report cover every European country?—It deals with general insurance in the respective countries—Austria, Belgium, Denmark, Finland, France, Germany, Great

Britain, Italy, The Netherlands, Norway, Sweden, Switzerland, Canada, New York, and other States of the Union

4021. Do not you think that a good percentage of the invalidity in the painting trade is due to the seasonal nature of the occupation, and the consequent insufficiency of food when the men are out of work? Do not you think that that would have a very important effect? A number of painters lose a great deal of time in England, as Mr. Parsonage knows?—Do you mean total invalidity or invalidity due to the special question of plumbism?

4022. I mean total invalidity. You said that invalidity was a test of the danger of an industry?—Yes.

4023. But you did not merely confine yourself to plumbism?—No.

4024. You were speaking of general invalidity?—The insurance point can only affect plumbism.

4025. A painter when he is at work diets himself very well, but when he is out of work he must very often go short?—I see your point. I am trying to work it out in my mind. Your suggestion is that when the painter comes back to work after an interval he is semi-starved, and during the first two or three weeks, until he has received his wages and begun to feed himself, he is more liable to illness. Is that it?

4026. No. I am speaking of the general lowering of the man's system which will take place when he is not well fed in the slack season?—A person who is not well fed is certainly more liable to illness.

4027. I do not say that they starve, but they cannot live as well in the quiet season as they do when they are at work?—I follow.

4028. (Chairman.) Would not that apply to several other industries?—Yes.

4029. (Mr. Sutherland.) Painting is specifically a seasonal occupation?—Might I try to put my point more clearly? Apparently I have not made it clear. It is this: The old statistics, which are the only ones we have to go upon which accurately represent the amount of invalidity suffered by painters as compared with other classes, show that the figure for the painter is high. When we seek for a reason for this increased invalidity we have to take into consideration the point that since lead poisoning was made a subject of compensation apparently lead is causing invalidity, because the premiums to cover the risk have risen. Our information as regards other forms of illness in the trade is nil. Your point may or may not be correct, but I have no figures at all to substantiate anything but the fact that lead sickness occurs in the trade.

4030. Has lead sickness any bearing on the statement that you made, that the invalidity was important as a test of the danger of an industry? Was that a quotation?—Yes.

4031. In that report was lead taken into consideration?—The value of that report is that it does not consider particular illnesses, but illness as a whole, and I give it a local and particular application. It was not prepared for this special point.

4032. You said that locality has nothing to do with the demands on the funds, as I understood you, of the associations or of the friendly societies, but that the demands were due to the amount of physical force called out by the occupations?—Yes. The words "physical force" are there used by the Registrar of Friendly Societies. He would have brought out his point equally if he had said "the form of the occupation." He must himself have introduced the question of physical force, because he does not take out any statistics of the physical force, but he probably had in his mind a man employed before a furnace. A puddler has to exercise an amount of physical force which produces occupational illness.

4033. There is no comparison between the force which a puddler or a man in some of the other occupations has to put out and that demanded of a painter. His is rather skill than heavy labour?—Perfectly, but it is occupation, and it is what happens in the occupation, that produces the invalidity.

4034. The term "the amount of physical force called out" rather throws us off the line?—I was bound

\* Sickness and mortality experience of the I.O.O.F., Manchester Unity, during the five years 1893-97. A. W. Watson, 1903, p. 49.

Mr. E. L. COLLIS, M.B.

[Continued.]

to quote the absolute words. He is speaking of the trade as a whole. Had he been speaking of a particular one, he might have modified his adjective.

4035. (*Chairman.*) If Mr. Sutherland's conjecture is a right one, that this invalidity is caused to a great extent by the fact of the man having seasonal work, and thereby not being properly fed in the interval, that would be a very good reason why the danger of lead should be withdrawn from the men?—Yes. A badly fed person is always more liable to take lead poisoning than a person in good health.

4036. (*Mr. Rice.*) I am not quite clear whether your evidence agrees with the evidence of Dr. Legge. Dr. Legge in his evidence mentioned 387 fatal cases in ten years, or on the average 38 per year, connected with lead poisoning. That would be coach-painters and house-painters?—No; it is house-painters and plumbers only.

4037. I would like, if I could, to get your estimate as to the number of deaths. You have prepared some information, and I daresay you could give us the number of deaths per year?—From lead?

4038. Yes; with regard to house painters?—It is something between six and seven per year in the members of the two societies with regard to which I have had figures given to me.

4039. Between six and seven a year directly due to lead poisoning?—Yes.

4040. In 10 years there would only be two deaths directly due to lead poisoning, as I understand the report from Scotland? There is one point I did not quite understand. You say 32 ordinary people die of Bright's disease, and 69 and 72 plumbers, painters and glaziers?—Yes.

4041. Thirty-two ordinary person per 1,000?—Yes, 32 deaths from Bright's disease out of 1,000 deaths.

4042. Against 69?—Yes.

4043. That is rather more than double?—Yes.

4044. Yet, on the other hand, 1,114 plumbers, painters, and glaziers die from Bright's disease?—No; from all causes.

4045. That is 11 per cent. more than the others?—Yes, it is all causes; the Bright's disease is lost in that.

4046. Insurance premiums must of necessity be increased where the liability is greater?—Yes.

(*Mr. Rice.*) It is not absolutely reliable.

Mr. JOHN BANCROFT (18, Petley Road, Hammersmith) examined.

4051. (*Chairman.*) What practical experience have you had in the house-painting trade?—My experience has extended over a period of 27 years.

4052. What branch of the National Society of Operative House and Ship Painters are you connected with?—I am connected with the Hammersmith Branch, and I am also the London organiser. My duties are to look after the accident cases and lead poisoning cases, and also any difficulty that may arise between workman and employer.

4053. Have you had any experience of lead poisoning among the members of your branch?—My experience has been in connection with the whole of London, and during the last 12 years I have been in close touch with most of the cases that have come forward, and the different lead poisoning cases during the last five years in which action has been taken.

4054. If any specific cases of lead poisoning have come before your notice I should like the figures given in evidence?—There are at the present time a matter of seven that are actually being dealt with by myself and looked after at the present time. May I state the number that we actually dealt with during 1910?

4055. What is the membership of the branch?—The numbers in London are roughly about 3,000.

4056. How many cases of lead poisoning have you had amongst those 3,000 workpeople?—We have only tabulated them, since the Act came into force.

4057. Since 1906, how many cases have you had?—We have had 20 cases in London since July 1906.

(*Dr. Collis.*) The Act came into force in July 1907.

4047. (*Mr. Sutherland.*) The liability reflects the danger?—Yes, the liability reflects the danger.

4048. And the experience?—Yes, and the insurance companies had to discover that the plumber and painter were liable to lead poisoning. The law did not tell them so.

4048A. (*Mr. Sutherland.*) The insurance rates have jumped from 20s. to 30s. after three years' experience of the 1907 Act?—None of the Companies had data to go upon, and they fixed three years, and then put the rates up from 20s. to 30s.

(*Mr. Parsonage.*) Insurance companies to-day are insisting that a man who has received compensation for lead poisoning shall not be insured, and that means that the man is prevented from earning his living. I can absolutely prove that from many towns.

(*Mr. Rice.*) For general building they have a lower rate?

(*Mr. Sutherland.*) Yes, but not much lower.

4049. (*Mr. Parsonage.*) I believe that the Hearts of Oak are the largest friendly society working from one central office in England, and they refuse to admit painters into that society. How would that affect the returns made to the Registrar? If the man applying for admission to the Hearts of Oak put his occupation down as a painter he would not be admitted on account of the danger of the occupation, so that it must materially affect the returns made to the Registrar?—But the Registrar of Friendly Societies when he published his statistics in 1864, and that may have been the rule of the Hearts of Oak then, separates out the painters entirely, so that it would not make any difference what society they are in.

4050. But this society would not admit painters?—Then all we can say is that the society cannot give us any figures. I do not think we can get any further than that.

(*Mr. Parsonage.*) With reference to the point that a painter does not get sufficient food, which, unfortunately, we know perfectly well, I have just got out my returns for the quarter from January to March 1911. Trade has been considerably better, and we have paid out about 5,000l. less in unemployed benefit than in the corresponding quarter of 1910, and I find that the sick and funeral benefit shows an increase over last year. That proves that when trade is good there is more sickness, because there are more men employed. That rather contradicts Mr. Sutherland's point.

4058. (*Chairman.*) How many deaths have there been?—Four out of that number.

4059. Please verify from the recorded figures your statement of the number of cases of lead poisoning you have had, and the number of fatal cases each year from the time that the Act came into force?—Very well.

4060. Now I will ask you a few questions about the different processes. Does the making up or mixing of stoppings and paints give rise to dust?—No.

4061. Does the mixer inhale fumes during the mixing?—Yes, undoubtedly.

4062. Do fumes arise when he cleans out the vessels which have contained paints?—To a greater degree when the vessels are cleaned out by burning them out as we term it.

4063. Is it customary to sandpaper the work between successive coats of paint?—Yes.

4064. Does this cause much dust?—It does.

4065. Do you consider the breathing of that dust one of the principal sources of danger in your employment?—Undoubtedly.

4066. I suppose it is quite impossible to remove this dust by a local exhaust draught arrangement?—I am afraid that it is.

4067. Certain parts of the work are rubbed down with pumice stone and water, are they not?—Yes.

4068. Would it be practicable to prohibit dry rubbing down?—No. It would be possible to reduce it considerably.

II 2

27 April 1911.]

Mr. JOHN BANCROFT.

[Continued.]

4069. It would be impracticable, would it not, to rub down mouldings or curves with pumice stone and water?—Yes.

4070. Or any new paint, between coats, which was dry but not fully hardened?—It would.

4071. How can we remove the danger from this dry sand-papery?—By the more practical appreciation of the treatment that is necessary. I mean to say this: The methods that are adopted to-day are only adopted for one purpose—convenience and cheapness. There is really no necessity for a great amount of glass-papery which is done to-day if the work was treated properly from the commencement. If the work is properly prepared in the first place and a competent workman puts on the coats, the necessity for removing the "nils," as we term them, is considerably reduced. Therefore the sand-papery is not necessary, to the extent that it otherwise would be.

4072. But is it possible to do away with this danger entirely?—No.

4073. Except, I suppose, by prohibiting or restricting the use of lead?—That certainly would be one direction in which to obtain the desired result.

4074. Are you acquainted with the operation known as stippling?—Yes.

4075. Will you tell us what you understand by stippling?—In stippling a wall the object first of all is to get as much colour on as possible, and at the same time to spread it out as uniformly as possible so that every part of the surface shall be equally treated. By so doing you serve two purposes: you prevent what we call a shady result. The work would look cloudy if not so treated. Then, again, you practically get a generally good effect by treating all the work alike, which could not otherwise be done than by what we term the flatting. With regard to putting flatting on with a brush, it would be absolutely impossible to distribute it effectively without the use of the stippler, because the nature of the paint used does not allow you to get over the surface quickly enough, and the brush, therefore, has not time to distribute it sufficiently without the use of the stippler.

4076. In such work and in all painting where the brush has to be pushed into crevices and corners, is there not a considerable splashing, or at least a spray or vapour formed of small drops of the paint?—Yes. The face of the man after working for an hour or two would be almost covered in some cases, where the work was rather intricate, and where the enrichments were many, and the character of the work required a certain amount of pushing into the crevices, &c.

4077. How can the worker be safeguarded against breathing such spray or vapour?—Ventilation would be the first safeguard, and even in that case, in the case of flatting walls, the average painter is not inclined to have too much draught coming in. He considers that it interferes with the possible result. Ventilation is undoubtedly one of the first things.

4078. Would ventilation remove the danger?—Ventilation would reduce it. It would not remove it.

4079. Have you had any experience of the aerograph or spraying machines?—I have not. I have had several complaints that this is very injurious to the workmen. At a large hotel about three months ago a sprayer was used, and the complaint was that two men within a few hours were compelled to leave off. One went home and was away for a few days.

4080. With regard to old paint-work. There are three methods in use for removing old paint, are there not?—Yes.

4081. Burning off, scraping off, and solutioning?—Yes.

4082. Which of these methods is most used?—The burning off.

4083. Can a painter avoid breathing fumes in the burning off process?—He cannot avoid inhaling the fumes, but that, again, could be reduced by a reasonable amount of ventilation.

4084. Is burning off generally followed by sand-papery?—Yes, or pumice stone and water, as the choice may be. It is more often sand-papery.

4085. This, then, introduces a further risk of breathing dust?—Yes; but the dead paint in that case,

in my opinion, would not be quite so injurious as the newer paint, which is more alive.

4086. Where scraping is done there are, I suppose, small particles which give rise to dust also, and this is breathed?—Yes.

4087. Is solutioning or pickling less dangerous than either burning off or scraping?—Undoubtedly. The only danger in that would be by contact—allowing the hands to get dirty, and so on.

4088. Is solutioning comparatively little used?—Yes, it is not used very much at the present day.

4089. Can you suggest any way in which the dangers may be entirely removed from the burning off and scraping processes?—I am afraid I cannot, only with a reasonable amount of ventilation you prevent the accumulation of the fumes in any room where the burning off is taking place.

4090. But, would a system of ventilation be practicable?—A system of ventilation would be practicable in burning off.

4091. Can you suggest in what way?—I would say open the windows at the top. Fumes naturally rise, and providing that a current of air could be got through it would certainly reduce the accumulation of the fumes.

4092. But when the wind was blowing in the direction of the window, would it not make it worse?—The average believer in ventilation does not worry himself about the direction of the wind. The average painter on going into a room which smells foul immediately opens the window.

4093. You seem to have a vague idea of ventilation, but no practical suggestion to make?—The ventilation would be limited by the amount that it was possible to obtain, for instance.

4094. Do you mean by ventilation the removal, by some air current, of the dangerous or noxious fumes and dust?—The accumulation of vapours would be mixed with the purer air, which must materially reduce the evil effects of the vapour.

4095. Can you name any other processes in which there is a grave risk of the painter inhaling dust, or fumes, or spray?—In the preparation of work originally, if pumice stone and water was more generally used, it would reduce the necessity in many cases not only for burning off but also for scraping and sand-papery—more particularly the latter.

4096. Are there any other processes in which there is grave risk of the painter inhaling dust, or fumes, or spray?—I think there are not.

4097. I suppose there are many processes in which the painter cannot avoid getting his hands soiled with paint or stopping material?—Yes.

4098. Do you think that the provision of washing conveniences and the regular cleansing of the hands is important?—Yes, and the mouth.

4099. Should hot water always be available?—Hot water should be used if possible.

4100. Is it generally practicable to get it?—No.

4101. Is food often kept in the pocket of the working coat, and eaten in the place where paint is being used?—Very often.

4102. Is it frequently impracticable to have the use of a separate place as a meal-room?—Not frequently. The greater possibility is that it is practicable for the men to move into a room where paint is not being used.

4103. Do painters usually wear overalls while at work?—In many cases.

4104. How are they kept clean?—By washing. The average man washes them once a week, or gets them washed.

4105. Do the men have to carry the overalls in their tool bags?—Yes.

4106. I suppose that the overalls would be rather dirty towards the end of the week?—Yes, they would.

4107. In other industries where lead compounds are used the Home Office have prescribed a medical examination at monthly, or even weekly intervals; and the examining surgeon has power to suspend men who show early symptoms of lead poisoning. Would you like to see this introduced for house painters?—It would be practicable, because the casual nature of

27 April 1911.]

Mr. JOHN BANGROFT.

[Continued.]

their employment would lend itself somewhat to that examination.

4108. Are the men that you are connected with generally desirous that lead should be prohibited?—No, there is not that desire, particularly in London.

4109. Have you had any experience in the use of non-poisonous substitutes for white lead?—My experience has been mostly on Government work.

4110. Do your men complain of the evil effects of coming into contact with lead?—I have a case at the present time in which a man who has not been working with lead is poisoned.

4111. But listen to my question. Do your men generally complain to you of the evil effects of having to work in contact with lead?—Yes, they do complain. They do not complain so much as they do of the lead substitutes.

4112. (*Mr. Parsonage.*) You are referring to the working of the material?—Yes.

4113. That is a different matter altogether?—The men often complain of the effects of lead.

4114. (*Chairman.*) But I want to know whether your men are very much in earnest with regard to the deliberations of this Committee, or do they want to be left in their present position?—I am afraid that they do not generally appreciate the usefulness of the investigations that are being made, but I believe that they have certain desires in the matter.

4115. What are those desires?—That they should be given a reasonable opportunity to carry out their work without too many of the present day methods, which they complain are more injurious and bring about a greater amount of lead poisoning than the methods of old.

4116. Have your men ever put forward any practical suggestions for relieving them of dangers which they undergo in their present work?—Only that the work should be done in the proper way; that is the only contention that they hold.

4117. What do you mean by the "proper way"?—They complain that the present day method of carrying on painting is injurious and brings about more lead poisoning than is actually necessary. That is their contention.

4118. Have they made any suggestions to relieve themselves of the danger that you speak of?—I cannot say that they have, only in individual cases.

4119. Do I understand that the men admit to themselves that there is an evil, but they have no practical suggestion for remedying that evil?—There is no collective suggestion in that direction, I think.

4120. Do you yourself think it is possible to make any recommendation to this Committee with a view of mitigating the evil which the men suffer from to-day?—Yes.

4121. What are your suggestions?—I suggest that lead is used to-day in a reckless way, that painting is done in a reckless way, and that the evils of lead poisoning are accelerated by the present-day process.

4122. What suggestions have you to put before us to alleviate the evil or to change the conditions in which the men have to work?—One of my suggestions would be that practical men should be first of all put in charge of painters, which is not the case to-day.

4123. Have you any practical suggestions to make with regard to the different processes in which the men are engaged?—With reference to the preparation, I would say that the use of glass-paper should be considerably reduced. It should be reduced as much as possible. It is undoubtedly one of the greatest evils.

4124. (*Mr. Sutherland.*) You say that the men are not desirous of having white lead prohibited?—Yes.

4125. They have not expressed any opinion one way or the other?—There has been no collective expression of opinion from our members in that direction.

4126. Has it been discussed as a problem at all?—It has only been discussed incidentally, not generally.

4127. What do you mean when you say that the present-day methods are reckless?—Because unpractical men are put in charge of workmen—men who are not able to direct the work and to safeguard the men to the best advantage.

4128. In what way?—Supposing that you put a man to work who does not appreciate the whole of the danger of the materials that he is using, he will supply the men with dirty brushes and dirty kettles, and he will give them no time in which to cleanse themselves, and so on.

4129. A sensible foreman does not do that?—But they are not all sensible.

4130. The bulk of the men are sensible when they are put in the position of foreman. How would you suggest the reduction of the use of glass-paper?—By employing a competent man who can spread the paint without leaving too many ridges.

4131. You think that good painters would do their work so that it would not need so much sand-papering?—Undoubtedly.

4132. Sand-papering is not really intended to cut down work to a surface like that (*indicating a painted door in the room*), is it?—No.

4133. If you were rubbing down a door, you would not get covered with dust?—If you rubbed a door down to make a good job of it, and the work underneath was bad, you would be covered with dust when you had finished.

4134. From white lead paint?—Yes, from paint.

4135. Would it not cut all the paint off to produce a dust like that?—It would cut some of it off.

4136. Does not the sand-paper get useless by the filling up of the surface of the sand-paper with the paint?—Yes.

4137. How can dust get on the floor and on the workman, then?—Some of it goes on the workman. It does not all go on the floor.

4138. But a great deal of it does?—It is necessary for the workman to shut his mouth just as much as it is for him to wash his hands before eating food.

4139. Speaking from a large experience, I have never seen work cut down to such an extent with sand-paper as to produce a sufficient amount of dust to cover the workman. The old distemper did because it was light. What is your experience?—I have heard a foreman say, "You will find the sand-paper inside the "paint kettle." It depends upon how you use the sand-paper.

4140. That sand-paper would not cut down?—No. You know what that means.

4141. Exactly. That dispenses with the danger that we have been referring to?—Quite so. If the customer is satisfied, the employer will be.

4142. With regard to ventilation and opening the window, you mean that the circulation of the air mitigates the effect of the fumes?—Yes.

4143. Do you think there is any danger arising from outside burning off?—Not to the extent that there would be inside, because the fumes are immediately, or almost immediately dispersed.

4144. (*Mr. Rice.*) With regard to rubbing down with glass-paper, what proportion of paint-work is rubbed down with glass-paper?—It is rubbed down to give the effect the employer wishes to produce at the finish.

4145. But what is the proportion of the work that is rubbed down with glass-paper?—To produce a good result, even if the brush work was good, it would be necessary to pass a little paper over each coat.

4146. But can you tell me the percentage? Is it 50 per cent, or 100 per cent.?—It depends considerably on the workmanship. If a man spreads paint on with an unbiassed mind and puts it all over the place, I think you will agree with me that a lot of it has to come off, especially if you want to produce a good result.

4147. I quite understand that, but I want to know your estimate of the proportion of painted work that is rubbed down with glass-paper. What would be the proportion of the work on which glass-paper is used to the work on which pumice stone and water is used, or on which there is a total absence of rubbing down?—Certainly, more than three-fourths would be glass-papered.

4148. Three-fourths of the painting work done in London is rubbed down with glass-paper—is that your answer?—Yes.

27 April 1911.]

Mr. JOHN BANCROFT.

[Continued.]

4149. Have you had much experience of the cheap form of painting in speculative building?—The experience that I have had has been with men who do not confess themselves to be speculative builders, but who actually are in the habit of adopting similar methods.

4150. Do you ever find glass-paper used on their work?—Yes, to a large extent.

4151. Even the speculative builder, the small property builder, uses glass-paper?—No, he makes no bones about it. He does not use it.

4152. You said that he did. Then your estimate does not include the speculative or small property builder?—No.

4153. Do you mean that three-fourths of the best work is rubbed down?—Yes.

4154. What are the proportions in London of good work and common work?—At present you may say that out of the whole work done, possibly three-fourths of it is done very badly indeed.

4155. That means to say that we have reduced the good work to a third, and that of that three-fourths is subjected to rubbing down with glass-paper?—I mean to say this, that the whole thing has practically had a bad slip as far as the workmen are concerned.

4156. Would you keep to the point. You have just said that you think that two-thirds of the work in London is common work, and that a third is good work. You say that three-fourths of the good work is rubbed down with glass-paper?—Yes.

4157. You mean to say that two-thirds of the work does not have any glass-papering at all, or 66 per cent. of the work in London has no glass-paper?—That does not follow at all.

4158. That is the conclusion from your answers to my questions?—It does not follow. I have seen work in which a good result was deemed necessary for a finish, and they have commenced very badly indeed and used a tremendous amount of glass-paper to remove the first evil.

4159. You have admitted that the cheap work, the small house property, does not receive any glass-papering?—No, they cannot afford it as a rule.

4160. And the outside work does not receive any glass-papering?—Except the front door.

4161. I want an estimate of the amount of painting done in which glass-paper is used. I understand you

to say that for three-fourths of the best internal work glass-paper is used?—Yes.

4162. In the other case glass-paper is neither required nor used, nor can be afforded?—The speculative builder, as a rule, has not time for it.

4163. (Mr. Parsonage.) You spoke of ventilation. When work is being painted in London, the first thing that is done when men are putting on the paint is the closing of the windows?—Yes.

4164. They must be closed. They cannot have draught when they are painting?—No.

4165. I do not want to go into speculative builders' work; but with regard to rubbing down, as to the proportion of sand-paper to pumice-stone and water, you would say that three-fourths of the work was sand-papered?—Yes.

4166. (Mr. Gardner.) You agree that it is necessary in order that a man shall keep clean; that he should have hot water for washing his hands and so forth?—Yes.

4167. Is it customary in London at the present time to provide material for getting hot water?—No, it is not customary to provide any water. Men can possibly get it in their own time. In builders' shops, especially, they will not very often allow the men time to wash their hands. The whole system is bad.

4168. You are quite certain that you know of no shop—I am not speaking of builders merely, but I am taking the ordinary house decorators—where it is customary to supply hot water and soap for the washing of a man's hands before taking a meal?—I know of none.

4169. You say that a good deal of lead poisoning might be obviated by the alteration of the method. Do you mean by that that if there was more oil colour used and less sharp colour in the bringing up of the work, that would obviate a good deal of the evil?—To a considerable degree.

4170. (Mr. Parsonage.) Did you ever hear of moistening glass-paper with turpentine?—No.

4171. In the whole of your experience in London, have you come across that?—No.

4172. The statement has been made by an employer in London that generally his men moisten the glass-paper with turpentine when they are using it?—That is almost equal to putting it in the paint, of course.

The witness withdrew.

Mr. GEORGE WEBB (14, Gore Street, Newport, Monmouthshire) examined.

4173. (Chairman.) What practical experience have you had in the house-painting trade?—I have had about 31 or 32 years.

4174. Have you been builder's foreman and foreman decorator during that time?—For over 20 years I have been builder's foreman and foreman decorator. I was 17 years foreman to one firm, and I was for three years foreman in Bristol.

4175. Are you a member of a trade society?—I was for nearly 20 years.

4176. Have you any personal knowledge of lead poisoning?—I have had two attacks and I am suffering now, as you see. (The witness pulled down his lower lip.)

(Chairman.) Dr. Collis will look at you. (Dr. Collis examined the witness.)

(Dr. Collis.) I should not like to say for certain that he had been exposed to lead.

4177. (Chairman.) (To the witness.) You were saying that you were just recovering from a second attack of lead poisoning?—Yes. It is about three months since I commenced again. I had nearly five months under the doctor.

4178. Were you examined by a medical man?—Yes.

4179. Did he say that your case was one of lead poisoning?—I was examined by Dr. Lane, a medical doctor in Newport.

4180. Did he give you a certificate to say that you were suffering from lead poisoning?—Lead neuritis.

4181. Have you always been very cleanly in your habits?—Yes. I have been an athlete, and I have

always been used to washing, and I have always insisted on trying to keep myself as clean as possible.

4182. I mean in your work?—Yes. I never have had any food of any kind whatever without thoroughly washing myself.

4183. Have you been able to obtain nail-brushes and soap?—No, never.

4184. Have you had to provide them yourself?—I have had to provide them myself when I have wanted them.

4185. Have you always provided them?—I always kept a brush and soap in my bag when I was working as a journeyman. I use them at home now.

4186. Have you known cases of lead poisoning amongst other painters with whom you have worked?—Yes, I have known several cases of it, unfortunately.

4187. How many cases have you known?—I have known a good many of them. Sometimes the doctor's certificate does not say that it is lead poisoning, and you cannot say anything; but I have known men die from lead poisoning, and I know men in Newport to-day in whose veins you can practically see it.

4188. Does the making up or mixing of stoppings and paints give rise to dust?—It does. In mixing dry white lead for hard stopping the dust of the white lead flies about.

4189. Does the mixer inhale fumes during the mixing?—He does in making up paints.

4190. Do fumes arise when he cleans out the vessels which have contained paints?—Yes; that is the worst part of it. If you have zinc kettles you can possibly

27 April 1911.]

Mr. GEORGE WEBB.

[Continued.]

clean them out without any fumes arising, but in the provinces they go in for cheapness and they get tin kettles, and you burn them out every time, and when you burn them out you have the smell of the burning around you all the time that you are cleaning them out.

4191. Is it usual to sand-paper the work between successive coats of paint?—It should be done at every coat, but sometimes it is not with cheap work.

4192. Does this cause much dust?—Yes, it causes a dust undoubtedly, especially if the mixing of the paint is not satisfactory. There may be adulterated stuff there. Some paints you can bind harder than others.

4193. What proportion of the work that the painter does is sand-papered in this way?—On what we call middle-class work there is an ordinary amount, but they do not spend much time on cottages.

4194. What proportion of the time that is occupied by a painter is devoted to sand-papering?—I should say from actual working that it would take about one hour per room. I should say in regard to painting that it would be about one hour in six or seven.

4195. Do you consider that the breathing of this dust is one of the principal sources of danger in your employment?—I do not consider it as one of the principal. I consider that the making of the paint in itself is about one of the most dangerous things.

4196. (Mr. Parsonage.) By the man on the bench?—Yes.

4197. (Chairman.) Do you consider the breathing of dust caused by sand-paper to be a source of danger?—Yes, I do; because you get it in the lungs, and you have to throw it out from your chest afterwards. It gets in the nostrils and so on.

4198. Is it quite impossible to remove this dust by local exhaust draft apparatus?—I do not think it could possibly be done. The dust would be created all the time they were rubbing down. The way in which I think it could be done away with is by rubbing down with pumice stone and water. That would remove a lot of it.

4199. Is pumice stone and water used a good deal now?—No; they do not devote the time to it that they used to.

4200. Would it be practicable to prohibit dry rubbing down?—Well, you would have to get a man to watch them.

4201. And if you got a man to watch them?—If it was prohibited, if this Committee put their foot down and said, "It shall not be done," it could be done without.

4202. Are you referring to sand-papering?—Yes.

4203. In every case, would it be possible?—In the majority of cases, it may not be possible in small mouldings or quirks, but it would remove 80 per cent. of it.

4204. In respect of new paint, which was dry but not fully hardened, what would you do then?—It would be better to rub it down with pumice stone and water. Otherwise, if you rubbed it down when it was dry, you would cut it all up and make it rougher, unless it was thoroughly hard.

4205. Then, in your opinion, sand-papering could be dispensed with?—It could not be absolutely dispensed with.

4206. But 80 per cent. of it could be?—It could be, if time was taken to rub it down in the old-fashioned way with pumice stone and water.

4207. Does the application of pumice stone and water take longer than sand-papering?—It would take a little longer, but it would result in a better class of work, because, in a sense, even if the paint was a little fresh, the water would harden it, and it would be a better job.

4208. Are you acquainted with the operation known as stippling?—Yes; I have done an enormous amount of that.

4209. Will you tell us what you understand by stippling?—I have stippled in water colour and I have stippled in paint in flattening. I have done an enormous amount of it in regard to indoor work. I have stippled all classes of work.

4210. Is there a considerable amount of splashing when the brush is pushed into the crevices and corners?—If it was done carefully, there would not be a great amount of splashing—if it was not allowed to flow on too freely.

4211. Some witnesses have told us that a good deal of the paint falls on their faces. Is that your experience?—It would if they were doing ceilings, but it ought not to if they were doing walls. They should be above their work and work downwards.

4212. How can the worker be safeguarded against breathing such spray or vapour when stippling ceilings?—I have not seen any invention or any appliance for preventing it. I have always had to take it as it came.

4213. Do you think that it is possible to safeguard the workman under such circumstances?—I should think that it could be done.

4214. How?—Well, if there was some kind of pad or small face-covering.

4215. Do you mean if the workman wore a sort of mask?—Something after that style possibly might stop a lot of it.

4216. Do you think that the men would wear a mask?—If it was any advantage to them they would, I think. They ought to wear it, if it will protect them. I should have no objection to wearing one if I thought that I would be better for it, if it was a practicable one.

4217. Now with regard to old paint work. There are three methods in use for removing old paint, are there not—burning off, scraping off, and solutioning?—Yes.

4218. Which of these methods is most used?—Burning off is the quickest.

4219. Can a painter avoid breathing the fumes in the burning off process?—I do not think so. I never could. You have to keep close to your work, and you have the smell coming all the time when the lamp is going. I do not think that it was so bad when the charcoal burners were about.

4220. Is burning-off generally followed by sand-papering?—It ought to be.

4221. Must it be?—It must be sand-papered, or pumice stoned with water.

4222. If it is sand-papered, does that introduce a further risk of breathing dust?—You get more dust then than you do anywhere, because the burning off makes it crisp.

4223. Where scraping is done there are, I suppose, small particles which give rise to dust also, and this is breathed by the men?—Yes, you are bound to get small particles in scraping off, and the dust is bound to be breathed.

4224. Is there any remedy that you can suggest for that evil?—If they could get a solution that could be used without its getting round the hands and so on, they might possibly be able to wash it down; but I think that one is practically as bad as the other. With regard to dry scraping, if they give you time I do not think it would so injurious as the burning off.

4225. Is solutioning less dangerous than either burning off or scraping?—It possibly would be if they used their brushes and so on in washing it off a lot. The reason why they do not do much of it is, I believe, because of the mess that it makes about the place. They get their hands covered with it.

4226. Can you suggest any way in which the dangers may be entirely removed from the burning off and scraping processes?—I cannot suggest any way at present; but I do not believe that there was so much danger when the charcoal burning off took place as there is with the lamps, because the charcoal burner, the old style of burner, threw a dead heat on to the work and you could get it off better than you can with the dry heat of the lamp; and the fumes of the charcoal seem to clear it away a lot.

4227. Do you think that there is always danger in wet lead paint itself from the smell of the fumes?—Yes, I believe there is always danger in it.

4228. I understand that you wish to name a danger in connection with turpentine substitutes used in paints?—Well, I do not know what you gentlemen think of it, but I think it is a danger, and a serious

H 4

27 April 1911.]

Mr. GEORGE WEBB.

[Continued.]

danger. I have found out that if you put pure turpentine in with the oil the paint work stands and it hardens, and you get a good surface on it; but if you put imitations in, in less than three months you see it a dry powder practically, so that you can wipe it off. You pay to-day about 6s. 9d. or 6s. 10d. a gallon for turpentine. You can get petrol at about 1s. 5d. a gallon; you can get paraffin at about 8d. a gallon; and benzoline at about 2d. a pint, and an enormous amount of that is used. If it is not dangerous to have petrol mixed with paint, what is? Suppose it is used in a house where there is a family living, and by any means it explodes or a fire comes to it? The coroner's jury may bring it in that it is accidental death, but I reckon that it is murder.

4229. I suppose that there are many processes in which the painter cannot avoid getting his hands soiled with the paint or stopping material?—He cannot avoid it when stopping, because he is bound to get it on his hands. I generally use myself a small board; but where one uses a board, a dozen put it in their hands after they have mixed it up. With regard to putty and linseed oil, I do not think there is much injurious effect, but when it comes to white lead stopping and red lead stopping, I think there is a serious danger.

4230. Do you think that the provision of washing conveniences and the regular cleansing of the hands is important?—Yes, I think it is very important.

4231. Should hot water always be available?—Yes. You might not believe it, but I have never seen it in the provinces yet, and I have been working in my trade all this time. I have never seen the inspector put his foot down and say that it should be available. That is honest. I would like to see it. I would go and have a look at it.

4232. In your experience, is it impossible to get hot water?—It would not be impossible if they were compelled to do it. They would have to do it.

4233. But has it been impossible hitherto?—Yes; it has been impossible to me. It has been impossible to get cold water until I got home.

4234. Is food often kept in the pocket of the working coat, and eaten in a place where paints are being used?—I have seen them hundreds of times taking it out of their pockets and sitting down and eating it where the paint was made and where it was being used, without any provision at all for washing or anything else. I am not alluding to big firms—some are better than others; but taking the general run, right away outside of London, you have to contend with what I have described. If you were seen washing your hands in the employer's time you would get about two hours' wages stopped.

4235. Do painters usually wear overalls while at work?—They do in some towns, and in some they do not.

4236. Are the overalls washed pretty frequently?—Those who take a pride in themselves come on Monday morning with clean overalls. Sometimes men do not.

4237. For how long do those who do not take a pride in themselves wear unclean overalls?—Some of them get what sailors call dungaree blue overalls. You can put them on and they stop there until they fall to pieces, practically.

4238. Do you say that they are never washed at all?—Some are not. In large shops where men take a pride in themselves, they have a white jacket and overalls, and they bring them to work on Monday morning nice and clean.

4239. Do not the foremen insist on overalls being clean every week?—In some towns the foreman would not get many hands if he insisted on it.

4240. Do I understand that in your opinion the washing of overalls is very badly done?—It is in some cases. Some are done very nicely, but where men are slovenly they throw them about anywhere.

4241. Would you say that a large percentage or a small percentage of the men were cleanly in this respect?—A good percentage is cleanly. It is more the casual type of man who is the trouble—men who are here to-day and gone in a week's time.

4242. Is that a large or a small percentage of the men?—In towns the work comes in a rush, you want men, and you have to put on anyone. You keep a casual man on possibly for three or four weeks, and then he may be tramping somewhere else. It is the casual class of man who suffers most, I believe.

4243. When you are working with lead paint do you feel any ill effects yourself?—Yes, I do. I have had headache very often, and when I have got home I have scarcely been able to rise after I have sat down after using a lot of it, especially if I have been making up a large amount of paint for others to keep on going.

4244. Have you felt the same ill effects when you have been working with zinc paints?—I have not felt them so much with the zinc paints, but if I have been working with lead paints for a long time and then have used zinc paints I have felt an effect in the stomach for a bit—more of a gripping nature for the time being. That is due to just the change from one to the other—having the effects of one on you all the time.

4245. (Dr. Collis.) Have you used non-lead paints much?—I have used them, not as regards what you call paint, but in water colours.

4246. Not in oil paints?—Not in oil paints.

4247. In distempers?—Washable distempers and that sort of thing—but it has been always lead with me.

4248. You have always worked with lead paints?—And zinc.

4249. Zinc is a non-lead paint?—I have used zinc occasionally when we have wanted it for a bit, but it has been mostly lead.

4250. Have you used zinc to any extent—for a whole day or two days at a time?—I have used it when I wanted to do some classes of work, but of course in the buildings it has been all lead that I have been using. I have not used an enormous amount of zinc, only occasionally.

4251. Perhaps half an hour during a day's work. Is that what you mean?—Sometimes I may not have used zinc for a week.

4252. Have you ever used it for as long as a week?—I have used it for three or four days straight off sometimes.

4253. Do you think you could in any way tell whether you were using zinc or lead paints, if you had not been informed that it was a zinc or a lead paint that you were using?—I always feel heavier in using lead than with zinc. I always feel of a heavier nature and more tired, a lot.

4254. Do you notice any difference, for instance, in the smell that the two forms of paint give off?—There is a different smell noticeable, but nothing exceptional.

4255. Do you think it is sufficiently noticeable that if you were given two lots of paint you could say, with some amount of accuracy, which was the lead and which was the zinc?—Yes, I could possibly say that very clearly. I could tell the difference in the smell.

4256. (Mr. Gardner.) In your district do all the painters serve an apprenticeship to the trade?—They did years ago, but they do not now. It is cheapness now.

4257. You say you have suffered from lead poisoning. Do you chew tobacco?—No, I have never chewed any in my life.

4258. Do you smoke?—Yes, I smoke.

4259. I suppose there is no question of getting paint in your mouth through smoking a pipe?—No. In most of the shops and buildings they do not allow you to smoke in working hours.

4260. You have already told us that you could not get hot water on the buildings and that there are no appliances for cleanliness?—Yes.

4261. You are of opinion that the wet process between coats could be used, are you not?—If time was allowed.

4262. We will take the work as it is done. If you go in and coat a room down one day, you could not use pumice stone and water the next day on that work, to begin on the second coating?—You could not use it satisfactorily. If it were allowed to stand a little

27 April 1911.]

Mr. GEORGE WEBB.

[Continued.]

longer you would have a chance of it, but it is too much rushing work for that.

4263. But I am referring to the work as it is done. You could not use pumice stone and water under a week's time, could you?—Yes, you could in under a week's time, but you could not give it a coat to-day and another to-morrow.

4264. In ordinary oil colours you would not. When you are stippling, do you think the method of stippling, even stippling a wall, throws off spots?—It throws off spots.

4265. Do you think so?—I think so.

4266. We have heard here that when you are stippling a wall there are no spots?—I think he must have been dreaming; he has not done much stippling at any rate, whoever said that.

4267. Do you think that the men could wear a mask for doing work over their head. I suppose you have no experience of what a mask would be like in work?—I have never used one. I would not mind using it to try it, but some of the masters would not allow you time to put it on.

4268. You are also of opinion that the use of a substitute for turpentine causes white lead to chalk and flake much quicker than ordinary pure turpentine and oil?—Yes, in my opinion it takes the entire nature of the paint away.

4269. Would that not be a danger, even to public health, in an ordinary living room, if paint was flaking and chalking to such an extent?—There is a danger, I take it.

4270. Is it not quite customary in your district to take your food in a room which is being painted?—They have to do it when they are away from home. When they have only half an hour or an hour for their meal, they have to do it. In some places, where there is a large building, like when I was at Aston Gate with Messrs. Cowling & Son, they had mess-rooms put up, but that was a job worth a quarter of a million. In an ordinary building you have to take it where you can get it.

4271. That is to say, in the ordinary building you have always to take your meals in the room you are painting?—You have not always to take it there, because sometimes you happen to be close at hand, and you can go home, but usually you have to take your breakfast, if not your dinner.

4272. (Mr. Rice.) I am rather interested in this question of a substitute for turpentine. Do you say now that petrol is used as a substitute for turpentine as a thinner?—It is used, and a lot of other things are used in it. You have to compete with a lot of men that are practically unprincipled. They will use anything, and they do use it.

The witness withdrew.

Mr. FREDERICK BONNER examined.

4286. (Chairman.) Are you a working master house decorator?—Yes.

4287. Where is your business?—At 20, Park Street West, Luton.

4288. How long have you been in the painting trade?—Ever since I was 11 years of age; I am 40 now.

4289. How long have you yourself been an employer?—Nine years.

4290. What is the average yearly number of painters you employ?—On an average about 7.

4291. Are you a member of any trade organisation?—No, we have not any in the town. It has been tried, but it seems to fall through. There is too much jealousy.

4292. What sort of paints do you apply; do they all contain lead compounds?—They all contain lead compounds, but one that I have been using this last five years contains a very small proportion of lead; the bulk is zinc oxide.

4293. What proportion of lead do you use in this one particular paint?—I could not tell you the exact

4273. Are you a working painter or a foreman painter?—I am carrying on business on my own account now. During this last two years or so I have been working up a business of my own, but I have been a foreman painter for over 20 years.

4274. When you were a foreman painter, did you give facilities to the men working under you for washing their hands? I have always tried to keep a bucket of water there. I have gone to try and get it for them myself, if I could, but I have got in innumerable rows for getting it and wasting time. If they can get it in their own time they can do it.

4275. But you have got this water for washing?—I have got it for myself also, so that we could all have it.

4276. There has been no question about the men being willing to wash in their own time, has there?—If the man would not wash in his own time, he has had to go dirty, and he has often suffered for it.

4277. The masters never objected to the men washing, but they may have objected to their washing in their time. Is that so?—They could not possibly object to a man washing in his own time, but they would object to his washing in their time, and they would make no provision for the men to do it. I have never seen it.

4278. Now with regard to the question of glass-papery, I understand you to say that, in a room which took six or seven hours to paint, one hour would be occupied by rubbing down with glass-paper?—Yes, one hour would be occupied at least in rubbing it down, if he has done his work as he ought to do it.

4279. Is every room that is painted rubbed down with glass-paper between the coats, or is it only the best work?—Only the better class work. They will not allow you time to do it in the cheaper class work.

4280. In the cheaper class work there is no glass-papery?—It may be that there is a bit now and again on a door.

4281. But, as a rule, is that so?—There is some used, but a very small bit.

4282. Are you used to doing good class work or common work?—I have done all kinds of work. I have done the King's Head Hotel in Newport right away through with lin crusta and anaglypta and all kinds of decorations. I have done the better class work.

4283. And you have done common work, I suppose?—Yes, cottage work, to an enormous extent.

4284. (Mr. Parsonage.) You have done anything that pays?—Anything that you can get hold of now, you have to do.

4285. It is only on the best class work that the glass-papery is used? I will not say that. It is used occasionally on common work, but very little. They will not give you the time which ought to be used on the job. Of course they have to use glass-paper in buildings, and so on.

proportion, because it is sent ready made, but when I make it up myself I use zinc white as it is sent in the case, and a very small proportion of white lead to give it body.

4294. What proportion of white lead do you use?—About a quarter.

4295. That is to say, about 25 per cent.?—Yes.

4296. Have you known any cases of lead poisoning?—I have known of two personally. One was at the very first job I was on for myself. We had a conservatory to do, and the pantry opened from the conservatory, and some food got left in the pantry, and all that partook of the food in the house (some of them did not) were very bad. The food was left there all night, and, of course, the pantry ventilator was open all the time.

4297. Have you had to pay any compensation for lead poisoning since the Act came into force in 1907?—No.

4298. Does the making up or mixing of stoppings and paints give rise to dust?—No, there would be no

[ 27 April 1911.]

Mr. FREDERICK BONNER.

[Continued.]

dust arising from the mixing of them. White lead is ground in oil, and of course it is a paste.

4299. But what about the stopping?—That is made from the white lead and putty mixed.

4300. Do you not use dry white lead for that?—No, I have not known it in the painting trade to be used in that way. If we want hard stopping, we make it of white lead and putty, half and half.

4301. Then, the mixer does not inhale dust during the mixing?—No, there is no dust.

4302. Is there any danger when he cleans out the vessels which have contained paints?—Only in getting it on the hands. That would be the only thing.

4303. Do you ever burn out vessels which contain paints?—No, I always have them scraped, and that is, of course, only like paint skins.

4304. Is there any dust arising from that?—No.

4305. Is it done wet?—The paint skins are like thin leather when they are scraped out of the cans. The old-fashioned way was to burn them out, and then you would get dust.

4306. And you would get fumes, I suppose?—Yes.

4307. You would get fumes and dust?—Yes, it was abominable—a dirty method. It used to have to be done out of doors, because the smoke was as black as ink. It came up in clouds when they burnt the kettles out.

4308. Is it usual to sand-paper between the coats of paint?—Yes, and that is where you get the dust. A far better way would be if everyone insisted on all the work being rubbed down wet with pumice stone—far better than the dry rubbing with sand-paper.

4309. Would it be practicable to insist in every case on rubbing down with pumice stone and water?—I should think in 9 cases out of 10 it would be—quite.

4310. What would you do in the tenth case?—It would be fancy moulding where you could not get the pumice stone in. All flat surfaces could be always rubbed down damp. Another thing is, you can rub them down better with pumice stone when they are wet than you can rub them down dry.

4311. All flat surfaces could be rubbed down wet?—Yes.

4312. But it is only mouldings and curves that have to be done with sand-paper?—That is all, where you could not get pieces of pumice stone in.

4313. With regard to new paint which was dry but not fully hardened, how would you treat that between coats?—There is a way of rubbing it down, but you are sure to get a little dust then. You cannot help getting a little dust; if you rub too hard, of course, you fetch the lot of it up.

4314. In your opinion is it impossible to do away with this danger entirely?—I do not see how you can do away with it entirely. There is sure to be a dust.

4315. Are you acquainted with the operation known as stippling?—Yes.

4316. What is stippling?—It is simply that when the paint is put on the wall, another man stands beyond with a large square brush about 8 inches by 6, and simply puts the work to take all brush marks out. That is all it is used for.

4317. In such work, and in all painting where the brush has to be pushed into crevices and corners, is there not a good deal of splashing?—There should not be, at all.

4318. Is there any spray or vapour formed of small drops of the paint?—There should not be at all. I have never seen any.

4319. Not from stippling?—Not in stippling. It is a very sharp colour used for stippling. It is more turps than anything in stippling.

4320. Then, in your opinion, is there no danger in stippling?—No, not at all.

4321. Does not the paint get over the men?—No, I have never seen any, and I have worked from one end of the country to the other.

4322. For instance, in stippling ceilings, with his face turned towards the ceiling, would the painter not get any splashes on his face?—No, he would not get any in that way at all. The man would not be underneath; his hand would be extended. He would be away from it; he would be further back; he would

not work over his head, because it would make his neck ache too much. You cannot get the men to do it. They will reach forward rather than work over the head. Direct overhead work makes the arm ache too much.

4323. As regards old paint-work, there are three methods in use for removing old paint, I believe: burning off, scraping off, and solutioning. Which of those methods is most used?—Burning off is used almost as much as anything.

4324. Can a painter avoid breathing fumes in the burning-off process?—He cannot help it, and when you are burning off in some classes of work dust arises very badly. It all depends on the age of the work that is being burned off. Some of it that has got much varnish is sticky when you burn it off, and there is no dust from that, you can scrape it off; but if you burn off woodwork where there has been no varnish, you find at the bottom of the door almost a shovel-full of dust.

4325. Is burning off generally followed by sand-papering?—Yes, and you get dust in that way again. You get a good quantity of dust in that way.

4326. Is that process inevitable?—A good many use the pickling now. I think there are three or four paint removers on the market, known as solvents.

4327. Do you say this sand-papering introduces the further risk of breathing dust?—You cannot help it; there is no way out of it unless you have respirators for workmen burning off or sand-papering. Both those processes cause a lot of dust.

4328. Where scraping is done there are, I suppose, small particles which give rise to dust also?—Just the same.

4329. Is solutioning less dangerous than either burning off or scraping?—Considerably. There is a considerable difference between the two. The solution makes it damp and stops it from rising.

4330. But I understand it is comparatively little used?—They do not like to go to the trouble of it. They will not go to the trouble of it. It is a little more expensive than burning off.

4331. Can you suggest any way in which the dangers may be entirely removed from the burning off and scraping processes?—Only by wearing very fine respirators, the same as they do in asbestos works. I think they are bringing that into force in Belgium now—wearing respirators.

4332. Are there any other processes in which there are grave risks of the painters inhaling dust or fumes or spray?—There is in paper-hanging. You get a lot of it there, but of course that has nothing to do with paint. You get a lot of dust in that way. With those rough wall papers, the in-grains, when you paper a room you find all along the floor of the room all round nothing but dust, unless it is sanitary paper, and you get no dust then.

4333. Do the painters remove the old papers on the walls sometimes?—I wish that was generally done. They do not.

4334. What is the custom in the trade?—The painter does it sometimes, but it is not usually done at all, I am sorry to say.

4335. Is it generally the painter who removes the old paper, when it is done?—Yes; the painter does that work—when it is done.

4336. But very often they paper over the old one, do they?—Yes, they paper over the old one. A month ago I was doing a sitting-room that had not been done for 20 years. There were six papers on the wall, and the last time the room was done was 20 years ago.

4337. I suppose there are some processes in which the painter cannot avoid getting his hands soiled with the paint or stopping material?—Yes, there are plenty of them.

4338. Do you think that the provision of washing conveniences and the regular cleansing of the hands is of importance?—I think so.

4339. Should hot water always be available?—It would be difficult on new buildings. That is where the great danger comes in with dirty workmen; there is no provision for their cleaning.

27 April 1911.]

Mr. FREDERICK BONNER.

-[Continued.]

4340. But do you think it is very important that hot water should be available?—I do think so.
4341. But you do not think it is practicable?—You get a long way from home, and there is, perhaps, only a cold-water service laid on for the use of the bricklayers and plasterers. You can get no hot water, or anything, or any towels or soap provided for the workmen. Cleanliness, I think, goes a long way.
4342. You mean to say you cannot expect the men to preserve cleanliness if they cannot get the materials to use for that purpose?—That is so.
4343. Is food often kept in the pocket of a working coat?—That is often the case, I think.
4344. And eaten in a place where there is painting going on?—Yes.
4345. Frequently?—Yes, all over the country. I have worked in the south of England and in the north of England, and I have worked a good many years in Luton, and that is done everywhere.
4346. Is it, generally, impracticable to have a separate room for meals?—It is a difficult matter to provide a separate room for them.
4347. Do painters usually wear overalls while at work?—Yes.
4348. How are they kept clean?—For myself and my workmen, we have them clean every week, but that is not the case in all places.
4349. There is no regular system about it?—There is no regular system at all.
4350. For how long may they go without being washed sometimes?—A month or two, perhaps; I should not be surprised at that at all. From the state that I have seen some of them in, they could not get like it in a week.
4351. Do the workmen take their overalls home every day?—They generally leave them on the work, unless they are notified on the job that they will perhaps be taken to another job the next day.
4352. How do they carry them home, then?—Perhaps in a bag or a basket.
4353. Or in a tool bag, perhaps?—Yes.
4354. I suppose a dirty overall would involve a certain amount of danger, would it not?—It is sure to. I do not see how it can be avoided, because some men keep a piece of rag in their pocket, and as soon as they have done a piece of work their hands will go down to it and they will rub them. Of course, there is a great difference between them in that way; some are very clean and some are very dirty.
4355. In some industries where lead compounds are used, the Home Office have prescribed a medical examination at monthly or even weekly intervals, and the examining surgeon has power to suspend men who show early symptoms of lead poisoning. Would you like to see this introduced for house painters?—I should think it would be a good thing.
4356. Do you think it would be practicable to insist on medical examination?—Our trade is a rather peculiar trade. For instance, sometimes men will only be on for the season. It would come rather hard in some cases, no doubt. In the rush perhaps one man will be employing 20 men, and perhaps in two months, when things have slackened down, he will only have half that number, and some of the men will have gone back to a different trade for the time being.
4357. Would it be difficult for the examining surgeon to see the men?—No, it should not be at all.
4358. In your own case, for instance, how could the medical examining surgeon see them?—He could see them in the evening when they have done work.
4359. At his own surgery?—Yes.
4360. That would mean that the men would have to call there?—Yes, that would not be difficult at all.
4361. But who would pay the cost of their going for examination?—That is rather a delicate question. I do not know whether the master would want to pay for it or would care to pay for it.
4362. (Mr. Parsonage.) Would you?—Personally I should not.
4363. (Chairman.) In your opinion, would precautions such as the use of lavatories, overalls, separate rooms to have meals in, and medical examination, save the painter from the risk of dust or spray of fumes arising in the course of his work?—They would do so.
4364. To a certain extent?—To a certain extent.
4365. But not wholly?—Not wholly.
4366. The danger, for instance, of burning off and scraping would still remain?—That would still remain; that could not be avoided.
4367. Can you suggest any practical means of preventing the formation of such dust and fumes, or of removing them by fans or such like apparatus?—I think that would be rather difficult.
4368. Do you think it would be impossible to stamp out the evil of lead poisoning without replacing the lead by some non-poisonous substitutes?—I think that is the greatest solution of the difficulty. I have been using a substitute for five years, and I seldom use white lead now unless it is specified. If I get a specification which specifies that white lead is to be used I keep to the specification, but otherwise I do not use white lead at all—not wholly as a white pigment.
4369. But you have told us earlier in your evidence that you use about a quarter white lead?—I use a quarter.
4370. Do you ever use less than that?—I never use less than a quarter, because you would not get the body to the paint. I do not think you can get a substitute entirely free from white lead to have the body. Zinc white has not got the body. It is a splendid thing otherwise.
4371. Suppose the Home Office were to prohibit the use of white lead altogether, how would that affect your business?—I think they have done it in France. I believe so.
4372. Would you have any great objection yourself?—I should have no objection whatever.
4373. If it were made universal?—If it were abolished altogether, I think ways and means could be found of getting a good white pigment without the use of white lead.
4374. We have heard some suggestions of reluctance on the part of some painters to adapt their methods of working to the peculiar requirements of zinc and other leadless paints. Do you find any difficulty in using such paints?—No. It has wanted a little skill, because it rubs out so thin, but the only thing is to mix it a little thicker to start with.
4375. (Dr. Collis.) You mentioned, as one of the possible precautions which might be adopted, the use of respirators, did you not?—Respirators, in burning off, to save the dust, and in rubbing down.
4376. That is to save the dust?—To save the dust entering the mouth.
4377. You said you had seen respirators used in asbestos works?—Yes.
4378. Which asbestos works have you seen them in?—The United Asbestos Works.
4379. Is that at Luton?—No. I think they have amalgamated with Bell's Asbestos Works.
4380. In Luton?—No, in London.
4381. Have they always used respirators there?—They have, always, in the 18 years I have known it, in the carding rooms, because it is very bad there.
4382. I have been over some asbestos factories, and I have no recollection of seeing respirators worn to any extent at all, and I asked the question because of the great difficulty we have always found in getting any workpeople to wear respirators, even when they are required to for their own protection. I want to know whether your experience is contrary to that?—It is the same. They do not like wearing them.
4383. So you think that, although they might be ordered, there would be great difficulty in getting them worn?—Yes, that is it.
4384. Do you think it would be practicable to get them to wear them when they are employed, perhaps, on a piece of work which is 20 miles from the centre, in painting a house?—I think they ought to be insisted on.
4385. How do you think they could be insisted on?—I do not know, unless any provisions were made in an Act of Parliament to compel them to use them.
4386. But an Act of Parliament is no good, unless it is enforced. How could we enforce it?—I do not

27 April 1911.]

Mr. FREDERICK BONNER.

[Continued.]

see the way, unless there were inspectors going round all the time, and that, of course, means something in the country.

4387. And then an inspector has to enter a man's own private dwelling, does he not?—It is rather a peculiar question, I can see, but it would be a valuable thing if they did wear respirators.

4388. I am prepared to allow that to keep away the dust, a respirator for protection would be useful, but I want to know whether you have considered how this, if it were made a legal requirement, could be enforced?—Perhaps the local sanitary inspectors could be given power to do that.

4389. To enter each man's own private dwelling when he is doing his spring cleaning or having his drawing room painted?—It would be rather a delicate thing.

4390. (Mr. Rice.) How does this zinc oxide paint, that you have been using for five years, wear?—That is Vitulite, made by Carson and Sons, of Battersen. I have been using that for five years, and I find it stands better than white lead.

4391. You say you make it yourself, and when you make it you put the proportion of 25 per cent. of white lead?—Yes, when I make it, but I do not make a lot of it. I buy it from the firm ready mixed. Sometimes, if I run out, I make it myself.

4392. In rubbing down between coats with this particular paint, is there any dust from it?—Not much. It sets very hard. It is a slower drier: that is the one fault, I think. So much zinc in it makes it slower in drying. Zinc of itself is not such a good drier as lead, but it sets much harder, and my men do not like it because it sticks on the kettles so tight.

4393. In rubbing down with the glass-paper between the two coats, the dust is less with this particular paint that you use?—Yes, there is less dust with that.

4394. Have you used it for outside work?—I have used it for outside work ever since I started in business.

4395. And are you quite satisfied with the result?—I am more than satisfied, and my customers are too. It keeps a better colour: the atmosphere does not act on it and discolour it. I have got some fronts done five years ago which are better than white lead fronts done two years ago in the same street.

4396. I understood you to say that the cleanliness of the overalls worn by the painters depends on the men themselves and their own personal cleanliness?—Yes.

4397. With regard to the food that is carried in the pockets of the workmen, is there any other means of carrying it?—Very few of them ever trouble to carry a basket. They take a basket with their tools on the job when they go, and they leave the basket there till they have finished on that particular job, and then as they go backwards and forwards they wrap their food in paper perhaps—the bulk of them—and put it in their pockets.

4398. And they take off their coat, I suppose?—Yes, and hang it up anywhere. There is no particular place to hang it; it is hung anywhere.

4399. In a place of safety, I presume?—Yes.

4400. (Mr. Gardner.) In your district do all the men serve an apprenticeship to the trade?—I think apprenticeship is dying out all over the country.

4401. But in your district, instead of serving an apprenticeship, do they just go to it and pick up the trade casually?—That is just one of the great evils of the trade.

4402. I take it, as you are using so much zinc white, that all your work is brought up by that. Is that the custom in your district. Apart from your own shop, is the work brought up by oil colour or sharp colour?—That is left to the individual master.

4403. But what is the sort of custom in the district?—I should think about half, one man would use one and one another.

4404. That is to say, there is no general custom?—There is no general custom.

4405. You told us that you could use the wet method of polishing down between coats instead of sand-papering. If your colour takes so long to dry and harden, how long would it need to stand before

you could pumice-stone it with water between each coat?—You would not want to pumice-stone it down after you had put one coat on.

4406. (Mr. Parsonage.) You mean not between coats?—Not between coats, only before you put your first one on again.

4407. (Mr. Gardner.) I think, in your answer, you led us to infer that the wet method could be substituted between coats, and that is why I raised that point?—If I gave you that impression, that is wrong. It would be before the first coat was put on again.

4408. In the preparation of the work?—Yes, what they call preparation, in the specification of the architects, is really taking little nibs and little lumps and things off and making it smooth before you put your first coat on, if they specify two coats. I have never heard a specification worded in that way. I have simply heard: "wash down or rub down before the two coats." They would never specify it in between the two coats, unless you were going to do any enamelling, and then you would have to do a bit of rubbing down, but the colour then would be sharp, or what they call flatted.

4409. I can produce you specifications saying: "All work to be sand-papered between each coat"?—Yes, I have seen some very curious specifications. I had one a little time back: "four coats of oil, grain and twice varnish as existing woodwork," and the woodwork was new woodwork, simply stained and varnished. The man could have been putting coats of oil and graining from now to the end of the century, but he would never match the existing woodwork, because it was simply stained woodwork.

4410. In painting a wall such as the wall of this room, the man would not make many spots in putting the paint on it, would he?—There would be a few.

4411. But nothing much?—No.

4412. Then, again, suppose he stippled the wall with the flattening, where would the multitude of small spots come from on the moulding and skirting and all round the floor if the stippler does not produce a great amount of small spots?—The man would put the paint on in front of the man who was stippling, and as a rule it is very thin, and that splashes a little bit, but it is very, very fine stuff, and it generally falls straight to the ground, because as the brush is worked longways it would fly out, away from the man, whichever way he held the brush. They do not paint up and down; the stippler simply takes out the brush marks. There is no splashing with him at all, because the paint is already on the wall.

4413. Now with regard to the zinc paint on outside work, how does it stand on ironwork? Have you brought up ironwork from the beginning with zinc?—I have not brought it up with all zinc, but with a small proportion of white lead in it.

4414. How does it stand?—It stands on ironwork very well indeed.

4415. So that you think that zinc paint with 25 per cent. of white lead in it is a very good preservative for outside work?—I think you could go to even a smaller proportion of white lead than that.

4416. In mixing your zinc paint, what oil do you use?—Linseed oil.

4417. Is it raw oil or boiled oil?—I find raw oil stands better than boiled oil.

4418. Do you find any difficulty in it drying, except that it is a little slower?—It is a little bit slower, but that is no detriment to the paint, because paint dries too quickly sometimes.

4419. (Chairman.) We have been told by the representative of the Office of Works that the addition of 5 per cent. of lead to the non-poisonous paint would be just as efficacious as the normal lead paint used to-day?—I think it would. It only wants a small proportion of white lead to make the body.

4420. (Mr. Gardner.) Of course, with that they use refined boiled oil, not raw oil?—There is only the price of 2d. per gallon in that.

4421. (Mr. Parsonage.) With regard to stippling work, if you were going to flat and stipple an anaglypta ceiling, you would cover the floor with cloths, would you not, to protect it?—Yes.

27 April 1911.]

Mr. FREDERICK BONNER.

[Continued.]

4422. Then there must be splashes, or you would not do that?—There are sure to be splashes, as I say, from the end of the brush.

4423. If you are using a stippling like that (*producing an illustration*) the painter who is using the stippler will get the splashes all over the back of his hands from the stippler, will he not?—No, he could not, because you have got a brush 8 inches by 6 inches inside. I do not know whether it is the general practice in the stippler that you are showing me there, but in the generality of the stipplers the handle comes outwards and not on the back.

4424. I do not mean on the back; I mean the handle comes out at the end?—Yes, it comes out straight, something after the style of a hand broom.

4425. Now, with regard to rubbing-down work between coats, after the work is prepared for painting, we will say, that is rubbed down with pumice-stone and water?—Yes.

4426. You always use glass-paper or sand-paper, as you term it, afterwards?—Yes.

4427. You would not profess to rub down newly painted work with pumice stone and water, would you?—And not touch it with anything else afterwards? You must use something.

4428. But you would use sand-paper?—Yes.

4429. And, in a country town like Luton, you would use more colour than you would use, say, in London?—Yes.

4430. And there would be far more dust from sharp colour?—Yes, you would get far more dust from sharp colour.

4431. So there would be more dust from rubbing-down and glass-papering work in London than there would in a country place?—Yes, there would.

4432. And consequently far more danger?—Yes, there would be.

The witness withdraw.

## SIXTH DAY.

Friday, 28th April 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. A. L. C. FELL.  
Mr. C. L. MASON.

Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WEBNER } (*Acting*  
R. U. SHAXBY } *Secretaries*).

Mr. C. KINGGATE (a member of the Committee) examined.

4433. (*Chairman*.) You represent the United Kingdom Society of Coachmakers, and you are a member of the present Home Office committee?—Yes.

4434. What practical experience have you had in the coach-painting trade?—I am a practical workman of 35 years' experience as workman, piecemaster, and foreman.

4435. Have you worked at railway coach and tramcar painting, or only at carriages and motor cars?—Only at carriages and motor cars.

4436. Have you known many cases of lead poisoning among coach painters?—Yes, I have known a great number. I contend that the evil effects of the use of lead are much greater than shown by the returns made to the Home Office, and that a great number of cases are never reported.

4437. What are the grounds for your statement that a great number of cases of lead poisoning are not reported to the Home Office?—Men have refrained from attributing their illness to lead, when it is well known that it is the cause, for fear of being discharged from their employment, and men have had to leave their occupation owing to the effect the use of lead has had upon them; and many of the cases involve absence for only a few days, and so are not generally reported.

4438. Do you wish us to understand that you find this lead poisoning evil very extensive and very serious in your trade?—Yes. I may say that many men have to continually dose themselves with purgatives to keep at work, which must have a very injurious effect upon their system and lower their vitality, rendering them more susceptible to other ailments. I know many cases of men away for a few days very frequently. They know that the illness comes from lead—gout for instance. No report is made.

4439. Have you known men affected with other diseases which are intensified by their having lead in their systems?—Yes.

4440. Can you give us the number of members in your society, and particulars of the lead poisoning cases which have come to your knowledge in connection with those members?—The average number of members in round numbers is 8,000. I have furnished Dr. Collis with detailed information as to deaths of members of my society during the last six years, and he has agreed to classify and arrange the material in the form of a table which he will put before the Committee. I might say here, that I have gone through the number of our members, and that the number of painters out of the 8,000, is 2,700. The number of body and carriage makers that are brought into contact with lead, is 3,100.

4441. So that, out of your membership, 5,800 are brought into actual contact with lead?—Yes.

4442. Were the records of deaths compiled specially for the purpose of this inquiry?—No; they were compiled without any reference to their being used for a purpose such as that of the present inquiry. They are taken from our reports, issued quarterly.

4443. How have they been collected?—Every certificate is sent to the head office, and the member's name and cause of death is published in our quarterly report. These are taken out of our quarterly report, and sent to Dr. Collis.

4444. Then we may rely upon their being absolutely trustworthy as far as your society is concerned?—Absolutely.

4445. Now, I should like you to deal with each of the processes which involve risk of lead poisoning in the coachbuilding trade. First, as regards the body makers; are they exposed to any risk?—Yes, to great risk.

4446. For what purpose do they handle lead material?—All woodwork is put together with lead. The joints are well leaded, and all ironwork is also fixed with lead. For instance, in putting in the panels

28 April 1911.]

Mr. C. KINGGATE.

[Continued.]

of a carriage, the grooves are filled with lead, and the forcing together of the woodwork with the panels, causes the lead to spurt out. This is wiped off with a piece of canvas. The men's hands are, generally, while putting work together, covered with lead.

4447. Why is lead used in jointing?—It is used to give a further fixing so that joints shall not show, and also to prevent water having any effect.

4448. In what way is the jointing done when metal fittings are being attached to the woodwork?—The jointing is done in the ordinary way when metal fittings are fixed. The metal is generally bolted on in the case of body making. In the ordinary carriage the inside has what is known as an edge plate, which goes the whole length of the body. This is fixed on with bolts and is always well bedded with white lead. The jointing of the woodwork is made in the ordinary way.

4449. Why is white lead used for that specific purpose?—Only because it is useful for helping to fix the joint, and to prevent its moving, and to prevent any action that water may have upon it.

4450. Has any other material been tried?—I have not any personal knowledge of other material, but I have inquired from those who use it, and find that there is a very effective other material, non-poisonous, which could be used in the place of lead for this purpose.

4451. Does the vehicle in course of construction next pass into the hands of a carriage maker?—Yes.

4452. Please tell us exactly what his work consists of?—The body as it comes from the body maker is just an outline of the body, and he has to attach everything to it. He has to make the under-carriage and also give details for springs and axles, and fix them, and generally make patterns, and supervise the work of the smiths.

4453. Does the carriage maker come into contact with lead?—Yes, more than in any other branch. He constantly uses white lead. All work is fixed with white lead. The carriage is composed of wood and iron—wood heavily plated on account of its lightness—and this is always well bedded with white lead. Every bolt has to be white-leaded before it is put in, and generally, where fixing with clips, a small piece of Morocco or thin leather is placed between two pieces of iron. That has to be well covered with lead before it is put in.

4454. What does he use the white lead for?—That is supposed to give, I take it, extra fixing, so that there shall be no movement between the wood and the iron, and also to prevent the iron from rusting. Most of the old firms, especially, were exceedingly strict with regard to the use of lead.

4455. Is it generally considered necessary to use white lead for this purpose?—Employers have always considered it so, and they are very strict on this matter. I have known men to be discharged for simply putting in a bolt without white-leading under the head. Consequently in using so much lead his hands are continually covered with lead.

4456. When the carriage maker has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

4457. The first coats of paint applied are termed priming coats, are they not?—Yes, generally there should be three coats of priming. The first one is frequently done at the body-makers' bench, but generally whilst the coach maker is working at it.

4458. Does the priming contain lead?—It is all lead practically.

4459. Is sandpapering done between the successive priming coats?—Yes. In all work, generally, sandpapering between different priming coats is done.

4460. In what shop is this generally done?—It is generally done in the shop where the carriage is being hung, as we term it—where the carriage maker is working. Afterwards it is generally taken into the paint loft.

4461. So that the body makers and carriage makers are frequently exposed to dust made by the painters?—Yes.

4462. Do you regard the breathing of this dust as one of the most serious dangers of the industry?—Absolutely the most dangerous.

4463. Can it be replaced by a wet rubbing process?—No.

4464. Why not?—Because it would raise the grain of the wood. The first coats of priming enter into the grain of the wood. If that was rubbed down with water it would have the effect of raising the grain, so it has to be sandpapered.

4465. Is it generally possible to use any form of local exhaust apparatus to remove the dust?—No, I do not think it would be easy in most cases, as far as my knowledge goes.

4466. How is this danger to be overcome?—The only way that I can suggest is by the total prohibition of the use of lead.

4467. Now, the next process is what is generally known as filling?—Yes; a body receives generally six coats of filling.

4468. Can you tell us what is meant by filling?—Filling is material made up of ground slate, I believe. It is called patent filling. In many cases lead is mixed with it, but in the patent filling itself there is no lead.

4469. What is the object of the filling process?—It is to thoroughly fill up the grain, so that nothing shall show. These coats are put on one after the other.

4470. Does the filling material generally contain lead?—In many cases lead is used. It makes it firmer and it faces down harder, and gives it a better surface. It is possible to use it without lead.

4471. There is, I believe, no rubbing down between the successive coats of filling?—No.

4472. Is stopping generally done after the last coat of filling has been applied?—Generally.

4473. Will you describe this stopping process?—The stopping that is known as hard stopping is made from dry white lead and gold size to fill up the pin-holes and various little places that are not made up level with the filling.

4474. By whom is the stopping material mixed?—By the man who uses it. He takes the dry white lead himself and mixes it with the gold size.

4475. Do you consider that the mixing of white lead and gold size is attended with danger?—Yes, undoubtedly. There must be a certain amount of dust arising from the handling of dry white lead powder.

4476. Is a staining coat applied after the last coat of filling, and on top of the stopping?—Yes, after the last coat of filling and the stopping, a coat of stain is put on the filling.

4477. Of what does this consist?—It simply consists of vegetable black and turps and driers.

4478. For what purpose is this staining coat applied?—There is rather a rough surface after the six coats, one on top of the other, have been put on. The man that rubs that down can see exactly whether he has got the whole of the staining out, and consequently got a good surface upon his work.

4479. But there is no danger in this process of staining?—No.

4480. How is the rubbing down done after the application of the filling coats and the staining coat?—It is always done, in my experience, with pumice stone and water.

4481. Is it ever done dry, for example, with sandpaper?—Not on a body, to my knowledge.

4482. What is the extent of the danger in the rubbing down after the application of filling and stopping?—It varies very greatly. If the filling is free from lead and there has been little stopping, the danger should be very slight. In any case, as the rubbing down is done wholly by a wet method, the danger is small in comparison with that of sand-paper processes.

4483. Does that answer apply to bodies only?—Yes, to bodies only.

4484. Are the wheels and the carriage under-work treated differently?—Yes. The carriage under-work and the wheels especially are always sand-papered, and a great deal of dust is caused in this operation.

4485. Is this dust of a poisonous nature?—Yes, practically all lead. And further, a large amount of hard stopping is used, on wheels especially and on the

28 April 1911.]

Mr. C. KINGGATE

[Continued.]

woodwork of a carriage, which is sand-papered down, and which is again all lead.

4486. This, then, is also an extremely dangerous process?—Yes; it is probably the worst process in the whole coach-building industry.

4487. Is it impossible to use wet methods of rubbing down in this work?—Yes, especially owing to the prevalence of curved surfaces; also it would raise the grain of the wood.

4488. Is it practicable to apply local exhaust ventilation generally?—I think it would be very difficult and expensive. I have never seen any such apparatus in use myself, so I cannot speak as to that.

4489. After the rubbing down of the filling has been completed, what is the next operation?—The application to the body of two coats of lead colour, both faced with pumice stone and water as a rule.

4490. Is the work then ready to be painted in the desired finishing colour?—Yes; it then receives a coat of ground colour—generally two coats of colour.

4491. Is the carriage then ready for varnishing?—Sometimes. I might mention here that assuming a body is to be painted blue, it would be painted a coat of prussian blue in the first instance and then a coat of ultramarine and then a coat of varnish colour, which means half colour and half varnish. That is generally called a coat of glaze.

4492. (*Lord Henry Bentinck*.) That is over all, is it not? Yes.

4493. (*Chairman*.) I will ask you a few questions on flattening. In the process of applying ground colour, finishing coats, glaze, and varnish, is there no rubbing down between successive coats?—There is no rubbing down, but the work is flatted with cloth and pumice powder.

4494. For what purpose is this done?—To make the surface dead, so that the next coat will adhere. It also takes out every mark or scratch that may be left on the panel.

4495. Is there any danger in this process?—No, none whatever I think.

4496. To what extent do your answers apply to the manufacture of motor-car bodies?—All that I have said about painting applies equally to motor-car bodies when made of wood. Lead is not used, however, in attaching the metal underwork to the body, as is customary in the carriage building.

4497. Have you anything special to say in regard to tramcar and railway work?—I have not myself worked upon tramcars or railway work, but I know that a very great amount of lead is used, especially on the roofs of tramcars, in fixing the canvas; and also generally, in making bodies, a large amount of lead is used.

4498. You have not yourself worked in railway or tramcar works, and would therefore rather not speak in detail of such work, I suppose?—No, not further than my knowledge by coming in contact with men who have done the work.

4499. Are you going to bring witnesses who have come in contact with tramcar work?—I could do so. You will have one this morning who will be able to speak about that.

4500. You have now told us all the operations in which there is a serious risk of lead poisoning in coach-building work. Is it, in your opinion, impossible to remove these dangers, except by prohibiting or closely restricting the use of lead?—That is my absolute conviction.

4501. There are, no doubt, many processes in which the workman cannot avoid getting his hands soiled with the material he is using?—Yes; it is impossible in the cases which I have stated.

4502. Is adequate washing accommodation provided by most of the employers?—No; very rarely in coach-making shops. I am speaking of private coach-makers. The big railway companies, and so on, generally provide adequate accommodation for washing, but the majority of the private coach-makers provide no accommodation whatever.

4503. Are nail brushes and hot water available as a rule?—No.

4504. Is time allowed to the men for washing before leaving off work for meals?—No.

4505. Are facilities for cleaning the teeth ever provided?—No.

4506. Is food often kept and eaten in the work-rooms where lead paint is being used?—Yes; in many cases that is done.

4507. Are meal-rooms provided, equipped with suitable seats and tables, and properly warmed in winter?—Very rarely indeed.

4508. Do the men have the use of a cloak-room?—No.

4509. Do coach painters wear overalls while at work?—No, they do not. I think that the employers should be compelled to provide overalls for them, if it is possible, if lead is to continue to be used.

4510. Can you tell us what are the usual hours of work for coach painters?—The ordinary hours generally worked are from 50 to 55 per week. But many hours are being worked at the present time beyond the ordinary hours. There is a very large amount of overtime being worked at the present time.

4511. What are the hours when they are working overtime?—At the present time they are working a very large amount of overtime. Men are working all hours nearly, very late at night and all day on Sunday. At the — motor-car works they have been working on Sunday for a very long time.

4512. Does that particularly apply to motor-car works?—It applies particularly to motor-car works.

4513. To any other branch of industry?—There is hardly any other industry except with regard to railway coaches and cars. The private coach maker is in the same position as the motor-car company. There is very little call for horse drawn vehicles.

4514. Have you noticed any alterations in the hours of employment as the result of the development of the motor-car industry?—Yes; that is the point I wish to mention—the increased number of hours that are worked by the men, especially in the painting.

4515. Have you any idea how many hours overtime they work?—I should think in many cases they make two weeks in one.

4516. (*Lord Henry Bentinck*.) With the same staff?—Yes, with the same staff.

4517. Is that legal?—Yes.

4518. (*Mr. Fell*.) That is not calculated on the actual hours but on the overtime basis?—It is not calculated on the actual hours. They would be working perhaps till 10 o'clock at night and Saturday afternoon and all day Sunday.

4519. (*Chairman*.) Would it be desirable to have a periodical medical examination by a surgeon with powers to suspend from employment in lead processes?—No, I should think not under present conditions.

4520. But you understand that if lead is allowed to be used in the future in this industry, the Home Office will insist on that?—I am only thinking that there would be a strong objection from the workman's standpoint to this, because it might be the cause of his being discharged on account of being subject to lead-poisoning. I think that was brought out when Mr. Steinitz was here. He admitted that they would not employ a man if they knew he suffered from lead-poisoning.

4521. Supposing this Committee are able to recommend the adoption of stringent regulations in regard to lavatory, meal-room and cloak-room accommodation, wearing of overalls, and medical examination, together with exhaust ventilation, wherever it can be applied, and that these regulations are fully observed, do you still consider that the dangers of the industry would only be reduced and not removed?—I do. I consider that it is impossible to remove the dangers entirely in any other way except by prohibiting the use of lead.

4522. Have you had any experience in the use of coach-painting materials which are entirely free from lead?—No, not personally.

4523. Do you think it would be possible to abandon the use of lead paints generally in the coach-building industry?—Yes. I consider that efficient substitutes

28 April 1911.]

Mr. C. KINGGATE.

[Continued.]

of a non-poisonous character are available, from all the information I can obtain from those that use them.

4524. Do you think, taking the motor-car industry, for example, that if lead was prohibited in this country, it would interfere with the industry in regard to foreign competition?—No, not at all.

4525. (*Lord Henry Bentinck*.) You are not acquainted, I suppose, with the possible substitutes for lead for jointing purposes?—Not personally, but I have information from those that use the substances, and they assure me that they are quite equal for the purpose to lead.

4526. They are using them?—Yes. The largest coach-making shop in Manchester uses them. I tried to get the foreman to give evidence, but he says he cannot spare the time. He assures me after many years' experience that it is quite equal to lead. He is a practical man, and a teacher in the Manchester Technical School, and he assures me it is quite equal to lead for the purpose of jointing.

4527. There is an increase of lead-poisoning since these long hours have been the order of the day?—I have no statistics upon that.

4528. But it is your experience, is it not?—Yes.

4529. The health of the men is deteriorating?—Yes; I know many cases of men who are frequently ill.

4530. How many hours a day do they work on the average?—The normal hours are 50 to 55, but there is a very large amount of overtime being worked, especially in the large motor firms, including the principal firms in Coventry.

4531. Have you any idea what that works out at?—About four hours each day for six days—24 hours—and the Sunday—perhaps 20 to 30 extra a week.

4532. Do the same staff work all through Sunday?—Yes. It naturally must exhaust them physically.

4533. Do you think that is common to the motor-car trade, generally speaking?—Yes, when there is a boom. There is this to be said: it has been practically impossible to get men during the boom lately.

4534. What kind of men?—Body-makers, at the present time. I could find places for a great number of body-makers to-day, but I cannot get them.

4535. How long has that been the case in the motor-car industry?—Only lately, the last six months.

4536. There is always a good demand for body-makers?—Yes. A little while ago there was a very heavy slump. The worst of this kind of thing is that a very large number are discharged generally when the slump comes. There is not that stability of employment that there was under the old coach-making firms.

4537. When was the slump?—About two years ago. We paid 1,000*l.* per month unemployed benefit, taking the average. We paid 13,000*l.* in the year.

4538. (*Dr. Collins*.) I understand that you consider that stopping and filling can be done entirely without the use of lead?—Yes.

4539. And that, in the painting of coaches in general, a considerable amount of varnishing is done before the work is finally completed?—Yes.

4540. More varnish is applied than in the case of house painting?—Yes. There should be three coats of varnish on the body of a motor-car or carriage.

4541. Is it a fact that almost any pigment will stand well under three coats of varnish; it does not much matter what it is?—As far as my knowledge goes, that is so.

4542. Even the cheapest of pigments would wear pretty well with three coats of varnish?—Yes.

4543. So that, for that reason, it should be easier to replace lead in this industry than in the house painting, from the point of view of the work?—Yes, undoubtedly.

4544. (*Mr. Fell*.) On the question of pigments under three coats of varnish, if you get any chipping or cracking, then the nature of this substitute comes in?—Many materials crack under the surface if they are badly mixed or, as we say, put on "hot," that is quick drying colour to get work out quickly.

4545. Unless you keep on varnishing to keep the pigment covered, if the pigment powders, or anything of the sort, you feel the effect at once?—Yes.

4546. Whereas with lead you might not?—There would always be sufficient cover over any lead that was used in painting to prevent any action of the atmosphere.

4547. You think it would never get down to the pigment?—Not with proper work. I cannot answer as to cheap work, but I am speaking of high-class work, which I have been used to.

4548. Take tram-cars, where you cannot have cars going in to be varnished every day? Suppose there is an accident?—You would put sufficient on them to keep it for the time being.

4549. Could you give the Committee the number of men working in paint shops and the number in body shops?—Only on the lines of the different branches. 2,700 are painters and 3,100 are body-makers.

4550. Are there any figures available to show, of those numbers, how many have been affected with lead-poisoning?—No. That could be obtained as far as the deaths are concerned, but not as far as the ordinary cases are concerned. Hundreds of cases are never reported at all.

4551. It would be interesting to try to differentiate between the two classes of men?—My experience has been, in the positions I have held for 30 years in London, that the man most liable to lead poisoning is the carriage-maker. I have known in my time three deaths of carriage-makers, but they are a very small number comparatively.

4552. That is apart from the painter?—Yes, apart from the painter altogether—a separate branch.

4553. That is the man simply working in woodwork, putting the wood and iron together?—Yes. Generally speaking, the body is painted with priming coats, and there is filling up in the place where he is working at the same time. He has the sandpapering and the priming coats to contend against, and the constant using of lead himself.

4554. With regard to substitutes, you have to have a substitute which will give the same adhesion as lead?—Yes.

4555. The chief trouble, I understand, at the present time with patent stoppings is that they powder, and that bolts bedded in a substitute for lead shake loose?—In jointing paste?

4556. In jointing paste?—I believe that in some kinds of pastes that are used with an iron base that is the case, but in other cases it is not so.

4557. Does that apply to woodwork and iron?—It applies to woodwork and iron.

4558. Is it not a fact that in motor-car works where substitutes are used, particularly on French motor-cars, you get much more cracking where you have panel work?—I have not any knowledge as to that.

4559. I believe that is so. With metal panel work you get a good deal more working between the parts?—There should not be the slightest working.

4560. I am speaking of steel panel work where you have bending?—I do not understand you.

4561. Take doors of motor-cars.—The majority are made of wood at the present time, and some of aluminium.

4562. Aluminium or steel.—The wood framing is the same. There must not be any movement whatever, or the joints would show.

4563. Suppose there was a jar?—Then the joint might show.

4564. Would it be so with lead as much as with a substitute?—I am not speaking from personal experience. Those who use it say that it is quite equal to lead for the purpose. The class of work that the Manchester firm I spoke of are turning out is the highest class that there is in the country; and that substitute has been used for years.

4565. Is that all motor-car work?—Yes, and carriages.

4566. Do not you find that where the springs are painted with the substitute you get more cracking?—I do not know. I am speaking now of jointing paste

28 April 1911.]

Mr. C. KINGGATE.

[Continued.]

4567. On wheels and under-frames and things like that?—I do not think so. There will be other witnesses who will speak upon that, practical painters, and they will be able to answer that question better than I can.

4568. One of the principal reasons why the carriage-builders suffer more from white-lead poisoning is that they have, up to now, not been treated under the ordinary Act applying to white lead?—Practically. Very few in either of the branches have been treated that way.

4569. They have not been provided with any washing arrangements?—No. It has been quite a usual thing for the painter to wash his hands in the pail he has been rubbing down with.

4570. Do you know if, in the trade, it is common to have the one break system like they have at Loughborough?—No. A firm in Manchester work for 50 hours instead of 53 with one break. I believe it was introduced at the Motherwell car works, but they reverted to the old hours. At Preston car works they work 50 hours with one break.

4571. Do you suppose that the men bring their food into the shop?—They have breakfast before they start.

4572. Do they bring lunch?—Mr. Steinitz said that owing to the men having such a long shift they found it necessary to have some food. That has been very usual even when they have had breakfast in the shop. In many cases they have had lunch. In the old firms in London it was always recognised. They have breakfast at half-past eight and lunch at eleven o'clock.

4573. You spoke just now of the varying number of men employed, a large number being taken on, and then a large number standing off. Is not that due a great deal to the fact that it is a trade where you want all motor-cars out in the summer, for instance, and therefore painting has to be done early in the spring?—No, that is not so. The reason mainly why there has been the number of discharges has been the possibility of a change in the shape or design of the motor-car, and the manufacturers would not make a stock. In the old time coach-makers in London generally know what would be wanted during the next season. In the winter time they would make a number of broughams or victorias or landaus, and there was practically a permanency for wood-workers and smiths. There was generally a fluctuation with painters and trimmers. Now that motor-cars are getting somewhat more standardised there is not the same liability, I think, to that large number of discharges as there has been. They feared that there would be a change in the form or the design of the car, and that, therefore, they would practically have to scrap the work they made for stock.

4574. Coach-painters' work is not so irregular as house-painters' work. It is more continuous all the year round?—Yes. There is, as you say, at this time of the year perhaps a larger number employed. That would be mainly repairs. The older vehicles, as the summer is coming, would have to be touched up and varnished, and so on. There is generally a larger number of painters unemployed than men of any other branch at certain periods.

4575. Your men would not have the same possibility of being run down through long spells of work?—No. They do not have long spells. Some would always be on, and some would be off for a few weeks.

4576. (Mr. Mason.) Is not washing accommodation compulsory under the Factory Act?—That is quite true, but unfortunately the Factory Inspector does not visit the places very frequently. It is practically impossible for him to do so. Very few coach-making shops in London, when I was working in London seven or eight years ago, had any washing accommodation at all.

(Chairman.) Coach builders will probably be very much startled, if lead is allowed to be used in the future, at the restrictions that will have to be observed. They will have to level up with all the other lead industries, if the use of lead is allowed to continue.

4577. (Mr. Mason.) You mentioned just now the use of men washing in pails and buckets?—Yes.

4578. Is there any objection to their doing so?—When they have been rubbing down, especially where lead is used in the filling, there is a quantity of lead in the water.

4579. You are speaking of using the water which they have been using for rubbing down?—Yes. If a labourer was rubbing down a body, and the dinner time came, he would wash his hands in the pail that he had been working with.

4580. Is there any objection to his washing in the pail, provided he uses clean water?—No.

4581. In your opinion, a pail is equally as good as a basin?—Yes. It would be preferable to have hot water, where he could get it.

(Chairman.) Dirty water would not be allowed in labour industries. A man must have clean water to wash in. If one man has washed in a pail of water, there is no objection, if the pail is emptied, to another using it, if he has fresh water. It is absolutely essential to get his hands thoroughly clean, and he cannot do that if he washes in a muddy pail.

4582. (Mr. Mason.) There is no difficulty, in the ordinary course of things, in a man getting clean water in his own bucket?—No.

4583. In your opinion, it is not necessary to lay down a regulation enforcing basins for men who already have a pail?—He should have a basin, if possible. A proper washing place is far preferable, undoubtedly.

4584. Why?—Because of the greater possibility of cleanliness. The clean pail might have to be fetched from a distance, and that would not be done, and, consequently, a large number would wash in the same pail. Water would not be very convenient, perhaps.

4585. Has not every man a bucket himself?—No.

4586. Not in the coach-building trade?—No.

4587. In the railway carriage trade, every man has a bucket?—He might not need a bucket. He might be working for many days, and not require any water at all. Water is only used for flattening and rubbing. Generally, the rubbing is done by a labourer, and only the flattening is done by the man himself. With 20 men there would not be half a dozen buckets among the lot.

4588. Do you say that in the railway carriage trade each man is not provided with a bucket?—I am not speaking of the railway carriage trade, but of the private coach trade.

4589. You cannot speak to the efficacy, or otherwise, of buckets for washing?—No.

4590. Can you tell me what the membership fee in your society is, as compared with the boilermakers or some such society as that?—Our entrance fee is simply half-a-crown. The boilermaker pays the same, but if a man comes out and rejoins it goes up to a large amount, up to 2l. Many societies vary in that direction.

4591. Is your society more costly to join than an average society?—Less costly to join.

4592. To be a member of?—I should say that there are some societies with considerably less contributions. Our nominal contributions are a shilling per week, and then there are levies.

4593. Can you tell me how your sick pay compares with that of any other society?—Our sick benefit is on rather peculiar lines. The amount of benefit expended one quarter is paid for the next by levy. It is a very small amount.

4594. (Dr. Collins.) Is the levy or the sick pay, a very small amount?—Both.

4595. (Mr. Mason.) Is it not rather curious that, in a society composed principally of men exposed to lead, the sick pay should be so small?—No, because a great number are off for a few days who never think of going upon the sick fund.

4596. What is the average time men are off sick who declare upon the funds?—I could not tell you that. I have no statistics.

4597. (Mr. Robins.) With regard to washing accommodation, do you not think that for men to wash in a bucket would be a dangerous process, from the simple fact that the bucket is never clean?—Yes.

28 April 1911.]

Mr. O. KINGGATE.

[Continued.]

4598. It corrodes, and dirt catches round the sides of the buckets. It takes a great effort to clean a bucket after a man has been rubbing down for two or three days?—I quite agree that there is considerable danger in washing in the bucket for that reason.

4599. Do you think that the process of facing lead colour after it has been rubbed down (it is usually given two coats of facing matter) is a very dangerous operation, seeing that the water to a large extent is filled with lead, which is likely to enter into the pores of the skin?—No, I do not. It is not generally understood that it can enter through the pores of the skin.

(Chairman.) It cannot. That has been established beyond question.

(Witness.) No, I do not think there is that danger in the operation at all.

4600. (Mr. Robins.) With regard to the cracking of paint, is it not a fact that the cracking of the paint is more general where work has been done in a quick

slip-shod manner?—Yes, that is generally the case. The cause of cracking is that it is done with a quick-drying colour.

4601. Not with oil?—Not with oil.

4602. You mentioned, with regard to cracking of joints, motor-cars particularly. Do you not think that the reason why it cracks at the joint is that, generally speaking, two metals meet together. Whereas in the old coach trade metal and wood met together, in the new motor industry metal and metal meet together, and there is likely to be a slipping apart and consequently a great tendency to crack from that fact?—Yes, that would be so if you are speaking of metal mouldings.

4603. I am?—Yes, there would be that tendency.

4604. (Lord Henry Bentinck.) White lead is used between metal mouldings to prevent possible rattling?—No; it is generally more that water should not get between. It is generally fixed sufficiently well to prevent rattling.

Mr. DAVID WILLIX (59, Hatfield Street, Belfast) examined.

4605. (Chairman.) What is your occupation?—I am a coach-painter.

4606. What practical experience have you had in the coach-painting trade?—My practical experience ranges over a term of 16 years in all classes of coach-painting—that is, ordinary private vehicles, motors, and railway and tramcar work.

4607. What branch of the United Kingdom Society of Coach-Makers are you connected with?—The Belfast branch.

4608. Are you prepared to answer questions regarding the various processes in detail?—Yes.

4609. I should like you to deal with each of the processes which involve risk of lead poisoning in the coach-building trade. First, as regards the body-makers; are they exposed to any risk?—They are exposed to great risk in the use of lead.

4610. For what purpose do they handle lead material?—For the jointing of wood and iron.

4611. Why is lead used in jointing?—Principally to keep out wet and to stop rust, if possible.

4612. Will you tell us exactly in what work jointing is done?—In the jointing of the frame and the putting together of the panels by mortice and tenon.

4613. In what way is the jointing done when metal fittings are being attached to the woodwork?—In the jointing of the iron to the wood it is bolted and sometimes screwed, and the white lead is placed between the wood and the iron. I might emphasize that that is where the great danger comes in. The body-maker, holding the iron in his fingers, is likely to come in contact with the lead. I might say that that is the real danger with body-makers and carriage-makers. We emphasize the difference in the branches.

4614. Does the vehicle, in course of construction, pass from the body-maker into the hands of a carriage-maker?—It does, from the body-maker. The body-maker makes the body, and the carriage-maker has to do with the under-carriage. The body-maker has nothing to do with that.

4615. Please tell us exactly what the carriage-maker's work consists of?—The carriage-maker makes all the under-carriage proper—that is what we speak of in regard to private vehicles—and does the putting together, and the hanging of the carriage, and so on.

4616. He fixes springs and axles?—Yes, and brake handles.

4617. Does the carriage-maker come into contact with lead?—Equally with the body-maker.

4618. What does he use the white lead for?—For the jointing of the iron and wood of the carriage.

4619. Is it generally considered necessary to use white lead for this purpose?—It is, unfortunately.

4620. Do you know of any substitutes that have been tried in place of lead?—Yes, there is a substitute for lead called jointing paste, which is practically non-poisonous, and is said from experience to be equal to that made with white lead for durability.

4621. By whom has it been said that it is equal?—The men who have wrought with it.

4622. Have you ever heard any manufacturer say that it is equal to lead?—No.

4623. When the carriage-maker has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

4624. The first coats of paint applied are termed priming coats, are they not?—Yes, they are.

4625. Does the priming contain lead?—All lead with the exception of a little black.

4626. Is sand-papering done between the successive priming coats?—It is.

4627. In what shop is this generally done?—In all the shops.

4628. So that the body-makers and carriage-makers are frequently exposed to dust made by the painter?—Yes, when working in the paint-shop.

4629. Do you regard the breathing of this dust as one of the most serious dangers of the industry?—I do.

4630. Can it be replaced by a wet rubbing process?—No, it cannot.

4631. Why not?—Because you would be liable to raise the hair of the wood, as it is commonly called, and the owners of the vehicle, whatever it may be, would certainly object to water going on to it so early.

4632. Would it be possible to use any form of local exhaust apparatus to remove the dust?—No, not that I know of.

4633. Then how is this danger to be overcome?—By the abolition of lead.

4634. Is there any danger in filling?—There is to the rubber, that is the pumice, as we call him.

4635. Does the filling material contain lead?—It does—two-thirds.

4636. Then in regard to stopping, is stopping generally done after the last coat of filling has been applied?—It is, in body work. I should say after the priming it is stopped. The nail holes are filled up, as we call it, with sand and grit.

4637. What is the stopping material made of?—Dry white lead, gold size and turpentine.

4638. By whom is the stopping material mixed?—The painter.

4639. Do you consider that the mixing of white lead and gold size is attended by danger?—It is.

4640. Does any dust arise from the operation?—No dust arises from the making of it, but a man cannot keep his hands free from it.

4641. There is no danger in staining, is there?—No.

4642. Then in regard to rubbing down, how is rubbing down done after the application of the filling coats and the staining coat?—With pumicestone and water.

28 April 1911.]

Mr. DAVID WILLIX.

[Continued.]

4643. Is it ever done dry; for example, with sand-paper?—No, that is never done to body work. It is used for carriage work.

4644. What is the extent of the danger in rubbing down after the application of filling and stopping?—In the rubbing off of the filling, the pumicer cannot keep himself free; his hands and arms are covered with the dirt, and necessarily he must get a certain amount of white lead.

4645. Does he get it on his hands and arms and on his clothes?—Yes. Very often from the neck down he is covered with dirt.

4646. Do these answers apply to bodies only?—Yes.

4647. Are the wheels and the carriage underwork treated differently?—Yes, they are treated with dry sandpaper.

4648. Is this a dusty process?—It is very dusty and very dangerous. I might say it is the most dangerous part of it.

4649. Is it impossible to use wet methods of rubbing down in this work?—Yes, it is impossible.

4650. Why?—You could not possibly get pumicestone in between the spokes of a wheel, for instance.

4651. Is it practicable to apply local exhaust ventilation to this process to get rid of the dust?—No, you could not apply it.

4652. After the rubbing-down of the filling has been completed, what is the next operation?—Priming again, with two coats.

4653. With finishing coats?—Yes, two priming coats of lead colour.

4654. Is the work then ready to be painted in the desired finishing colour?—Yes.

4655. Is the carriage then ready for varnishing?—It is ready for whatever colour may be put on it.

4656. There is no danger in flattening, is there?—No.

4657. To what extent do your answers apply to the manufacture of motor-car bodies?—Just in the same degree as to ordinary work. There is the same danger attached to it.

4658. Have you anything special to say in regard to tramway and railway work?—The danger is even greater, because there is a larger bulk of work. In the case of railway and tramway work a man cannot possibly free himself, because he has to look up to it, as it were, when he is sandpapering, for instance. It is above him all the time. He cannot get above it, and he gets the dust on himself.

4659. You have now told us all the operations in which there is serious risk of lead poisoning in coach-building work. Is it in your opinion impossible to remove these dangers except by prohibiting or closely restricting the use of lead?—It is.

4660. You have told us also that there are many processes in which the workman cannot avoid getting his hands soiled with the material that he is using?—Yes.

4661. Is adequate washing accommodation provided by most of the employers?—No, unfortunately not.

4662. Are nail brushes and hot water available, as a rule?—I never saw a nailbrush in my life in any works that I was in. I might say, that I only saw hot water in one works that I was in.

4663. How many works have you been in?—Many. Between England and Ireland, I have been in a good few.

4664. Is time allowed to the men for washing, before leaving off work for meals?—Not in general. In one shop that I was at work in, and only one, it was allowed.

4665. Are facilities for cleaning the teeth ever provided?—No. That applies all round, to painters in general, and body-makers.

4666. Is food often kept and eaten in the work-room, where lead paint is being used?—Yes, often. I might say always, or with very, very rare exceptions.

4667. That is breaking the law, as it exists to-day?—There is only one shop that I know in Belfast where you are compelled to leave the paint shop when you take food, and that has only been in existence for a short time—twelve months.

4668. Then, I suppose that meal rooms are not provided?—No.

4669. Do you think that meal-rooms should be provided, equipped with suitable seats and tables, and properly warmed in winter?—Yes.

4670. Do the men have the use of a cloak-room?—No.

4671. Where do they put their clothes when they are at work?—Just by their work.

4672. So that they collect as much dust as possible on their clothes?—Quite so.

4673. Do coach-painters wear overalls while at work?—No; very rarely. I wear overalls myself. There are only about six of us in Belfast who wear overalls. Coach-painters think that they are above the average painter, and a black apron is more in their line. They look upon overalls as something which they should not use. I wish that they would use them a great deal more.

4674. What are the usual hours of labour for coach-painters?—Fifty-four per week.

4675. Do they work much overtime?—Not generally.

4676. Not in Belfast?—In Belfast there is not much overtime worked.

4677. Do they work any overtime?—Yes, they do. I have worked overtime since Christmas myself.

4678. What would be the average hours of work that these men would do, including the overtime?—I have never thought about averaging it up. The overtime is so very small that I could hardly just name it to you.

4679. Have you noticed any alterations in the hours of employment as the result of the development of the motor-car industry?—No.

4680. Do you think that a restriction of hours of work in the lead processes would be a salutary measure to adopt in the interests of health?—I think it would.

4681. Would it be desirable to have a periodical medical examination by a surgeon, with powers to suspend from employment in lead processes?—Yes, I would say so. It is quite necessary. It is done in a good many other industries, and I have wondered why it has not been done in our own for the benefit of the men themselves.

4682. Supposing that this Committee are able to recommend the adoption of stringent regulations in regard to lavatory, mess-room and cloak-room accommodation, the wearing of overalls, and medical examination, together with exhaust ventilation wherever it can be applied, and that these regulations are fully observed, do you still consider that the dangers of the industry would only be reduced and not removed?—Only reduced—that is all.

4683. Have you had any experience in the use of coach painting materials which are entirely free from lead?—All the colours that we use are free from lead.

4684. But with regard to ordinary paint?—No, certainly not—primings and such like.

4685. You have not?—No. Do you wish me to speak of substances that we have used occasionally?

4686. Have you ever come across any substitutes for lead paint?—Yes.

4687. Have you heard them spoken well of?—I can recommend them. One I have found to be the most serviceable of all, and I can recommend it.

4688. Have you given it a fair test?—We have given it every test it is possible to give it.

4689. For how many years have you tried it?—Not years—I have not known it for years.

4690. Only just a few months?—Yes. We came across it in October last.

4691. You could not say that it would be possible to abandon the use of lead paint generally in the coach building industry, from your own experience?—It would be possible to abandon the use of lead paint if you had a proper substitute.

4692. But you do not know of a proper substitute?—Yes; one.

4693. What is it called?—Fordite.

4694. (Dr. Collis) Your work is chiefly the building of motor carriages, is it not?—Yes; and coach-building

28 April 1911.]

Mr. DAVID WILLIX.

[Continued.]

in general, and railway and tramway work. That is what our men are all employed at.

4695. Do you know anything at all of the amount of the payments made for sickness to members of your society?—I could not answer that. I did not think of looking it up, but the secretary can look it up.

4696. You do pay for sickness?—Yes.

4697. For sickness due to disease as well as for sickness due to accident?—Yes.

4698. Would it be possible for you, at some later time, to let us have figures showing the amount that you have paid for sickness due to illness and sickness due to accident?—Yes, I dare say that it would be. The secretary could look up the books.

4699. Will you let our secretary have that information?—Yes.

4700. (*Mr. Kinggate.*) That must come through me. Dr. Collis is speaking of the whole society, and not only the Belfast branch?—Yes, that must come through Mr. Kinggate.

4701. (*Mr. Fell.*) You said that on tramway and railway work, the process was much more dangerous for the man because the work was above him?—Yes, and in greater bulk.

4702. Are you only speaking of where he does dry rubbing down?—He does dry rubbing down in other work as well. He does a good deal in the smaller work.

4703. I am speaking of tramcar work?—He has to sandpaper and dry rub down between coats.

4704. Is it not possible to do wet rubbing down in tramcar work?—It is after filling, but not before.

4705. Is it not possible, up to that point in the process, to omit lead and use some substitute?—Up to the completion of the lead colour?

4706. Yes?—Yes it is. I have some patterns in my pocket.

4707. There is no difficulty in that?—None whatever.

4708. Have you had actual experience yourself in tramcar work?—Yes.

4709. Do you think that, with a tramcar, you can go through the whole of the processes without dry rubbing down?—No, I do not.

4710. You say that there are certain processes in which you could omit lead?—Yes, and use a substitute.

4711. When you came to the final coats you could use lead paint, could you not? Would you have to rub down dry?—I do not quite follow. Our first two coats we call priming, and we fill up and give two coats again. It may be yellow or it may be red, blue or green. After you have the job filled you apply the colour. You have two coats of priming. If the colour is a yellow, or in that range, you have to dry rub until you get the varnish colour on. It is all wet rubbing from that to the finish.

4712. You mentioned the use of Fordite?—Yes.

4713. Does that spread in the same way as ordinary lead colour spreads?—I may say that it spreads easier.

4714. Do you get the same opaqueness?—You do.

4715. You do not know about the lasting properties of it?—As far as I have tested it, it has lasted very well.

4716. You do not know what the wearing properties would be as you have only tried it since October last?—I do not know what the wearing properties would be over a number of years.

4717. We have cars that have been running for 25 years. They have practically never been repainted. They have just been touched up and varnished?—I should say that they are badly cracked.

4718. No, they are not cracked?—I never yet saw a vehicle that had been out for that length of time that was not cracked, whether it was a railway carriage, a tramcar or a private coach.

4719. (*Mr. Mason.*) You were asked a question about the provision of tooth-brushes. Would you suppose that, if tooth-brushes were provided the men would use them?—I could not answer for the men in general; I would not even answer for myself in that respect. Unfortunately I have not many teeth.

4720. Would it be a wise plan to supply tooth-brushes?—I think that it would be a standing joke for a long time, but it would wear off.

4721. How much dry rubbing will a man do on a carriage?—Have you had any experience of railway carriage building?—Yes.

4722. Take a 50-ft. coach. How many hours of dry rubbing would a man do on that?—That is taking the whole coach through?

4723. Yes?—It would depend on the length of time that he has in which to paint the car.

4724. Yes, but taking the ordinary railway carriage practice, what should you say?—The answer that I gave you previously I might say applies to that, because if the man has plenty of time he will sandpaper his job well, and that causes him to get more dust. If he has not much time he gets over it more quickly and gives it less rubbing, and therefore he gets less dust.

4725. Can you give me any idea of the two extremes?—No, it is so broken up that I cannot possibly answer.

4726. Would it be as much as five hours?—Taking the coach all over, yes.

4727. Would it be more than five hours?—Yes, in many cases. If a man had plenty of time for his job he would probably take two hours in sandpapering one side only, and he would be worked pretty well if he sandpapered a 50-ft. coach properly on one side in two hours.

4728. Do you think he would take ten hours over it. I am not speaking of exhibition jobs, but of ordinary coach painting as carried on to-day?—No, he would not. Your question now applies to one coat. I take it.

4729. No, right through the entire job?—He would take certainly ten hours if he was doing it properly.

4730. Would you be surprised to know that about four hours is a very general practice?—Are you speaking of England or Ireland.

4731. England?—I know nothing of railway work in England. I could give an answer to that, but I would rather not.

4732. Have you had any experience of Fordite as used outside?—Do you mean on the outside of a building.

4733. No, I mean as opposed to the interior of a tram-car, for instance. Where Fordite is frequently used, do you know of Fordite being used with white uppers?—For outside work?

4734. Yes?—No, we have no white work in Ireland on railway carriages that I know of.

4735. Your experience of Fordite having been used has all been connected with inside work?—Yes.

4736. (*Lord Henry Bentinck.*) Have you ever used it on the panel of a carriage?—Only as an experiment for our own information.

4737. How many coats of varnish do you give Fordite? Do you give it more than you give to ordinary paint?—We have not tested it in that way. We gave it two coats, but we never went to the length of varnishing. We wanted to test the Fordite itself, so we did not varnish it.

4738. You put it to a more severe test than ordinary paint. You did not varnish it?—We did not. I have some samples.

4739. You have no experience of it with regard to the finished article?—No.

4740. (*Mr. Kinggate.*) Have you used Fordite at all as a priming coat on coaches?—Not outside—only for samples.

4741. For the inside of coaches?—Yes.

4742. It has not been used for priming purposes for outside work?—No. We cannot get it to use, unfortunately.

4743. Do you mean that they will not allow you to use it?—Yes; we are compelled to use lead.

4744. I understand that Mr. Gardner stated that it was preferable to and was equal to lead?—In our experience of it we have found that it is, but we cannot get the firm to use it. I daresay that they have their own reasons for that.

4745. Have you any knowledge of what Fordite is composed of?—No.

28 April 1911.]

MR. BERNARD DALY.

[Continued.]

4746. Do you know what the base of it is?—No.  
4747. Have you any knowledge of the cost of it in comparison with lead?—It is dearer than lead.

4748. Would it work out considerably dearer than lead?—No, I do not think it would work out dearer than lead, in the end I think it would be cheaper.

4749. On account of its covering properties?—On account of its covering properties. It is so elastic that you can cover a greater space with a certain amount of Fordite than you can with a certain amount of lead.

4750. Is it quite as opaque?—Quite. We have found it so.

4751. (Mr. Robins.) You were speaking just now of the use of Fordite in the inside of a coach. Is it a different class of paint for the inside?—Not as far as lead is concerned.

4752. Is there an inside painter and an outside painter?—There is in some works. In others the man who does the outside does the inside.

(The witness withdrew.)

Mr. BERNARD DALY (7, Herbert Street, Everton, Liverpool) examined.

4757. (Chairman.) What is your occupation?—I am a coach-painter's brush-hand. If you can get a job as a painter you get a higher rate.

4758. Are you a member of any trade union?—No.  
4759. Do brush-hands usually belong to a trade union?—No.

4760. Why is that?—It is rather a conservative method of the union. They try to exclude brush-hands. They think they would be dangerous to the painters proper—that they would do away with the painter proper. They would be interlopers, as it were, they think.

4761. Then the workmen employed in coach-painting, and subject to the dangers which have occasioned this inquiry, are divided into different classes?—Yes.

4762. What practical experience have you had in the coach-painting trade?—I have been working at the trade since I was 14 years of age—all my life.

4763. Have you worked at railway-coach and tram-car painting or only at carriages and motor-cars?—I have worked at railway-coach and tram-car painting, and coach and motor painting—all branches.

4764. Have you known any cases of lead poisoning in this time?—Yes.

4765. How many fatal cases have come to your knowledge?—Three.

4766. Covering what period?—The whole period, but there have been several cases where men have left the trade and died off. They have really died from lead poisoning in my opinion, but the doctor has given it as phthisis. The lead has induced consumption and other diseases, but the lead has really killed them.

4767. Do labourers suffer to the same extent as regular coach-painters?—Well, so I believe.

4768. How do you explain that?—Because they do the priming work mostly, that is, they get the body in the bare wood. They have the priming coats to put on, which are composed almost entirely of white lead and thinners—turpentine and gold size. The lead is used to fill up the grain. It is a preparation for the final coat afterwards, and the danger is in the priming.

4769. Do I understand that you find this lead poisoning evil very extensive in your branch of the trade?—Yes.

4770. Are you prepared to answer questions regarding the various processes in detail?—Yes, as far as I know, I am.

4771. First, as regards the body-makers, are they exposed to any risk?—Yes.

4772. For what purpose do they handle lead material?—They impose it on the plates and in mortices and joints to make them adhere together, to prevent vibration and to prevent water going in and swelling the wood. It makes a close joint so that nothing can penetrate between the plates and the wood.

4753. How long is it since they started using Fordite?—About October last.

4754. Have you seen any perceptible difference in regard to the health of the men and their vitality at the end of a day's work since they ceased to use white lead? I have heard them say they were very pleased to use it, as they did not feel so depressed, as it were at the end of the day.

4755. (Mr. Mason.) Would it alter your opinion as to the cheapness of Fordite as compared with lead, if you were told that the London and North Western Railway Company used tons of Fordite for quite a long time, but had to give it up because it was found to be so much more expensive than lead?—No, having regard to my experience, it would not.

4756. I gather that your experience is not very large?—It extends over the time that I have stated.

4773. Why is lead used in jointing?—Because it is impenetrable. It prevents the water getting between the plate and the wood which is not painted. The only chance that it has of getting any paint is when it is put together. If it were put together without the white lead between, the water would penetrate.

4774. Does the vehicle in course of construction next pass into the hands of a carriage maker or body-fitter?—Yes.

4775. Please tell us exactly what his work consists of?—He makes the under works and hangs the body, balances it, screws it up, fits the brakes, and sees that the whole thing swings correctly.

4776. Does the fitter come into contact with lead?—Yes.

4777. What does he use the lead for?—He fits the plates on to the wood bed, and the bolts and the springs. The spring is composed of several plates, and there is lead put between each plate.

4778. Is this a very dangerous process?—Yes, it is dangerous, but of course there are more dangerous processes.

4779. When the carriage-maker or fitter has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

4780. The first coats of paint applied are termed priming coats, are they not?—Yes.

4781. Does the priming contain lead?—Yes; it must do to be effective—to be any use.

4782. Is sand-papery done between the successive priming coats?—Yes.

4783. In what shop is this generally done?—In most shops they sand-paper between the priming coats just to smooth it a bit.

4784. But in which shop?—Usually in the coach-makers' part of the shop or the carriage-makers' shop.

4785. So that the body-makers and the carriage-makers are frequently exposed to dust made by the painters?—Yes.

4786. Do you regard the breathing of this dust as one of the most serious dangers of the industry?—It is the most serious danger of the industry.

4787. Can sand-papery of priming coats be replaced by a wet rubbing process?—It would raise the grain. You see you are too near the wood and you would raise the grain. There is no filling on.

4788. Is it possible to use any form of local exhaust apparatus to remove the dust?—I have never had experience of anything of the kind, and as far as I know it would be very cumbersome and very expensive and difficult to use.

4789. How can this danger be reduced?—There is no way of reducing it unless you do away with sand-papery altogether between the primary coats.

4790. Is the next process what is generally known as filling?—Yes.

28. April 1911.]

Mr. BERNARD DADY.

[Continued.]

4791. Does the filling material contain lead?—Yes, always in my experience. You cannot have filling without lead.

4792. Is there much danger in this process? I think so. I think there is considerable danger to-day in the smell, and in the handling of the brush. You have to put it on in such great quantities. The more you put on the better you fill. You use heavy brushes, pound brushes they call them. It runs down your hand if you are doing overhead work. There is great danger of it getting on your hands, and a bad smell arises from filling.

4793. There is, I believe, no rubbing down between the successive coats of filling?—No.

4794. Is stopping generally done after the last coat of filling has been applied?—It is generally done, not always. The most effective way is to do a little bit of stopping between each coat of filling.

4795. What is the stopping material made of?—White lead, with just sufficient thinning to make it into a paste. The less thinning you put in the better is the stopping for hardness and durability.

4796. By whom is the stopping material mixed?—Usually by the painter or the brush-hand who is using it. Sometimes an apprentice is told off to make sufficient for half a dozen men.

4797. Do you consider the mixing of stopping material dangerous?—Very.

4798. Why?—Because the white lead is in a dry powder. Dry white lead is used for making stopping. As you mix it and gradually blend it with a knife—you have a knife in your left hand and a mallet in the other—the dust rises and you inhale it. You have to beat it to get it into a paste of the right consistency.

4799. How is the rubbing down done after the application of the filling coats? With pumice stone and water.

4800. What is the extent of the danger in the rubbing down after the application of filling and stopping?—When you start to rub the filling you remove a certain portion of it, about a third, before you produce your level surface. That goes into the bucket of water you are using, and unless you change it every 10 minutes, the lead cleaned off by the stone comes off the sponge into the water, and you are always handling a white lead mixture in a liquid state. You have to change it to see what you are doing. I believe that it is absorbed into the pores of the skin. If not, it will dry on you in the form of dust and be brushed off.

4801. You cannot absorb it through the pores of the skin. That has been proved beyond question. The latter part of your explanation is material. Are the wheels and the carriage underwork treated differently from the body?—Yes.

4802. Is a good deal of dust caused in the operations of painting the wheels and carriage underwork?—Yes, in the sand-papery.

4803. Is this dust of a poisonous nature?—Very poisonous.

4804. Is it impossible to use wet methods of rubbing down in this work?—It is impossible. The underwork of carriages and chassis get less priming. They get two coats of priming on the wood or iron and then sand-papery and stopping. They do not reckon to get as good a surface, but they want a fine surface. There are so many crevices and corners and bends and places to turn round that it could not be done in the time with pumice stone and water.

4805. Is it practicable to apply local exhaust ventilation generally in this process?—I have never seen it done. I do not know whether it is feasible. I think that it would be very costly and cumbersome.

4806. Is there any special danger in the finishing work?—There is a danger when there is a lot of wet work about, especially at any time during the evening, when most of the finishing work is done. In the majority of shops they use naked gas lights for illumination and to heat the atmosphere and make the varnish flow better. The wet varnish makes a smell in the room, and the naked lights consume the oxygen, and the two things together seem to make a very poisonous smell, which affects the throat and

makes you choke, and makes the eyes and nose of the men run, and affects the lungs. I believe that one of the causes of colic is varnishing. They do it in the evening time when the shop is quiet and there is no vibration, and I would advocate electric light and steam heating. Coke fires give off a dangerous smell, and they use those.

4807. Is there any danger in the process of flattening?—No, I do not think so.

4808. To what extent do your answers apply to the manufacture of motor car bodies?—It is practically the same as with regard to horse carriages, except that there is more sand-papery of the under works in one case than in the other. The horse carriages are smoothed up much better by coach-makers than chassis are by engineers. The woodwork and sides of a chassis are terribly rough compared with coach-makers' work. The gun-carriage wheels, as they are called, and the framework of the chassis are done by engineers, who do not understand the fine finish required in coach work. They do not seem to think it is necessary to get the work up so well, and it needs some sand-papery, and, therefore, more dust is created.

4809. Is there any other special danger in the motor-car trade?—There is the danger of piece-work being hurried. I am working on piece-work myself. I cannot help it, because the exigencies of the trade demand it. The men are rushed and working at a given price, and have to do so much before they earn a week's wages; they have not time to be as cleanly in their methods.

4810. Have you anything special to say with regard to tram-car and railway work?—I believe there is more danger in tram-car work and railway work than there is in ordinary coach painting, because the insides of railway coaches are mostly got up in whites or creams or colours derived from lead, and tram-cars are got up in light colours which always have a strong foundation of lead. The canvas on the roof has a bucket of lead poured on it to keep the water out, and it is spread and allowed to dry.

4811. You have told us that there are many processes in which the workman cannot avoid getting his hands soiled with the material he is using?—Yes.

4812. Is adequate washing accommodation provided by most of the employers?—In some cases it is, but in others it is not. There is nominal washing accommodation, but not sufficient.

4813. What kind of washing accommodation is provided?—Supposing that there are 20 men, there is a little bowl about 2 feet in length; the bell rings for dinner and the 20 men rush to wash all at once.

4814. In the one bowl?—In the one bowl. They cannot all do it, it takes several minutes, and they get impatient and they go to the white lead bucket to take the rough off. If they waited their turns, a quarter of an hour of their meal time would be gone. They will not stand it.

4815. Are hot water and nail brushes available as a rule?—In some case, but not in all. They are supposed to be, but they are not. I have known cases where a clean towel was hung up over the bowl, which must not be used. It has been there as a make-believe, and has always remained clean.

4816. Where you have found washing accommodation, how many towels would be provided for the 20 men which you have spoken of?—If there were four towels, say, for the 20 men, they would have to last for a couple of days, and they would be used two or three times a day.

4817. Do the towels get very dirty by the end of the two days?—Yes, they get very dirty.

4818. You say that nail brushes and hot water are not generally provided?—No, they are not.

4819. Is time allowed to the men for washing before leaving off work for meals?—In some cases, but in other cases no time is allowed.

4820. How much time is allowed in the cases where time is allowed?—Five minutes at the most.

4821. Is that taken out of the employers' time?—Yes, but the time is never stated. They look askant at you if they see you washing your hands, but they

28 April 1911.]

Mr. BERNARD DALY.

[Continued.]

do not like checking you, and they do not check you. Some firms will not allow you to wash your hands in their time.

4822. Is food often kept and eaten in the work-rooms where lead is being used? Yes, nearly always. The men hang their coats up in the room where they work, and they sit and eat their meals there.

4823. No meal-rooms are provided? Only in one case—in Liverpool. There was another case where a room was provided, but they have abolished the use of it as a meal-room and made it into an office. They must have thought better of it.

4824. In your opinion should meal-rooms be provided, equipped with suitable seats and tables, and properly warmed in winter? Yes.

4825. Do the men have the use of a cloak-room?—No.

4826. What do they do with their coats when they are at work?—They knock a nail in the wall of the room where their job is, and hang them up.

4827. I suppose that their coats get saturated with dust?—Yes.

4828. They are bound to be?—Yes.

4829. Do coach painters wear overalls while at work?—Very rarely. I have known cases. I have worn them myself, but they get so thick with paint in a day or two that they are offensive to you.

4830. Can you tell us what are the usual hours of work for coach painters?—The nominal hours of work are about 9½ a day; but latterly they have worked all hours. They work from six o'clock in the morning to ten o'clock at night, and on occasions work all night. They work late on Saturday and on Sunday. I have worked Sunday after Sunday myself. I remember a statement by one of the leading coach makers in the country with regard to getting work out. He said, "There are seven days in the week, and 24 hours in the day, and it has to be out at a certain time."

4831. That is in the very busy season? Yes, that is in the summer time.

4832. In the winter do they have a slack time?—Yes; there is very little chance of getting a job in winter if one happens to be out of work at that time of the year.

4833. So that you take advantage of the overtime in the summer to make up an average wage?—That is the way in which it works out generally. It would be better if it were more equally distributed.

4834. Do you think that a restriction of the hours of work in lead processes would be a salutary measure to adopt in the interests of health?—I do. There is an agitation in the Coachmakers' Union in the North for the reduction of the hours from 53 to 50 a week. That would be very good if it were adopted; I would suggest only one break in the day, starting at 8 o'clock and working till half-past 12, then taking the dinner hour, and working on from half-past 1 to 6. That would be 9 hours a day. That, with from 8 to 1 on Saturday, would be 50 hours a week. That would reduce the danger of unclean hands at meal times by half. At present they start at 6 with an empty stomach and work until 8 o'clock. They wash their hands, if they have a chance, and eat their meal, and then have the dinner hour. In that way there are two chances of their eating meals with dirty hands.

4835. Do you consider it dangerous for men to work before they have had a meal in the morning?—Very dangerous. I know from my own feeling and from what other men have told me, that if you have a meal before you start you are fortified against the danger of colic and that sort of thing.

4836. Would it be desirable, in your opinion, to have a periodical medical examination by a surgeon with power to suspend from employment in lead processes?—It would be desirable, in my opinion.

4837. (Mr. Fell.) What technical work are you working on?—I am working on the priming and getting up of bodies of coaches.

4838. In large works?—Yes, in a large firm.

4839. Do your remarks with regard to the conditions as to washing, and so on, apply to fairly large works, or only to small works?—To large works also. With regard to the firm that I am working with now, the

conditions are very fair, but I have found large works just as bad as any very small and poor works where the employer was a struggling man and could not afford better conditions. Some years ago I wrote to the local factory inspector and complained of some tramway works. The conditions were terrible. There were men going off with lead colic day after day. They were boiling dinner cans, and the lead was actually dropping into the cans. I have seen it and others have seen it. There was no chance of cooking except at this place, which was an old engineers' shop that had been turned into a tramway works. It was not fit for coach building or coach painting at all. When the factory inspector went there he insisted on very great improvements, I believe, and it cost them hundreds of pounds to put things right. The result was that I was dismissed, because they knew that I had been complaining.

4840. Does your criticism apply to all paint shops in Liverpool, do you think?—No, not to all, but generally, what I have said about represents the average conditions.

4841. What particular class of work do the brush-hands work on?—A brush-hand is supposed to be a handy-man, he is what is known in the trade as a "broken painter," if you understand. He is very often a better man than the so-called proper painter, and more skilled. Many painters do not know how to make filling, or how to handle it, because they have never been on that work.

4842. Are you speaking of a man who has served his time?—Yes, and who has not been very successful at the lining work as a pencil-hand, and has become a brush-hand.

4843. Does the brush-hand ever become a painter?—Yes, I could become a painter, but the society is so very conservative in its rules.

4844. (Lord Henry Bentinck.) It would improve your position if you became a painter?—Yes, I should have higher wages, easier conditions and less danger. The coach painter proper has not nearly the danger that the brush-hand has.

4845. Why can you not become a painter?—You should ask Mr. Kinggate.

4846. (Mr. Fell.) Have you been actually engaged on the painting of tramcars?—Yes.

4847. Have you used substitutes for white lead?—Yes, I have used what is known as Purex. It is supposed to be genuine white lead, but innocuous. In my opinion it is not absolutely innocuous.

4848. Have you known any case of lead poisoning due to Purex?—No, I have not.

4849. Is Purex as easy to apply as ordinary white lead?—Yes, it is as easy to apply as ordinary white lead, but not nearly as serviceable. It has not the body, it has not the solidity of white lead. It would take about three coats of Purex to equal one coat of genuine English white lead.

4850. Does it last as long?—Well, I dare say that it does. I have never heard any complaint about the durability of it.

4851. You were saying just now that you recommended the one break system for men in the shop. Would not it mean that the men would want something to eat between 8 o'clock in the morning and half-past 12?—They work now from 9 till 1—four hours. I was advocating a stretch of four hours and a half, so that it is only half an hour longer.

4852. Would not there be a tendency for the men to bring food into the shop, or to want to bring food into the shop?—I do not think so. Some men would be eating all the time, some also are very dirty and uncleanly with regard to where they eat.

4853. Is the average brush-hand more dirty in his habits than the trained painter?—I believe so.

4854. That is probably the reason why brush-hands suffer more from lead poisoning?—The work is dirtier. The brush-hand uses much more paint. The coach painter is putting spirit colours on with fine soft brushes, and it is gentle work, but the brush-hand has to splash the paint about. It does not matter how it flows, because it will all be levelled with the stone; but the coach painter has fine colours already ground

28 April 1911.]

Mr. BERNARD DALY.

[Continued.]

with turps at the mills, and mixed with gold size or varnish according to what they want.

4855. (*Mr. Kinggate.*) You made the statement\* that the carriage-maker puts lead between the plates of the springs. It is somewhat new to me to hear that any lead is ever put between spring plates?—Lead colour.

4856. No, there is no lead colour?—I cannot agree on this point. My observations since I was in London and my whole experience emphasise the fact that there is lead colour between the spring plates, and when the plates are tightened up the lead squeezes out and gets on to the hands of the man handling them.

4857. With regard to old springs, when you take them off and reclean them, a labourer will put a little lead colour in when he cleans them. The carriage maker has nothing whatever to do with putting springs together?—The coach-maker handles them when they are freshly coated with lead. The carriage-maker puts lead under his clips, does he not?

4858. I am a coach-maker myself. Now do you think the men would be favourable to medical examination?—I think so. I think that intelligent men would be favourable if they grasped the situation.

4859. Have you any knowledge of men being victimised on account of the fact that they are suffering from lead; that is to say, that the employer, knowing they were suffering from lead, will not employ them?—Yes.

4860. That is an objection to medical examination that would weigh with many, is it not?—I have in mind a foreman, a very clever man, a painter in a big firm in Liverpool, who was taken ill and who gave up because he was suffering from lead poisoning. When the employer went to enquire how he was going on, he gave out to his employer that he was suffering from some other disease altogether, for fear that he would be discharged.

4861. What is your reason for thinking that varnishing is one of the most deadly things in connection with finishing?—There have been four finishers in the firm that I am working for now who have all died as young men.

4862. Has that been traced to lead?—Yes. A doctor came in to see his carriage and he said that the atmosphere was deadly, and he did not know how the men lived in it. These four men have all died young from working in this close room. As I said, the gas consumes the oxygen of the pure air, and when there are two or three wet bodies there is a large area giving off a strong smell of japan or varnish. Some makes of varnish are worse than others.

4863. You generally have a special room for finishing, on account of dust?—Yes.

4864. That is kept up to a certain temperature so that the varnish shall flow, but there is no lead there? No, but I believe that there is danger from the gas and the strong smell.

4865. But that cannot be attributed to lead, which is what we are dealing with in this Inquiry. You are aware that there is a firm in Liverpool who do not use white lead, but Purex?—Yes.

4866. They find it perfectly satisfactory for all purposes?—I am working there myself.

4867. A member of the firm told me himself that it was satisfactory?—It is said that you can spread it on your bread, but I would not like to try it. I was using Purex yesterday. The general opinion of workmen is that Purex is not absolutely innocuous, and that it is not nearly so good as white lead.

4868. Your objection to overalls was that they would become offensive very easily and very quickly? You know perfectly well that the clothes which are generally worn by a brush-hand or painter are covered with paint and other matter. Would not they be worse than an overall? Would it not be better to wear overalls than to get the paint on your own clothes?

—A woman cannot wash a painter's overalls any more than she can the black apron. She could not get the splashes off.

4869. You might not be able to get some of the marks off, but it would be quite possible to keep them clean. On the Continent there seems to be no difficulty?—There would be a little time taken in putting them on in the morning and taking them off at night, which, perhaps, the man would jib at. If men were two or three minutes late, and the foreman saw that they had not their overalls on they would see that the men were late. Would the boss allow time for putting them on and taking them off, do you think? They are very keen nowadays.

4870. I know, but would it not be much better that a man should wear overalls which could be cleaned once a week?—Yes, it would be better, there is no doubt about that. Our wives always complain that, before we enter the house, they can smell the paint.

4871. Yes, before you get to the door?—Yes.

4872. (*Mr. Robins.*) For how long have you used Purex or a substitute for white lead?—About three or four years.

4873. Have you noticed at all that the men are more healthy and the vitality of the men is better after a day's work than it was when they used white lead?—You cannot very well tell, because all the time you are using Purex you have to use pure dry white lead stopping, so that it is neutralising the Purex all the time. You cannot use Purex for stopping.

4874. For how long have you been in the coach trade?—Since I was 14 years of age; and I shall be 37 on Monday.

4875. Do you think that the habits and conditions of the working painters are much more clean than they were when you first went into the trade?—I think so.

4876. You think that he is cleaner in his habits and takes more pride in himself than he did when you first went into the trade?—Yes.

4877. (*Lord Henry Bentinck.*) Have you had any experience of substitutes for white lead stopping? There are substitutes, are there not?—The only substitute that I know of is japan putty. That is made of japan and whiting. It is put on with a knife. There is no rubbing. You spread it as level as you can and leave it.

4878. Is it as effective as white lead?—It will fill up the holes, but you cannot get as good a finish. You can put white lead on and put it over the hole sticking up in a lump, and then get a piece of stone and wear it perfectly level. With the putty you press it in as well as you can and square it. It is very good, and with a bit of care I believe that putty is a good substitute on chassis and the underworks of carriages for stopping. One firm in Liverpool say that they would discharge any man that they saw using white lead sand-paper stopping on wheels. That is to their credit. If a man who has a good reputation as a coach-maker, and can produce splendid work, can take that stand, why cannot others? It costs a little more, not in the stuff, but because it takes a longer time to put it on. Sand-paper stopping you can slap on anyhow.

4879. (*Dr. Collis.*) Do you know any men, who have been employed with you, who have been using Purex only, apart from any other form of paint?—No, I do not. They have all been subjected to the dust of sand-paper stopping, even if they have not been using it.

4880. You know that Purex is lead?—Yes; it says on the label "Genuine English White Lead."

4881. As regards your own experience in working with it, do you feel any different after you have been working with it from what you would feel after you had been working with ordinary white lead paints?—Not a bit.

4882. Neither better nor worse?—You feel no different. I do not know whether the effect on the system is the same or not.

\* See answer to Q. 4777.

The witness withdrew.

28 April 1911.]

Mr. J. T. SWAIN.

[Continued

Mr. J. T. SWAIN (1, Bishop Gate Green, Coventry) examined.

4883. (*Chairman.*) What is your occupation?—Foreman painter.

4884. What practical experience have you had in the coach-painting trade?—Thirty years.

4885. What firm are you at present employed with?—The Daimler Company.

4886. Have you worked at railway carriage and tramway painting or only on carriages and motor-cars?—Only carriages and motor-cars.

4887. What branch of the United Kingdom Society of Coachmakers are you connected with?—The United.

4888. Are you prepared to answer questions regarding the various processes in detail?—Yes.

4889. What do you use for jointing?—We use the non-poisonous lead.

4890. Do you find that in every way efficacious? Yes.

4891. Have you had any complaints at all in connection with it?—None whatever.

4892. Not with regard to its durability?—No, none.

4893. Is that the only material used by body-makers in your firm?—Yes.

4894. Does the vehicle in course of construction next pass into the hands of a carriage-maker or body-fitter?—Yes; a body-fitter.

4895. Will you tell us exactly of what his work consists?—Fitting the body on to the chassis.

4896. Does the body-fitter come into contact with lead?—No.

4897. How is that?—He does not use it at all. It is not necessary in fitting a car body on to a chassis to use lead.

4898. Is it generally considered necessary to use white lead for this purpose?—No.

4899. When the carriage-maker or body-fitter has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

4900. The first coats of paint applied are termed priming coats, are they not?—Yes, that is so.

4901. Does the priming contain lead?—No.

4902. Is that unusual in carriage-building?—Yes, I believe so. All the other firms that I am acquainted with use lead, but I do not. I have a particular process of my own.

4903. Is it a process that is patented?—No.

4904. Is it a process that you would divulge to your competitors?—Yes, with pleasure.

4905. Is sand-papery done between the successive priming coats?—No.

4906. What do you substitute for sand-papery?—It is not necessary to sand-paper at all.

4907. Can you explain to us why?—With regard to that which I speak of in the place of the lead, it is not necessary to sand-paper it. It is a smooth liquid substance, which it is unnecessary to sand-paper.

4908. It fits in completely, does it?—Yes.

4909. Is the next process what is known as filling?—Yes.

4910. Does the filling material contain lead?—Not to my knowledge.

4911. You are not quite sure about it?—You see I receive it from the manufacturers and apply it as received.

4912. Do you ask for non-poisonous filling?—Yes.

4913. You believe that it contains no lead?—That is so.

4914. There is, I believe, no rubbing down between the successive coats of filling?—None whatever.

4915. Is stopping generally done after the last coat of filling has been applied?—Prior to the last coat.

4916. What is the stopping material made of?—The stopping material used generally is made of lead, but the stopping that I use is not made of lead.

4917. And you find that in every sense as good as the lead stopping?—Yes.

4918. When did you first begin to discontinue the use of lead?—Two years ago.

4919. You have had no complaints at all from your customers?—No.

4920. Nor noticed any defects yourself?—None whatever. I may say that the work has been absolutely satisfactory.

4921. How is the rubbing down done after the stopping and filling?—With German brick and water.

4922. Is it ever done dry in your works?—No.

4923. Do you think it is necessary ever to do it dry?—No.

4924. Then is there any danger in the rubbing down after the application of the filling and the stopping?—None whatever.

4925. Does that answer apply to bodies only?—To chassis as well. You see using the non-poisonous stopping there is absolutely no danger whatever.

4926. Are the wheels of the carriages and the underwork treated differently from the body?—Differently from the body—yes.

4927. What do you use for the wheels and the underwork of the carriages?—The wheels, to commence with, of the Daimler cars are enamelled.

4928. Do you use no dangerous material at all on the wheels?—No; we do not touch the wheels, the wheels come to us all ready for use. They are made and enamelled away.

4929. Is there any lead used in the enamelling, to your knowledge?—No.

4930. You are sure there is not?—Yes, quite sure.

4931. After the rubbing down of the filling has been completed, what is the next operation?—The next operation would be to give a foundation for the colours that are to follow, and that foundation is composed in exactly the same way as that which is applied to the body when finished by the body-maker.

4932. Is the work then ready to be painted in the desired finishing colour?—Yes.

4933. And then the body is ready for varnishing?—When the colours are all applied.

4934. In the process of applying ground colour, finishing coats, glaze and varnishing, is there no rubbing down between successive coats?—None whatever.

4935. How do you fix the canvas on the roof of your vehicles?—With a composition of non-poisonous lead and varnish.

4936. Do you think it would be possible to abandon the use of lead paints generally in the coach-painting industry?—Yes.

4937. Do you know why other important firms have not taken the same steps as you have?—No, I cannot tell you why. My principle of painting is simply the same as the American.

4938. I was going to ask you whether from your knowledge there is any lead used in painting American motor-cars?—No, not by the American process, and mine is an adaptation of the same system.

4939. Is it more expensive than the ordinary lead?—No; from a commercial standpoint it is not.

4940. Is it cheaper?—Well, it might cost a little less for material but a little more for labour.

4941. Could you say from your knowledge whether it could be applied to tram-cars and to the railway carriages?—I do not see any reason why it should not be applied to all kinds of vehicular painting, taking into consideration the fact that the carriage and the motor-car are of the highest class. If it is put into those I do not see why it should not. In fact I should apply that system to almost any degree of quality of painting. I can use it for cheap work or I can use it for the highest class of work. The principle of it is simply in the foundation work, and my opinion is that it is in the foundation work where the great liability occurs in reference to lead poisoning.

4942. Did you introduce this system in view of your knowledge of the dangers of using lead?—Yes, I used it purely for the purpose, if possible, in my own way of getting rid of this evil of lead poisoning.

4943. (*Dr. Collis.*) I was not quite aware in what processes exactly you were using what you have termed non-poisonous lead. Would you mind recapitulating them?—First in the priming, and in the second place

28 April 1911.]

Mr. J. T. SWAIN.

[Continued.]

in the foundation of the colour that the car has to be painted.

4944. That is to say that this material is only used in two processes, and is never rubbed down, and is only used in the form of paint?—Yes.

4945. Do the same men carry on these two processes?—No.

4946. They are carried on by different men?—Yes.

4947. Who are also carrying on other processes as well?—No. There are different sections of men for different processes of the work.

4948. So that one man will be doing priming entirely with this material, and another man will be laying on the final colour on the car with this material?—Yes.

4949. This would be in the last three years?—Four years.

4950. Have you had any sickness at all among these two classes of operatives?—Not directly from my own establishment. The sicknesses that have arisen have been among men who have come from other works, and it has developed. For four years I have been without a case of lead poisoning.

4951. Then is it from the fact that, as you have stated, for four years you have been free from lead poisoning, or from other information, that you consider the material which you use to be non-poisonous lead?—From the fact that I have been free in my own process.

4952. But when you originally started it you could not have had that information. Did you look upon it as a non-poisonous form of lead when you originally started using it?—When first I commenced it was from commercial interests.

4953. As being cheaper?—Yes.

4954. And you found afterwards that there was less sickness?—Yes.

4955. There was no statement made that the material was non-poisonous?—No. When I first commenced this process, non-poisonous lead had not been brought to my notice. I used the ordinary lead, but I so reduced the quantity that was necessary to be used that it took away the greater part of the liability.

4956. So that you consider that your immunity from sickness in these two classes of people, one doing priming and the other laying on the final colour, is not to be attributed to the material they are using but to the way in which the material is used?—Yes.

4957. (Mr. Fell.) Do you receive the bodies complete before you start painting?—Yes.

4958. So that there is a certain amount of work done on them before they come to you?—They have the priming coat before they come to me, and I send the material down to the body department.

4959. That is non-poisonous?—Yes. I mix up off superintend the mixing up of all the material that is necessary for carrying on the painting.

4960. Do you know at all what the bodies are put together with?—Yes. They are jointed with a mixture of Japan and whiting.

4961. Does that stand?—Yes.

4962. Without any shaking?—Yes. You see the panels are steel, and, that being so, it takes much more to hold your frame than if they were wood, and I have mixed up this composition. We were troubled with panels wearing loose in the frame, and I mixed this up as a trial, and it proved very satisfactory, and we still continue to use it.

4963. Do you find that there is any crack in between the beading and the other part of the sides of, say, the doors, or anything of the sort?—Yes, there is that kind of thing taking place, because of the wear and tear.

4964. Do you find that that is the same whether you use lead or whether you do not use lead?—Yes, but not so much since we have used this particular composition that I speak of.

4965. I understood that you were prepared to give the Committee some description of what this composition was?—The priming?

4966. Yes, first of all the priming, and then the stopping too?—The priming is composed of what we should otherwise pass on one side practically as useless

or waste. It is the refuse japan and varnish mixed together with a little lamp black, or white, or green, or yellow, whichever is necessary to put into it, and then thinned down with turpentine.

4967. That is the priming?—Yes.

4968. What do you make your stopping of?—Whiting and japan.

4969. You were talking just now of rubbing down the chassis with German brick?—Yes.

4970. How do you manage to get round all the corners and everything with the German brick?—There is only the side of the frame really to be dealt with in the chassis. The springs and the crossbars are all polished before I receive them, and it is only the side of the frame that requires this particular attention from the painter.

4971. What do you call the American system of painting?—The American system of painting is exactly the same, only they have a preparation which they call wood filling. I have used it. I do not know exactly what it is composed of, but it occurred to me that I could use this japan and varnish mixed together, and that it would answer the same purpose. Its purpose is, of course, to fill up the grain and to form the foundation. By the old method of painting with lead the priming coat was applied to the woodwork, and when you came to look at it, it was only the liquid that the lead was mixed with that entered really into the grain of the wood. The lead remains on the top. That being so, the Americans produced this wood filling, which they stated would enter right into the pores of the grain, and completely close it up and so form a perfect foundation to work on. I used it some years ago, and very successful it turned out. When it was properly applied and a fair amount of work was applied to it, there was an excellent result. That is the American. Well, I thought "Why should not our varnish and japan do just as well? it is higher grade," and that being so, I applied it, and I claim that it does just equally as well. It is quite as good, and it does away with the necessity of using lead. It forms a suitable foundation for the work, and especially on motor-cars where there are steel panels. It will adhere more perfectly to the panel, and last longer, and there is less fear of chipping than there was when lead was applied.

4972. I understood you to say that for bedding your canvas you use a non-poisonous lead?—Yes.

4973. What do you call a non-poisonous lead?—That is paint supplied to us as non-poisonous.

4974. Can you tell me what it is?—No. You have to take it. It is up against the manufacturers if it is poisonous.

4975. (Mr. Mason.) I gather that the cheapness of your process depends on your being able to use such part of the varnish that you would in the ordinary course throw away?—No, I do not think so. Take it from the commercial standpoint. How much more do you think it would cost if you took the varnish and japan clear out of the bottle and mixed it up and used it? How much more would it cost than if you took the lead?

4976. Are you asking me a question?—You must excuse me but you were asking me a question. We considered the cost.

4977. I understand, then, from you that it is very much cheaper to use this waste from the varnish?—Yes; it is certainly cheaper.

4978. May I ask you what price do you pay for this varnish that you speak of?—Well, you see, I could not give you the price, not being in the buying department.

4979. In such a trade as railway carriage painting, that part of the varnish would be used on inferior work?—Yes.

4980. Therefore, would you get the same saying that you claim in what we may call the higher-grade work of the Daimler Company?—I can only speak for the class of work that I am connected with.

4981. You said just now that this could be equally well applied to railway carriage painting as to any other?—Yes, the system could be used exactly the same as far as the application goes.

28 April 1911.]

Mr. J. T. SWAIN.

[Continued.]

4982. Would there be the same saving to a railway company?—That I could not say. Those who are in railway painting would be able to test it. Personally I do not think there is anything very serious about it.

4983. (*Mr. Kinggate.*) Would there be a considerable saving from the fact of there being no necessity for sand-papering?—Yes, there is a saving there certainly.

4984. Two coats of priming and two coats of sand-papering?—It is only necessary to put on one coat of what I spoke of instead of two coats of lead priming. You see it saves considerably in time. It is only necessary to put one coat of the mixture of that description on to a body. That is all that is necessary. But by the old process you put on two coats of priming at least—I did—or three coats.

4985. In some cases three?—Three coats was my standard of priming for a body. Now I only put on one by this particular method.

4986. (*Mr. Mason.*) And get the same result?—And get the same result.

4987. (*Mr. Kinggate.*) The object of putting on the priming is to stop the grain?—Yes.

4988. The method you think is effective for that purpose?—Yes. If you care to try it, just put a little of the lead colour on to your hands and put a little of this composition that I speak of, and see which takes the most to get off. You would have something to do.

4989. There would be less tendency for this to crack than there would with ordinary lead?—Yes.

4990. More elasticity?—Exactly. I am so taken up with it and so satisfied with the result of it that I say it is better all round, and after two years without a complaint I may very well take a little credit for it now. I have said nothing about it for two years. Had it not turned out successful, I should have dropped it, and shut the door, and said nothing about it. It was purely with the object of reducing the liability that caused me to use it in some parts of the work.

4991. The same thing occurs after the filling which is naturally porous. To stop the suction you put on two more coats of lead colour in the ordinary way. This has the same effect?—Just the same. In the American system they put this wood filling again on to their filled up rubbed down surface, the same as they put on to the wood in the first place.

4992. (*Mr. Mason.*) Are you using genuine turpentine with the filling, or a substitute?—Genuine. I am very particular about turpentine.

4993. There would be less suction with the genuine turpentine in the filling than there would with a turpentine substitute?—Exactly. I could not use a substitute, because of what would come on afterwards. Even if we got through successfully with the colour, we should have trouble with the varnish. It would begin to fall out then.

(*Mr. Mason.*) You are a lucky man if you can get turpentine.

4994. (*Mr. Robins.*) Have you seen any of the motor-cars after they have been out in use for two years?—Yes, plenty of them.

4995. What is their condition compared with cars painted with white lead, from a painter's standpoint, after wear and tear for two years?—It would be a very difficult matter when you came to view a car that had been out for two years to know exactly what it had been in contact with. A car under some people's care would look very satisfactory at the end of two years, while in other people's hands at the end of six months it would look a wreck. The only way

in which you could come to a conclusion as to the painting and the quality of the work would be to see whether that painting had cracked or peeled off or sealed. I have not found anything of that.

4996. You have found it far superior to painting with white lead? Yes. If any perishing has taken place it is in the finishing coat of varnish, which is a usual thing. The varnish is the first thing to give way, and it is very seldom that you find the paint destroyed down to the filling up.

4997. I take it then that, with regard to painting with your system, the perishing would be from the top?—Yes.

4998. And with white lead the perishing would come from the bottom?—Yes. You find that with the white lead ground or foundation your painting will have very large cracks, which take all the coats of paint and varnish and everything. They will go right through to the bare wood. That is with lead, but you will not find that with this principle of mine—or I have not found it yet.

4999. Do you find that since you have used non-poisonous paint for the painting of motor-cars the health and vitality of the men after a day's work has been better than when you used white lead?—Yes. The general health of the men is better altogether.

5000. Not that languid appearance?—Oh dear, no.

5001. (*Chairman.*) Does the Daimler Company belong to the Employers' Association?—Yes.

5002. Can the ingredients which you use in your non-poisonous paint be bought in England?—Yes, you can get them from varnish manufacturers.

5003. How many men do you employ?—I have 135 at the present time.

5004. I suppose, on the ground of saving of cost, that that saving would be enormously enhanced if you were exempt from such things as providing overalls, medical examination, exhaust draught, &c.?—Yes.

5005. If lead is permitted to be used in the future in the industry, the provision of overalls and other precautions would have to be enforced?—Yes, if the use of lead is prohibited in future, it will not affect us at all in any way.

5006. Then there is the other very important point, and that is, that you are also exempt from paying compensation?—Yes, it will make a considerable difference, no doubt.

5007. Would you send us a specimen of your non-poisonous lead, or perhaps you can tell us where you get it?—Yes; it comes from Docker's, of Birmingham.

5008. (*Mr. Kinggate.*) You have used non-poisonous lead exclusively for two years?—For two years previously to that I used the ordinary lead with the same system.

(*Dr. Collis.*) You cannot, then, put the difference down to the non-poisonous material, but rather to the way in which the material is used.

5009. (*Mr. Kinggate.*) What do you use the non-poisonous lead for?—The non-poisonous lead that we use now is used to bring up the light ground colours—white and cream.

5010. You do not use it all for priming purposes?—No.

5011. In painting colours that do not need any lead, you do not use lead in the ordinary way?—No.

5012. Only for special purposes?—Yes. It is used to bring up the ground colour for a white or a similar colour.

5013. For dark colours you do not use it at all?—Not at all. As the greater portion of the cars turned out are of a dark colour we use very little.

The witness withdrew.

Mr. HARRY ALLEN (106, Woodhall Road, Thornbury, Bradford) examined.

5014. (*Chairman.*) What is your occupation?—Coach-painter.

5015. What practical experience have you had in the coach-painting trade?—About 26 years.

5016. What class of work have you been employed in?—I have been employed on many classes of work. I have been employed the longest on tram-car work; I have also been on engine work and private work.

28 April 1911.]

Mr. HARRY ALLEN.

[Continued.]

5017. What branch of the United Kingdom Society of Coachmakers are you connected with?—I belong to the Bradford branch.

5018. Are you prepared to answer questions with regard to the various processes in detail?—Yes, to the best of my ability.

5019. What do you use for jointing?—It is a mixture of Griffith's priming white and purple brown which contains ferric acid to a great extent, I suppose. That is my information from the manager. I only give it in that way.

5020. The body-makers in your works do not handle lead?—No.

5021. Does the vehicle in course of construction pass from the body-maker into the hands of the body-fitter?—We do not call him a body-fitter. He is the ordinary fitter—the mechanic. He mounts it on to the truck.

5022. Please tell us exactly of what his work consists?—His work consists of putting the body on to the truck and bolting it down, and generally coupling up.

5023. Does the fitter come into contact with lead? No, not at all.

5024. Is it generally considered necessary to use white lead now for fitters' work?—Not now, at any rate. We have done away with it altogether. It was thought at one time that it was necessary, but we do not use it now. For all I know, it is as satisfactory as it was before.

5025. When the fitter has completed his work, is the vehicle ready to pass into the painter's hands?—Yes.

5026. The first coats of paint applied are termed priming coats, are they not?—Yes.

5027. Does the priming contain lead?—No.

5028. Is sandpapering done between the successive priming coats?—Yes.

5029. In what shop is the priming done?—Very often in the body shop; sometimes in the paint shop, but more often in the body shop.

5030. Is the next process what is generally known as filling?—We have practically done away with filling at the firm that I work for. They do a little. The next process, as generally understood in the painting trade, is filling.

5031. Why have they done away with it in the place that you work at?—Because they think it is not necessary. They think that the cars do very well without it. They think that the durability of the cars is as good without as with it. They, of course, admit that the job has not the finished appearance. That is their contention.

5032. Is stopping generally done next?—Yes. We use stopping.

5033. What is the stopping material made of?—It is made of a non-poisonous substitute, the same as the paint. It is supplied in powder and mixed by ourselves. There is no lead.

5034. How is the rubbing down done after the stopping?—It is done by both processes; rubbing down by pumice-stone and sandpaper.

5035. Is there any danger in the rubbing down after the application of the filling and stopping?—Not at all, if it is non-poisonous.

5036. Are the wheels treated differently from the body?—We do not treat the wheels of the cars at all.

5037. You buy them already finished?—Yes. I do not know that they are treated in any shape at all. They are only rubbed over with oil. I believe they have some black kind of stuff, but we do not deal with them at all.

5038. Do you know whether any lead is used on the wheels?—Some of them when they come are painted, but they are never painted by our firm.

5039. After the rubbing down has been completed, what is the next operation?—The first coat of paint is then applied.

5040. Is the work then ready to be painted in the desired finishing colour?—There are other coats to follow before the finishing coat is applied. It is a repetition of what the first coat is.

5041. Is the body then ready for varnishing?—We enamel them. We use white enamel on our cars.

Sometimes we use what is known as varnish colour; that is a mixture of varnish and a substitute, but more often it is enamel.

5042. In the process of applying ground colour, finishing coats, glaze and varnishing, is there any rubbing down done between successive coats?—Yes; sandpapering.

5043. How do you fix the canvas on the roofs of your vehicles?—We use the same mixture as is used by the body-makers for joint making and bedding—that is a mixture of the Griffith's white priming substitute and purple brown.

5044. How long have you used, in coachmaking, materials which are entirely free from lead?—About two years in my present occupation, but I used a substitute many years ago.

5045. Have the results been satisfactory with these leadless materials?—Very satisfactory.

5046. Have the cars worn as well?—Yes; that is due, we think, to the protective coats of varnish that go on the top.

5047. Is it any more costly than the ordinary lead paint?—I understand that it is not. It has greater covering properties than lead. Weight for weight it goes much farther. It carries a great amount of oil and therefore it goes a long way.

5048. What is the composition of this substitute?—I can give you an analysis that was supplied to me by the firm who manufacture the substitute.

5049. Would you tell us what it is?—Zinc sulphate 13·3, barytes 31·2, zinc oxide 44·4, refined linseed oil 11·1. They gave me that as an approximate analysis when I wrote to them.

5050. (*Dr. Collis.*) Before you gave up the use of lead in your works, you were accustomed to work with lead?—Yes.

5051. Have you known of any illness occurring during that period?—Yes.

5052. What has been the state of health of the men since you have given up using lead?—Much better. I might say, in connection with that, that I was particularly reminded by one of my workmates to tell you that the general state of our health was better since we were using the substitute than it was before. He asked me particularly to mention it if I had an opportunity.

5053. (*Mr. Fell.*) Have you had any actual cases of men being knocked off their work since you started using this substitute?—No, I do not think we have had one.

5054. As to this bedding that you use for the canvas, do you find that it powders at all after it has been out in the weather?—I am told by the body-makers that it does.

5055. I suppose the erection of the body does not come under you. You do not have anything to do with that?—No.

5056. Do you know anything about the jointing?—I only know what has been told me by the body-makers. They say that the mixture we are using powders and they do not favour it, and they point out that the tendency is to loosen the joints. If it powders, it does not resist water in the same way as lead would. I can only say what our body-makers have told me.

5057. You say that this substitute goes farther. Is it as opaque?—Yes. Weight for weight the thing has a deal more covering power and will go a lot farther. You do not use the same amount at all, in weight, in painting a car as you would with lead.

5058. But to get the same effect of opaqueness, do you have to use more coats?—No; we just use the same number of coats.

5059. And you get the same effect?—We get the same result practically. We find that the first coat covers very poorly, but when it is applied on its own material the second coat surprises us. It covers very well. We also find that it is a better filler of the grain than lead. One of the reasons, perhaps, why we have knocked the filling off so much is because it fills the grain of the wood up better than lead.

28 April 1911.]

Mr. HARRY ALLEN.

[Continued.]

5060. Is it as easy to apply?—Yes. It needs a special education to apply it efficiently; it is as easy when you get used to it.

5061. Does it require special tools?—No, the same brushes and tools answer: you get an aptness when you get used to it. When you try to apply it in the same way as lead which you have been used to, it does not act as well.

5062. (Mr. Mason.) Judged by the experience of coachmakers, it would appear that this material depends entirely for its life upon the varnish?—They do not use varnish at all in what they use for jointing.

5063. It powders?—Yes, it powders.

5064. Judging from that it will only stand if it is protected by the varnish?—That is my impression. I have seen it tested by exposure to the weather for 12 months alongside a board that was done similarly with lead. It has been tested protected and unprotected, with the result that the unprotected coats have left the board in the case of the substitutes whereas the lead has stood. But when it comes to the coats protected with varnish, the substitute is equal to, if not better than, the lead; because it does not crack and it does not change colour. It does not go as black or as yellow.

5065. How long do you go between the painting of the cars?—That is rather a difficult question to answer, because so many mechanical damages occur to cars that some of them get painted two or three times. They get painted out of their turns.

5066. What do you aim at?—There is an attempt to get them through every two years.

5067. While they are standing at night, I take it, the cars are protected in sheds?—Yes.

5068. And are not exposed to the weather to the same extent as railway carriages?—No.

5069. Have you had cars which last considerably longer than two years?—We have been using the substitute about two years. The condition of some of them that have not had what I call mechanical damage is as good as the lead was. After being subjected to extra soap washing and the varnish gets away, they very soon begin to look shabby. We reckon that a car's life, as far as its appearance goes, is according to the mechanical damage that it receives. A car looks shabby when it gets scratched and kicked and knocked, even where the paint itself is fairly good when it has not been subjected to these mechanical damages, and it has to be repainted. The same mechanical damages will occur under lead as under a substitute, and therefore the life of a car with the substitute is just as long as with lead. It answers the purpose in the double sense that it is not poisonous and there is not the liability attached to it, and as painters we like it better now that we have got used to it.

5070. What system of washing do you use for your cars?—The car washers use a specially manufactured soap, but we have nothing to do with that in the painting department.

5071. Can you give me any idea how often they are washed?—No, I could not. Some cars get dirtier than others. Some roads are dirtier than others.

5072. (Chairman.) Are they washed every other day or every week?—They are supposed to be gone through in some form or another every night.

5073. (Mr. Mason.) I only wanted it approximately. With regard to the mechanical damage, I understand you use white enamel for the uppers?—Yes.

5074. Is that quite satisfactory?—Yes; we get very satisfactory results with enamel.

5075. How many coats of enamel?—Only one, occasionally two on new work.

5076. That would be applied in place of the varnish colour in an ordinary car at the same time?—Yes; we used to use the varnish colour. They like the cars very white, and by using white enamel we get them

whiter than we should with varnish colour. We did use Ripolin for a long while. We are using Noble and Hoare's enamel now.

5077. (Mr. Kinggate.) As you do not use any filling do you give a larger number of coats of paint?—No, we do not, but personally I think we ought to.

5078. Are the jobs really satisfactory from a painter's standpoint?—They are satisfactory for the amount of coats they get.

5079. That is a very qualified answer. Seeing that there is practically no lead left, it seems to me that there must be something more left with regard to this material, or else it would not hide the grain. The first priming coats are practically sandpapered off except the liquid that enters the grain. After the filling they are stoned down, and there is hardly any lead left in the filling. It has simply stopped the pores. There is really no lead left?—No. If you use lead in filling, you must leave the body on.

5080. But I mean in the filling is there as much sandpapering done and as much taken off?—There is middling sandpapering done and middling taken off.

5081. It seems to me from my practical knowledge that it is not possible to make a good job with this method that you adopt?—It is satisfactory for the number of coats it gets. It is not filled up, but it would not be filled up with lead. I say that as a practical painter. The life of a car is supposed to be so long, and it lasts that length of time.

5082. Taking ordinary coachmaking work as a whole, do you know that it is usual to have six coats of filling?—It was, under the old process. Things have been altered and revolutionised very much in the painting trade in my time. We used always to make our own filling at one time, and we thought you could not do a job at all without six coats. Now the manufacturers are supplying enamel filling, and three coats of that are equal to what six coats were. I have used a lot of Mander's enamel filling which I believe is non-poisonous, but I am not sure.

5083. (Mr. Robins.) You were speaking with regard to the covering capacity of zinc white and of white lead. You say that it does not cover quite so well on the first coat but that it covers wonderfully well with the second?—Yes.

5084. Supposing you are painting over an old surface, you, as a painter, will know that very often the underneath surface eats through the first coat if it is wet?—Yes.

5085. Do you find that it will eat through more with lead than with zinc white?—No.

5086. If it does not eat through your substitute, is not that the reason why the second coat covers better than you really think?—No, I do not think so. When I said what I did, I was alluding to new work. In the case of old work, I do not think that anything will strike through a job that has been well matured in the weather and rubbed down. Anything in the way of tar coming in contact with it would have to be killed or it would come through. Here nothing strikes through. I think that it is much more successful when it is applied on its own material. There is a certain amount of greasiness about lead which there is not about this substitute, and that is probably the reason why it does not cover as well. You may be using the substitute much thicker, much more round as we call it, than you would ordinary paint, and yet it will cover very poorly the first coat of new work. You may have sometimes to give it double the number of coats as with lead, but with the second it covers surprisingly well.

5087. What is your standard colour?—White.

5088. With regard to reds and so on, they would eat through white?—Yes.

5089. White would not eat through white?—They would do the same with lead, so there is no preference to be given to lead. If you were painting white with lead it would have the same effect.

The witness withdrew.

28 April 1911.]

Mr. CHRISTOPHER JOHN SPENCER, A.M.I.E.E.

[Continued.]

Mr. CHRISTOPHER JOHN SPENCER, A.M.I.E.E. examined.

5090. (*Chairman*) Are you the general manager of the Bradford Corporation Tramways?—I am.

5091. Have you held that position for some years?—I have.

5092. For how long have you held it?—Since 1898.

5093. What other experience have you had?—I have had 21 years' experience in the operation of electric tramways at Blackpool and South Staffordshire, and at Bradford at the present time. I am a past president of the Municipal Tramways Association of Great Britain and Ireland, which association I think comprises every municipal tramway undertaking in the United Kingdom, and I am an associate member of the Institute of Electrical Engineers.

5094. Can you give us an idea of the magnitude of your tramway undertaking? How many cars do you run, for example?—We have in stock 240 cars. We have about 55 miles of route. We serve a population of 337,000.

5095. Do you use any lead compounds in the painting of your tram-cars?—None whatever. Since the 4th January 1910, we have not used white lead of any description in my department either for the painting of cars or anything else where paint is used. At the present time 120 out of the 240 cars have been painted with the substitute.

5096. Before January 4th, 1910, did you exclusively use white lead for some cars?—We had been experimenting with substitutes for about three years, and we did not want to change until we were quite certain that the substitute was good enough or as good as what we proposed abandoning.

5097. Why did you abandon the use of white lead?—We had a rather serious case of lead poisoning some years ago in our paint shop. A workman somehow got lead into his system and died, and I turned my attention to substitutes to do away with the possibility. Our shop then was fairly well equipped with washing arrangements and so on, but it did not prevent this lamentable fatality. It is only fair to say that we have had some structural alterations since the death of this workman which have improved the washing facilities in the shop, but that is all. I then turned my attention to the use of substitutes in place of white lead. I heard that they were being used on some railways, and that some countries on the Continent were doing without lead in tram-car works, and we started experimenting with various substitutes which were then on the market.

5098. What experiments did you make?—First we experimented with a compound which I think is sold under the trade name of Purex, which seems to be a basic sulphate of lead. We used that instead of white lead, which is a carbonate plus a hydrate of lead. We experimented a great deal with Purex.

5099. Did you get satisfactory results with this material?—No, we did not get very satisfactory results. I hope shortly to be able to show you the result of our experiments with some boards that we have had weathering for some time.

5100. In what sense was it unsatisfactory?—We found that it did not seem to lay very well on the wood. Instead of getting a nice smooth coat, it crumbled and ruffled a little bit.

5101. What other substances did you experiment with?—We have experimented with a good many other substances. They seemed to be, in the main, mixtures of zinc sulphide, zinc oxide and barium sulphate. We have found some of these to be quite satisfactory—all of them more or less—some more than others—and we are informed that they are absolutely non-poisonous. That is on the analyst's reports which I will shortly put in.

5102. Could you give us the trade names of any of these various non-poisonous paints that you have used?—Yes; first Bayer Co.'s "Lithopone." Then we have had material from Docker Bros., known under the trade names of "Galvanised Iron Primer," "White Primer and Filler," and "Premier White Non-poisonous"; then material by Griffiths Bros., known as "White Priming," Noble and Hoare's "White-Filling,"

and "First Coating White," Wilkinson, Heywood & Co.'s "Vulcan White Paint" and "White Filler," and from various firms "Zinc White," which I suppose is just a zinc oxide.

5103. Which of these substitutes have you found to give satisfactory results?—One scarcely wants to advertise any particular ware.

5104. We would rather you did not give names, but would you tell us one or two of them?—One of the mixtures of zinc sulphide and barium sulphate is about the best; in fact it seems to be, if I can judge at all, the base of most of the others mixed up in different ways by the different sellers. As a matter of fact we have now decided almost entirely to use that which we consider best purely and simply.

5105. Do none of them contain any lead compounds at all?—I have here some reports from our city analyst, Mr. F. W. Richardson, and I will hand those in (*handing in the same to the Committee*). He says there that they are non-poisonous.

5106. How do the substitutes for lead paint compare as regards price?—The cost of painting cars with white lead or substitutes is approximately equal. The extra cost per hundredweight of substitute seems to be counterbalanced by its greater bulk for a given weight and consequently greater covering capacity. This statement is to some extent qualified by the fact that, when priming and painting new wood, three coats of substitute may have to be given where two coats of white lead would be sufficient, the substitute not having the same body or opacity. When, however already painted boards have to be dealt with, there is no necessity to use any more of the substitute than white lead.

5107. We have had evidence from a representative of H.M. Office of Works regarding house-painting. He told us that at first the zinc paints supplied require four coats in place of three lead coats, but more recently he has achieved the desired result from two coats of zinc paint in place of the usual three of lead. Would this information lead you to modify your view?—No. I think it is quite possible that with further experiments it may be possible to get the substitute to be as efficient in that direction as white lead, but up to the present, in my experience at any rate (and I can only speak from that) of priming new wood, you must have two coats of the substitute to one coat of lead for the first coat. After that it is the same.

5108. Do you find varnishing always necessary in order to protect your non-poisonous paint and keep it from falling to pieces when exposed?—I do not think that the substitute will stand the weather so well as white lead without a coat of varnish, but with a coat of varnish one is in our experience quite as good as the other.

5109. Generally speaking, you find that the non-poisonous substitute is as cheap as white lead?—Yes.

5110. Do you insist on any standards either of fineness of grinding for your paint pigments or of total weight of solid pigments, in a given quantity of mixed paint?—No. Up to the present we have not got down to specifications. We have simply been buying the materials makers have offered under certain guarantees.

5111. How do the substitutes compare with lead paints in the matter of permanence of colour?—I have some boards here, if you would let me show you them. I think they will show something about that (*producing some boards*). This board here was painted on the 21st December 1909, nearly 18 months ago. It is painted with ordinary white lead paint. There are the first, second, third, and fourth coats. These boards have been weathered. They have been exposed to the south-east and the heat of the sun, and they have been in a position where there is some smell of ammonia. In addition to that about each fortnight they have been washed with soap and water to approximate the conditions that you get on a tram-car. This is white lead. Here is a coat of varnish mixed with the paint. The cracking of the varnish is a fault of the varnish and nothing to do with the paint

28 April 1911.]

Mr. CHRISTOPHER JOHN SPENCER, A.M.I.E.E.

[Continued.]

underneath. *This* is the Purex paint. *This* was put on on the 11th February 1910. *This* is in better condition than the white-lead considerably, but if you look along *there* it does not seem to lie so well as the white lead. The varnished substitutes have stood equally as well. *This* is known as "Griffiths's." Speaking generally, they were put on in the early part of January last year. *This* is one of the absolutely non-poisonous paints. The first coat has perished as compared with *that*. *That* is not so good, and *that* is not so good. When you get the varnish on them they stand quite as well, if anything better, under the varnish, than the original white lead when you get to the top coats. *These* are pure zinc whites. *This* is lithopone, and it is the best that we have yet. It has been on for about 12 months, and it seems to stand quite as well as white lead. The colour is purely a question of the varnish. As I have said, I think that, without varnish, lead is perhaps better. Under a good coat of varnish one is as good as the other, in durability as well as other respects. After considerable experience I have no hesitation in saying that the substitute is equal to the white lead in durability when there is a sufficient protection from the weather by good varnish.

5112. To sum up your evidence it amounts to this: that you to-day use no lead paint whatever, and you have no cause to regret the change?—That is so. We have definitely decided to use nothing but substitutes in the future.

5113. Is there any reason that you know of why other makers of similar vehicles should not abandon the use of lead paints?—I am a tramways manager, and I would rather hesitate to say what may be right for other people. At the same time, for vehicles working under similar conditions to tram-cars, I do not see why they should not do the same.

5114. I ask you as a matter of public policy, taking into consideration the grave evils which ensue from using lead to-day?—There is no reason that I know of why people who are painting other vehicles operating under similar conditions to tram-cars should not do without white lead.

5115. (*Dr. Collis*.) You were working with white lead paints up to January 1910?—Yes.

5116. That is to say, that for 2½ years since lead poisoning was included in the Workmen's Compensation Act, under diseases for which the occupier had to pay, you were working with lead, and had to pay for any illness that occurred from lead?—Yes.

5117. Since January 1910, has there been any difference in the charges that insurance companies have made to you for your workpeople?—We have not insured against workmen's compensation risk. We have taken our own risk, but we have paid nothing in compensation to our workpeople for lead poisoning during that period.

5118. Could you tell us what you paid in compensation during the 2½ years previously?—No, I could not; I have not those figures.

5119. Could you ascertain the figures?—I can tell approximately correctly. The only claim that we have had since we had a paint shop was the death claim of the man who unfortunately died. That cost about 150l.

5120. You have not had any claims for sickness apart from death?—No.

5121. (*Mr. Fell*.) Are the conditions very special in your shop, that is to say the facilities?—The facilities are very good.

5122. The washing arrangements are good?—Yes, very good.

5123. Is all the painting work done in the paint shop, or is it partly done where you prepare your bodies?—All the painting that is done is done in the paint shop. The bodies are all painted there, and anything portable is painted there; but in the case of car trucks, and so on, they are painted in the painting shop or in the running shed sometimes, outside the paint shop. But they have the same washing facilities, it is only fair to say.

5124. Was that case of lead poisoning in your paint shop or body shop?—In our paint shop.

5125. Do you do rubbing down wet or dry?—It is done wet.

5126. In bedding down the canvas on your roofs, do you use this patent substitute?—Yes.

5127. Do you find that you get bad powdering after a short time?—No, I have not found that. Mr. Dawson, my assistant, tells me that we are using this with a mixture of ferric oxide for bedding on the canvas.

5128. To try to make it adhere?—Yes. I have a plate here which may be interesting. It is perhaps rather outside the scope of the inquiry. For stopping purposes we had some trouble with the non-poisonous stuff. It cracked when we used it in stopping up damaged panels, but the makers of lithopone have supplied us with material which does not crack.

5129. Have they taken to mixing it with a different carrier?—I cannot tell you. I have no idea how they have done it, but it is still guaranteed as non-poisonous.

5130. (*Chairman*.) Is it analysed and found to be non-poisonous?—The analyst states, "This is a compound of zinc sulphide and chiefly barium sulphate. It is free from lead and contains nothing injurious to health in the using. It is evidently what it is given out to be by the company."

5131. (*Mr. Fell*.) Do you use this substitute for jointing in connection with bodies?—Yes, along with ferric-oxide.

5132. You find that there is no difficulty from powdering there?—No, I have had no complaints.

5133. Do you use much metal work on your trucks?—We use ferric-oxide paint only. It is a rough cheap paint with no lead at all.

5134. Do you find that, cost per cost, this is about the same?—Approximately the same.

5135. How often do you paint your cars?—About every two years.

5136. That is renovation? Yes, it is renovation when the varnish starts to perish.

5137. You do not really get down to the wood-work?—No.

5138. (*Mr. Mason*.) Can you tell us the cost of labour as compared with material in painting coaches?—My assistant tells me that the cost of labour is about double the cost of the material.

5139. So that with material costing the same, if one had to put on more coats it would increase the cost considerably?—I pointed out that it is only in the case of new wood where it is necessary to use more coats with this than it is with white lead. When we do not do very much new wood painting and our work is almost entirely repainting, we are scarcely affected. Obviously, if we were painting on new vehicles and had to get down to the bottom, a double coat would be more expensive than a single one.

5140. If you had known that the paint used by H.M. Office of Works was composed very largely of varnish mixed with the pigment, that would tend to confirm your opinion that this substitute depends very considerably on the varnish for its life?—Yes, I think it would.

5141. What do you use for cleaning your cars?—Neutral soap.

5142. Plain soap?—Plain neutral soap.

5143. Do you use no acid or alkali cleaners whatever?—No.

5144. You have no experience of that with this form of material?—No. Some years ago we experimented with some of the paint-stuff that is sold by car washers, which seemed to be largely alkali. I abandoned it very quickly, because it was damaging the varnish. Before the substitute and after, we have used nothing else but plain neutral soap.

5145. A man in your position would have knowledge of other people's shops I take it?—Yes.

5146. Is it your experience that in the larger shops the washing accommodation is very poor?—My experience is confined to other tramway shops in the main, and the tramway shops that I have seen—the large tramway concerns that I have seen at any rate—are all under municipal management, and are pretty well equipped as a rule. Municipalities pay pretty good attention to the comfort of their workpeople.

28 April 1911.]

Mr. CHRISTOPHER JOHN SPENCER, A.M.I.E.E.

[Continued.]

5147. Do you find that workmen are apt to get into trouble if they wash their hands during working time or between leaving off one job and going to another?—No, we cannot get the men to wash as they should. That is the trouble. We give them five minutes at the end of each shift to wash their hands, but they take the five minutes and do not like to do the washing.

5148. You would be considerably surprised if you heard a witness say that his experience of large tramway companies was exactly the opposite?—I have no experience of companies. I am only speaking of municipalities.

5149. (*Mr. Kinggate.*) Do you use the usual vehicles and thinners that you do with white lead?—Yes—mostly raw linseed oil.

5150. The mixing is done the same?—Just the same.

5151. You have not experimented with different vehicles or different thinners?—We have experimented with petrol in place of turps, but it is a very small experiment. I would not like to put it forward seriously. (*The witness produced a board.*) There are turps down there and petrol here.

5152. The report of H.M. Office of Works pointed out that the way in which to get over the difficulty with regard to the durability of zinc oxide lay in the vehicle that was used. That report was made after the carrying out of experiments. I do not know whether possibly you might have experimented at all on the vehicle or thinner?—I have not.

5153. You do not know whether that would obviate the perishing which you have pointed out on the boards which have been exposed?—I was speaking to a representative of the Bayer Company some time ago, and I was complaining to him that some material that he had sent along was not quite so satisfactory as it might be, and he was curious to know whether we were using raw or boiled linseed oil for mixing. I told him that we were using raw linseed oil, and he said, "You are using the best. I should not advise any change there."

5154. Several witnesses have pointed out that much of it is with regard to the mixing, and if used as white lead is used it is a failure, but if used with other vehicles and thinners it is generally a success?—My

experience is that the life of a car paint depends on the varnish, and it must be so, I should think, with other vehicles. I do not care what you have underneath, if you do not attend to the varnish you are very soon in queer street. We should keep the varnish right whether we used white lead or substitute, and then we should have no trouble.

5155. (*Chairman.*) Do you say that it does not matter what you have underneath?—Yes.

5156. Is that opinion of yours a very emphatic one?—Yes.

5157. If you had ordinary lead would it fall to pieces in the same way as the non-poisonous paint?—Once the varnish is gone it does not matter what you have underneath, it is not long before you have to repaint the whole job—to get right down to the bare wood.

5158. (*Mr. Kinggate.*) How many coats of varnish do you give a new car?—Two.

5159. (*Mr. Robins.*) With regard to the men washing, do you consider that the habits of the men since you first came into contact with painters in the tramway industry are more cleanly now than they were 11 years ago?—In my experience they are. You may take it that since this case of lead poisoning, and since the men have been threatened with dismissal if they did not wash properly, they have been driven to that position, and now they appreciate it, I think.

5160. (*Chairman.*) Do you provide hot water?—Yes.

5161. And nail-brushes and soap and towels?—Yes.

5162. How many men to a basin?—About three to one basin.

5163. You give them five minutes out of the Corporation's time?—Yes, out of our own time.

5164. (*Mr. Mason.*) What kind of driers do you use for your white uppers?—This is the analyst's report with regard to a sample of patent driers that we are using (*handing the same to the Committee*).

5165. I notice that it contains a small portion of lead oxide—about 4·58 per cent. of lead oxide?—Yes.

5166. (*Chairman.*) That is the percentage of lead in the driers?—Yes.

5167. It would be infinitesimal in the bulk of the paint?—Yes.

The witness withdrew.

## SEVENTH DAY.

Monday, 15th May 1911.

### PRESENT :

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

Lord HENRY BENTINCK, M.P.  
Sir GODFREY BARING, Bart., M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. A. L. C. FELL.

Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.  
E. A. R. WERNER (*Acting Secretary*).

Mr. ERNEST BAILEY (63, Blenheim Gardens, Cricklewood, W.) examined.

5168. (*Chairman.*) You are one of the witnesses selected to give evidence on behalf of the Institute of British Carriage Manufacturers?—Yes.

5169. Are you a carriage manufacturer?—At present I am head muster of a school.

5170. What is the name of the school?—The Polytechnic, Regent Street.

5171. What length of experience have you had in the carriage trade?—About 32 years in the carriage-building trade.

5172. How many men have you had in employment under you?—I have never counted them. At times I have had as many as 16 or 18 going at the same time—all body-makers.

5173. You have been in comparatively a small way of business if you have employed only 16 men?—I have only been an employer indirectly. I have only been a piece-master in the trade.

5174. How many cases of lead poisoning have you known?—None absolutely—not fatal cases. But I

15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

have come across two where they have been ill through it.

5175. Do you know that in the carriage-building industry, taken as a whole, there have been 767 cases of lead poisoning recorded by the Home Office in the 11 years 1900 to 1910?—I was not aware of it.

5176. And that of these 47 were fatal?—I was not aware of it.

5177. There has been no apparent reduction in the rate of attack during that period?—I was not aware of that.

5178. As there has been no reduction in the average number of cases reported each year, I am sure you will recognise that something must be done to remove the evil?—Yes, I should say so, if what you say is correct, certainly.

5179. Do you contend that the risk of lead poisoning arises almost entirely in certain classes of works?—I should say, yes, it does.

5180. Of which class have you the most experience?—The best class.

5181. Of motors or carriages?—Both.

5182. Are you aware that, of 376 cases of lead poisoning reported in the five years from 1905 to 1909, 46 arose from motor-car works?—No, I was not aware of that.

5183. And out of 697 cases reported in the 10 years 1900 to 1909, 297 arose in the ordinary coach and carriage-building works of the country?—I was not aware of any of those.

5184. Have you tried substitutes for white lead in your painting works?—Never.

5185. Do you think it would be possible to prohibit or greatly restrict the use of lead without inflicting a hardship on the industry?—I think if it is done under the present process there should not be any cause for white lead poisoning at all. The old process of dry white lead, which was frequently used, caused a dust to arise, and inhalation, whereas now it is nearly all done by the wet process and there is not that danger.

5186. Then how do you account for the fact that the lead poisoning cases have not been reduced during the last 10 years?—Carelessness and dirtiness on the part of the workmen, and possibly the addition of drink.

5187. Do you want to put that in your evidence?—I should say it was quite possible. The two together would certainly have an effect on the human system—a very material effect.

5188. Do you speak from your own knowledge on that point?—I do.

5189. What is your knowledge on the question of the effect of alcohol on the system with regard to lead poisoning?—My knowledge is that those workmen who are dirty very frequently drink, and I take it that there is the possibility that the two poisons might affect a person far more than the lead would affect an ordinary healthy person.

5190. Are you aware that it has been proved beyond question that some of the men who observe the most cleanly habits are among the most susceptible to lead poisoning?—I should say, then, that they were men who were suffering from some skin disease or something of the sort.

5191. But supposing I told you that they suffered from no such skin disease, and that they were still among the most susceptible people to lead poisoning, what would you say then?—I should say that it was very extraordinary indeed, because I never came across such a thing myself.

5192. You would agree, no doubt, that if a substitute could be found that would be in every way as good as white lead, the use of the latter should be prohibited?—Yes, if it was in every way as good, certainly.

5193. Do you know that for the past six years the Midland Railway Company have used no lead in their carriage and waggon works?—I know that there is a substitute used, but I did not know that they used it.

5194. And that they are entirely satisfied with the results obtained from a mixture of zinc and baryta?—I believe that one of our witnesses will give evidence on that point. I will not touch on that.

u 7790

5195. We have also had similar evidence from the representative of the Bradford Corporation Tramways Department?—I do not know anything about that either.

5196. Are you surprised to hear that?—Yes.

5197. Are you aware that white lead is no longer in use in the Daimler Motor Car Works at Coventry?—No, I was not aware of that.

5198. You still think that white lead is the most perfect substance that can be used?—I do.

5199. How did your work compare with that of, say, the Daimler motor-car bodies?—I should say that there was no difference.

5200. Are they not one of the largest firms in the industry?—I believe so.

5201. They turn out work of the highest finish, do they not?—I cannot say that.

5202. But are not some of the motor cars which they turn out of the highest finish?—They are very good, but I do not say that they are of the highest finish. I should think there are some turned out in London equally as good.

5203-4. Are the buyers of Daimler cars about the same class as the customers of other leading coach-body firms?—Yes, I should say so.

5205. The witness representing the Daimler Company told us that they are entirely satisfied with the substitute that they are using for all purposes for which white lead is commonly used in coach-building works?—Yes.

5206. Are you astonished to hear that?—Yes, I am rather.

5207. The Daimler Company have used no white lead for two years, and they have had no complaints from customers. Are you surprised to hear that?—Yes.

5208. They claim that their paint work is thoroughly durable?—I should doubt that.

5209. If it was not thoroughly durable, do you not think that the customers would complain?—I think they do, very likely.

5210. But we were told that they had no complaints?—I am surprised to hear it.

5211. I repeat, are you surprised to hear that the Daimler Car Company's paint is thoroughly durable, and that their customers make no complaint?—Yes.

5212. They also tell us that it is a little more economical than when they were using white lead?—I am surprised at that, too.

5213. Do not these considerations dispose you to modify your views?—Yes, they do.

5214. If the Daimler Motor Car Company can do without the use of lead in painting their cars, do you think that any great hardship will ensue if this Committee should recommend that any other motor-car people should be prohibited from using lead?—Yes, I do, because, as I say, I feel doubtful still, though I have answered your question, whether there is the finish and the lasting, when it is done with their substitute, that there is in our white lead finish.

5215. But do not you think that the Daimler Company, which is a very large commercial undertaking, would hesitate before they abandoned the use of white lead until they were absolutely certain that it was going to give satisfaction to their customers?—Yes, I should think they would.

5216. Do not you think that the Home Office car take that as a standard, and tell all the other motor-car makers that they must use a similar material?—I think when you have heard the other witnesses you will alter your opinion, too.

5217. It is not my opinion. I am not putting my opinion. I am asking you for yours?—Candidly, I do not believe that there is a better finish than the carriage painted with white lead.

5218. You do not answer the question. What I am trying to get you to admit is this: if it is good enough for the Daimler Company to discontinue the use of lead, and they get a finish that is highly satisfactory to their customers both in appearance and durability, do you think that any hardship would ensue if the Home Office insisted on all motor-car people doing the same thing?—If the finish is good, I should

K

15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

say that there would be no injury whatever, but I have a doubt about that.

5219. Do you contend that the danger of lead painting can be practically eliminated by regulating the various processes?—Yes, I do.

5220. But surely the most simple way would be to prohibit the use of lead?—Unfortunately, I believe, although there are a lot of paints on the market which they say there is no lead in, if you have to paint white on black they would tell you, those very manufacturers, that you must put two or three coats of white lead on to get the white.

5221. But that does not answer the question, if you will excuse me. I asked you whether the simplest form of precaution would not be the abolition of the use of lead?—I could not say.

5222. That is the simplest form of precaution, is it not?—Certainly.

5223. Are you prepared to answer questions regarding the various processes in detail?—Yes, I think so.

5224. First, with regard to the body-maker; he uses jointing paste in putting together the different portions of the woodwork, does he not?—Yes.

5225. What material did you use for jointing paste?—White lead and linseed oil, as a rule, or white lead and gold size.

5226. Is a lead paste generally used for jointing?—Yes. It is the best thing that can be used.

5227. From your point of view?—Yes.

5228. But not from the Daimler Company's point of view?—No, I do not say that.

5229. Where a lead jointing paste is used it must, of course, be attended with danger?—I cannot say that I see where the danger comes in.

5230. For example, in making up the paste, does the worker use dry lead compounds?—No, wet.

5231. In any case, he can hardly avoid the lead paste getting on his hands and clothing, can he?—He would if he was a careful man. There is no reason why he should not prevent it if it is carefully stirred up in mixing. The paste should be quite free from lumps and that sort of thing when it is used. When it is taken out of the tin it should be placed in a fairly large pot, and only sufficient oil should be put in to make it thick enough for his absolute use.

5232. Then, in your opinion, there is no danger at all in mixing?—As I say, I have never come across a case of lead poisoning in all my experience from a body-maker's point of view.

5233. I have told you that there are a very large number of cases?—I admit that.

5234. You have been very lucky, that is all?—I admit that probably I have been fortunate.

5235. You must remember that the Home Office have to deal with the facts which they have before them; and, although you have been immune from any lead-poisoning cases, that does not alter the fact that it is a very terrible evil?—I have used a great quantity myself.

5236. My first question is, whether you think there is any danger from the lead paste getting on the hands and clothing of the workman?—Not, if he carefully washes his hands before meals. That is what I say.

5237. But if he does not do that, then there is danger?—Certainly. He is then eating it.

5238. What special precautions can you take to safeguard the worker in this operation?—Ensure that there is ample lavatory accommodation.

5239. I will ask you further about that later. Why is jointing paste used?—When dry, it simply holds the joint and prevents it moving.

5240. There are a number of leadless jointing pastes in use, are there not?—Yes.

5241. Are those as satisfactory in every respect as lead pastes?—I have tried two, and I have not found one yet.

5242. In what respect are they inferior to lead paste?—They do not seem to keep the wet out. The main object is keeping the wet out of the joint.

5243. And yet the Daimler Company has a formula which is quite satisfactory. How do you account for that?—I cannot account for a thing that I have never

seen. I have never seen any material used, as I have already stated, that I consider as satisfactory as white lead for the purpose. I cannot speak of a thing that I do not know anything about.

5244. But you can speak on the general principle. I bring before you the question of the Daimler Company. I say that the Daimler Company turn out these excellent cars; they satisfy their customers, and they do not use any lead in the jointing?—I think that they are very fortunate.

5245. Do not you think that other people might try to be fortunate too?—Certainly. There is no reason why they should not try it.

5246. You do not seem to have made any experiment with non-lead paste?—I have not with the particular thing they use.

5247. The carriage-maker attaches the ironwork to the wood, does he not?—Yes.

5248. He uses lead in this operation in the same way as the body-maker, does he not?—Yes.

5249. Would what you have said with regard to the jointing of woodwork apply equally to the attaching of ironwork to wood?—Yes; it is the same operation practically.

5250. When the carriage is ready for painting, is it first given priming coats?—Yes.

5251. How many?—Three, as a rule.

5252. Does the priming you use contain lead?—Certainly.

5253. Is the work sandpapered between successive priming coats?—No, we do not sandpaper priming coats.

5254. Can you dispense entirely with rubbing down between the priming coats?—Yes. There is no necessity to rub down between the priming coats at all.

5255. Is it the general practice in coach-painting to sandpaper between the various priming coats?—It used to be. It is not now so much; in fact, it is practically done away with.

5256. What is done instead?—It is rubbed down with pumice-stone and water.

5257. The wet process?—Yes, the wet process. I am talking about after the filling. There is no sandpapering done in the three first coats.

5258. Is this operation generally carried on in the body-making or carriage-making shop?—In the body-painting department.

5259. The body next receives a number of coats of filling, does it not?—Yes.

5260. Is the filling you used a leadless one?—No. There is some lead in it. It is a silicate really—the filling-up is.

5261. Why is lead frequently added to the filling material?—To make it harder and denser and generally better.

5262. The filling is not rubbed down between successive coats?—No.

5263. Then with regard to stopping, what stopping did you use on coach bodies?—That is where so many have the dangerous point. The white-lead stopping is generally made of dry white lead, but this would not, if done properly, cause any injury, because it should be put on between the coats of filling up, so that when it is rubbed down it is rubbing down only on the filling, not on the stopper. Therefore there is no dust.

5264. Is it the general practice to use hard stopping made from dry white lead and gold size?—Yes.

5265. Does the man mix the stopping himself?—Yes.

5266. In the process of mixing there must be danger arising from handling the dry white-lead powder?—That is the only danger. If it is carefully used it need not be dangerous.

5267. What special precautions did you take to safeguard the workers against this danger?—There are none as far as I know.

5268. You admit that there is a danger?—As I say, if you look at it like that, yes, that is the most dangerous part of the whole business.

5269. So far you have made no attempt to cope with that danger?—None at all.

[15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

5270. After the filling and stopping have been applied, a coat of staining is generally added, is it not?—Yes.

5271. What is the purpose of this?—To guide the rubbing down—to see that there is a nice surface. It is a sort of guide to the rubber.

5272. Is the whole surface then rubbed down until the staining has been removed and the flat surface left?—Yes.

5273. Is this always done with pumice-stone and water?—Yes.

5274. The danger in this process is confined, then, to the lead which may have been used in the filling and stopping?—The stopper is really the only dangerous place.

5275. In any case, it is of necessity wet?—Of necessity wet.

5276. The above answers apply to bodies only?—Yes.

5277. The carriage under-work is generally sandpapered, is it not?—Yes.

5278. And the wheels?—Yes.

5279. This sandpapering gives rise to a great deal of dust, does it not?—I believe it does.

5280. Does this dust not contain a large proportion of lead?—It need not. They sandpaper the filling if it is filled up instead of using pumice-stone and water to face it down. They do not sandpaper the actual white lead. There is a small proportion of white lead in the filling, as I have already mentioned.

5281. You have told us that there is lead in the filling?—But you see that there is not a large proportion of lead in it, and therefore I should not think it very dangerous. It is the filling that forms the dust.

5282. There would be some white lead in the dust, which these men might breathe in the process of rubbing down?—There would be some.

5283. A considerable amount of hard stopping is used on the wheels, is it not?—There ought not to be a large amount.

5284. And on the woodwork of the under part of the carriage?—Yes, on the woodwork.

5285. The sandpapering of such surfaces must create a considerable amount of dust?—It does create dust, undoubtedly.

5286. And there is a good deal of lead in the dust?—There is a good deal of lead in it.

5287. That, from our point of view, is an extremely dangerous operation?—Yes.

5288. How is the risk to be overcome?—By using a wet process again; I should say, pumice-stone it down.

5289. Is it possible to use wet methods of rubbing down such work?—Yes, I believe it is.

5290. Would your industry object if it were made compulsory?—Yes, I think they would object.

5291. Why?—From a commercial point of view, I should think it would take too long and it would be too costly.

5292. What would you suggest should be done as a remedy to combat that evil?—I cannot suggest any.

5293. Do you think it is impossible to invent anything to collect the dust? I do not know of any method.

5294. Does what you have said with regard to coach-building apply equally to the manufacture of motor-car bodies?—Yes. There is only one thing about it that I might mention, and that is that in the old carriage bodies we rarely used metal panels; now metal is used very largely for panels, and therefore so much white-lead filling is not required. It is really a very important point, because panels are the largest surfaces that we have to cover.

5295. But you said just now that there is not any particular danger in filling?—No, but there is in the stopper.

5296. You admit there is danger in stopping?—I told you that was the only danger I consider there is, because that is the only place where you use the dry white lead.

5297. Lead is not used in attaching the metal under-work to the body of the motor-car, is it?—No, not to the same extent.

5298. Is it used at all?—I believe so, a little.

5299. Now, in preparing the bonnet, the curved work of the chassis, and other under parts of a motor car, is it not necessary to use a great deal of hard stopping?—No, I do not think so.

5300. Do you know any firms who use hard stopping for these purposes?—I do not.

5301. Did you finish the roofs of your closed cars with canvas?—The outside, yes.

5302. How was that bedded?—Dipped in glue generally, and spread over and pulled very tight.

5303. Is it usual to bed canvas in white lead?—No, I have never seen it done. It has been done for what I call the common vehicles—carts and vans—but not carriages.

5304. Are you aware that the Daimler Company have dispensed with white lead in this us in other processes?—I never used it there.

5305. I will ask you a few more questions about the precautions that must be taken where lead is used. You attach, I understand, considerable importance to personal cleanliness on the part of the men?—I do.

5306. Did you provide washing accommodation?—Certainly.

5307. What proportion of basins to the number of men employed have you known to be provided in your experience?—We did not have basins, you see. We had a utensil, and each one could have that utensil to himself.

5308. What utensil?—A pail. The water was brought up, and they washed their hands before every meal on leaving the premises.

5309. Was hot water as well as cold laid on?—Warm water could always be obtained.

5310. Was it laid on?—Yes, it was laid on.

5311. It was not brought to them in a can?—Yes, it was brought to them in a pail.

5312. Then it was not laid on?—It was laid on, but a boy fetched it. They did not fetch it themselves.

5313. But was it laid on so that the men could go to the trough and wash their hands?—No. It was made hot.

5314. It was brought to them in cans by a boy?—Yes.

5315. Were clean towels supplied regularly?—The men supplied their own towels.

5316. When were they generally cleaned?—Once a week.

5317. How long do you think they remained clean?—I insisted on their being cleaned once a week.

5318. One towel for each man per week?—Yes, one towel.

5319. Did you ever have those towels inspected?—I cannot say that I did.

5320. Do you think that one towel a week for each man is sufficient?—No, I do not. I should say that one towel per week for some men is not enough.

5321. Then why did you only make it a rule to have a clean towel once a week?—Because some of them were not earning as much money as others, and so I insisted on it at least once a week.

5322. Were soap and nail-brushes always available?—Yes, they were.

5323. Who provided the nail-brushes?—I supplied those.

5324. And the soap?—Yes.

5325. Was time allowed to the men for washing before leaving off work and before meals?—No, it was not.

5326. Then if they washed their hands they had to do it out of their own time?—Yes.

5327. Were they not rather apt to scamp the washing in that case?—I do not think they did, but there is that possibility. You see, most of them had their meals at the works.

5328. Was a room provided for the men to take their food in?—Yes; there was a room in the factory to which they could all go for meals. They did not all go.

5329. Was a room always set aside for the men to take their meals in?—Precisely.

5330. Was it warmed in the winter?—Yes.

K 2

15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

5331. Was it provided with suitable tables and chairs?—With tables and chairs all ready for them; and somebody was paid to look after it every week.

5332. Was the room kept cleanly?—Perfectly clean.

5333. Was provision made for the storage of the food brought by the workers, so that it need not be taken into the working room?—The meals were kept in their own bags, and they took them back. They only left the utensils there.

5334. But I want to know, did they ever take their food in the rooms where they were working?—Yes, they did.

5335. Of course that could not be allowed in the future?—No, I suppose not.

5336. Did you provide overalls for your men?—No.

5337. Is not that a necessary precaution?—I have never found it so.

5338. You have been so fortunate in not having any cases of lead poisoning that you have not taken any precautions?—I have not. There was no necessity to take any precautions but those I mentioned. I insisted on their washing before meals.

5339. Did not the men's ordinary clothes get covered with dust?—I never noticed it. If they did they brushed them down.

5340. The very fact of a person brushing down is dangerous?—Just so. Under the circumstances it is.

5341. Had you impervious washable floors in your painting shops?—No, ordinary wooden floors.

5342. Are you aware that in other factories where lead is used the Home Office insist on impervious floors being adopted?—I believe so.

5343. Would your people object to the provision of impervious floors?—I could not say, now that I am out of it; you see.

5344. Were the floors cleaned down wet?—Yes; they were generally sprinkled with either damp sawdust or something of the sort, and then swept up.

5345. What were the usual hours worked by your coach-painters per week?—I think it was 56, but I am not quite sure.

5346. Did they frequently have to work overtime?—I should not say frequently, but they did work overtime, and generally about this season of the year.

5347. Do you know that a very great deal of overtime is worked in certain branches of the trade, such as motor-car body-making?—In motor-car bodies I believe there was a great deal of overtime worked, but I do not think there is so much now.

5348. Would you welcome a strict limitation of the hours of employment, say, to 48 hours per week?—I cannot say that I see the necessity for reducing it.

5349. That has been the limitation recommended in the potteries, and the Home Office may wish to limit the hours of labour to 48 hours in this industry. Do you see any objection to it?—I do not see the necessity for any reduction in the hours.

5350. Did you have a periodical examination of your workers?—No, only when there was an epidemic.

5351. Then how do you know that they never suffered from the ill-effects of lead?—I think the effects are so disastrous to the person that you could not fail to see them.

5352. That is not always the case. Lead poisoning is a most insidious thing and of a slow growth?—But ultimately they are very ill, are they not?

5353. A man may go on absorbing lead in very small doses, and it may take years before it breaks out into a case of lead poisoning, and his general health may be being impaired all the time. How do you know you have never had any cases, if you have not had medical examination?—If that is the case, I do not know.

5354. Do you withdraw your original statement?—I have certainly only known of those cases where they have been ill.

5355. Where there have been marked signs of lead poisoning?—When the doctor has said they have had lead poisoning.

5356. You have never had a doctor to examine all your men?—It is impossible for me to act as a witness at all if I have to say that.

5357. The practice of periodical examination obtains in all important industries where lead is used, except in this industry that you represent and the house-painting industry. You are not aware of that?—No.

5358. Would you welcome a system of periodical medical examination in your industry?—Certainly, if it is necessary.

5359. Together with compensation for any workers who are suspended by the doctor on account of doubtful health?—That is a very awkward question to ask me now, because, you see, at present I am not an employer.

5360. You would rather not answer that?—I would rather not.

5361. Do you realise the very great expense which the industry would have to bear in connection with stringent regulations for lavatories, meal-room and cloak-room accommodation?—I do not think that the mess-room should be a great obstacle.

5362. Also overalls, washable floors, medical examination and the like?—It would pretty nearly ruin the trade, I should think.

5363. To this you must add the cost of compensation whenever a man is withdrawn from work in lead?—Yes.

5364. Also the cost of installing efficient exhaust draught apparatus, wherever it is possible to apply it, for the removal of dust?—Yes.

5365. You must also take into account the cost of setting up a system which will secure continuous observance of all the regulations?—Yes.

5366. You realise, do you not, that the first duty is laid on the employer of securing the observance of the regulations?—Yes. I believe all the regulations, so far as the Factory Acts are concerned, are carried out most religiously.

5367. The factory inspector can only visit at more or less long intervals. Are you prepared to provide the necessary inspection within your own works to secure full observance from day to day and from hour to hour?—The factory inspector was permitted to enter at any moment.

5368. Taking all these points into consideration, do you still consider it would be better to regulate the industry than to prohibit the use of lead?—If what you say is correct, I should certainly say, if we can find a substitute that will do this work, we had better do without lead.

5369. Do not you think that, in view of what I have said about the Daimler Company, it would be possible for you to find a substitute if you tried?—I should certainly like to have some experience of the material before I answered that question.

5370. But would not your experience in the past be sufficient?—No, I do not think it would.

5371. (*Lord Henry Bentinck*). Is the finish on a motor car as high as the finish on horse-drawn vehicles in the old days?—No, not so good.

5372. You admit that the atmosphere is often very dusty?—I admit that it is sometimes.

5373. But you said in the beginning of your evidence that it was only the men who were dirty in their habits who got lead poisoning?—That is so; I said so from my experience.

5374. Is a man who is dirty in his habits more liable to inhale the dust than a man who is clean in his habits?—I have never known of a man suffering from the inhalation of white lead at all, you see.

5375. But that is the way in which it is got?—It is got in other ways as well.

5376. That is a fallacy, I am afraid?—I am afraid it is not.

5377. What is your idea of how it is got?—My opinion is that white lead can be taken in from round the nails, and it can only be taken by eating food with dirty hands covered with white lead.

5378. That is the same as swallowing dust?—Perhaps so.

5379. I do not think it is true that you can get it through the pores of the skin or a cut?—Then why is it that a person who is subject to cuts in the hands and blistering of the hands is more likely to get it than anybody else?

15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

5380. (*Dr. Collis.*) Is he?—Well, I say yes.
5381. (*Chairman.*) You are not stating it as a medical expert?—Might I give an instance?
5382. Certainly?—I have been for 30 years in that trade, using and seeing white lead used every day, and I have not come across more than two cases (both cases of dirty men) of men who were ill from it. I have been teaching now for six years. One of the boys left my school two years ago. I said to him on leaving, "You will have to be very careful with your hands and wash them every day. You have hands that are subject to white lead poisoning." He had not been away for six months before he came back with a poisoned hand.
- (*Lord Henry Bentinck.*) He might have got that from anything.
5383. (*Dr. Collis.*) Was it lead poisoning?—The doctor said it was.
5384. He had a poisoned hand; you do not mean that the poison was in his system?—I do not mean that he had a poisoned hand. He had a festered finger and white lead got into it, and the doctor said he was suffering from white lead poisoning.
5385. (*Lord Henry Bentinck.*) He might have got anything from a festered finger?—That was the doctor's opinion.
5386. How many pupils have you in your school?—Counting the evening class, about 120.
5387. Are they all engaged in the trade?—They must be.
5388. Are none of them affected?—I have not known any to complain. It may be I am not sufficiently expert to know, after what I have been told.
5389. But do they complain?—They do not.
5390. I thought you said they do. They are all healthy boys?—Yes, apparently. They are not all boys. Some of them are men. Some of them are 40 years old, and they come for the purely technical side of it.
5391. Do you use lead paint in the Polytechnic?—Very little; we do not use much. Only once a week we have our painting class, and we do not use lead at all for putting our joints together, because we do not think it necessary.
5392. You do not think it necessary?—Not in teaching them to make joints in our school. Our school joints are not exposed. They do not go out as part of the carriage.
5393. You teach in the school a different practice from that of the shop?—Not at all; we say that the joint must be put together with white lead. We show them how to make it, but we do not use it.
5394. Why not?—Because we do not see the necessity to make a model joint and put white lead in it.
5395. You use no lead?—None at all.
5396. You do not use any substitute?—No. We do not have to keep water out.
5397. (*Sir Godfrey Baring.*) Have you had any experience in using substitutes for white lead in paint?—Only glue instead of white lead.
5398. How, then, can you speak with such authority on no substitute being satisfactory?—Because, of all those I have heard of as being used, I have never known or seen one satisfactory that was under my immediate notice.
5399. Have you seen work painted with substitutes for lead which was unsatisfactory?—I have seen material used which they said there was no white lead in, and it has been unsatisfactory.
5400. You have known in your experience two cases of white lead poisoning?—Yes.
5401. What work were those men engaged in who suffered from white lead poisoning in those two cases?—One was a painter and one was a body-maker.
5402. You said that the leadless paste for jointing was unsatisfactory?—The one I have seen was very unsatisfactory.
5403. Have you tried leadless paint?—I have not tried it, but I saw some.
5404. In what way was it unsatisfactory? Did it let in the moisture?—Yes, it parted and let in the moisture.
5405. In your opinion sandpapering is a dangerous process?—Yes, if it is done to any extent. I should say that is the dangerous part of it.
5406. You cannot suggest any way of meeting the danger of the inhalation of lead dust?—No.
5407. You admit that however clean and careful a workman might be, if he was sandpapering, he could not help inhaling a certain amount of lead dust?—No; I should say it was impossible to prevent inhaling.
5408. No cleanliness or precautions on his part would save him from that danger, you think?—No.
5409. (*Dr. Collis.*) I understand that you are of opinion, with regard to the way in which lead causes poisoning, that it is due to dry compounds?—Yes; it is the dry compounds that I should say were most dangerous.
5410. In the use of paints do you prefer matured paints to new paints?—It is always better, I have understood, to let a paint settle, and not use it at once. A newly mixed paint does not cover so well as when it has settled a little.
5411. How long would you allow paint to mature?—An hour, or something of the kind, would be sufficient.
5412. When you are buying paints you prefer them to be matured longer than that, I believe?—I do not think so. Varnish we do, but not paints. Varnish we like matured, but I have never heard of paint maturing to any extent. There is the necessity for a certain time for saponification in the mixture of the stuff, but that is all.
5413. I have heard differently. I wish to go into a few medical points. Are you aware that an examination of the blood will indicate if a person is exposed to the influence of lead?—Yes, I have been told that.
5414. Are you aware that Professor Baly, of Liverpool, has recently shown that wet paint gives off, at the ordinary temperature of the air, an organic lead compound?—No, I was not aware of that.
5415. You will not be aware, probably, that an individual in a house which has been spring-cleaned and painted this year, one of the inhabitants, was found with blood showing traces of lead absorption, although, naturally, not being a working person, the lady in question had never had anything to do with touching or coming in contact with either the paint or the dust. Taking those matters into consideration, do you think it would ever be possible to safeguard the workpeople against inhaling this volatile lead compound which Professor Baly has shown to exist?—Very likely they would throw up their work altogether if you made them use something of the sort suggested to prevent it.
5416. You have not followed my question. Do you think it would ever be possible to safeguard the workpeople against inhaling this volatile lead compound which Professor Baly has shown to exist?—I suppose it would be possible.
5417. In what way?—I have heard of a helmet being used.
5418. By whom?—I was reading a piece in an art journal the other day where it stated that helmets had been used, but I do not know with what success, and I know nothing about the composition of the helmet.
5419. You have not seen it used?—No, I have not seen it used.
5420. Are you surprised to hear that that was only an experiment, and that it had never been put to practical use?—No, I should not be surprised to hear that.
5421. Is that the only method which you think might be adopted?—Other than doing away with the use of lead altogether.
5422. You have stated that you consider that lead may be absorbed through the skin, have you not?—Yes.
5423. Are you aware that it is the custom with surgeons, when a person sprains his leg or a joint, to dress that sprain or joint mostly with acetate of lead lotion?—No, I did not know what the composition was.
5424. And probably there are hundreds and hundreds of gallons of acetate of lead lotion put on to the limbs

15 May 1911.]

Mr. ERNEST BAILEY.

[Continued.]

of the population of the British Isles daily, and no one has ever seen the slightest sign of lead absorption. Do you think that surgeons would continue to use it if lead could be absorbed through the skin?—I should not think so.

5425. Do not you think that your statement is rather an extraordinary one?—I do not think it is. I am speaking from what I have actually seen.

5426. Have you seen lead going in through the skin?—I have seen a person suffering from that; at any rate, that is what the doctors have said.

5427. I am telling you the opinion of doctors as a doctor myself, sir, and I tell you that lead acetate lotion, the most absorbable salt of lead, is put in hundreds of gallons on people's limbs daily, and no one has ever heard of a case of lead absorption. Do you still maintain your opinion in face of the opinion of the whole medical profession?—Are the whole medical profession of one mind?

5428. They are practically of one mind on this point?—I am glad to hear it.

5429. Otherwise do you think they would continue to put lead lotion on people?—Certainly they would not.

5430. I think that is sufficient. You will allow, then, that the only danger is from dry white lead, that it is not absorbed through the skin, and that it is practically impossible to protect the worker against the danger to which he is exposed?—Yes, I do not see any method by which the ordinary coach-maker can be protected, at any rate if it is only by inhalation and you do not know when he is suffering from it. I am going by the facts put before me.

5431. (*Mr. Fell.*) You are speaking as a coach-maker and not as a painter?—As a coach-maker.

5432. Therefore it is from a coach-maker's point of view that you are approaching the subject?—Certainly.

5433. Were these gangs that you had working under you, where you were working as a piece-master, constantly changing?—Yes.

5434. So that you would not have any particular men under your observation for a very long time?—Yes, I should. Some of them were working with me for 14 or 15 years. They were not all changed, but some of them changed.

5435. You have come across painters to a very considerable extent?—Yes. You know what a workshop is. You see the painters every day, the same as other workmen.

5436. Do not you think that, even with a most careful painter, you would get splashings with a fine spray?—Undoubtedly, I agree.

5437. And that in time would dry and form dust?—I do not know about that. The paint that dries on a carriage does not form dust. If it dries it sticks there.

5438. But if the paint falls on the floor?—It equally dries there, I suppose.

5439. It must get pounded up again into dust, in time?—Possibly in time it does—by being trodden on, you mean, and that sort of thing.

5440. My point was, that if in the majority of cases lead poisoning is caused by this dust it would not depend on the cleanliness of the workmen?—I say that in those cases that I have met where they have suffered from lead poisoning they have been dirty people. That is all I can say. I cannot say that it is the general cause of it—not at all—I simply say that it happens to be so.

5441. I understood you to say just now that you had never used white lead for bedding canvas on high-class coach-work?—No, I never used it. When we used the whole leather on carriages, the stretched hide, it was always a trimmer's paste that was used. That was made principally of flour and alum and several other constituents. That was made into a paste and rubbed on the body where the hide was to cover. When we did away with the leather work we put on a canvas. That was glued on, and no white lead was used at all in it.

5442. Do you know that canvas bedded in white lead is used very extensively at the present time?—In coach-building?

5443. On motor-car work?—All I can say is I have never seen it used. I have known white lead to be used for rough canvas which goes on those covering hoods of vans, and so on.

5444. Have you had any experience of tramcar building?—No.

5445. It is used very extensively in connection with that class of work?—I dare say it is; I have never experienced it.

5446. Have you ever tried to use any substitute for white lead stopping?—No.

5447. You cannot say whether it is satisfactory or not?—No, I cannot.

5448. (*Mr. Kinggate.*) A point you have brought forward several times is with regard to carelessness, dirtiness, and the drinking habits of the workmen. Your experience is somewhat equal to mine. Have not the habits of workmen during the last 30 years materially improved?—Yes, my word, wonderfully.

5449. Is it a fact that the cases of lead poisoning to-day are as many as they were at the time men were drinking so much?—The Chairman tells me so. I am not aware of it.

5450. Do you withdraw the statement that drink is the cause of lead poisoning?—I do not say drink alone. I put the two together, and, with less drink, we ought not to have as much lead poisoning. On the other hand, you must remember that during the last 30 years the use of white lead and the number of persons engaged in the car and carriage trade has much increased, and therefore you are increasing the number of poisoning cases possibly.

5451. You have never tried any substitute whatever?—No.

5452. You have never seen any leadless jointing paste substituted?—I have seen it but not used it.

5453. You know that Cox and Company, of Manchester, one of the largest firms in the trade, do not use white lead in the jointing?—So I am told.

5454. For many years they have not, and they find it perfectly satisfactory?—Do they?

5455. With regard to the finish of ——— cars in the last exhibition that was held here, you will admit that the finish was as good as anything in the show?—I saw nothing particularly brilliant about theirs, but I did not study them and compare them with others.

5456. They appeared quite equal to the others?—To the ordinary passer-by I should say they were.

5457. Now, what has led to do with the finish of a car?—It has more to do with the ground-work than finishing.

5458. You said that you did not think it was possible to finish a car without lead?—Just so, because the ground-work is the basis on which the other coats come, and a bad ground will give a bad finish. A good ground will give a good finish.

5459. What is the object of using lead in the first place in painting?—Because we have never found anything better.

5460. But what is the object of the lead—not whether it is good or bad?—For one thing, it preserves, and we have found no better substitute for it.

5461. That does not answer the question. I want to know what is lead used for. First of all, is it not used with the main object of filling up the grain?—Yes.

5462. If something could be found to fill up the grain equal to lead, should not that be used?—Yes, if it will do so as well.

5463. We have found this with regard to the Daimler, because we have had before us a man who, I might almost say, tumbled across an invention or system of doing his work—a very excellent painter, one of the best we have in the country, and I have known him many years, and I have had a considerable amount of painting experience—he has found out a very simple matter which fills and closes up the grain equally with lead, and the finish is obviously quite equal to-day to that of any other car in England. Now, with regard to

15 May 1911.]

MR. ERNEST BAILEY.

[Continued.]

body-makers, you said that if they were very careful there was no occasion to get lead on the hands?—Yes.

5464. It is impossible to put plates on without getting lead on the hands?—Yes, that is right.

5465. Now, I can hardly agree with you, with regard to keeping water out of the joints, that lead is for that purpose. If water got to where the joint is, what would the effect be on the coach?—That is just it.

5466. But you never find a body where the joint gets exposed to water like that. I am speaking as a practical man. The joint must be covered?—Certainly.

5467. When once the paint gets off so that the water can get to the joint, what condition must the vehicle be in?—But what happens if the joint gives, and then the paint cracks and so lets the water in?

5468. If the joint is properly fixed it is a very rare thing indeed?—That is not my experience.

5469. The vibration will ultimately move it a bit, but the white lead is more for the purpose of keeping the joints together than for keeping the water out?—We used to build our carriages 12 months before they ever went out of the shop in the old-fashioned carriage-making. The motor car goes out in a few weeks. In the old carriage works you rarely saw the joint, but with the present motor car, however well built, you see the joints.

5470. That is mainly because of the way in which it is constructed?—In the old days the white lead had time to get set. In the present case it has never set, and the joints open.

5471. (*Lord Henry Bentinck.*) Then there is very little use in putting in white lead?—That is true, but if the joint was given a fair chance it never would open.

5472. (*Mr. Kinggate.*) It is not a question of water getting to it that causes it to shift?—No.

5473. How long has sandpapering been left off between the coats?—I never saw a priming coat sandpapered at all. What is the good of sandpapering when you put half-a-dozen other coats on?

5474. You always sandpaper to take the rough off?—I have never seen it done.

5475. That is my experience of 35 years. Any painter will tell you it is the practice. It may not be so far as your knowledge is concerned?—I have never seen it done.

5476. With regard to gluing canvas on the roof, I have never heard of it. It may be put on with japan, but not with glue. You know how susceptible glue is to wet and damp?—It does sound rather peculiar, but we have made a very great success of it. Every bit of the canvas must be saturated with glue, otherwise, on the first hot day, up comes a blister.

5477. It is put on in many cases with lead in tram-car work and motor-car work?—I believe so.

5478. With regard to lavatory and washing accommodation, I know that your experience with the firm you were with is exceptional. Do you know another firm in London that has had such an experience in the years you were in the trade; I do not mean the last year or two?—My services were so wanted there that I never had much opportunity of going to other firms in London at that time.

5479. The firm in which you were employed had a room in which the men could have their meals, but I know of no other shop in London that allowed that, or even washing accommodation. The Committee may think from your statement that it is general, but it is not so. Now, with regard to sandpapering?—I maintain that that is due to the bad finish of previous work.

5480. Instead of putting on a number of coats some spokes have a good deal of sap in, and they plaster them over with dry white lead, then it is sandpapered?—Yes.

5481. (*Mr. Robins.*) I have been a painter for 30 years up and down the country, and I can truly say that within the last 15 to 20 years the painter has become much cleaner and much soberer in his habits than ever he was. I should like to ask you how it is, considering these better conditions amongst the working classes, these cases have not been decreased. It is known to me that there are all these cases which have been stated. I fully agree with you that the ordinary working man works under very much better conditions and he is a better man than he was 30 years ago?—I am quite willing to admit that. I see every evidence of it.

5482. I believe you said in your evidence that you had about 16 body-makers in your employ when you were a piece-master?—Yes.

5483. Much of your time would be taken up, naturally, as a piece-master with those men?—Yes.

5484. I should think that you had very little opportunity to study the theory or the practical part of painting?—That was largely done during my apprenticeship.

5485. I may take it that the conditions of the paint shop to-day are very far different from what they were when you were apprenticed, which would be much the same time that I was apprenticed?—Very different indeed.

5486. Now, you said that some of the men worked for short periods and some for long periods with you. Would there be many changes, or would most of them work for long periods?—I had about four that were with me from 6 to 12 years.

5487. You spoke about the wheels being filled up. Thirty years ago or more the wheels were filled up, and only the bed and so on of the carriages were rubbed down. You know it would be impossible to rub wheels down in the spokes with stone?—Unless it was shaped.

5488. It would be a most expensive process, and never could be accomplished. With regard to wheels, they would have two coats of lead colour?—Yes.

5489. Between each of those coats they would be sandpapered?—It is done sometimes with wheels, I know. I was referring to bodies when I said there was no necessity to sandpaper down between the priming coats.

5490. Your experience is very different from mine. In nine cases out of ten a body receives it, and it is beneficial. There may be burr or grain or what not on the wood that should be removed, and in nine cases out of ten in my own experience sandpapering is done between coats?—Is it?

5491. Now, with regard to stopping on wheels, is it mostly done with sandpaper?—Yes.

5492. We are glad to think that is a practice that is going to be discontinued?—Yes.

5493. You admit that there is great danger from sandpaper stopping?—I do. I consider that that is the greatest danger.

5494. You mentioned a matter with regard to metal panels. You said in your evidence that they did not require as many coats as wood did in the olden times?—Yes.

5495. I certainly disagree with you, because from practical experience I find that the beaten panels of a motor car require more filling and more stopping, which is highly dangerous when done with white lead, than the ordinary carriage, on account of the panels being hammered?—I know a lot of painters who paint aluminium panels and never put any filling at all.

5496. Should you be surprised to know that there are more steel-beaten panels used now than aluminium?—I admit that.

5497. It is the steel panels I principally refer to, and those are principally in use to-day. It requires more white lead stopping on the beaten panel than there ever was on the wood panel that was made in the olden times?—I follow.

The witness withdrew.

K 4

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

Mr F. A. MAYTHORN (Biggleswade) examined.

5498. (*Chairman.*) You are attending to-day as President of the Institute of British Carriage Manufacturers?—That is so.

5499. What is your business?—I am a carriage-builder and motor-car body-builder.

5500. What length of experience have you had?—My father was a carriage-maker before me. I went into business with him immediately on leaving school, with the exception of a short time when I went to town and was apprenticed to heraldic painting.

5501. How many men do you employ?—About 150 at the present time.

5502. How many cases of lead poisoning have you known?—None at all.

5503. Have you consulted the doctors practising in your town with regard to lead poisoning?—I have letters from four of them here, the whole of the doctors practising in the town, and they have not had a case in the last 10 years. I did not ask them to go farther back than that.

5504. To what do you attribute this gratifying immunity at your works?—Principally to general cleanliness and the system of painting which we employ.

5505. Does your firm use less lead in the priming processes than some carriage-builders do?—I think so.

5506. Are your men continually sponging the surfaces and washing their sponges in pails of water, so that very little falls on the floor?—That is so. Rubbing down is done with block pumice-stone. Rubbing down the surface we call filling-up. There are about six coats which are put on over priming coats, and when that is hard we put on a guide coat of black—a staining coat. The object of the black is that wherever that is seen it must be hollow, and must require rubbing till it is all gone. The man keeps washing off with a sponge in order that he may see where the black is left. The pumice dust and the rubbed-off filling-up go into his pail to such an extent that our drains get choked. We have to take them up and regularly dig them out sometimes.

5507. Do you do any rubbing down between the priming coats?—No, they are not rubbed down.

5508. I am very glad to hear of such an excellent record as you have just given us of immunity from lead poisoning, but I am not surprised. You are doubtless aware that in the Potteries there are a very large number of works which have been immune for many years?—I do not know much about the work in the Potteries.

5509. You see, the trouble is that even some of the very best works are not immune. A great number of works that have been free from lead poisoning for many years will sometimes have a succession of cases quite unexpectedly?—I understand what you mean.

5510. It is no test because you are immune?—I quite understand. I put it down to some extent to good fortune, but I do not think it is entirely that, because we use very little lead.

5511. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—As far as I know, we have not any special clause put in on that account.

5512. Do you know that, in the carriage-building trade, taken as a whole, there have been 787 cases of lead poisoning recorded at the Home Office in the 11 years from 1900 to 1910?—I did not know it until I read of it recently.

5513. And of these 47 were fatal cases?—Is that 47 fatal cases amongst carriage-builders?

5514. Yes?—I was not aware of it.

5515. It includes the whole of the carriage-building industry. There has been no apparent reduction in the rate of attack during that period; that is to say, on the average of eight years, 1900 to 1907 inclusive, there were 661 cases annually. In 1908 there were 70 cases; in 1909, 95 cases; and in 1910, 70 cases. As there has been no reduction in the average number

of cases reported each year, I am sure you will recognise that something must be done to remove the evil?—I quite agree that it is a very serious thing, and we are desirous that our men should work under the most favourable conditions; but my feeling is that we, who subject our men to much less risk than many coach-builders or people classified with us may subject their men to, will suffer to some extent by any restrictive measures which are made. If it simply means a matter of extra cleanliness, we being already fairly clean, it will not make much difference to us or to our men, but if I might mention it, I should deprecate the use of anything like a helmet to prevent inhalation.

5516. My question to you was this: I am sure you recognise that the Home Office must do something to remove this evil?—Certainly.

5517. Now, do you contend that the risk of lead poisoning arises almost entirely in certain classes of works?—Yes, I should think so.

5518. Of which class have you the most experience?—I should think of my own class of work, coach-painting. I do not think I follow what distinction you mean to draw. You are speaking only of coach-painting, I take it.

5519. Yes. Are you aware, that of 376 cases reported in the last five years, 1905 to 1909, 46 arose in motor-car works?—I was not aware of it. Do you mean motor-car works or motor-body building works? We make a difference, you see; there are motor-car works where they make their own bodies, but we coach-makers do not make the chassis.

5520. I mean, by motor-car works, works where they make the various parts of a motorcar?—In the engineering part lead would be used in very much greater proportions than by the coach-builder. We have the chassis and we put the bodies on them. Then there are motor-car builders who have a coach-building department. You would have to take a tremendous lot in to take the whole of those works in. There would be men there who are using lead who would never be classified as painters.

5521. The cases I am putting to you are only cases that have arisen when painting motor-car bodies in motor-car works?—Very good, I only wanted to understand.

5522. Out of 697 cases reported in the last 10 years, 1900 to 1909, 297 arose in the ordinary coach and carriage-building works of the country. Have you tried substitutes for white lead in your painting works?—No, not direct substitutes. We have used a great deal less in our mixtures, but we have not tried to exclude the use of white lead entirely, and we have not used any of the so-called substitutes.

5523. Do you think that it would be possible to prohibit or greatly restrict the use of lead without inflicting a hardship on the industry?—I think it would. In many cases I think a substitute could be found. The only difficulty, I think, is as to the permanency of it. That we have not been able to test at present.

5524. The durability?—The durability.

5525. You would, no doubt, agree that if a substitute could be found which was as good as white lead the use of white lead should be prohibited?—There are so many purposes for which lead is used. We might find a substitute perfectly satisfactory in one place for one object, but for another it might be unsuccessful.

5526. But I say, if a substitute could be found which would be as good as white lead the use of lead should be prohibited?—If I could find a non-poisonous substitute as good as white lead I would use it in preference.

5527. Do you know that for the past six years the Midland Railway Company have used no lead in their carriage and wagon works?—I did not know that.

5528. And that they are entirely satisfied with the results obtained by a mixture of zinc and baryta?—I did not know that.

5529. We have also had similar evidence from the representatives of the Bradford Corporation Tramways

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

Department. Are you aware of that?—I was not aware of that.

5530. Are you aware that white lead is no longer in use at the Daimler motor-car works in Coventry?—I do know that; I have heard it.

5531. Do you still hold that white lead is the most perfect substance that can be used?—For some purposes I certainly think that no substitute has been found.

5532. In your experience, how does the general work of motor-car companies compare with Daimler motor-car bodies?—In point of quality of work, do you mean?

5533. As regards both quality and durability?—Durability I cannot speak about.

5534. Then as to quality only?—For quality Daimler work is quite all right.

5535. As good as anybody else's?—I think so.

5536. The Daimler are, in fact, one of the largest firms in the industry, are they not?—Undoubtedly.

5537. And I suppose that they turn out work of the highest finish?—Yes, I think that I may say that.

5538. I suppose that the buyers of Daimler cars are of about the same class as the customers of your own or other leading coach-body firms?—Certainly.

5539. And they would demand the same finish, would they not?—I have seen Daimler cars in the show alongside my own, and they have been beautifully finished, but I cannot say what happens otherwise.

5540. The witnesses representing the Daimler Company told us that they were entirely satisfied with the substitute that they were using for all purposes for which white lead is commonly used in coach-building works. I want you to realise this point—that the Daimler Company have used no white lead for two years, and that they say that they have had no complaints from customers?—I follow.

5541. They claim that their paint work is thoroughly durable?—Yes.

5542. And that it is, in fact, a little more economical than when they were using white lead?—I quite believe that.

5543. Do not these considerations dispose you to modify your views at all?—No, I am afraid not, on certain points. That is a big ground to cover.

5544. But surely, if the Home Office have evidence of a company like the Daimler, who say, "We have done without white lead. We find it cheaper to work without it, and that the work is as durable, and we produce just as good a finish," do you not think that the Home Office will think that, if a firm like that can do without white lead, you must do without it?—If you say that we must, we must. As I said on another occasion, if it is a matter of using a helmet, I shall not use white lead.

5545. We are sitting here, as a Departmental Committee of the Home Office, to inquire into lead poisoning in this industry?—Quite so.

5546. When we report to the Home Office and tell them that an important firm like the Daimler have been doing without white lead for two years, and that in every respect they, themselves, and their customers are satisfied, do you not think that the Home Office might reasonably say to other people, "You must do without it, too"?—I went the other day to the Building Trades Exhibition, where a large number of motor-cars and paints, and so on, were being exhibited. A great number of firms were exhibiting very beautiful white enamels, and I was particularly attracted to one. The surface was very lovely. I asked, "How many coats have you put on that?" and the answer was, "We have put one coat of filling-up stuff on the wood, two coats of matt, as you see over there, and one of enamel." I said, "That is zinc." "Yes, there is no lead in it." If we could get, without lead, a surface like that which I saw it would be pounds and pounds in our pockets. I went into the stand to look at the matt. I said, "Do tell me candidly, if I have a black surface to cover, how many coats would it take to make a surface as white as this?" The answer was, "I should put on two or three coats of lead first." I said, "That does me, because I want to be able to say I have

"not used any lead." Lead is more opaque than any other white. I think that must be granted.

5547. If all the firms were in the same position there would be no hardship, would there? You have not quite answered the question. We have the evidence of the Daimler Company, the Midland Railway Company, and the Bradford Corporation Tramways Department. The Home Office will naturally ask, "If these people can do without white lead, why should not others be made to"?—Are you sure that, in excluding lead and getting a substitute, you will not get a worse poison?

5548. Will you, please, deal with my point first?—Lead and zinc are the principal whites.

5549. But will you answer my question?—I could not admit that the Daimler are better judges than I am; if you ask me to admit that, I cannot.

5550. If Parliament, the supreme authority, and the Home Secretary have the evidence of firms like the Daimler, who have proved beyond question to us that the disuse of lead by them has had no ill-effects, but that, on the contrary, they have satisfied their customers entirely, do you not think that they will be justified in telling other motor-car makers that they must abandon its use?—No; because two years' life with regard to a carriage is nothing.

5551. How often is a motor-car repainted?—It ought to be varnished once a year, or twice, perhaps. It need not be fundamentally repainted.

5552. If Daimler motor cars last for two years without showing any ill-effects, is not that a sufficient test?—I do not think so.

5553. Not if motor cars are usually painted or varnished once a year?—The foundation might go entirely wrong. We have had a car come in, and we have faced it down to the filling and repainted it, and had to take it all off to the wood.

5554. What period of test do you consider sufficient before you would agree that the Daimler formula is satisfactory?—Well, you see, ours is an ancient craft.

5555. (Mr. Kinggate.) You are conservative?—I quite agree that we are conservative. I should say that 10 years would be a much more satisfactory period.

5556. (Chairman.) I want you to be reasonable?—I hope to be reasonable.

5557. You would not like it to be put in your evidence, as the opinion of the president of this very important association, in answer to my question, that a reasonable period of test would be 10 years, would you, when no motor car will ever last for more than three or four years?—The cars may not, but the bodies will. Our carriages had to last for 30 or 40 years.

5558. I do not want to press you unduly. You maintain that a proper test would be 10 years?—Yes, I think so.

5559. That answer will be put in your evidence and made public?—I am quite agreeable to that.

5560. Do you contend that the danger of lead-poisoning can be practically eliminated by regulating the various processes?—I think so. I contend that there is no danger if the work is carried on properly.

5561. (Chairman.) Have you, as a society, taken any steps to test the merits of the different substitutes on the market?—No.

5562. Or to institute any inquiry as to the precautions which are necessary to combat the evil that exists in many branches of the industry?—Not so far as I know.

5563. Now, first, with regard to the body maker, he uses jointing paste in putting together the different portions of the woodwork, does he not?—Yes, he uses white lead.

5564. Is a lead paste generally used in jointing?—Yes.

5565. Where a lead jointing paste is used it must, of course, be attended with danger?—I was not aware of it.

5566. For example, in making up the paste does not the worker use dry lead compounds?—No. The compound is a thick white lead paste. It is white lead ground in oil. What we call tub-lead is ground in oil,

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

and we mix oil and gold-size with it to make it set. It liquefies a little bit.

5567. Is he not exposed to the danger of poisonous dust?—There is no dust at all.

5568. Whatever the form of jointing paste that you use, must the worker not get it on his hands and clothing?—On his hands occasionally.

5569. What special precautions can you take to safeguard the worker in this operation?—We can only give him every opportunity of keeping himself clean.

5570. Why is jointing paste used?—To prevent the possibility of moisture getting into the joints.

5571. There are a number of leadless jointing pastes in use, are there not?—I have heard of one coach-maker, one of our members, who is using a substitute. He told me that for this purpose he was using yellow ochre and oil, or something of the kind.

5572. Does he say that is satisfactory?—Yes, I believe so.

5573. The Daimler people say that their leadless paste is satisfactory?—I do not know what they use. The gentleman to whom I refer uses oil or varnish, or some medium and yellow ochre. That is an earth and perfectly non-poisonous.

5574. The carriage-maker attaches the ironwork to the wood, does he not?—Yes.

5575. Does he use lead in this operation in the same way as the body-maker?—Yes, the work is bedded in lead.

5576. Does all that you have said with regard to the jointing of woodwork apply equally to the attaching of ironwork to wood?—Yes.

5577. When the carriage is ready for painting, is it first given priming coats?—In our case it is. We rub it over with a preparation first—a wood filler.

5578. How many coats?—We give it two coats of wood filler. That is a thing which we buy. I believe it to be plaster of Paris and oil. It is all rubbed off and you could not tell that anything had been done.

5579. Does the priming which you use contain lead?—A certain proportion of lead is used. It is not pure lead. There is no lead in the first process that I was describing.

5580. Is the work sandpapered between successive priming coats?—No; not after the application of the priming containing lead.

5581. Is it the general practice in coach-painting to sandpaper between the various priming coats?—It is not our practice.

5582. Is it the practice in other works?—I should not think so.

5583. The body next receives a number of coats of filling, does it not?—Yes.

5584. Do you use a leadless filling?—No, not leadless. It contains a very small proportion of lead.

5585. Why is lead frequently added to the filling material?—Partly to bind it.

5586. Is it absolutely essential to use lead in the filling?—I do not know that it is absolutely essential.

5587. Would you agree on behalf of your institute to have it prohibited?—No, I could not do that. I have not at present used any substitute, but I think that lead might be done away with.

5588. The filling is not rubbed down between successive coats, is it?—No.

5589. What stopping do you use on coach bodies?—Generally white lead.

5590. Is it the general practice to use hard stopping made from dry white lead and gold-size?—I think so.

5591. Does the man mix the stopping himself?—Yes, as a rule.

5592. In the process of mixing there must be danger arising from handling the dry white lead powder?—I think not. I was half a mind to bring a sample of lead with me, but I thought that you might have plenty of samples here. Lead is such a very heavy powder that I believe that pulverised white lead would hardly be blown about. I do not think that any powder would arise in the mixing of white lead, or that any inhalation would occur then.

5593. Would you explain to the Committee why, in your opinion, there is no danger in this process of stopping?—The material is only used in very small

quantities at a time. A little is taken on a palette with the medium. The medium is usually gold-size. I do not think that much dust occurs.

5594. Other witnesses have told us that there is danger?—If it were dealt with in large quantities there might be danger from handling, but there is a very small quantity on the palette and palette knife, and I do not think there would be any danger.

5595. After the filling and stopping have been applied, a coat of staining is generally added, is it not?—Yes, but in our case the stopper goes on before the filling-up. We have six coats of filling on the top of our stopper, and it is a very, very rare thing for the lead to show through anywhere. If it is left very bold it sometimes does occur that a little white patch comes through.

5596. Is the whole surface then rubbed down until the staining has been removed and the flat surface left?—Yes.

5597. Is this always done with pumice-stone and water?—Yes, it is always done with pumice-stone and water.

5598. The danger in this process is confined, then, to the lead which may have been used in the filling and stopping?—Yes.

5599. What you have told us applies to bodies only?—Yes.

5600. The carriage underwork is generally sandpapered, I believe?—It is.

5601. And the wheels?—The wheels are sandpapered. We treat the broad parts of the chassis in the same way as the body, but the wheels we lead-colour, or prime them with partly lead-colour.

5602. This sandpapering gives rise to a great deal of dust, does it not?—I contend that it does not. The pigment does not dry hard enough, or quickly enough, to make a dust. The result of sandpapering paint as mixed by us, or most people, would be that a very, very fine curl would occur. I do not think anything can possibly arise so as to be inhaled.

5603. In regard to some of these operations there is much difference of opinion?—It is elastic, like rubber, and will cling together. The sandpaper cuts it into little ribbons, and there is not an atom of dust.

5604. It creates a certain amount of dust, does it not?—Very little.

5605. The dust contains a large proportion of lead?—It would be half and half.

5606. A considerable amount of hard stopping is used on the wheels, I suppose?—No, not much.

5607. On the woodwork of the under part of the carriage?—No, not much.

5608. Is sandpapering used in this process?—Yes.

5609. Must that not be rather dangerous?—I can only speak from experience. I do not think there is any danger.

5610. Is there not a considerable amount of dust?—No; and what dust there is falls immediately on the ground. It does not rise. If this room were sandpapered, immediately there would be a line of white on the ground. The dust falls vertically.

5611. I suppose that the dust must fall on the workmen's clothes?—I do not think it does, as a rule.

5612. But you cannot have dust around you without some of it clinging to your clothes?—I say that it falls vertically. It does not rise.

5613. You would get dust on the lower part of the body?—A man does not have his legs under his work. He does not sit down and work at it. He stands like *this* (demonstrating).

5614. Do you affirm that there is no danger whatever in the process?—I reply that there is no danger.

5615. Is it possible to use wet methods of rubbing down such work?—Not the under parts.

5616. Why?—Pumice-stone is not flexible. You could not very well rub down intricate work with pumice-stone.

5617. So that if there is any danger in this process you can suggest no remedy to combat it?—No.

5618. Would it be possible on curved surfaces to use a wet method of rubbing down?—It was the small

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

curved surface that I was thinking of; the wet method would be difficult there.

5619. Is it practicable to apply a local exhaust draught generally to remove the dust in this process?—I suppose that it would be practicable where anyone had sufficient power for the apparatus, but in many cases the coachmaker would have to put up the power to get the exhaust.

5620. In all other industries where lead is used and where dust is generated, the Home Office have insisted hitherto on exhaust fans being introduced to remove the dust. Do you think that that would be a regulation which your Institute would welcome?—I think that it would simply close down a great many factories.

5621. Why?—Because they would have no chance of getting an exhaust fan. The small coach painter could not afford an engine to run a fan or luxuries like electric power.

5622. I am only telling you the system that obtains in other industries where the use of lead is permitted and where dust is generated. In those cases the Home Office insist that there shall be an exhaust draught apparatus to remove the dust?—I understood you to ask me whether I recommended it. I could not on behalf of my Institute.

5623. I will ask you, do you think it possible to introduce such a system of exhaust ventilation?—Of course I know that, as an engineering problem, it is quite easy to put up exhaust apparatus to get rid of dust.

5624. But you think that the cost would be prohibitive?—Yes, in nine cases out of ten it would be prohibitive in the case of the coach-painter.

5625. Now, with regard to finishing coats. After the filling has been rubbed down, the body gets about two coats of lead colour, I believe?—Yes.

5626. Are these faced with pumice stone and water as a rule?—Yes.

5627. Are they ever sand-papered lightly?—They might be, but not with us.

5628. Is the work then ready to receive its finishing colour and be varnished?—Yes.

5629. Is it, in your opinion, possible to dispense with all sand-papering in the final stages of the body work?—Yes; in fact you could not use sand-paper in the final stages, I think.

5630. Now, as to motor-car work. Does all that you have said with regard to coachbuilding apply equally to the manufacture of motor-car bodies?—Certainly.

5631. But lead is not used in attaching the metal underwork to the body of a motor-car, is it?—No, we usually use japan.

5632. Lead is not generally used?—No, not between the chassis frame and the body.

5633. Then, if it is not generally used in connection with motor-car body-work, why cannot it also be dispensed with in ordinary carriage work?—We never try to hide the joints between the body and the chassis frame, but in the case of what you were speaking of before, what we call the under-carriage, where a piece of thin wood has a top and bottom covering of iron, when that is properly painted you could never tell iron from wood. It looks all one piece. I think that practical gentlemen would agree with me there. But in regard to the chassis, when the body goes on the frame there is a hard and fast line which we never seek to hide.

5634. In preparing the bonnet, the curved work of the chassis and other under-parts of a motor-car, is it not necessary to use a great deal of hard-stopping?—No. We do not put much stopper on it. It would not do to put much on the bonnet.

5635. Wherever hard-stopping is used on such surfaces, it is usually sand-papered, is it not?—Yes, I believe such surfaces would be.

5636. Could all this sand-papering be dispensed with by doing more facing with pumice stone and water?—Yes, I think so.

5637. And in some cases by substituting stove enamelling?—I do not think the stopping would be effected by stove enamelling at all—in fact, I doubt if you would be able to do stove enamelling over stopper.

5638. No, but instead of it?—It is in substitution. Stove enamelling is excellent, but it is putting enamel directly on to iron. If you had softer materials in between, there would be trouble.

5639. Would you go so far as to advocate the prohibition of all dry rubbing down in this process?—I am perfectly prepared to do that.

5640. Do you finish the roofs of your closed cars with canvas, or some similar material?—Yes.

5641. How is that bedded?—It is usually bedded with japan and varnish.

5642. Is it not usual to bed canvas in white lead?—I do not think so, but I do not know. We do not do it.

5643. Have you anything to tell us with regard to railway or tramcar work?—No, I do not know anything about them.

5644. Now, I will come to a few precautions which I think the Home Office might wish to introduce into this industry if lead is permitted to be used in the future. You attach a good deal of importance to personal cleanliness on the part of the men?—Yes.

5645. Do you provide washing accommodation?—Yes.

5646. What proportion of basins to the number of men employed do you advocate?—About one to five.

5647. Is hot water as well as cold laid on?—No, not with us. They can get it, but it is not laid on.

5648. Do you think that it is imperative that hot water should be laid on?—I do not think so.

5649. Do you not think that it is important that hot water should be available for the men?—Yes, I think that it ought to be available.

5650. Are clean towels supplied regularly?—Yes.

5651. How often?—I think twice a week, but I do not remember. The storekeeper has that in hand, and I have not thought about it.

5652. I suppose that you would agree that it is very important that they should have clean towels at frequent intervals?—Certainly. One man is in charge of the soap and towels and nail brushes and everything.

5653. The Home Office regulates the supply of towels to workmen in other industries?—It does with us.

5654. Are soap and nail brushes always available?—Yes.

5655. Have you any system by which the soap and nail brushes are watched and cared for?—One man has charge of the whole business of replacing them when necessary.

5656. Are the nail brushes sufficiently good to enable the men to clean their nails with them?—I think so.

5657. Is that carefully looked into by your people?—Yes, I believe so.

5658. Is time allowed to the men for washing before leaving off work and before meals?—Yes.

5659. How much time?—I forget how long; I think five minutes.

5660. Is that allowed out of the employers' time?—Yes.

5661. Is a room provided for the men to take their food in?—No. They go home for all their meals except that when working overtime they stop and have tea. The painters are not allowed to eat anything in the paint-shop. They usually retire into the trimming shop next door.

5662. Are any of your men allowed to have their meals in rooms where lead is used?—No.

5663. Is provision made for storage of food brought by the workmen so that it need not be taken into the working room?—No.

5664. Where do they take their food when they bring it with them in the morning?—The only food taken in the place is tea, when men are working overtime. Their children bring it at six o'clock, and when the bell rings the men sit down, and then the children take the things away.

5665. Where do they have tea?—In the shop.

5666. Where they are working?—Yes.

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

5667. Then they do take a meal where lead is?—The painters are not allowed to have it in the paint shop: Are you speaking of painters only?

5668. I am speaking of all classes of work people. I want to know whether, on any occasion, tea, dinner, or anything else, they are allowed to have their meals in a room where lead is used?—I suppose that the body makers might.

5669. That is breaking the law?—I did not know that it was. The painters are not allowed to have meals in the paint shop.

5670. Do you provide overalls for the men?—No, most of them find them themselves.

5671. Do you know how often they are washed?—I should say once a week. Are you speaking of painters or of other men now?

5672. I am speaking of the men who come into contact with lead?—Painters do not use overalls. The body-makers use overalls, and very effective ones, and they are washed at least once a week.

5673. Do you know that of your own knowledge?—Yes.

5674. Do you make that a condition of employment?—No, we do not make it a rule.

5675. How do you know, then, that they are washed once a week?—I can judge by seeing them on Monday morning in very bright clean clothes.

5676. Is a cupboard provided for storing them when they are not in use?—No; there is no store for them.

5677. Do they take them home with them in their bags?—They take them home to be washed; I do not know how they carry them.

5678. Do they take them home every night?—No.

5679. Where do they keep them in the day time?—They hang them up on the benches, I imagine.

5680. I suppose that after a few days they are covered with lead dust?—Not with lead dust. They might have wood dust on them, but not lead dust.

5681. They are covered with dust which they come into contact with in their work, are they not?—The dust which they come into contact with is principally wood dust.

5682. You have said that there is a certain amount of lead dust in some of the operations?—I am speaking now of one shop, and I think that you are referring to another.

5683. I am speaking of overalls, and I asked you whether there is not a certain amount of accumulation of lead dust on the overalls in the course of two or three days?—I do not think there is. I will explain. A coach body-maker only uses lead, as I have already said, in a thick paste, which lead creates no dust whatsoever. If I am strictly obliged to say it, a coach body-maker is in a place where there is lead because he uses lead for his purposes, and he wears overalls. He gets very dusty, but I contend that there is no lead dust.

5684. Then what is the object of his wearing overalls?—To keep himself clean and save his clothes. They used to wear an apron in body-making, but now a body-maker has a suit of overalls, which covers him entirely. He wears overalls simply for the sake of his clothes and for comfort.

5685. You have told us that painters do not use overalls?—No.

5686. Are they not the very people who should use them?—I do not think so. They use an apron usually—that is all.

5687. A certain amount of paint falls on the floor and is kicked, and dust is created?—There is not very much.

5688. I said a certain amount, and these little amounts tell?—Our floor is covered with a patent preparation to stop dust. We have found that very effective. It is not quite like a drawing-room floor, and I cannot keep it as near that as I like, because the men have a nasty habit of throwing things down just where they happen to be.

5689. Is a separate cupboard or cloak-room provided for outdoor clothing put off during working hours?—Not a separate cupboard for each man. The men have a place to hang things in.

5690. Is that separated from the ordinary workshop?—No, I cannot say that it is, but it could easily be.

5691. Have you impervious washable floors in your painting shops?—No, they are ordinary wooden floors done over with the patent material that I have just spoken about.

5692. What are the usual hours worked by your coach-painters per week?—Fifty-eight is the usual number of hours.

5693. Do they frequently have to work overtime?—Not very frequently, but fairly frequently.

5694. Do you know that a very great deal of overtime is worked in certain branches of the trade, such as motor-car making?—I believe so.

5695. Would you welcome a strict limitation of the hours of employment, say, to 48 hours a week, the same as in the Potteries?—No. If you gave us double the number of men that we have, we should like to work less hours, but we cannot get them.

5696. Do you have a periodical medical examination of your workers?—No.

5697. You know that in other industries where lead is used the Home Office insists on a monthly, or even weekly, examination by the certifying surgeon?—I did not know it.

5698. If you have never had your men examined by a doctor, is it possible that some of them may be suffering from the slower and more insidious forms of poisoning?—I do not think so.

5699. But you do not know?—No, I do not know.

5700. Do you know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—I did not know that.

5701. Then would you welcome a system of periodical medical examinations in your industry?—Yes, if it is going to do any good.

5702. Do you know that there is practically no important lead industry in existence now where periodical medical examination is not insisted upon?—I did not know it.

5703. If, as I suggest, the Home Office introduced periodical medical examination, would you agree that compensation should be paid for any workers suspended by the doctor on account of doubtful health?—I could not agree to it, speaking on behalf of the Institute, as their President.

5704. But that would be a corollary?—I suppose that it would follow from that.

5705. Now, with regard to the cost of regulations. Do you realise the very great expense which your industry would have to bear in connection with stringent regulations for lavatories, meal-room and cloak-room accommodation, overalls, washable floors, medical examination, exhaust apparatus, compensation, &c.? Do you realise that probably the Home Office would insist on all those?—I realise that it would kill the industry if you do it. That is all. It would not, perhaps, matter to me. I could set up abroad.

5706. Will you be kind enough to take into account the cost of setting up a system which would secure continuous observance of all the regulations that I have foreshadowed?—Do you mean as against the doing away with using lead?

5707. I am coming to that in a moment. I have put the whole position before you?—I quite realise that it is pretty awful, if that is what you mean.

5708. And you realise, do you not, that the first duty is laid on the employer of securing the observance of all these regulations?—Yes, I realise that—more work for the poor employer.

5709. Taking all these points into consideration, do you still consider that it would be better to regulate the industry than to prohibit the use of lead?—It would be the same thing in my case, and I think that you realise that too. I should simply do away with lead. It has only a certain value, and gold can be bought too dearly. I think that it is quite possible that you might pay too much for lead.

5710. I understand you to mean that that would be the case if these restrictions which I have foreshadowed are introduced?—Yes. They will not affect

15 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

me. If people want a white car they must go elsewhere to get it.

5711. They are restrictions which obtain in other lead industries to-day. Rather than have these restrictions you would agree to the prohibition of lead?—Certainly.

5712. (*Lord Henry Bentinck.*) It would only affect, then, the people wanting white cars?—We should have to paint them with something. As my friend at the exhibition told me, they put white lead underneath to make it solid. But that is a detail.

5713. You said that the jointing paste was applied in a semi-moist state, did you not?—Yes; it is really quite moist.

5714. How soon is it dry? Is it dry before the body leaves the shop?—Yes.

5715. Therefore it is liable to create dust?—Oh, no, it would not create dust. If it made dust it would not be any good. It has to set very, very hard, like cement. It must not create a dust.

5716. Then it is not sandpapered, or anything of that sort?—No. It is wiped off, you see, with cloth or a piece of canvas.

5717. Do you work much overtime?—A good deal.

5718. On Saturdays?—No.

5719. Never on Saturdays or Sundays?—We may do so just to finish a car if a man wants to take it away, but not as a regular thing.

5720. Is it very difficult to find men now?—It is extremely difficult.

5721. For how long has that been so?—I do not know. It has been a growing difficulty in the last year or two, and now we are all in the same boat, I think. We all want men.

5722. Do you have a slack time every year? Is it a seasonal trade?—We do have a slack time. I do not think that many motor-body builders have been slack for the last year or two. We have a boom now—we are perfectly willing to admit that. A slump will come by-and-by.

5723. (*Dr. Collis.*) You were speaking of tub-lead. Do you mean lead paint as issued by the paint manufacturer?—What is known as ground white lead is what we call tub-lead.

5724. As it comes from the factory to you?—Yes. There is dry white lead and there is tub-lead.

5725. I mean the mixed?—Ground white lead is what we call tub-lead.

5726. Do you prefer to have that matured at all, or do you use it as fresh as the manufacturer can let you have it?—We usually want it of a certain age.

5727. How old?—What we specify for, as a rule, is about three years old.

5728. Are you aware that recently Dr. Baly, of Liverpool, has shown that lead mixed with oil gives off at the ordinary temperatures of air a volatile organic lead compound?—I did not know that.

5729. And that this compound is specially given off by lead which has been mixed with oil for a certain period—what is known as matured lead?—Would that occur if it were covered with water?

5730. If the paint were covered with water, do you mean?—Yes, if the surface were covered with water.

5731. From his experiments, probably not, but he is not satisfied on that point yet. It is not covered with water when you are using it, is it?—Tub-lead is always covered with water.

5732. But not when you are using it?—No, not when you are using it.

5733. Then you would have the compound given off apparently?—Yes, I suppose so.

5734. You have suggested that, in sandpapering, there is little or no dust getting into the air?—Yes, that is so.

5735. Would you be astonished, then, to hear that tests of air taken at the breathing point of the worker during sandpapering and dusting show (to give four or five of the determinations) in one experiment 193 milligrammes of lead in 10 cubic metres of air, 135 in another case, 182 in another case, 278 in a fourth, and 258 in a fifth? It may be interesting to you to know, for comparison, the amount of lead found in the air in other industries. In the

whole of the earthenware and china industry no test by the same investigator ever showed more than 13. In potteries, exhaust fans are applied in most instances; but in regard to the 13 the note that I have against it is "Bad exhaust"?—May I say that I do not think that I made a general statement that I did not think that danger would occur from the dust. I can imagine danger from what is known as the dry sandpapering. Where that is applied there might be a great deal of dust. You see it means that a man sandpapers at a high angle. I think that my remarks with regard to dry sandpapering were principally with regard to the under-works, where a man works above his work. I can imagine that if a man is sandpapering up here (*pointing*) a certain amount would come within his ken.

5736. (*Chairman.*) You really led me and the Committee to believe that there was no danger in the process at all?—No, I did not mean to imply that. I was only speaking of a certain process.

5737. (*Dr. Collis.*) This is the sandpapering of car bodies?—I cannot go against your statistics. The only thing is how the thing occurs.

5738. Would he be likely to be above or below a bench board?—He would be above a bench, I suppose.

5739. After one coat of lead colour and sandpaper stopping, the air was taken at the breathing point of the worker, and was found to contain 182 milligrammes per 10 cubic metres of air?—Do you mean 182 milligrammes of lead?

5740. Yes; found in every 10 cubic metres of air. So that you will allow, therefore, that the dust from sandpapering gets extensively into the air which is breathed by the worker?—It rather looks like it from your figures.

5741. (*Chairman.*) This is a special investigation that has been made by a Home Office official for this Committee?—I follow.

5742. (*Dr. Collis.*) I would like to know whether you can verify these figures: a painter is occupied in sandpapering one or two hours per day; a brush-hand from two to three or three and a half hours a day; and a painter's labourer from four to five. Would that be about a fair proportion?—I should imagine so. Some people would keep a certain class of man doing all sandpapering, I suppose. I do not say that that is out of the way.

5743. So that, although these people would be employed at a dangerous process for, perhaps, only one-third of the time per day, still during that time they would be exposed to something like 90 times the amount of dust in the air, as, for instance, in the china and earthenware industry. I gave you 13 as the highest, but it runs 1, 2, 2, 2, 6, and 1. These people are getting 182, 278, and 258; so that there must be at least 90 times as much dust in the air as there was in the china and earthenware trade. It may interest you on that point to know that in one case with motor-car wheels, after two coats of lead colour and after sandpapering, when the exhaust was not running we got the lowest reading—38·7; but when they had their exhaust running even then it only fell to 14·7, which is higher than anything apparently in the china and earthenware trade?—It seems to me that it would be very difficult to put the exhaust so as to clear the whole shop. You can hardly say where a man is going to work. I have seen it very satisfactorily used in a wood-working shop. I have seen a wood-working shop almost like a drawing-room. Then you have machines, and you can arrange the apparatus so that you exhaust the waste material right away, and off it all goes; but painting could not be done quite like that. You see we have things of such varying size to work on, and they are movable things:

5744. The difficulty would be almost insuperable, I think. I quite agree?—It is quite expensive at a wood-working machine, but it is possible there. Everything has to be brought to the machine. The work is fixed, and the exhaust is put over the machine.

5745. Having considered the extreme difficulty of applying exhaust to remove the dust, and having further, too, considered the volatile lead compounds

13 May 1911.]

Mr. F. A. MAYTHORN.

[Continued.]

which Dr. Baly has shown to be given off by wet lead paints, do you think that it would be in any way reasonably possible to protect the worker against the dangers to which he is exposed?—I do not know any means. I believe in a place being ventilated. We have Boyle's ventilators and torpedo ventilators, which take off a great deal, but they are not sufficient from that point of view.

5746. (*Mr. Fell.*) Do you provide the same washing accommodation for your body-makers and for your painters?—No.

5747. Only body-painters?—Only body-painters. One lot of body-makers have it—working at a newer place—they have a lavatory; but the old body-shop has not been at present fitted with it.

5748. Have you any regulations in your workshop as to men washing who are working at body-work?—No.

5749. So that there is no accommodation for them of any sort?—One lot have, but the other lot have not. In the old body-shop there is not any accommodation.

5750. Do you wash down the floors of your paint shop?—Yes.

5751. How often?—Well, they are not washed, but they are done over with this stuff and they are swept up twice a week. They are done over with this dust-preventing material, which is always moist.

5752. The floor is always moist?—Yes. It looks something like tar. I believe it has some affinity. It is not tar, but it looks rather like a thin coat of Stockholm tar put on the floor.

5753. Have you tried any methods of exhaust in your shop?—No.

5754. How do you ventilate your shop?—I ventilate with Boyle's ventilators and torpedo ventilators.

5755. Does that send the air up towards the roof?—Any wind makes an upward draught, blow how it will.

5756. So that if there is any dust blowing about the tendency is to draw it up?—Yes. There are case gratings with inlets in the walls.

5757. The inlet is on the ground?—Yes.

5758. The exhaust is above?—The exhaust is above. The inlet does not come direct on the ground. It has a shaft.

5759. (*Dr. Collis.*) A Tobin tube it is called?—It is a sort of tube—a wooden casing.

5760. (*Mr. Fell.*) How do you heat, except the forge shop?—By hot water exclusively, except the forge shop.

5761. Where is the heating apparatus placed?—The pipes are down below.

5762. So there is a current of warm air constantly arising?—Yes.

5763. (*Mr. Mason.*) Do I understand, with regard to this impervious floor, that the Stockholm tar or similar preparation is put down on the principle of a fly paper to catch the dust?—I think that that must be the idea of it. I cannot tell how it works. I only know that my coach painter asked me for a new supply which he put down only on Saturday. He said it was very satisfactory.

5764. Is this put down once a week?—No. It is two or three months since the first lot was put down.

5765. Does it remain tacky?—I do not think you can call it tacky.

5766. How do you brush it up?—They brush over it in the ordinary way. It comes up apparently clean.

5767. It is rather a mystery to me?—It is a mystery to me. It seems to be very satisfactory. I cannot say that it stops all dust, but we have had a great deal less dust since then. Dust is a great bugbear to us apart from any lead in it?—It is the greatest possible bugbear we can have.

5768. (*Mr. Mason.*) Would there be any advantage in having an impervious floor in a paint shop?—You mean like a fireproof floor made of concrete?

5769. A blue brick floor, for instance?—I would not like a blue brick floor. It would be an advantage in swilling down, certainly.

5770. (*Chairman.*) We agreed, in the Pottery Inquiry, that the floors of the painting shops should be swilled down every morning?—Yes. Then you must have them impervious. I should like to say that a good many larger coach-builders than ourselves have, in their rubbing-down shops, impervious floors, so that they can swill them right down. I have only been giving you my own personal experience, but I know that a great many people do have them.

5771. (*Mr. Mason.*) It would be satisfactory not only to have them impervious, but also smooth?—Yes, they should be smooth.

5772. (*Mr. Robins.*) With regard to applying this tar to your floors, from a painter's point of view is it not rather to hold down the grain of the wood and make it possible that you can swill down your shop with greater ease than if the shop was constantly being worn by the traffic of people up and down throwing the grain up in the floor?—That is not the object. The thing which we employ is a preserver. It is a patent thing that is supposed to prevent its rising. We bought it and put it down in good faith, and we seem to be perfectly well satisfied with it.

5773. What do you consider is the life of a motor-car, with regard to the painting of it?—That depends a great deal on the treatment it receives. It might want repainting in a very few months.

5774. Would you think that two years was a good test? If a motor-car wore two years, would you think that a fair test of its durability?—I should certainly think that if a motor-car was in good condition after two years' hard wear it was very well painted.

5775. Would you think that that car would require painting every two years?—I should think it would not have much paint left on it at the end of two years, if it had had much wear.

5776. You would think that if it wore satisfactorily for two years it was satisfactory?—Yes, it was a good job.

5777. I believe we had it in evidence from the Daimler Company that they had tested non-poisonous paints for two years, and they had found them satisfactory. Would you think that that was a fair test?—That is to say, that they have been using them for two years, and they have found them satisfactory. That is not quite the same thing as saying, "Here is a car which has been painted two years. What do you think of it? Is it all right?"

5778. The process has been in operation for two years?—The process has been in operation two years. You can hardly expect the Daimler Company to come here and say that their cars want painting every six months.

5779. You know that a motor-car has harder wear than a private carriage, and if any motor-car, whether it was painted with non-poisonous paint or not, wears satisfactorily for two years, you would consider it was satisfactory?—If it was thoroughly good at the end of two years I should think it was very satisfactory indeed.

5780. Would you think it would want painting at the end of two years?—If it was mine, and I thought I could afford it, I should have painted it to preserve it.

5781. You said that in sandpapering wheels the lead colour came off in ribbons or strips?—Yes, not in dust.

5782. Would you consider that sandpapering under those conditions was satisfactory to get a smooth surface, because I should consider myself that if you were sandpapering you were ripping it off, and you would never produce a level surface. You would be ripping it up, and consequently you would find that your sandpapering was getting clogged all the time, would you not?—If you had a very fine sandpaper you would get most of it off, except what was in the grain.

5783. With regard to the sandpapering, you said that it would all fall to the ground?—Yes.

5784. You know, do you not, that the wheel-horse is very near to the man, to start with?—Yes.

5785. He is sandpapering almost direct to his mouth?—Yes.

5786. How is it possible that all that is going down without affecting his breathing and his clothes, when

15 May 1911.]

Mr. F. A. MATTHORN.

[Continued.]

he is standing by the wheel?—If any of it rises or floats, he must get it, I am afraid.

5787. You must admit that as it falls it gets on to his clothes?—On to his boots.

5788. And on to his trousers, too. I have seen men look like millers from sandpapering the wheels?—I have never seen men like that. The only time I have seen them look like millers is when we have had a spring clean, and they have been taking the whitewash off the ceilings.

5789. Would you not have just the same effect if you were sandpapering filling. It is bound to fall when you sandpaper a wheel, and you get it on your hands. It is coming off all the time—there is the motion?—Of course, with quick stuff that may be so.

5790. The motion is stirring it up all the time?—If it is quick colour that would be so, but we do not do it like that.

5791. (*Chairman.*) Have you anything else to add?—I should like to say that the Institute sent out a number of letters to its members asking them if they had had any cases of lead poisoning within the last 10 years, and the Institute had 103 answers all disclaiming having had any lead poisoning in that period. I have not those letters with me, but if it is desirable, the Committee can have those.

5792. Are the names of the firms given?—I have not the names of the firms.

5793. I think if you give us those with the names of the firms it may be useful?—Very well.

5794. How many firms are there in the whole industry?—I am afraid I could not answer that question.

5795. I understand that you have made inquiries from your local practitioners as to the number of cases of lead poisoning which occurred in your district in the last 10 years?—Yes, that is so.

5796. What were the replies to those inquiries?—The reply in all cases was that they had no cases. All four replied that there were no cases.

5797. Owing to the fact that you have had no medical examination of your workers, you cannot be quite sure that there have not been slight cases of lead poisoning. Is not that so?—Certainly, but my point is that if anybody had been ill, they must have gone to one of those doctors, and I wanted to know whether such illness was traceable to lead poisoning.

5798. (*Mr. Kinggate.*) Is it a fact that many men may be suffering from lead poisoning and never go to a doctor?—I should imagine so.

5799. (*Chairman.*) Will you also let me have the number of members in your Institute?—Yes.

5800. If your secretary would come and be examined at some time, I can ask him the question when he has got the particulars?—Very well.

The witness withdrew.

Mr. ABRAHAM MEIER examined.

5801. (*Chairman.*) I think your business is in Red-hill?—Yes.

5802. You are one of the witnesses selected to give evidence on behalf of the Institute of British Carriage Manufactures?—Yes.

5803. Are you a carriage manufacturer?—I am.

5804. What length of experience have you had?—All my life.

5805. How many men do you employ?—55 or 56.

5806. How many cases of lead poisoning have you known?—One.

5807. I am very pleased to hear such an excellent record, but I am not surprised. You are doubtless aware that in the Potteries there are many large works which are immune for many years?—Yes.

5808. The trouble is that even some of the best works are not immune?—Yes.

5809. Moreover, a works that has been free from lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly?—That is a surprise to me.

5810. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—I insure my men under the usual policy which I suppose embraces that—I am not clear.

5811. Do you know that in the coach building industry, taken as a whole, there have been 767 cases of lead poisoning recorded by the Home Office in the eleven years from 1900 to 1910?—I was not aware of that; that is a surprise to me.

5812. And that of these 47 were fatal?—All this is news to me.

5813. And that the average for the last eight years has been 66½ cases annually in the United Kingdom?—I do not know that.

5814. In 1908 there were 70 cases, in 1909 there were 95 cases, and in 1910 there were 70 cases. As there has been no reduction in the average cases reported each year, you will recognise that something must be done to remove the evil?—Yes, I suppose so, if there is an evil it ought to be rectified.

5815. Do you contend that the risk of lead poisoning arises almost entirely in certain classes of works?—Inasmuch as I have come across no cases except the one I mentioned, I hardly know how to answer that.

5816. Of which class of work have you most experience?—Carriage building in all its various branches—the old-fashioned style years ago, and now during the

last 15 years, I have built motor bodies in particular; the old style of carriage being practically dead.

5817. Are you aware that of 376 cases of lead poisoning reported in the five years, 1905 to 1909, 46 arose from motor car works?—I was not aware of that.

5818. And out of 697 cases reported in the 10 years 1900 to 1909, 297 arose in the ordinary coach and carriage building works of the country?—I did not know it; I never heard of it; it is a surprise to me.

5819. Have you tried substitutes for white lead in your painting work?—No.

5820. Has your institution made any combined effort to take precautions against the evils which exist?—Our attention has never been drawn to it whatever. I have been a member of the council for many years, and there has never been anything mentioned about it at all. We have never heard of any danger or difficulties at all.

5821. Are you aware that white lead is no longer in use at the Daimler Motor Works at Coventry?—I was only told so to-day; I did not know it before.

5822. Do you still hold that white lead is the most perfect substance that can be used?—Absolutely.

5823. How does your work compare with the Daimler motor car bodies?—I consider my work is as good as their's, anyhow, if not better.

5824. I suppose they are one of the largest firms in the industry, are they not?—Undoubtedly.

5825. And they turn out work of the highest finish, do they not?—It looks so.

5826. The buyers of Daimler cars are of about the same class as the customers of your own, or other leading coach-body firms?—I should say so.

5827. And they would demand the same finish, would they not?—I should say so.

5828. The witness representing the Daimler Company told us that they are entirely satisfied with the substitute they are using for all purposes for which white lead is commonly used in coachbuilding works. The Daimler Company have used no white lead for two years, and they have had no complaints from customers. What do you say to that?—I do not believe that a carriage painted without white lead can possibly be so durable as one which has a white lead foundation. I would never believe it.

5829. The Daimler Company have used no white lead for two years, and they have had no complaints from customers. What do you say to that?—I cannot understand it.

15 May 1911.]

MR. ABRAHAM MEIER.

[Continued.]

5830. I suppose they are a practical business body?—Yes, exactly, but two years is not a sufficient life of a carriage to judge.

5831. They claim that their paint work is thoroughly durable?—I would never believe it. It cannot be. In two years it may be, but two years is not sufficiently long.

5832. Surely the customers would point out to them if the work was not good?—Two years is not sufficiently long. Five or six years would tell the tale, one as against the other.

5833. Are you aware that the Daimler Company affirm that their substitute is a little more economical than when they were using white lead?—I do not know, but I should imagine it is more economical, and that is the reason why they use it.

5834. Do you contend that the dangers of lead painting can be practically eliminated by regulating the various processes?—Most emphatically.

5835. We have had before us the President of your institute?—Yes.

5836. I suppose you would feel inclined to corroborate anything he said in regard to the various processes in this industry?—Considering he is a practical carriage builder, I should say yes.

5837. I will confine my questions to you entirely to priming. When the carriage is ready for painting, it is first given priming coats?—Yes.

5838. How many coats?—Two or three coats; three if time permits it.

5839. Does the priming you use contain lead?—Yes, certainly.

5840. Is the work sand-papered between successive coats of priming?—No.

5841. What process do you use?—We put two or three coats of priming one on top of another, one each day, and the following day we put on what we call filling-up. We put about six coats, a coat each day. That helps to fill up the pores or grain in wood. When that is dry we put a coat of thin black over it, which black is a guide for the men who have to rub it down.

5842. Could sand-papering for priming coats be prohibited?—It is absolutely quite useless. I do not admit it in my place at all. It is not necessary, it is utter waste of time. If men do it, it is to prolong time wastefully.

5843. The body next receives a number of coats of filling?—Yes.

5844. Do you use leadless filling?—It is used, but for good work a very tiny piece of lead is allowed, and rightly so.

5845. What do you call a very tiny piece of lead; about what per cent.?—About one-twentieth or one-thirtieth part only—a little knob as big as a small fist for a big pot of filling.

5846. About 5 per cent.?—Yes, that is about it, roughly. That is all that is necessary.

5847. Why is lead necessary for the filling material?—In order to make a substance for those five or six coats of filling—to make it more dense. Without it that rubbed down surface would be somewhat porous, and would then absorb the next coat of paint more than it would otherwise. The lead makes it of a glossy surface after it is rubbed down, with less absorption for the next coats.

5848. What stopping do you use on coach bodies?—It is made of white lead.

5849. Does a man mix the stopping himself?—The head painter usually does it for his men.

5850. In the process of mixing there must be danger arising from handling the dry white lead powder?—No.

5851. Why not?—Simply because the white lead in its dry condition is very heavy, as we are all aware. That is put on a stone, and a little gold size is mixed with it, or japan, and that is simply mixed up into a kind of paste, until it forms the substance of a paste or dough. Therefore there is no dust whatever, the dry white lead being very, very heavy. It is simply squashed, and made quite fine on the stone until it is of a doughy nature, as I say, and then it is applied with a knife in the little screw holes or pin holes on

the body to an extent to fill them up, which is very, very tiny.

5852. Is the rubbing down of the body done with pumice stone and water?—Yes.

5853. Do you finish the roofs of your closed cars with canvas or similar material?—Yes, canvas or moleskin.

5854. How is that bedded?—We put a strong coat of gold size on the panel, and when it is nearly dry, when it is sticky, we spread our canvas over it, and force it on like a drum, very tight.

5855. Is it usual to bed canvas in white lead?—Not often; we usually use japan. It is like the priming on the body, there is no dust whatsoever. The bare panels receive two coats of lead colour, then pin holes are stopped up, followed with a thick coat of stout, sticky japan, to which the canvas is sleeked on tightly.

5856. Have you realised that if lead is allowed to be used in this industry, in the future, there will be very costly regulations introduced to protect the workman?—I am very sadly aware of that.

5857. Are you aware that in all the important lead industries there is a code of regulations issued by the Home Office which the employer is obliged to observe?—No, I was not aware of it.

5858. Let me give you a few illustrations. In the first place you would have to provide lavatory accommodation, supply hot and cold water, introduce a system by which the men could get soap and nail-brushes without any question; towels would have to be provided at stated intervals. Mess-room accommodation would have to be provided; a cloak-room for the men's clothes put off during work; overalls which would have to be maintained and washed at the employer's expense; washable impervious floors would have to be introduced so that the floors could be swilled down regularly once a day; and medical examination of all the workers. I might say, in passing, that it is only when you have medical examination that you can find out truly whether the men are suffering or not from lead poisoning. Then you must add to these the cost of compensation whenever a man is withdrawn from work in lead, and also the cost of installing efficient exhaust draught apparatus, wherever it is possible to apply it, for the removal of dust. You must also take into account the cost of setting up a system which will secure continuous observance of all the regulations, and I hope you realise that the first duty is laid upon the employer of securing the observance of this special code of regulations?—Yes.

5859. To sum it all up, the question I want to put is this. Taking all these points into consideration, do you still consider it would be better to regulate the industry than to prohibit the use of lead?—In order to have best quality work I would do almost anything rather than do away with lead. If lead is done away with, our good quality of work hitherto produced will suffer in proportion.

5860. But supposing the prohibition was to cover the whole of the trade, in what way would you suffer?—Then we should be all alike, but the clients would not get such good work, that is all.

5861. But the Daimler Company, and the Midland Railway Company, and the Bradford Corporation Tramways Department use no lead at all in any of their carriages?—I can only go back to my original idea, that two years' test is not sufficient to prove that their work without lead is as good as ours with lead.

5862. You have told us that the manufacturers, as a body, have made no serious attempt to find a substitute for lead. Is that so?—Personally I have never been asked to use it. It has never been offered to me at all in my factory. Nobody has offered me any.

5863. Then you are not quite sure that there is not a suitable substitute in the market?—I believe there is, but in such a small degree that, strange to say, I never heard of it at all until to-day. If the law imposes all this upon us, God help us.

5864. What I want you to realise is this, that Parliament has introduced Factory Acts?—Yes, I am aware of that.

15 May 1911.]

MR. ABRAHAM MEIER.

[Continued.]

5865. The Factory Acts are administered at the Home Office?—Yes.

5866. In all dangerous industries the Home Office introduces special regulations for the protection of the workpeople?—Quite right.

5867. It has been proved most conclusively that the evils existing in the carriage building trade are very serious, by the statistics which I have read out to you to-day. Now I am certain that you, as a humane employer of labour, would wish to do something to eradicate that evil?—If the evil exists, I should be the first man to do all in my power to prevent it.

5868. There are two ways of doing it. The first way is to prohibit the use of lead altogether, which at once removes the danger. The second way is to introduce regulations for the protection of the workpeople?—Yes.

5869. Those regulations I have outlined to you?—They frighten me to death.

5870. They are the same which are in vogue to-day in every important industry where lead is used. Now what I want you to consider with your colleagues is this: This Committee has been formed to institute the most searching inquiries into this evil, and to suggest a remedy. We want you employers to help us?—I shall be pleased to do so to the best of my ability.

5871. But as far as I can see, at the present moment, there are only two alternatives. One is the prohibition of lead, and the other is the code of regulations which you so strongly deprecate. It is for you employers to tell us whether you can help us?—Do you wish me to give my opinion which of the two I prefer?

5872. Yes?—For Heaven's sake do away with white lead. The other is simply awful—absolutely. The regulations which you have mentioned would make me mad, and the men themselves would simply go cranky. Do away with lead, please.

5873. (*Dr. Collis.*) How long do you think would be a fair period to have used non-lead paints to get a reasonable test?—Four or five years would be much better than two years.

5874. Do you think that a test for about five years would be reasonable?—Three or four years would be reasonable. Two years is hardly sufficient.

5875. Then you accept the opinion of the Midland Railway Company who have been using non-lead paints for six years?—Yes, if they say in six years it is as good as work painted with lead, I should accept it, certainly.

5876. They have been doing so for six years, and I presume they would not continue unless they had had good results?—I understood it was only two years.

5877. That was the Daimler Company. It is the Midland Railway Company I am speaking of now?—I bow to their decision.

5878. They have used it in painting their carriages—not in the rest of their work, I am bound to admit, but in their carriage building department?—Six years is ample—more than ample.

5879. Have you men in your employ who are painting, and also making bodies?—Yes, both.

5880. Do you insure your men as a whole?—Yes.

5881. There is no distinction made between those who are using lead paints, and those who are not?—No, I have never been asked by anybody.

5882. Has there been any difference in the rates you have been paying insurance companies in the last five or six years?—No.

5883. They have not varied in the slightest?—No, nothing at all. The question has never been raised.

5884. They have not fallen at all?—No, and they have never been raised. They are just the same.

5885. Has there not been a tendency for the insurance rates for the workmen's compensation to fall in the last few years?—The last two or three years the companies have come and asked me to insure the men at the lower rates.

5886. But up to the present you have made no arrangements, at any rate, for any reduction in their insurance?—No, but it is pending now.

5887. For the last four or five years?—For the last six months only.

5888. They have only come to you quite recently, then?—Yes, only quite recently.

5889. So that you have not participated in any way in the general reduction that has taken place in the insurance rates since the first Workmen's Compensation Act came in?—No, not yet, except that the last six months the companies have been writing, and they want me to insure for the lesser rate than I have hitherto insured at.

5890. (*Mr. Fall.*) In regard to your emphatic sentence that lead is the most perfect substance, have you made any enquiries at home or abroad as to the use of other paints which have not got lead in them?—No, I have not. I have used nothing but lead all my life, from boyhood up to now, and I never thought there was any substance equally good as white lead to maintain the durability of a painted carriage, but if we all use no white lead, of course, we are equal. I maintain that the work would deteriorate, it would go down instead of up; but, if we are all alike, we are all alike.

5891. (*Mr. Kinggate.*) With regard to the cases of lead poisoning we have had, how do you know that you have not had some of your men suffering from lead? Do you get a doctor's certificate every time a man is off from his employment?—No, but I have been singularly fortunate. I have had hardly any cases of illness the last many, many years. It may have been a coincidence.

5892. You are situated in a pretty healthy spot, of course?—Probably. I live in the country, in Surrey.

5893. In many cases men suffer from lead, and you do not know it. We know perfectly well that men are occasionally off from illness which is the result of lead, but it is not directly brought to your knowledge?—It may be.

5894. You may have a good many men suffering from lead, and not know it?—That I cannot answer. Now and again, of course, a man is unwell, and he stays away, and comes back again. We do not know why he has been unwell. I have been unwell myself at the thought of the danger in front of me, *i.e.*, the danger of extremely worrying legal restrictions which are threatened. If these things are enforced I would like to sell my business and go away. It means awful trouble.

5895. If it could be proved, as it has been proved, that there is a substance equal in every way to white lead, what is your objection?—I have an open mind. If there is a substance which I do not know of which is as good as white lead, I should be most anxious and happy to use it, and do away with white lead.

5896. The only point is the proof that it is equal to white lead?—I have not sufficient knowledge at present to say whether the substitutes are as good as white lead, but I would rather have white lead than shoddy work.

5897. I do not think any of us in the painting trade want shoddy work?—No.

5898. But we want some substitute which is equally good?—Yes.

5899. If it can be obtained, you are willing to use it?—Yes; I long to do it.

The witness withdrew.

x 7790

L

15 May 1911.]

Mr. S. C. L. FULLER.

[Continued.]

Mr. S. C. L. FULLER examined.

5900. (Chairman.) Do you carry on business at Bath?—Yes.

5901. You are one of the witnesses selected to give evidence on behalf of the Institute of British Carriage Manufacturers?—Yes, as a coach-builder; I cannot speak for them as a body, but I represent the institute.

5902. Are you a carriage manufacturer?—Yes; I have had 40 odd years in it.

5903. How many men do you employ?—From 60 to 80.

5904. How many cases of lead poisoning have you known?—I have never known a case of lead poisoning—not a pure case. I have known men who have been ill, but I have never had a case of lead poisoning.

5905. I am very glad to hear such excellent records, but I am not surprised. You may not be aware of it, but in the Potteries there are a large number of works which are quite immune from lead poisoning?—Yes, I happen to have read for some years a great deal about that.

5906. And the trouble is that even some of the best works are not immune, and, moreover, a works that has been free of lead poisoning for many years will sometimes have a succession of several cases of lead poisoning, quite unexpectedly?—I am surprised to hear it. I have never had it myself.

5907. Do you insure against the liability to pay compensation for lead poisoning under the Workmen's Compensation Act, 1906?—We insure against employer's liability.

5908. Do you know that in the coach-building industry, taken as a whole, there have been 767 cases of lead poisoning recorded by the Home Office in the 11 years, 1900 to 1910?—I have just heard it to-day but it is absolute news to me. I have never heard anything like it.

5909. And that of those there were 47 fatal cases?—I maintain that it cannot be in the coach-building proper.

5910. There has been no apparent reduction in the rate of attack during the last eight years?—I quite accept that.

5911. In the average of the eight years there were 66½ cases annually. In 1908 there were 70 cases; in 1909 there were 95; and in 1910 there were 70?—I am quite open to correction, but I have never heard of it, and I took the trouble, after I was appointed a member of this deputation, to write to all the leading coach-makers proper in the West of England, and I have their letters. They all, without exception, say that they have never known a case of lead poisoning in their own shops.

5912. There are statistics which you cannot explain away, and there has been no reduction in the average number of cases reported each year. I am sure you recognise that something must be done to remove the evil?—I quite agree. We are open to that and we are anxious to do it.

5913. Do you contend that the risk of lead poisoning arises almost entirely in certain classes of works?—Yes, it must do.

5914. Of which class have you the most experience?—Only the road coach-building proper.

5915. How do you define coach-building proper?—Not trading wagons and not trestle wagons, and not railway work and not perambulator work.

5916. Have you, as a society, to your knowledge, taken any steps to test the merits of the different substitutes for white lead on the market?—No, I have never heard of it. We have always had them offered to us as individuals in the competition of trade.

5917. Have you ever heard of lead poisoning in your industry?—Yes, I have heard of it.

5918. Have your institution made any inquiries as to the precautions necessary to combat the evils which exist in the industry?—We maintain that it does not exist in our industry.

5919. Has your institution ever made any combined effort to combat the evils?—No, it has never been a

serious evil in our trade. We have never realised that it was a serious evil in our trade. I should like to look over those statistics and analyse them.

5920. Have you anything special to say with regard to the jointing in the carriage-makers' work?—Yes. I have been general manager to our works almost from my earliest days. We use invariably white lead for the body-making, and white lead for jointing up all the ironwork. As coach-builders we are notorious for using an unusual quantity of forged work in the carriage work instead of using so much wood. We use almost entirely all iron, and in fitting the splices white lead is used, but the amount of white lead that we use under those conditions, with the body-makers and the others, is not 5 per cent. of the labour. The labour and time, when they are using white lead, is not 4 per cent. of the total job.

5921. I suppose you realise why this Committee has been called together?—Yes, I quite realise it, and I quite accept. I heard this and I quite agree. I am not objecting to the Committee at all, and should be only too pleased, as a man, to help them.

5922. The Committee has been called together because of the deplorable figures which have been presented showing the evil existing in this industry?—It is absolute news to me; I cannot understand it. As I said before, I have only known of one case of wrist drop, and that was due to drinking from a lead pipe.

5923. In every other important industry where white lead is permitted to be used the Home Office, under the Factory Acts, introduces a special code of regulations to protect the workpeople. Let me tell you what those regulations are. In the first place the Home Office insists on lavatory accommodation being provided for all the people who come into contact with lead. The rules also require that hot and cold water should be readily at hand; that a supply of soap and nail-brushes in good repair must be always at hand; that towels should be supplied periodically, but frequently enough to ensure their being clean when they are used; that a messroom should be provided, properly heated in the winter, with proper tables and chairs, so that they can have a decent meal away from any contact with lead; that cloakroom accommodation should be provided, so that the men can hang up their clothes free from any contact with lead dust; that overalls should be provided at the employer's cost and washed by him at least once a week, and, in fact, in some industries more frequently than that; that washable impervious floors should be put down in all the workshops, so as to allow daily swilling of such floors; that medical examination should be introduced at the employer's expense, so as to ensure that every workman who was feeling any effects of lead poisoning should be at once notified, and that compensation should be given to the workman who is withdrawn from working in the lead processes. There is also the cost of installing efficient exhaust draught apparatus to carry away the dust wherever it is possible. Then you must take into account the cost of setting up a system which will secure continual observance of all these regulations. I feel sure that you realise that under the Factory Acts the first duty is laid upon the employer of securing the observance of these regulations?—Yes.

5924. Now, taking all those points into consideration, do you consider it would be better to regulate the industry by such a code of special regulations, or would you, as a manufacturer, prefer the prohibition of the use of lead?—In the first place, as a sensible man, I do not admit that there is any necessity for such regulations in our particular trade.

5925. Let me recall this fact to you once more, that the figures I have read out to you, showing the evils of lead poisoning, are, in the view of the Home Office, deplorable. This Committee has been formed with the sole object of arriving at some plan to remove that evil. I have pointed out to you what the system is in other important industries, where lead is used, and I ask you this question: whether, in your view, you would prefer a code of regulations, such as I have fore-

15 May 1911.]

Mr. S. C. L. FULLER.

[Continued.]

shadowed, or would you, as a manufacturer, agree to the prohibition of lead?—At the expense of the reputation of British work, we should like to give up lead in preference to any further factory restrictions, but at the same time I say that in the way of jointing the amount of white lead used is not a large proportion of the work. I have asked the others, and we have been discussing the question, and we all agree that 5 per cent. of the time will amply cover the whole time the men in question are using the white lead.

5926. That is not the point. The point is this: we have in these statistics a state of affairs which is deplorable?—I quite agree with that.

5927. When Parliament sees these statistics in our report they will insist on something being done to relieve the men of this evil. The only way it can be done is by introducing a code of regulations or special rules which would bring your industry up to the same level as the other industries?—What about engineers? We use it the same way that engineers do. They are using white lead every day.

5928. Do I understand you to say that, rather than have this serious and stringent list of regulations, you would prefer that white lead should be prohibited?—We do not use the dry-lead process.

5929. Would you, as a manufacturer, prefer that white lead should be prohibited rather than have this code of regulations introduced?—It does not apply to our men, but, if necessary, we must put up with it.

5930. If you use any white lead at all you must put up with the code of regulations?—We all work with poisons more or less, but we do not try to eat them or absorb them.

5931. (*Dr. Collis.*) Do you maintain that there are many cases of lead poisoning that occur from such things as you suggest, like drinking from lead pipes?—I know one absolute practical case. I know of one man personally who was reported to be suffering from lead poisoning, and it was proved that he was continually drinking from a lead tap in his father's house.

5932. But we have notifications of lead poisoning received under the Factory Acts at the Home Office week by week, and we have no such statistics coming in of these industries such as you suggest, for instance, the engineering industry. Do you suggest that we should put them under the regulations at the same time? We have no such statistics showing that there is the illness in their occupation, so why should we?—I say that in our trade the use of white lead, except with painters, is entirely on all fours with the engineers.

5933. But the painters are rather a large number of men?—But not one of these master coach-makers of our own standing have had a case of lead poisoning.

5934. I think it has been suggested to you by the Chairman that, as we know perfectly well, many big factories go for a long time without any case—perhaps 10 or 15, or even 20, years or more. Their confrères, at the same time, may be having lead poisoning; and it may be their turn to have lead poisoning while their confrères are free?—The men I have communicated with all say that they have not known it in the course of 30 years.

5935. Are you drawing any distinction between the painter and the carriage-maker?—The carriage-maker is a technical term for the constructor or erector. The words "carriage-maker," as such, are applied to a man who puts the carriages together. He receives the axles, wheels, and springs, and he makes the turntables and puts them together.

5936. He is not in the paint shop, is he?—No, he is not in the paint shop, and he uses the white lead. That is the part I call the fitting.

5937. Are you drawing a distinction between the painter and the body-maker?—Yes, because the body-maker and the carriage-maker, as a rule, work together. The painters are a separate body, very often working in a separate building or a separate loft.

5938. The contention which you are putting forward now is that the painter does not require protection, but the carriage-maker does, is it not?—Against

this, not against the white lead. I say it is harmless with the body-maker.

5939. The painters ought to be protected against the use of the dry white-lead process, the sandpapering down, and so on. That is an objectionable process which you consider the painter should have some protection against; but your point, for the moment, is that you do not think that the body-maker is exposed to a similar danger?—I do not think so. It is so infinitesimal in its use. Using as much as he could, or is likely to want, it is very, very small. I have never heard a complaint of it from them, or of any trouble. If you provided them with lavatories alongside their bench I do not think they would use them. They would think that they were not required.

5940. (*Mr. Fell.*) Do you provide the same washing accommodation for your body-makers and your painters?—No, the body-makers never want it and never use it; they are clean.

5941. But, surely, in jointing they are apt to get a certain amount of white lead on them?—Very little. In making a brougham body there is 15l. spent in labour, and there is not two days out of the seven or eight weeks spent in using white lead. They simply have a pot, say, about that size (*indicating*), and they do not use a quarter of that pot on a brougham.

5942. Have you tried any substitutes for that, such as jointing paste or anything of that sort?—They have used red lead occasionally for the ironwork, but white lead is better.

5943. For the woodwork?—No, except varnish work. We have never had it suggested, and there has been no inducement to the manufacturers to have substitutes.

5944. I suppose you would be quite prepared to use a substitute?—Quite so, if it is going to benefit the men. It is not a question of cost or anything of that sort.

5945. (*Mr. Kinggate.*) You say that, with regard to the body-maker, he does not need any washing accommodation. Is it possible for a body-maker to put on edge plates or bracket plates without getting his hands covered with white lead?—He always has a piece of rag or paper beside him that he can wipe it off with.

5946. But he cannot do that without getting his hands dirty?—He gets a certain amount on.

5947. He needs washing accommodation for that purpose if he is going to have his meals, does he not?—They can generally get a wash at home, or they can go down below and wash. There is a row of basins there.

5948. You do not provide washing accommodation for the body-maker?—No, but he can go down in the room below and wash there.

5949. You do not object to his washing?—No, painters, carriage-makers, body-makers (if they like) are all—with us—free to use the basins with taps, &c. in middle floor of factory.

5950. With regard to carriage-making, we are speaking now, of course, of a different class of carriage-making. The carriage-maker, as a rule, would work much more than 5 per cent. of his time with lead?—Not much more. There is all the carving of the beds and putting on the plates, but putting on the plates with the lead is not much more than 5 per cent. of it. That is the actual time of using the lead.

5951. When a man is putting a carriage together from beginning to finish, is he not using lead all the time with every bolt head and every clip?—With all the clips, but then he has to make it up as well.

5952. I have made hundreds of carriages myself, so I know something about it. Is not he using it all the time?—Not actually using it.

5953. Is it not the practice also that the body is frequently taken into the carriage loft and the priming coat is done while the carriage-maker is hanging it?—That is so, sometimes, but he is not touching the lead.

5954. Apart from using it, the lead is being used in the same workroom?—Yes.

5955. (*Dr. Collis.*) He is in the workroom when the paint is used, is he not?—Yes.

L 2

15 May 1911.]

Mr. S. C. L. FULLER.

[Continued.]

5956. I asked you specially if he was in the work-room where it was being painted, and you said no?—It is being painted while he is there.

5957. (*Mr. Kinggate.*) He gets smothered with it sometimes, does he not?—The carriage-maker is never smothered with the paint. You would very soon have a complaint about that. He would not tolerate it.

5958. (*Chairman.*) If the regulations are introduced, they would doubtless apply equally to the carriage-builder as to the painter?—Of course, if you stop the use of paint with white lead you would stop the other.

5959. But the regulations issued by the Home Office apply to all workpeople who come into contact with lead?—They do.

5960. (*Dr. Collis.*) As that point has been brought out, that they are in the same room where paint is used, I want to ask you this question. Are you aware that it has been shown that wet-lead paint gives off a volatile, organic, lead compound, quite apart from any dust or anything else, which affects people when they breathe it?—If you tell me that, as a chemical fact I will accept it.

5961. It is a fact which has been brought out quite recently in Liverpool by Professor Baly?—As a matter of fact, I have always been accustomed to thoroughly well ventilating every place, and we have never found any unpleasant smell from it whatever.

5962. So the distinction between the body-maker and the painter, since the body-maker is often in the room where the paint is laid on, does not hold good?—Of course, in every shop the bodies are shifted about, and they are painted where they are.

5963. (*Mr. Robins.*) Is it not a fact that on nearly every body-maker's bench and carriage-maker's bench his white-lead pot stands?—They all have their pot of lead.

5964. It is on their bench, and they are constantly breathing the smell of it?—It is generally covered with oil.

5965. Would you hold that it is a healthy practice for these men to have that pot of thick paste, white lead, on their benches?—There is generally one to about four or five of them. He is always working in proximity to the pot of white lead, but the average ordinary painter is always with his nose over the pot of paint.

5966. Is it not the practice that generally the priming coats are put on in the carriage-maker's and body-maker's shop, and very often the coats are put on and finished and the filling-up done in the carriage or body-maker's shop?—Undoubtedly sometimes it is so.

5967. Do you not think that these men in the body-maker's shop or carriage-maker's shop are placed in equally as dangerous a position as the painters?—No, because the painters have the danger of sandpapering.

5968. I quite admit that danger, but at the same time the men are constantly coming into contact with white lead, apart from the painting?—How is it that our men are so seldom on the sick list? I am not disputing your statistics, but at the same time I say, with regard to those who use pure white lead and

who use pure oil, you do not get that abominable smell like you get in some painters' shops.

5969. (*Mr. Kinggate.*) Of course you do not know, when the men are off work, whether they are suffering from lead poisoning or not?—They are not away on the sick list from it.

5970. You do not know that, do you?—Very seldom.

5971. It may be attributed to other things, not directly to lead, although lead may have been the cause through the lowered vitality of the man. You do not have a doctor's certificate from your employés when they are away, do you?—We have a sick club and they are always carefully checked for that, and they are never off for intestinal troubles.

5972. It may not be intestinal, because that is not always the result of lead poisoning?—I am not a medical man, qualified to argue on these points. There is one point about the white lead for the painter which I wish to make. Mr. Maythorn said that the use of tub-lead, as such, ought to be allowed for decorative purposes of striping and what not, but there is no substitute for paint at all that would enable us to get the finish and the fine lines that tub-lead will give. For instance, take a spoke of that size (*indicating*), very often there are four lines of white on that.

5973. (*Chairman.*) Is that put on by hand?—Yes, with a pencil.

5974. There is no sandpapering done, or anything of that sort, is there?—No, there is no dust. It is put on and the next morning it is varnished.

5975. (*Mr. Robins.*) Is that for decoration?—Yes.

5976. (*Mr. Kinggate.*) It is a better white, is it not, than dry lead? It does not go yellow so quickly?—It ought to be mixed with oil to go on.

5977. (*Chairman.*) Do I understand you mean that, if lead is prohibited generally, you want to be allowed to use it for that purpose?—That is the point. A question was asked about the tub-lead being used, and Mr. Maythorn said that for artistic purposes we want to be allowed to use that occasionally for white striping.

5978. If we recommended the Home Office to prohibit the use of lead generally, you want the right to use it for that purpose?—We want to be allowed to use it for that purpose, for artistic purposes. I will put it in that way. I am not talking about ordinary white painting or filling, but we should be allowed to use it for artistic purposes on the surface.

5979. (*Mr. Mason.*) I understood you to say that you used zinc-white for fine work?—Zinc-white is a very pure white.

5980. That can be used for fine lining?—Yes, and it can be used for glazing. If we wanted a very, very clear, clean white we would use zinc-white.

5981. Then why do you want to use lead?—It will not do for any other colour, only white. It would break your heart to try and paint a thing with zinc-white.

5982. But it is suitable for fine lines?—Not for ordinary fine lines. You must have the tub-lead for that. I know of nothing else. Of course, there can be little or nothing from that in the way of lead poisoning.

The witness withdrew.

Mr. PETER CROALL examined.

5983. (*Chairman.*) Do you carry on business in Edinburgh and Kelso?—Yes.

5984. You are one of the witnesses selected to give evidence on behalf of the Institute of British Carriage Manufacturers?—Yes.

5985. You are a carriage manufacturer?—Yes. I was, of course, a carriage manufacturer, but we are now motor-body manufacturers really.

5986. Your business is a very high-class one, I believe?—It is.

5987. What kind of vehicles do you make?—We hardly make any open motors at all. It is all the large closed bodies, and a few horse carriages—not many.

5988. How many men do you employ?—We employ over 80 in Edinburgh and 40 at our other works.

5989. How many cases of lead poisoning have you known?—We have never had one.

5990. To what do you attribute this immunity of your works?—I think the men usually take something to eat before they come out in the morning, and they are very cleanly in their habits. We insist on their washing their hands before they go away to their homes, and we never have any illness with any of the men.

5991. You may not be aware of it, perhaps, but in the Potteries there are also very many large works which have been immune from lead poisoning cases

15 May 1911.]

Mr. PETER CROALL.

[Continued.]

for many years?—No, I have not heard of it. I do not know anything about the Potteries.

5992. And even some of the best works are not immune; moreover, a works that has been free from lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly. Do you insure against your liability for the payment of compensation for lead poisoning?—No, we never mention lead poisoning in our insurance.

5993. Do you insure against the risk of claims under the Workmen's Compensation Act, 1906?—Yes.

5994. Do you know that in the coach-building industry, taken as a whole, there have been 767 cases of lead poisoning recorded by the Home Office in the 11 years from 1900 to 1910?—I never knew that until to-day.

5995. And that of those, 47 were fatal cases?—I do not think there can be many among the real coach-builders.

5996. There has been no apparent reduction in the rate of attack during that period?—Is not that partly owing to the men not taking care of themselves and washing their hands?

5997. That is not the point. The average for the last eight years shows 60½ cases annually. There were 70 cases in 1908, 95 cases in 1909, and 70 cases in 1910?—Then they are decreasing again.

5998. No, the figure for 1910 is higher than the average of the last 10 years. As there has been no reduction in the average cases reported each year, I am sure you recognise that something must be done to remove the evil?—Yes, certainly.

5999. Are you aware that, of 376 cases of lead poisoning reported in the five years 1905 to 1909, 46 cases arose from motor-car works; and out of 697 cases reported in the 10 years 1900 to 1909, 297 cases arose in the ordinary coach and carriage building works of the country?—I think it must be carelessness on their part to have so many.

6000. Do you know whether your Institution have made any united effort to combat this evil?—I know very very little about the Institution, because I never attend any of the meetings. They only just wrote and asked me to come and be a witness.

6001. Have you tried substitutes for white lead in your painting works?—No. We have never thought of doing so. We have never had any cause to do so.

6002. Are you aware that white lead is no longer in use at the Daimler Motor Car Works at Coventry?—Just about two months ago we had one of the Daimler motor cars in our place which was finished by themselves, and we had to scrape all the paint entirely off because it was so badly cracked. It was very badly painted indeed.

6003. Do you still hold that white lead is the most perfect substance that can be used?—Yes.

6004. How does your work compare with the Daimler motor-car bodies?—After our bodies have been out for two years they just require a coat of varnish, but they do not require painting.

6005. But the Daimler Company are one of the largest firms in the industry, are they not?—They are.

6006. And they turn out work of the highest finish, do they not?—When it goes out first it is of the very highest finish, of course.

6007. Are the buyers of Daimler cars of about the same class as the customers of your own or any other equally high-class firm?—Yes, because they buy them from the agent.

6008. And would their customers demand work of the same finish?—Yes, of course they would.

6009. The witness representing the Daimler Company told us that they are entirely satisfied with the substitute they are using for all purposes for which white lead is commonly used in coach-building works?—That is not my experience.

6010. You are surprised to hear that?—Yes, I am.

6011. The Daimler Company have used no white lead for two years and have had no complaints from customers?—That one car had to be scraped right down and all the paint taken entirely off.

6012. I am speaking about the Daimler Company's own people. I suppose you will admit that they are a very responsible business body?—Yes.

6013. And they would not be likely to agree to do without lead unless they found it could be done with commercial prudence?—No, one would not fancy so.

6014. They claim that their paint work is thoroughly durable?—I do not think it will stand nearly as well without the white lead.

6015. They say it does, and they say also that it is a little more economical?—I do not know anything about that, of course.

6016. Do those considerations which I have put to you with regard to the Daimler works dispose you to modify your views at all?—Judging from what I have seen of their work coming in in that way, I do not consider that their work stands in anything like the same way.

6017. Would not their customers be the first to complain, and would not their shareholders be the very first to insist on the introduction of lead, if the work was not turned out satisfactorily?—One would fancy so.

6018. Then the Midland Railway Company, for the past six years, have used no lead in their carriage and wagon works. Are you surprised to hear that?—Yes, I am.

6019. And the Bradford Corporation have had similar experience. They have used no white lead for a considerable period. Are you surprised to hear that?—I am.

6020. Have you anything to say about the finishing work?—If you abolish white lead it will be very very difficult to draw the lines.

6021. The decorative lines?—The fine lines. They are done with the hand, and you require white lead to fill out the line, because it runs smoothly with that.

6022. Do I understand you to suggest to the Committee that, in the event of the Home Office deciding to prohibit lead, they should allow white lead to be used for these decorative lines?—We would almost require that.

6023. Mr. Maythorn went very fully into the various processes. Are you prepared to accept his dictum on those points?—Certainly.

6024. You know why this Committee is sitting, do you not?—Yes, I quite understand.

6025. We are called together to see what can be done to remedy the evil, which the Home Office thinks is deplorable?—Yes.

6026. As far as I can see there are only two ways of doing that; one is to prohibit the use of lead altogether, and the other is to introduce a code of regulations which will bring this industry, in regard to the care for the workpeople, up to the level of all other large industries where lead is permitted, and I will just give you an indication of what those special regulations would be. In the first place there would be stringent regulations introduced in regard to lavatories. I think the regulation is that you must provide washing accommodation to the extent of at least one basin for every five people; that soap and nail brushes must be provided and properly looked after; that sufficient clean towels should be provided every day; that a messroom should be provided so as to make it absolutely sure that the men have no meals where they can come into contact with lead, and further, that cloak-rooms should be arranged so that it should be quite certain that the men's clothes put off during working hours do not come into contact with lead; that overalls should be provided at the employer's expense, and washed, so that they would be quite sure that there was no accumulation of dust in those overalls which the men might come in contact with; that washable impervious floors should be introduced so that they may be swilled down regularly every day; that a medical examination of each lead-worker at the cost of the employer should be introduced, and that the cost of compensation, whenever a man is withdrawn from work in lead, would have to be paid by the employer, and also the cost of installing efficient exhaust draught apparatus, wherever it is possible to apply it, for the removal of dust. You must also take into account the cost of setting up a system which will

15 May 1911.]

Mr. PETER CROALL.

[Continued.]

secure continuous observance of all these regulations, for you realise, I have no doubt, that under the Factory Acts the first duty is laid on the employer of securing the observance of the regulations. Now I want to ask you this question. Taking all those points into consideration, and having in view the fact that we must introduce some remedies for the evil which undoubtedly exists, do you still consider that it would be better to regulate the industry by these special rules, or would you, as a manufacturer, rather see the use of lead prohibited?—I consider that the industry could not stand these regulations.

6027. Then do I understand as an alternative that you would rather see the prohibition of lead?—Certainly, but then what about the fine lining?

6028. That the Committee would of course bear in mind?—But we use so very little white lead in our trade. Could not higher-class coach builders have been put on a different footing?

6029. It would be impossible to exempt a particular kind of goods. That would include others. The Home Office regulations would apply irrespective of the class of goods. They would apply entirely to where lead is used, and these restrictions would have to be introduced to protect the workmen who worked with lead. I am only putting this before you, not that this Committee has made up their mind in any degree as to what they shall do, but to show you what is the practice in other industries where lead is permitted to be used?—It is hard on us when we use so very little of it.

6030. But you injure more people in your industry than they do in some other industries where such regulations are in force?—It is very strange. I had never heard of white lead poisoning before this.

6031. But you see the importance of it, because the lead poisoning evils in this industry are greater than in other industries where these regulations are in force?—Yes.

6032. (Dr. Collins.) When you say you use so little white lead in your industry I do not quite follow you. Do you mean you use very little white lead in painting motor-car bodies?—Yes, in painting a motor-car body I should say the whole thing will run to about 10 lbs. of white lead altogether on a whole body.

6033. How much less paint do you use in painting a motor-car body than you do in painting a similar surface of a brougham?—We use just about the same quantity. There is a bigger surface on the motor body than there is on the carriage.

6034. Then the workpeople who do the painting are continuously employed?—They are.

6035. I do not quite follow your point?—They are employed, but it is all wet white lead in our case; we have practically no dry white lead at all.

6036. You are not aware of the fact that we have had shown to us recently that wet lead paint gives off a volatile organic compound?—I am not aware of that.

6037. Which when inhaled will affect you in just the same way as if you were inhaling the dust?—Then I fancy the reason that we have been exempt is that we have large premises, and there is plenty of air in the premises.

6038. That may have its influence, but it only shows you what a subtle material you are dealing with. You have not merely got the question of the dust to take into consideration, but you have also the compound, which you cannot control, practically given off from the wet lead paint. I do not quite follow your point when you say you use so little. If I follow you, you mean that the amount of lead paint used to the coat of a motor car as compared with the amount of lead paint used to the coat of a brougham is less?—I consider that we have never used a great amount of white lead in our manufactory.

6039. But you have a certain number of employees constantly using white lead in your business?—Yes, certainly; but after putting on the flat colour and the varnish colour they use ground pumice-stone and water to flatten it, and the flattening takes longer to do than the coating.

6040. Is not that the same with a brougham?—It is the same with a motor and the same with a brougham, yes.

6041. I cannot follow your distinction when you say that there is a smaller amount of lead used. The men seem to be constantly employed at it?—But for the number of men we have we do not get through much white lead at all.

6042. When you speak of your trade, do you mean the trade of carriage building and motor-car building?—Yes, both.

6043. But we have our statistics showing that lead poisoning occurs very frequently in this trade?—Yes.

6044. Have you ever taken out the statistics of illness among your workpeople?—No, I have not, but we have very, very little illness.

6045. Little is a comparative term. Have you ever taken it out in another trade?—If there had been any case we should have heard, I am sure.

6046. I do not agree with you at all there. I have so frequently found that employers have not a knowledge of the health of their workpeople. That is our constant experience?—But our painters are practically never away ill, to my knowledge.

6047. What is the average age of all your painters?—It would be about 40, I should say—40 to 50.

6048. Do you know how much invalidity is suffered by a man who is 20, on an ordinary average?—No.

6049. Do you know how much is suffered by a man who is 60?—No.

6050. If you do not know these points, how can you possibly state that there is little illness going on among your workmen?—Because they are so seldom off work for illness.

6051. These are very intricate points, and you come before us and make a statement that there is very little illness when it is absolutely proved statistically?—I can actually prove it by my books if I have the time.

6052. But you can only prove it by your books if you compare it with the other trades. You must have a comparison before you can say whether a thing is big or small?—Yes.

6053. You must compare the amount of sickness among your own people with other people in other trades before you can make the statement that you have little sickness. I only wish to draw your attention to the point that personal opinion, as I know too well from my own experience, is not to be trusted until you get the figures?—I would be very glad to give you figures on that point. I could take any of the men's time for a year, and you will find that they are only off for perhaps half an hour or an hour in the morning sometimes. It is hardly ever that they are off work.

6054. Until those figures are collected, the statement that you have a small amount of sickness among your workpeople is only a personal opinion?—I will be very glad if my official will call and look at our books.

6055. You have given me the average age of your workers at about 40. Do you know what the average age in another trade would be? Is that a high average age of workpeople, or is it a low one? I am referring to painters?—It is not a high age just now.

6056. Have you men who are not in any way exposed to the influence of lead, either wet lead or dry lead, in your works?—Yes.

6057. Men who never come near the paint work?—Yes.

6058. Men who are employed continuously by you?—Yes.

6059. Will you find out the average age of those men as compared with the average age of the men who are exposed to lead—that is the average age of the living men?—Yes.

6060. We know as a matter of fact that the average age at death is younger, considerably, of those exposed to lead than those working not exposed to lead in the same trade. Will you look out the statistics on that point from your own books?—Yes.

6061. (Mr. Mason.) You seem rather to doubt the lasting qualities of the Daimler cars apparently from your own experience; but, as the Chairman pointed out, the customers by this time would have complained

15 May 1911.]

Mr. PETER CROALL.

[Continued.]

had the quality of the cars not been up to the standard. Do you consider that the average customer would know whether his painting was right or wrong?—Certainly he ought to know, but I do not think that so many customers who use motor cars had carriages. There are a great many who have motor cars who never had carriages, and they do not know so well how long it will last.

6062. Under those circumstances, what evidence do you think this Committee ought to have before suggesting such regulations as the Chairman has just mentioned, if the Daimler experience is not sufficient?—It would certainly be very nice if we could get a substitute, after all those cases, but it would be a great pity if white lead were abolished, and then we looked for substitutes, and did not get one that really took its place.

6063. What evidence would you be satisfied with in order to change over from white lead to a non-poisonous paint? You do not want to take a leap in the dark, and you would want to be satisfied first that there was some reasonable chance of making it a success with this substitute?—Yes.

6064. What sort of evidence would you require?—I suppose you would require to know how they had stood for a few years.

6065. How many years?—Three or four years.

6066. (Chairman.) In the interim you would not object to the introduction of these regulations to protect the workpeople?—I think we would be better out of the trade if we are to have these regulations.

6067. But you say you would want three years' exemption, and you would not wish that these men should go on suffering for those three years without any protection, would you?—No. Of course, speaking personally, I do not think that they have suffered.

6068. But you cannot get away from the statistics. I am basing everything on these statistics. They are not my statistics, they are the Home Office statistics. My question is this. If you want three years to look round and find a substitute, you would not object to special rules being introduced which would protect the workmen in the interval?—I should certainly object to all those regulations.

6069. Then you prefer the abolition of lead within a reasonable time to the regulations?—Yes, certainly, I prefer it to that.

6070. (Mr. Kinggate.) Do you think that the fact that you had a car of the Daimler Company which was so badly painted is sufficient to condemn the system?—Perhaps it is hardly fair, I admit.

6071. You know that bad painting may come from other sources than from the fact of not using lead; for instance, if a thing is painted very hurriedly—what we call hot stuff, or presto?—Yes, but they are supposed to paint all their cars well. They usually take time.

6072. All coach makers are supposed to do that, but you know perfectly well they are sometimes painted hurriedly, and have to be done hurriedly because the customer says it must be done by a certain time?—Yes.

6073. Is it not possible that that was the cause of the car that you saw having all the paint taken off? You have no evidence that it was caused by the method of painting?—No, I have no knowledge.

6074. Have you any knowledge of the method of painting which the Daimler Company adopt?—No, I did not know until to-day.

6075. Do you know that they do not exactly use a substitute, but that it is a different method of painting?—I was told to-day that they use a substitute.

6076. Not a substitute in the sense that we mean a substitute. You do not think that it is sufficient to condemn the method of painting simply from the fact that you saw one car that was badly painted?—No.

6077. The object of lead first of all is to fill up the grain, is it not?—Yes, and to bind it.

6078. There is practically very little of it left at the finish. The coats of priming, for instance, are practically all rubbed off again, except what is filled in the grain?—Exactly.

6079. So that really there is not so much in that, so long as you can get some substitute to fill up the grain?—It is not so much that as to bind it. You want it properly bound, it is the filling that fills up the grain.

6080. The lead first of all goes into the grain of the wood?—Yes.

6081. As long as you can get something to stop that suction there is not much in it. The object of the whole of the filling and the priming is to stop up the pores, or to stop up the suction of the wood, so that you can get a good surface?—Yes.

6082. If something could be got to do that, if it were durable, could not that be used instead of lead?—Yes, I should think that would be a very good plan.

6083. If this Committee has proved to it that a substitute can be found or a method can be adopted which would be as good as lead, do you not think that lead should be prohibited, having regard to the statistics?—Yes.

6084. With regard to illness in your firm, do you require a doctor's certificate if a man is off ill?—No.

6085. So you have no definite knowledge as to whether he might not be suffering from something brought about by lead?—No. I will look into that, because I can give you the proper statistics of the painters.

6086. Of course, the carriage makers would use more lead than the painters?—Not a large quantity of lead. It is just coated over the plates, I think.

6087. The bolts, and the clips, and the rivets, and so on?—Yes.

6088. I know one of your carriage makers who suffered with lead poisoning many years ago?—Yes. I spoke to old Mr. John Croall just before I came away here, and I asked him about it, and he said he knew of no case.

6089. I have been over your firm on occasions, and I know that a man did suffer from it. I am only pointing this out, that there are many cases that are not attributed to lead, but which we know are due to lead?—Yes.

6090. (Mr. Robins.) With regard to the case that you mentioned of the motor-car that you examined, and that you thought had worn very badly, I suppose you have considered the different conditions that a motor-car has to experience to what a private carriage had to in years gone by?—Certainly.

6091. Do you think it would be possible, after a car had been running a journey, to go and wash that car down, the same as you would wash a brougham after it had done a journey? Could you wash it with the ordinary method of sponge, leather, and water?—You require the hose.

6092. With the hose and all, do you think you can get that car clean with your hose, sponge, and leather?—I should say no.

6093. In nine cases out of ten the cleaner of the car has to put paraffin or petrol in his water to help him to clean the grease that is constantly flying from the speed of the car?—With the wings that are put on now, I consider that no grease should go up on the body. The wings are protected on the inside entirely, and the platform steps have either leather or steel running right along underneath. We close ours entirely at the front, so that I consider there should be no grease going on the body.

6094. But in nine cases out of ten paraffin or petrol is used in the water to wash the car, and I maintain that that has a great effect on the varnish. Of course in keeping paint good there is use and abuse, and I maintain that it would be impossible to clean a car out with water, sponge, and leather. The second point is that you laid special stress on this: that why you were sorry to abandon white lead was because of the greater difficulty of a painter putting fine lines on?—Yes.

6095. With regard to lead, it has always been experienced that lead for fine lines is very heavy?—For cream lining what would you use?

6096. You have to add yellow to it, which makes it a little lighter still. If you had pure white you would have to have blue with it to a certain extent to produce

L 4

15 May 1911.]

MR. PETER CROALL.

[Continued.]

the white. The zinc white I use myself, and the painters under my charge use it, and I prefer it. A better colour can be made to run; it is lighter on the pencil, and it produces quite as satisfactory an effect, and it is better for the painter to use than white lead for drawing a fine line, because if you use white lead to make a fine white line, you have to

adulterate it with a little blue, whether you have white lead, or whether you have zinc white?—But if you have this drying colour, it does not draw nearly as well, does it?

6097. You can make oil colour from zinc white as well as you can make oil colour from lead?—I have never used zinc white.

The witness withdrew.

MR. WALTER JOHN ARNOLD examined.

6098. Are you in business in Dublin?—Yes.

6099. You are one of the witnesses selected to give evidence on behalf of the Institute of British Carriage Manufacturers?—Yes.

6100. Are you a carriage manufacturer?—Yes.

6101. What length of experience have you had personally?—28 years.

6102. How many men do you employ?—It varies with the time of the year—from 60 to 75.

6103. How many cases of lead poisoning have you known?—One.

6104. Mr. Maythorn, the President of your Institute, has spoken of the processes generally, but it will not be necessary, unless you wish it, to ask you to corroborate all those details. Are you content with his opinion on the main questions?—I am quite satisfied.

6105. We have had evidence about the bodies. You wish to speak principally about the wheels, do you not?—Yes.

6106. These are usually sand-papered, are they not?—They are sometimes, if they are in a rough condition.

6107. Are they generally sand-papered?—Sometimes. It is just according to the condition.

6108. What proportion of them are sand-papered?—Perhaps one in six.

6109. What is done to the others?—We have adopted a system by which we get ground pumice stone in three different grades. It is like flour. A man has a box and puts it into that with water, and he gets a rug and rubs it on. It is a sort of wet pumice-stoning of the wheels; not with pumice stone in a lump, but with ground pumice stone.

6110. When rubbing down is done, it must produce a certain amount of dust, must it not?—It does, but I have found, on looking at it, that it is more like paint coming off. It is not like sand-paper dust, but it is more like little curls of paint.

6111. Wherever that dust is formed, it contains lead?—Yes, it does.

6112. How is that danger to be overcome?—I could not suggest that. The lofts are swept every morning. They are dumped first and then swept every morning.

6113. Have you known of any cases of lead poisoning in your works?—Only one.

6114. Do you know that in the coach-building industry, taking it as a whole, there have been 787 cases of lead poisoning recorded by the Home Office in 11 years from 1900 to 1910?—I am surprised to hear it.

6115. And that of those 47 were fatal. Does that surprise you?—It does, because before I came away I made inquiries from the coach-builders in the City, from the insurance companies that insure us, and from several doctors, and not one of them has come across a case.

6116. I am not surprised altogether to hear that, because I know of my own knowledge that there are a large number of factories in the Potteries where they have had no cases of lead poisoning for many years. The trouble is that even some of the best works are not immune, and, moreover, a works which has been free from poisoning for many years will suddenly have a succession of cases. But the real facts are these: I have given the number of cases in the last 10 years, and apparently there has been no reduction in the attack rate during that period. The average number of cases in the last eight years is 66½ per annum, and the attack rate in 1908 is 70 cases, in 1909, 95 cases, and in 1910, 70 cases. Now, as there has been a reduction in the average cases reported each year, I am

sure you recognise that something must be done to remove the evil?—Yes, I should think so.

6117. What particular kind of work are you engaged in?—Carriage building and motor-body building and painting, and all works connected with carriage building.

6118. Are you aware that out of 376 cases reported in the five years, 1905 to 1909, 46 arose from the motor car works, and out of 697 cases reported in the 10 years, 1900 to 1909, 297 arose in the ordinary coach and carriage building works of the country?—It surprises me; I have never heard of it.

6119. Have you ever tried substitutes for white lead in your painting work?—No, we never have.

6120. I suppose you would agree that if a substitute could be found which would be in every way as good as white lead, the use of lead should be prohibited?—Certainly, I would prohibit it if there was something as good.

6121. Do you know that the Midland Railway Company for the past six years have not used lead in their carriage and wagon works?—No, I am not aware of it.

6122. We have had similar evidence from the representative of the Bradford Corporation Tramways Department?—I am not aware of that.

6123. Are you aware that white lead is no longer being used in the Daimler Motor Car Works in Coventry?—Yes, I am aware of that.

6124. How does your work compare with the Daimler motor car bodies?—They do very good work. It looks well, but I doubt whether it will stand so well as work that the white lead has been used on.

6125. They are one of the largest firms in the industry, are they not?—Yes, they are.

6126. And they turn out work of the highest finish?—They do.

6127. The buyers of Daimler motors are of about the same class as the customers of your own or other leading coach-body firms?—Yes.

6128. And they would demand the same finish, would they not?—Yes, they do.

6129. The witness representing the Daimler Company told us that they are entirely satisfied with the substitute they are using for all purposes for which white lead is commonly used in coach building works?—As a coach builder I do not think the Daimler people have had long enough experience yet to be able to say how the work will stand.

6130. At any rate, their customers are perfectly satisfied. Is not that the test?—If they have had long enough experience of the thing.

6131. The Daimler Company have used no white lead for two years, and they have had no complaints from customers?—Two years is a short time. I would like to see some of our carriages out five or six years and see how they would compare.

6132. The Daimler Company claim that the painting of their cars is thoroughly durable. Do you think they would continue to use it if it was not durable?—No, I do not think so.

6133. Does it not rather weigh with you that they should have abandoned the use of lead entirely after this two years' experience?—Yes, I should think so, if it is giving satisfactory results without the lead.

6134. I do not propose to take you through all these questions, as you have already told me that what Mr. Maythorn said you would accept; but I should like to point out to you, as I have to other witnesses, the position that this Committee occupies. We are

15 May 1911.]

Mr. WALTER JOHN ARNOLD.

[Continued.]

sitting here to find some solution for this very deplorable state of affairs, and we have two alternatives, and only two. The first one, which is the simplest method, would be to prohibit the use of lead. The other is to regulate the trade by special rules, such as those which obtain in all the leading existing lead industries. Those special rules involve the following stringent regulations. First of all lavatories; proper provision being made for washing accommodation. That regulation is, I think, one appliance for five people?—We have that in the paint loft.

6135. You would have to supply soap and nail-brushes?—We do so.

6136. Towels, frequently changed?—I must say, although we put them up, we do not get all our men to use them. They still stick to the old idea of using a piece of horse-hair. Every painter is provided with a pail in our premises which he uses for washing down his carriage, and he prefers washing his hands in that pail to using the wash basin.

6137. But if the regulations apply to both the workpeople and the employers, they can be punished for not complying with the rules. The usual enactment in other industries is that a mess-room should be provided so as to avoid the possibility of the men eating their meals in a room where they can come in contact with the lead?—None of ours eat their meals in the paint lofts.

6138. And that cloak-rooms should be provided?—We have no cloak-rooms.

6139. The idea of the cloak-room is, as has been enacted in the potteries trade, to provide a cloak-room where the man can hang up his clothes while he is at work and then take them home again and so avoid the danger of dust and contamination. Also that overalls should be provided at the employer's expense. Do you provide your men with overalls?—No. They have some overalls or coverings, but we do not provide them.

6140. That washable impervious floors should be provided, so that they may be swilled down regularly once a day, and that a medical examination of all the employes at the employer's expense should be introduced; and, added to that, it must be remembered that the cost of compensation, which is payable to a workman whenever he is withdrawn from working with lead, would have to be paid by the employer?—Of course we have all our men insured.

6141. Then a very important innovation would be, where it is possible, the installing of an efficient exhaust draught apparatus for the removal of dust?—We have two or three ventilators in the roof.

6142. I mean local appliances, so that the dust can be withdrawn from the men while they are at work. Then you must take into account the cost of setting up a system to secure the continuous observance of these rules. Now the question I put to you is this. Taking all those points into consideration, do you consider that it would be better to regulate the industry by this special code of rules, or would you, as an employer, prefer the prohibition of the use of lead?—I would sooner do without the lead.

6143. (Mr. Mason.) In speaking of the rubbing down of wheels, do you apply this wet pumice powder with horse-hair?—No, with an old piece of rag, generally an old piece of plush or cloth.

6144. Do you find that gives a smooth finish and gets out all the hollows?—Yes, if the lead paint is put on properly it is only the little nibs that want to be taken off. It is only a matter of smoothing it before the next coat goes on. We do not rub off the lead; we want to leave the lead on as a ground colour for what comes after. It is only a little thing like a hair out of the brush, or out of the horse-hair,

that would have to be taken off, or a little nib or some dirt.

6145. You find that the wet rubbing down is perfectly satisfactory?—Yes.

6146. And that you can do away with the dry rubbing down of wheels entirely?—Yes, I do, generally speaking. Of course with varnish work we use a good bit of sand-paper, but there is not much harm in that. We do not rub it down.

6147. That is for finishing colours?—Yes, varnished wood.

6148. (Mr. Kinggate.) Do you mean that you use the wet pumice powder for the first priming coats?—Yes.

6149. Does not that raise the grain of the wood again?—No, not if the lead is put on properly.

6150. The majority of the spokes are a little rough, are not they?—Yes.

6151. When you have given it the first coat of priming, you must rub it into the wood if you want a proper surface, and if you get wet upon that what is the result?—My difficulty is that our spokes are waxed before they come to us, and they do not hold much.

6152. You say some of them are waxed?—Yes.

6153. It all depends whether you make your own or buy them?—They are nearly all machine made spokes now, and they are waxed. They are so smooth that they scarcely hold the paint. You have to give them two or three coats. We have less sand-papering and rubbing down now than ever we had, because the spokes are so smooth, there is not the same grip on the smooth spokes that there is on the rough ones. We might put two or three coats of lead colour on before we would rub it.

6154. Do you use any hard stopping on yours?—Not on the wheels.

6155. On the felloes?—Not as a rule: now and again. We used to use a little on the best carriages, years ago, but not now.

6156. You do not paint these so well as you used to the old carriages?—If you go to paint a vehicle now, there is not so much care taken with it, except on a good motor car, as there used to be before.

6157. I have never seen it done with wet rubbing down on the priming coat?—Do not think I am saying that it is done on the first coat; it might be the second or third coat before we thought it necessary to do it.

6158. But it would depend on the spokes?—Yes.

6159. (Mr. Robins.) Do I take it that you use no stopping on the wheels at all?—Very rarely.

6160. But when you use stopping on the wheels you have to sand-paper it off?—Yes.

6161. You made another point about the painter preferring to wash in his pail rather than go to a lavatory to wash?—Yes.

6162. I do not think much of the painter, because he has got his water greasy and his sponge and water full of soap. I should not like that method, and if I were the employer I should certainly stop him at it?—I do not know that you can dictate to a man about that.

6163. You can when the special rules are introduced, because the workman must keep the rules just as much as the employer?—Yes, if that is so. The paint loft is a place I am very much in during the day, and for many years I have looked after the paint loft department. I go upstairs a quarter of an hour before we knock off at night, and I always catch half-a-dozen of them washing their hands ready to go away. I may say it is very different at the dinner hour.

6164. Do you give them time to wash their hands?—We give them five minutes' grace every day. They do not do it in the dinner hour.

The witness withdrew.

## EIGHTH DAY.

Tuesday, 16th May 1911.

## PRESENT:

SIR ERNEST F. G. HATCH, BARR. (*Chairman*).

Lord HENRY BENTINOK, M.P.  
 Sir GODFREY BARING, Bart. M.P.  
 Mr. E. L. COLLIS, M.B.  
 Mr. F. G. RICE.

Mr. W. G. SUTHERLAND.  
 Mr. A. GARDNER.  
 Mr. J. PARSONAGE.  
 E. A. R. WERNER (*Acting Secretary*).

Mr. J. PUTTBELL examined.

6165. (*Chairman*.) Do you attend to-day as the representative of the National Association of Master House Painters and Decorators?—Yes.
6166. What is your business?—Painting and decorating.
6167. How long have you been in the painting business?—Fifty-eight years.
6168. Were you apprenticed to the trade?—Yes.
6169. How long have you been an employer?—Forty-nine years.
6170. Have you held office in any trade society?—Yes.
6171. Please give particulars?—I was the president of the National Association in 1909. I am the president of the Sheffield and District Master Painters' Association for the present year, and I was president last year.
6172. What is the average yearly number of painters employed by your firm?—About 50.
6173. Have you known any cases of lead poisoning or painter's colic?—I have only known of one case—an apprentice—some 15 years ago.
6174. I am not surprised to hear that you have had no cases, because you may be doubtless aware that in the Potteries there are many large works which have been immune from lead poisoning for many years. The trouble is that even in some of the best works, and in works that have been free from lead poisoning for many years, they sometimes have a succession of cases quite unexpectedly. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—Yes.
6175. Do you pay a special rate for that?—We pay an increased rate.
6176. Have you known men who have broken down temporarily on account of lead absorption?—No, we have not had any—only this one young man.
6177. Have your men had occasional days of sickness due to lead?—No, they have not suffered from sickness due to lead.
6178. Do you have a periodical medical examination of your men?—No; we have no need.
6179. Then how can you say for certain that your men never suffer from slight attacks of lead poisoning?—They do not to my knowledge.
6180. But they may suffer without your knowledge?—Yes, they may, of course.
6181. Now you take a prominent part in the work of the Master House Painters' Association?—Yes.
6182. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—Sometimes.
6183. What has been the result of such discussions?—At the last meeting I was at, I could not hear of a single case of lead poisoning in their shops; and that was last week.
6184. Did you take any steps to discover how much illness there was among the men employed by your members?—No. Well, there is no illness—only perhaps a man having a cold or something of the kind.
6185. But you have heard that the prevalence of lead poisoning is very serious, have you not, in the trade?—Yes, I have heard.
6186. Were not you surprised to find that not one of the members of your association had any case to report?—Yes, seeing that there is so much talk about it.
6187. Did not your association think it necessary to make any further investigations?—Well, we had nothing to investigate. Our men are healthy and well.
6188. But you must have heard of the prevalence of lead poisoning amongst the men who handle lead paints?—I have heard more about it since the liability has been included in the Workmen's Compensation Act.
6189. But did your association never attempt to collect statistics concerning the number of days' absence from ill-health among their employes as compared with workers not in contact with lead paint?—We have not had it. There may have been people who may have had colds.
6190. Did your association ever consider the advisability of having a medical examination made of persons employed by them, with a view to discovering the proportion of those showing any symptoms of lead impregnation?—They have spoken about this, but they have not decided upon anything. The question of the liability is so great that we wondered if we had to really have our men examined, or examined before we employed them.
6191. Do I understand that the idea of having a man examined medically was occasioned by the extra rate charged by the insurance companies?—And the prominence given to the question of lead poisoning.
6192. Has your association ever taken any collective measures to discover a substitute for white lead in paint?—We have talked it over in our association.
6193. Have you done anything else but talk it over?—We have not found anything that we consider equal to white lead.
6194. Have you collectively taken any measures to discover a substitute?—Only by each of us trying for ourselves various articles that are put upon the market.
6195. Have you employed a chemist to make scientific investigations into the chemical properties of different pigments and vehicles?—We have not.
6196. There are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead?—Yes.
6197. Has your association carried out any practical tests with them?—We have tried various articles that are put upon the market—pigments.
6198. Can you tell us of any other steps which your association has taken to find a remedy?—We are trying to educate our young people.
6199. In what form are you trying to educate them?—In teaching them to be careful and clean in their habits, and clean in their bodies. We teach them to wash their hands before they have their meals, and to wash their hands when they have finished.
6200. In what way is this teaching performed?—We have our technical school in Sheffield, and it is brought before the apprentices in the technical school

16 May 1911.]

Mr. J. PUTRELL.

[Continued.]

In our own shops, we each one of us impress upon the young people the duty of keeping themselves clean.

6201. Is the technical school confined to Sheffield only?—No; the technical school in Manchester is larger than that in Sheffield.

6202. How many attend the technical schools?—In Sheffield they have a class of about 70—a school of Art.

6203. How many painters are there in Sheffield?—About 800, I should think.

6204. So that only a very small proportion enjoy the benefit of this teaching?—Yes.

6205. Are the 70 students all painters?—Yes—apprentices.

6206. Is the practice of indenturing the boys as apprentices, then, kept up in Sheffield?—Yes; we think it better.

6207. Have you any idea how many apprentices there are in Sheffield, approximately?—No; I have not come prepared to answer that question.

6208. Are there a large number?—No; if there are only 800 men, I should think there would be about 120 apprentices.

6209. Then 70 out of 120 go to the technical school?—Yes. We also teach them how to use their paint can and brushes (that is a very important matter in teaching youths) so as to keep free from the paint.

6210. Do you think that the members of your association realise the magnitude of this lead poisoning evil?—I think so.

6211. Do they know that the Registrar-General has recorded no less than 284 definite deaths from lead poisoning among house painters in the last ten years?—Yes.

6212. They know that?—Yes, I think so.

6213. And that his mortality figures show for painters a death rate considerably higher than the normal, from troubles which are the frequent effects of exposure to lead, such as Bright's disease and nervous diseases?—Yes.

6214. Do they know that?—Yes, we know that in the trade.

6215. Do you know that about 2,000 cases of lead poisoning in the trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the same ten years?—Yes, I have heard that.

6216. Do they realise that these cases, reported voluntarily, are only a fraction of the whole, inasmuch as the Home Office have no legal right to pay for such reports and are therefore bound to discourage reporting to some extent?—Yes, quite so.

6217. I am sure you agree with me that all this sickness and death is very deplorable?—Oh, yes, there is no doubt about that.

6218. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes.

6219. And that the use of white lead has been prohibited to an appreciable extent abroad?—It has in some cases.

6220. And that the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed?—Yes.

6221. Do not you think it regrettable that this country should be behind other nations in this respect?—Yes, if there is a remedy.

6222. But do not you think it, in any case, regrettable that this country should be behind other nations in such a matter?—Yes. We ought as a nation to find out something to take its place.

6223. We ought to be abreast of foreign nations, do not you think, in preventing this evil affecting our workmen?—Some of those countries have changed their front a bit.

6224. I want you to answer the question: Do not you think that we ought to be abreast of foreign nations in protecting our workmen against the evils of lead poisoning?—Yes; we ought to do it as far as possible.

6225. A great many small dangers attend the use of lead, for instance, the risk of contamination of food by unwashed hands?—That is a serious matter.

6226. Do you teach the importance of personal cleanliness on the part of the men?—Yes.

6227. Then you consider lavatory accommodation essential?—I do.

6228. Including a supply of hot water for washing?—Not necessarily hot.

6229. But can you wash paint off your hands with cold water?—Yes.

6230. In any kind of weather?—Yes.

6231. Have you tried it yourself?—I have done it.

6232. I understand that in some cases the men have only a minute allowed them to wash their hands. Do you say that a man with cold water on a winter morning can get the lead washed off in a minute?—A man can do better if he can have hot water.

6233. But I ask you: do you think it possible that a man on a winter morning, with perhaps a temperature of 30° to 40°, can get paint off his hands in one minute in a pail full of cold water?—I consider he can get it off in that time—in one minute.

6234. You think he can?—Yes.

6235. But you think that hot water would be better for him if he can get it?—There is no doubt about it. It is better than cold water.

6236. Is it generally practicable for the men to have hot water to wash in?—Generally.

6237. For example, when the exterior of a house only is being painted and the men are not expected to go inside for any purpose, can they get hot water then?—The householders are always pleased, or as a rule they are, to supply what the workmen require.

6238. But they are dependent on getting it from the householder, are they?—The householder would allow them to have hot water.

6239. But they are dependent on getting it from the householder?—Yes, they are dependent.

6240. Do you advocate definite rules regarding the wearing of overalls?—Yes, I approve of wearing overalls.

6241. How can you ensure these being kept in a cleanly state?—The men ought to attend to it for themselves.

6242. How often should they be washed?—Every week.

6243. What do the workmen do with their overalls when they have finished work?—They put them in their bags.

6244. In the bag that they carry their luncheon in to their work?—Some may.

6245. And their tools?—Yes, some may do it.

6246. Is not that rather asking for trouble?—Well, a man, of course, can keep them quite away from his food.

6247. But if he puts them in the bag which contains his food, some dust must accumulate in the bag, and the next morning he is mixing his food with lead dust. It is in actual contact with it?—Yes. Some leave them on the jobs ready for the next morning.

6248. Where can the overalls be kept from day to day when men are working continuously on the job?—It is only a question as to whether he can find a place at the house or the premises where he works.

6249. But supposing he is working outside a house, where can he put them then?—In some of the out-buildings.

6250. Are out-buildings always available?—As a rule.

6251. Do you advocate a rule requiring meal rooms, so that a man shall not eat his food in the place where paint has been handled?—I do not think that a man ought to get his food where his paint has been mixed or used.

6252. Would you go so far as to say that he ought not to eat his food in any place where lead dust accumulates?—It is better to be away from it.

6253. I may tell you that in all other industries where lead is used there is a prohibition, and a very strict prohibition, against allowing men to come into contact with lead dust in any respect. The men are not allowed to eat their food in any room where it can come into contact with lead dust?—Quite so.

6254. It is against the law?—Yes.

16 May 1911.]

Mr. J. PUTRELL.

[Continued.]

6255. Can a place always be found quite free from risk of contamination where the painter may eat his food during his working hours?—As a rule he can. He can find a place generally.

6256. Are you sure of that?—That is my impression.

6257. Are you quite sure that, in the majority of cases, a man has an opportunity of eating his food away from the place in which he is doing his work?—Sometimes a man has to sit outside. He would in weather like this.

6258. Yes, I know, but, generally speaking, is it possible for a man to find a place to eat his food in the winter where he will certainly be away from the contamination of lead dust?—Sometimes he may and sometimes it may be difficult.

6259. But do you think that it ought to be made an absolute rule that he should not be able to eat his food where lead is handled?—It is a difficult question as to whether a man might really be able to find a place. Generally, at houses that we work at, there is an outbuilding, and in offices very often there is a room set apart.

6260. Do you think that it ought to be made a definite rule that under no circumstances should a man be allowed to eat his food in the place where he has been doing his work, when he is likely to come into contact with lead dust?—I do not think that he ought to get his food where the paints are.

6261. That is not my question. I am not speaking about mixing paints. I asked you the definite question whether you think a man ought to be prohibited in the future from eating his food in any place where he can come into contact with lead dust?—No; I think it is better to avoid it.

6262. And you would agree that it should be a fixed rule?—Yes.

6263. Now these precautions of washing hands and so on which I have just described to you as well as others, are insisted on in other industries for the mitigation of lead poisoning risks. Would it not be exceedingly difficult to carry them out faithfully in connection with house-painting operations?—I do not see that it would.

6264. At the best such precautions would not deal with the most important risk, namely, the risk arising from dust and spray which the workman can inhale during the whole of his working hours?—There is not much of the lead dust knocking about as a rule.

6265. I did not speak about the quantity. I said the risk arising from dust and spray which the workman can inhale during the whole of his working hours?—Yes. Well, there is not much dust from the work as a rule. We rub down with pumice-stone and water.

6266. Do I understand you to say that there are no dangers in the various operations?—There is very little dust. We rub down with pumice-stone and water, so I take it that the danger is very slight.

6267. Then in your opinion, the danger to the house painter is a very small one?—In being in the room where we are preparing for the painting and rubbing down with water, there is not much danger.

6268. Then how do you account for the enormous number of lead poisoning cases which the Home Office have had reported to them?—Because of the carelessness of the workmen.

6269. During their work?—During their work. A man will handle a brush covered with paint, and rub it on his hands and rub it anywhere.

6270. Do you think that he does that wilfully?—I know of men that do it and they do it carelessly. They are quite indifferent.

6271. Quite indifferent to their own health?—Yes.

6272. Now as regards dry rubbing down with sand-paper, I understand that this process is indispensable?—It can be done without.

6273. But I understand that the wet process cannot be substituted for dry rubbing down between the first and second coats when ordinary paint has been used?—It is only in the first-class work that we rub down the second coat.

6274. But in the first-class work a certain amount of dust is created in rubbing down?—There is very little dust from a newly painted surface.

6275. There is a certain amount of dust?—It is dust from the sand-paper more than anything else.

6276. Do you mean to say that the wall rubs the sand-paper off and not the sand-paper the wall?—The sand-paper of course rubs off any little particles.

6277. You rather suggested just now that it was the dust from the sand-paper and not the dust from the wall which collects?—More dust comes from the sand-paper than from the wall.

6278. Then the wall rubs down the sand-paper; that is what it comes to?—Yes.

6279. I will ask you this: Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing some of the lead dust?—By putting something on to cover his nostrils.

6280. Is that the only method?—I do not know of any other.

6281. Could you use an exhaust fan to remove the dust?—It would be a very difficult matter, and the dust is so small a portion that it is far-fetched to think about it.

6282. The amount of dust arising from this sand-papering, we have been told, is very considerable?—Not very much.

6283. We have been told that it covers the man's clothing as well as the floor and surrounding objects. Now, how is it possible to save the workman from the very serious danger involved in breathing this dust? You think it is very small and other people think it is very large?—You are perhaps alluding to the places where, before the first coat of paint is put on, it is rubbed down with sand-paper. Then there is bound to be a lot of dust. I say we do not do that. We rub down with pumice-stone and water.

6284. I want you to realise the question. Where they do rub down with sand-paper, how are we to protect the workman from breathing this dust which we know to be very injurious?—I take it, if it is in the second coat, there is very little dust stirring, and it is of a moist kind—just little particles that have been moistened with oil.

6285. You say just now that it is the sand-paper that created most of the dust, but I am asking you now how we are to deal with the small amount of dust that arises from the rubbing down after the second coat and the large amount of dust which you spoke of just now?—I do not see how you can deal with that. Whatever paint you have you are faced with that difficulty.

6286. Then are the Committee to understand that there is no remedy for the amount of dust, whether it is much or little, that is created by the process of rubbing down with sand-paper?—Only having fresh air in the room, and keeping the room swept up.

6287. Those are the only things?—Yes.

6288. Might not fresh air rather disperse the dust than otherwise?—You must have fresh air in a room.

6289. But might not fresh air, a good draught, tend to blow the dust about that was collected on the floor and make it worse?—I would sweep it up.

6290. But how often would you sweep it up?—As often as necessary.

6291. Every hour?—It depends how much has been done—every hour, if necessary; or oftener, if necessary.

6292. Would not that be rather an expensive operation?—We should leave it to our men.

6293. The men would have to do it as part of their work?—Yes, certainly.

6294. Now the next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

6295. This gives rise to splashes which frequently fall even on the face of the workers?—Yes.

6296. How can you deal with the spray which arises in this operation?—You cannot deal with it very well.

6297. Could you have an exhaust draught to catch the spray?—You cannot very well.

6298. Then again we are confronted with the problem of how to save the worker from the grave danger involved in breathing the spray?—With regard

16 May 1911.]

Mr. J. PUTTELL.

[Continued.]

to inside ceilings, I would suggest that lead might be done away with.

6299. For that particular work?—Yes, for inside ceilings.

6300. But who is to tell whether there is any lead in a paint pot or not?—There are articles on the market now that might be used.

6301. But who is to know whether the particular master painter is observing the rule as to not allowing lead paint for this particular operation?—I take it that the master painter, as a rule, if any law was passed, would fall in with it.

6302. But who is to prevent them breaking the law if they wish to do it?—No one. Anyone can break the law.

6303. Do you think that that would be an efficacious suggestion, when they could not be checked as to whether they were breaking the law or not?—I think if a law was made that no ceilings inside a house or premises should be painted with white lead, we should want to carry it out.

6304. You would all want to carry it out?—Yes, I think so.

6305. You think all the employers in your industry would want to carry it out?—Yes, I think so. Taking it as a rule they would do so.

6306. Now, precisely the same conditions apply to the process of stippling, do they not?—Yes.

6307. It would be impossible, I take it, to protect the workman from the dangers involved in stippling?—Yes, but not so much comes off with stippling.

6308. The other day I saw the process myself, so that I know exactly how much comes off. I agree that it is not very much, but you know in this lead poisoning trouble it is the multiplicity of small things which makes up the great evil. I quite agree with regard to stippling that there is not very much in it, but we saw a splash fall into a man's eye?—From the painter, not the stippler.

6309. It was the stippler's eye?—The splash would be from the painter.

6310. But in the stippling: The drop of paint fell into the stippler's eye—caused, I agree, by the painter. They were working very close together, one man painting like that, and the other stippling like that (demonstrating)?—Nothing comes from the stippling, but it is from the man that is painting.

6311. I do not agree. A certain amount must come from the stippler, but not much. Tiny drops come down, they are almost imperceptible, but they are there. Now my question was this: How are you to protect the workman from the evil effects of stippling?—By prohibiting the use of white lead on those surfaces.

6312. Do you have old paint burnt off with a spirit or charcoal burner?—With spirit.

6313. How can you prevent the worker from inhaling the fumes which arise from this process?—You cannot very well.

6314. It seems impossible?—You cannot avoid swallowing fumes when you are in the street from taxicabs.

6315. But you do not swallow them all day long, do you?—Nearly all day, when you are in London.

6316. Where do your men mix their colours?—They generally have an outhouse, or else a corner of the yard where they are working.

6317. Do you adopt any precaution to deal with the dust that arises when colours are handled dry?—We do not use dry colours.

6318. But some people use them dry. Do you know of any precautions which could be introduced to deal with the dust that arises when colours are handled dry?—No, I do not know anything except compelling that they shall be used in paste form.

6319. Compelling the painters to use them moist?—Compelling the manufacturers who produce them to put them on the market in paste form.

6320. It appears from your evidence that there are certain indispensable processes, in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. I understand you to suggest, first, that in some cases no remedies can be introduced,

and, secondly, that lead should be prohibited in some of these particular operations?—Yes.

6321. Now is it possible to remove the danger entirely in any other way than by using a substitute for lead?—Only, as I say, by taking care to educate your apprentices and men to be clean.

6322. But I ask you, is it possible to remove the danger entirely in any other way than by using a substitute for lead?—No, not entirely; I do not see that there is any other way.

6323. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience of such substitutes?—Yes.

6324. I understand that you have tried some zinc paints. What results have you obtained?—We have used zinc paint occasionally. I used it over 30 years ago, but I was never satisfied with it. It has not the wearing quality or covering power of lead, and I have never found it so satisfactory.

6325. The Office of Works and others have succeeded in obtaining efficient non-lead paint. I suppose you would agree that if an efficient substitute could be found, the use of lead should be prohibited?—I should be quite agreeable.

6326. What are the usual hours worked by your painters per week?—About ten hours a day—36 hours a week.

6327. Would you welcome a strict limitation of the hours of employment, say, to 48 hours a week?—We should be willing, of course, to adhere to that if it was the law.

6328. Paying the same wages?—That is another matter. We pay our men by time.

6329. Do you not pay them so much per hour?—Yes, that is it; so much per hour, and we find that our men prefer to work for many hours.

6330. Naturally; but in other industries where lead is used, it has been determined that 48 hours should be the limit of employment. The trade unions, of course, look after the rate of wages?—Yes.

6331. Now, you do not have a periodical medical examination of your workers?—No; we have had no need to do that.

6332. You think that you have had no need?—We think so.

6333. Do you know that in other industries where lead is used, the Home Office, acting under the powers conferred upon them by the Factory Act, insist on a monthly, or even weekly, examination by a certifying surgeon at the cost of the employer?—Yes, I know that that is done in regard to lead workers in lead factories and in the Potteries.

6334. Would you welcome a system of periodical medical examination in your industry?—We should be willing to fall in with it, if you felt that it was necessary.

6335. And to pay the cost of it?—We should have to pay the cost, of course.

6336. Together with compensation for any worker suspended by the doctor on account of doubtful health?—If an Act was passed that it should be done, we should, no doubt, fall in with it.

6337. You realise that if the free use of lead is allowed to continue, the Home Office would have to insist on the rigid observance of precautionary measures in the same way as in other industries where workers handle lead?—Yes.

6338. And you realise that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—Yes, if necessary.

6339. Again, this would involve an extremely complicated and elaborate code of regulations. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation, avoidance of dust, exhaust ventilation, limitation of hours, and all other such matters?—I think that I should give up the business. I think that the workmen themselves ought to provide their own overalls, and I think that the workmen or their wives ought to see that they are clean. I do not think that an employer ought to be compelled to do it.

16 May 1911.]

Mr. J. PUTTRELL.

[Continued.]

6340. I am only telling you now what obtains in another industry—the earthenware and china industry. The employers on the Departmental Committee which dealt with lead poisoning in that industry agreed to provide the overalls and to see that they were washed, and I think that that is a principle which might be adopted with regard to all other lead industries, for this reason—that if the employers are allowed to use a dangerous element in their business, that is to say, dangerous in the sense that it affects the health of their workpeople, they must apply all the precautions which are necessary to obviate the evil. Now do you not think that under the circumstances it would be better for us to recommend the prohibition of the use of lead rather than to have to insist on all these precautions being introduced?—I think it would be better, of course, to throw the responsibility on the nation—that is, upon the ratepayers.

6341. That is a little bit too vague. You may give a little dissertation later on on some further burden on the ratepayers, but my question was this: Do you not think that under the circumstances, in view of these precautions which must be introduced, or a great many of which must be introduced, it would be better for this Committee to recommend the abolition of lead, or at any rate to restrict it to, say, five per cent.?—Personally, I do not think it is necessary to make all these regulations.

6342. I know; but may I say this—that we are not asking you what you think is necessary; we are sitting here as a Committee to devise some means of protecting these workpeople who suffer so sorely. I have fore-shadowed to you the restrictions which obtain in other industries; and you may be certain of this, that most of those restrictions and special rules will be introduced into your industry, if the unrestricted use of lead is allowed to continue. In view of your remark just now that you would have to give up business if these regulations were introduced, I ask you whether you think, under the circumstances, that it would be better for this Committee to recommend the abolition of lead rather than the introduction of these precautions in the shape of special rules?—I should think so.

6343. (*Dr. Collis.*) What is the extent to which your liability for insurance has risen during the course of the last three years, compared with what it was six years ago?—It has been rising continually since the beginning of the insurance.

6344. Yes, but to what extent. Could you give me the figure that it stood at in 1905, for instance. We have not had the figure at any time?—No, I could not. Mr. Sutherland can through the association.

(*Mr. Sutherland.*) It was 12s. 6d.; it went up to 1l., and then it went up to 30s.

6345. (*Dr. Collis to the witness.*) Under the Act of 1906, which came into force in 1907, it has gone from 12s. 6d. to 30s.?—Yes.

6346. That represents entirely liability for lead poisoning?—No.

6347. That is the only difference between the old Act and the Act that came into force in 1907?—No.

(*Mr. Sutherland.*) There was contributory negligence under the old Act, and there is not such a thing under the new Act. Then there is the question of "arising out of." That is another clause which has brought in a lot of compensation cases. There was a 14 days' limit under the old Act, and there is only a week's under the new.

(*Mr. Gardner.*) A painter very seldom came under the old Act. A painter working on a house might meet with an accident, but he did not come under the Act at all. A painter in a shipyard came under the Act right away. Not 25 per cent. of accidents in the house-painting trade came under the Act until it was revised in 1906.

(*Mr. Rice.*) Height of building is another point.

(*Witness.*) There is this point in regard to liability—that if we set a man on to-day and next week we find that he has lead poisoning, we are responsible, although we have only had him for a few days, and although he may have contracted it elsewhere.

6348. (*Chairman.*) But that works equally all round, you know?—I know that it does, but that is one cause of the raising of insurance rates.

6349. (*Dr. Collis.*) Would you go as far as to agree that the main reason for this rise from 12s. 6d. to 30s. is the liability which you are now under to pay compensation for lead poisoning?—No; that is a great portion of it, but there are other things.

6350. I gather that it is not all?—No.

6351. Now I understand that you have been attempting latterly, at any rate since your attention has been drawn to it by the extra amount of premium that you have to pay, to educate your apprentices?—We have done all along.

6352. For how long?—Ever since we have been in business.

6353. Have you ever investigated yourself how lead poisoning is caused, or have you called in medical skill to tell you how it is caused?—No. We know.

6354. How do you know?—It is caused by a man handling paint and getting paint on to his hands.

6355. But how do you know that that causes lead poisoning?—Lots of men and lads too will get paint on their hands and then they will perhaps eat their food with dirty hands, and they are bound to take some particles.

6356. Yes, but you have jumped to the conclusion that that is the way in which lead poisoning is caused, and you have never called in any medical experts to tell you the real way in which it is caused. You have never studied the question?—No. I tell you that we have had no cases in our shop.

6357. That is not the point that I am asking you about. I ask you whether you ever studied the way in which lead poisoning is caused before you undertook to teach people how to avoid it?—Do you mean to say that washing the hands and keeping them clean is not one step?

6358. I say that if every man washed his hands and he never touched lead, out of 100 cases you would not save five by personal cleanliness. I undertake to say that without the slightest hesitation?—But there are other means helping to teach them.

6359. But you say as a point in your favour that you have been teaching people how to avoid lead poisoning. I now ask you whether you have ever studied the way in which it is caused, and I put to you the point which has been raised on the question of the amount of dust that gets on to a man being very small. We have had certain experiments carried out recently with sand-paper, showing that the amount of dust caused by sand-papering may rise to 250 milligrammes of lead in a cubic metre of air. A man in breathing breathes 17 cubic metres of air in an hour, that is to say about 140 in an eight-hours' shift, so that if there was only one milligramme of dust in a cubic metre of air he would then have inhaled 140 milligrammes purely by breathing?—Yes.

6360. Now 140 milligrammes is a considerable amount. If he had that on his hands when he was eating he would be soiling his food. You may teach him to get rid of that by washing, but he is breathing 140 milligrammes, so that it is straining at a gnat and swallowing a camel?—You are coming to the conclusion that there is a lot of dust.

6361. We have had experiments carried out?—But we do not experience much of that.

6362. Attention has been rather concentrated on the dry stuff at present, but are you aware that white lead paint at the ordinary temperature of the atmosphere gives off a volatile organic compound?—Yes.

6363. You are aware of that?—I am not a chemist.

6364. I wonder whether you might possibly have heard of the investigations that are now going on. Can you suggest any way in which you are to teach the worker to avoid breathing that volatile lead compound which comes off paint as he applies it to the wall?—I do not see how you can, except by getting as much fresh air in the place as possible.

6365. I agree that fresh air might be valuable there, but is it always possible, when you want your paint to be open near a dusty road?—It is not often the case that they are near a dusty road.

6366. Sometimes, I suppose, you want to let the paint dry in as clean an atmosphere as possible for the

16 May 1911.]

Mr. J. PUTRELL.

[Continued.]

work's sake?—Yes. I do not know that I can say anything. You gentlemen should know best about that.

6367. You have been undertaking to educate men to avoid lead poisoning, but I want to understand whether when you have undertaken this education you have really known what to educate them against, because it seems to me rather a bold thing to undertake to teach people something when you do not know what you are teaching them?—Surely the question of lead poisoning has been sufficiently to the front to help to bring the matter before us.

6368. Yes, but not the way in which it is caused, I think; at least it does not appear that you have paid attention to the way in which it is caused, so that you could teach people how to avoid it. For instance, you yourself have allowed the possibility of inhaling dust, but have you ever called upon your workpeople to wear respirators? That is an old thing?—We are not subject to much of this dust that you talk about, because our work is rubbed down with pumice-stone and water.

6369. Yes, but is that so in the whole of Sheffield, do you think?—Yes; the bulk of the work is rubbed down with pumice-stone and water.

6370. (Mr. Parsonage.) That is before the first coat is put on. Pumice-stone and water is generally used not only in Sheffield but everywhere else?—Yes.

6371. But the point is after it is applied, do you use sand-paper?—Exactly.

6372. (Dr. Collis.) There is a certain amount of dust caused?—Yes.

6373. Have you ever suggested respirators to your apprentices? A very small amount comes up to an appreciable amount in time?—We have not found it necessary. If you say it is, very well.

6374. You have stated that there is little or no illness among your workpeople, but the amount of study that you, as representing the National Association, have given to the subject of lead poisoning seems to be small?—Well, I have only told you part.

6375. We want to know all?—Supposing this inkpot is a paint can and the paint is put into it, I should teach a man or a lad that he should simply use his paint from one side, and that he should take his brush, and if he wants to put his brush down he should put the bristles on like that (*describing*) so that *this* side is kept perfectly clean. When the man takes it up again he has a clean brush. Many of the men and lads are careless. They will wet *that* side and they will wet *this* side, so that when they want to put the brush down they put it on the wet paint and it is on their hands at once.

6376. (Mr. Parsonage.) After he had found that out, he would still be so stupid as to do it again?—Yes, he would do it again. If you are a practical man you will know that that is one of the things that we teach our lads—that they should just keep one side of the kettle wet, where it is necessary, and that the other side should be kept perfectly clean so that there is no need to get any paint upon the body. If he is carrying this can he has a clean side to carry against himself.

6377. (Dr. Collis.) May I repeat my point? I do not hesitate for a moment to agree that you have been taking a great deal of trouble in teaching them, but you have not found out first what you were teaching them to prevent. My contention is that this will not prevent five out of a hundred cases, and the other ninety-five will go on notwithstanding what you are teaching?—I am speaking now as a practical man.

6378. I am speaking as a practical physician?—You may be a master painter. I do not know.

6379. I am not; I am a doctor?—If you were a painter you would understand what I say, and that is, that as a practical painter I want to keep one side of my can clean, and I want to keep my brush clean. If that is done workmen will not get the paint upon their person in any shape or form.

6380. (Mr. Parsonage.) Do you think that a painter wants showing what you have said?—Yes. If you are connected with the trade you will know that it is done.

6381. Is it necessary to show a man that?—It ought not to be. Personally I think that the question

has come so much to the front lately that people are being educated to avoid these dangers.

6382. (Dr. Collis.) You rather miss my point. I do not suggest for a moment that you do not teach, and teach carefully. My point is that you have not studied what you teach and that your teaching may be useful in its way, but it would not stop five out of a hundred cases if it was all completely done, simply because you have not discovered the way in which the lead enters the human body, namely, not so much by eating off the hands, which may be the cause of five cases out of a hundred, but by breathing and inhaling, which causes ninety-five cases out of a hundred. Could all the teaching that you could ever think of and devise prevent the ninety-five?—It is only a question of whether we get a medical man and bring the matter before our apprentices and others occasionally.

(Dr. Collis.) You miss my point, but it is no good labouring it further.

6383. (Mr. Gardner.) You are thinking of absorption through the skin?—Yes, and not only through the skin.

6384. (Dr. Collis.) Take it from me that it is a fact that lead is not absorbed through the skin at all?—Not at all?

6385. Never. You may practically take that as an accepted medical fact. I, as a medical man, can make that statement?—I am surprised to hear that it is not absorbed at all through the skin.

6386. Let me suggest something that, perhaps, has not occurred to your mind. Are you aware that surgeons, in dressing sprains and bruises, constantly apply the most soluble lead salt—acetate of lead—and that there are probably hundreds of thousands of gallons a day applied to the human body, and that no one has ever known of lead poisoning occurring through the skin by the application of all that amount of acetate of lead. That is a plain point if you have any doubt as to its absorption in any other way?—I do not doubt your word.

6387. By keeping the hands clean you are not going to stop lead poisoning. I want to clear your mind on that point?—That is only one thing.

6388. It does not represent more than five out of every hundred cases. It is a minor thing?—I beg your pardon, I think it is a lot more.

(Dr. Collis.) I will not bow in deference to your opinion, because I hold my own.

6389. (Mr. Parsonage.) You have had no lead poisoning cases in your shop at all?—Not that I am aware of.

6390. You take a great interest in the trade in Sheffield and in painters?—Yes.

6391. Would it be possible for a public meeting of operatives to be held in Sheffield without your being aware of it?—I dare say that it might, but it is not very feasible. The operatives could have a meeting without my knowing.

6392. In December last year, there was a largely advertised public meeting of painters held in the Co-operative Hall, and there were full reports in the Sheffield newspapers the following day?—Yes.

6393. The chair at this meeting was taken by a Sheffield town councillor, whose name I forget. He is not a Labour man at all, but a gentleman who came to take the chair. The meeting was for the purpose of presenting a cheque for 100*l.* to a painter who was paralysed from lead poisoning. It would not come to your knowledge at all?—Not for a while after.

6394. It has not done so up to the present?—Not for a while after.

6395. Not until to-day?—I have heard of it.

6396. You have heard of it before to-day?—Yes.

6397. I understood you to say that up to the present you had not come in contact with any lead poisoning?—Not in my shop.

6398. You are about the largest employer in Sheffield?—Well, I am one of them.

6399. Would you like to see this man about whom I am speaking, to satisfy yourself, because I will send him round to see you, and you can see him for yourself? He is still in Sheffield. He is totally deformed and paralysed?—Quite so.

16 May 1911.]

Mr. J. PUTTELL,

[Continued.]

6400. I should have thought that you would have known of it?—I should be pleased to see him.

6401. I can give you several other instances of cases?—If you will do so, I shall be pleased.

6402. The name of the man to whom a grant of 100l. was paid is Walker. So that you see there are cases of lead poisoning in Sheffield?—Oh, yes.

6403. Now, with regard to your technical school, it is not for the purpose of warning the boys to be careful against the dangers of lead, and the boys do not attend for the purpose of being taught cleanliness. They attend to learn a trade. They are educated in their own business?—I take it that even teaching them to avoid certain things is educating them.

6404. But you do not apply your mind to lead poisoning? The question of lead poisoning never enters into your mind?—This thing has only been on the tapis for a little while. There is no doubt we shall bring the matter more distinctly before the boys, and I hope the men as well.

6405. Do you think it would be a good thing if a law were passed that all painters shall be total abstainers? Do you think that that will have a great effect?—I do.

6406. We have been told before that painters generally suffer more on a Monday morning than at any other time. It is a singular thing which must apply to Sheffield just the same as to anywhere else, if it exists. Personally, I dispute the contention?—Do you not agree that the body would be purer if they were abstainers?

6407. Well, I do not see why a painter should be a total abstainer any more than any other man. With regard to lead poisoning, what I want to suggest to you is that there may be scores of cases of lead poisoning in Sheffield, and even in your own shop, that would not come to your notice whatever. Do you agree with that?—Yes, there may be.

6408. So that your evidence, really, with regard to the prevalence or non-prevalence of lead poisoning is of no value?—Only to this extent—that I have a list in my pocket of 18 men who have worked for me, and the average years they have worked for me is 22, and none of those have suffered.

6409. You have not the 18 that have suffered?—They are men who have worked for me for over 20 years, some for 30 and 40 odd years. I have nine apprentices who have served not less than 15 years' service.

6410. You have not nine apprentices at the present time?—No. I am talking of men now.

6411. (Mr. Rice.) You mean nine men working with you who were apprenticed?—Yes.

6412. (Mr. Gardner.) When you say that you did not know of any cases of lead poisoning having taken place in your firm, I suppose you mean cases of painter's colic or dropped wrist?—Yes.

6413. Men may have been off work through illness which was indirectly due to lead without your knowing that it was indirectly due to lead? It may have been so.

6414. Such as Bright's disease and some of the other troubles that affect painters more than anybody else?—It may have been so, but we have not known it.

6415. Of course you do recognise that the handling white lead is to a certain extent dangerous?—Yes.

6416. Because you have told us that you advised them always to keep their hands clean, and their pots and brushes clean?—Yes.

6417. But while you have done that you have done nothing to provide washing places for the men while at their work?—We provide them with soap, and there is always water for them.

6418. (Mr. Sutherland.) And buckets?—Yes, plenty of buckets.

6419. (Mr. Gardner.) In sending out men to an ordinary job where they are doing two or three rooms,

would you always send soap and towels and so forth for washing?—Yes. Our men, as a rule, have soap in their basses with them.

6420. Provided by yourselves?—Provided by ourselves.

6421. (Chairman.) You say "as a rule." Do they always have them?—Yes, they always have them.

6422. (Mr. Parsonage.) Where do they get the soap from?—We supply it in the shop.

6423. Does each man go to the shop and get soap and take it with him?—We give him some. In addition to that we have a barrel of soap that they all help themselves to.

6424. Soft soap?—Yes.

6425. For use for washing the stippler?—Yes, or anything they like. They help themselves to what they require.

6426. (Mr. Gardner.) Although you have recognised the danger, no action has been taken by the employers all through, except that they have said, "You can have soap for washing your hands. You must get hot water if you can, but if you cannot get it, you must do without." You have not made any provision for hot water?—We have not made any provision for hot water.

6427. You spoke of having used zinc paints 30 years ago?—Yes.

6428. Have you used them quite lately?—Yes.

6429. The zinc paint of to-day is not the zinc paint of 30 years ago?—No; but still I think there is not the quality in it, and there is not the covering power, that there is in white lead.

6430. But you have not experimented with it in any degree. You have just taken it and used it in the ordinary fashion?—Yes.

6431. We are told about fumes being thrown off, and about volatile substances, such as turps, that are used in the paints?—Yes.

6432. Do you not think that a substitute for turpentine is a dangerous article?—We do not use it.

6433. (Mr. Rice.) The precautions that have been suggested would, of course, make the work very much more costly?—Yes.

6434. And the public, or the employers, would have to pay that extra cost?—Yes.

6435. You were rather surprised to hear that only five per cent. of lead poisoning cases are caused through the want of washing the hands, were you not, or that it only saved five per cent.?—That is different.

6436. You were rather surprised to hear that washing the hands would only save about five per cent. of lead poisoning cases?—I am surprised. I thought that by neglecting to wash their hands they would get it on their food, and would inhale it, and so get poisoned.

6437. Do you think that the facilities which you give your men for washing their hands are a sufficient remedy, seeing that washing the hands only saves five per cent. of the men?—I think that it saves more than five per cent.

6438. But would you give sufficient facilities to save five per cent.?—Yes, we should be willing to give that, and we ought to.

6439. (Mr. Sutherland.) You, in your local association, have not taken steps to discuss this question, because really it has not forced itself on you in the way of a question properly?—No, it has not.

6440. It is only by the collected statistics that the magnitude of it has been shown?—Yes.

6441. In your own experience your men are generally very healthy?—Yes.

6442. So that there is no reproach attaching to the association for not investigating this?—I think not. We shall be willing to do what we can to help to mitigate the evil.

The witness withdrew.

16 May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

Mr. J. R. CHAPPELL examined.

6443. (*Chairman.*) Do you attend to-day as the representative of the National Association of Master House Painters and Decorators?—Yes.

6444. What is your business?—Painter and decorator.

6445. What town do you represent?—Leeds.

6446. For how long have you been in the painting business?—33 years.

6447. What is the average number of painters employed by your firm?—About 25.

6448. Have you known of any cases of lead poisoning or painters' colic?—No, not one case.

6449. Do you insure against your liability for the payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—Yes.

6450. Has the rate increased in the last few years?—Yes.

6451. Why is that, do you think?—Well, I expect on account of lead poisoning for one thing.

6452. Have you known men who have broken down temporarily on account of lead absorption?—Not to my knowledge.

6453. When did the insurance companies first put up their rates?—I do not know—perhaps three years ago.

6454. Do you have a periodical medical examination of your men?—No.

6455. Then is it possible that some men suffer from the slower and more insidious forms of poisoning without your knowing it?—I do not think so.

6456. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—From experience, I do not think that I am troubled with it, and I am amongst it constantly, and men who have been with me and my father for a long period are all right.

6457. You take a prominent part in the work of the Master Painters' Association, do you not?—Yes.

6458. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—Yes, we have talked about such things.

6459. Have you taken any steps collectively as an association to discover how much illness there was amongst the men employed by your members?—No, not that I know of.

6460. But you have heard of the prevalence of lead poisoning amongst men who handle lead paints?—We hear about it certainly.

6461. Has your association never attempted to collect statistics concerning the number of men who have become ill?—I do not know that they have—not to my knowledge.

6462. Why have they taken no steps to collect statistics?—That is a difficult matter to answer. I do not know.

6463. But you knew that there was a very great deal of lead poisoning about, did you not?—From my own experience, no.

6464. But the fact of the insurance companies having put up your rates gave a clear indication to you, did it not, that there must have been a good deal of lead poisoning about?—Taking it from a general standpoint, we should regard it as an indication, but from a personal standpoint I should not.

6465. But collectively, when you had the information before you that the insurance companies were putting up their rates, you took no action to mitigate the evil?—No.

6466. Did your association ever consider the advisability of having a medical examination made of the persons employed?—Not that I am aware of.

6467. Have your association ever taken any collective measures to discover a substitute for white lead in paints?—Yes.

6468. Collectively?—Yes.

6469. What steps have they taken? It will be very interesting to know what they have done?—We have had boards painted with different pigments and sent out all over the country to see the different

atmospheric effects of different towns—seaside towns, inland towns, and manufacturing towns.

6470. Did you employ a chemist to make scientific investigations for you?—No. What I have spoken of is in hand at the present time.

6471. The question of employing a scientific man to make investigations for you has not occurred to you?—It has not come to that stage yet.

6472. Do you realise yourself the amount of injury which obtains in your trade?—Well, from my own personal standpoint I say again I do not realise any great danger.

6473. Do you know that there have been 234 definite deaths from lead poisoning in the last 10 years?—No, I do not.

6474. And that the death-rate from Bright's disease and nervous diseases due to work in lead is very high?—I am not aware of that.

6475. Do you know that about 2,000 cases of lead poisoning in the trade were reported to the Home Office voluntarily without any legal compulsion whatever in the last 10 years?—No; it is news to me.

6476. Do you realise that these cases, reported voluntarily as I have said, are only a fraction of the whole, inasmuch as the Home Office have no legal right to pay for such reports and are therefore bound to discourage reporting to some extent?—I can only speak from experience.

6477. I am sure you will agree with me that all this sickness and death is very deplorable?—There is no doubt about that.

6478. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I know that there has been controversy in different countries about the same thing.

6479. And that the use of white lead has been most strictly regulated in many countries where the use of white lead is still allowed?—Yes.

6480. Do not you think it regrettable that this country should be behind other nations in this respect?—Well, if a proper substitute can be found for white lead, I should be one of the first to grasp it.

6481. Do not you think it regrettable that this country should be behind other nations in protecting their workpeople?—Just so. I think we ought not to be behind.

6482. Do not you think that we ought to level up to other nations?—Certainly. I am quite of that opinion.

6483. Even if it means the prohibition of lead?—I should be satisfied if there was something else.

6484. I am speaking of protecting the workpeople. I ask you again, do not you think that we ought to be abreast of other nations, even if it means the prohibition of lead?—I certainly think we ought to be up to other nations; I quite admit that.

6485. A great many small dangers attend the use of lead; for instance, the risk of contamination of food by unwashed hands. Do you attach much importance to personal cleanliness on the part of the men?—I think that is the first and the most important factor—that every man should wash his hands before he has a meal.

6486. Then you consider lavatory accommodation essential?—Certainly.

6487. Including a supply of hot water?—Hot is certainly better, but cold will do all the same if you cannot get hot water.

6488. Do you think it possible for a painter to wash his hands, in the very limited time which he has allotted to him, in cold water in severe winter weather?—Yes; if he can get the soap to lather he can wash in cold water.

6489. The time allotted to him is about one minute, is it not?—No. I think no master painter would complain of a man washing his hands. He would not stint him the time, surely. That is my opinion.

M

x 7790

16 May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

6490. I will put it in another way; would you agree to allow a painter sufficient time to wash his hands in cold water if he could not get hot?—Certainly.

6491. And take it out of your time?—Certainly.

6492. Whether he uses hot or cold water?—There is nearly always an opportunity to get hot water.

6493. You think hot water better than cold water?—Certainly.

6494. Do you advocate definite rules regarding the wearing of overalls?—Yes. Every man is expected to wear overalls, if you call overalls an apron and long jacket. I do not mean trouser overalls. Some do that even, but not many.

6495. Do not you think that trouser overalls are important?—No, I do not.

6496. But is it not true that a workman in the course of his operations gets his trousers covered with some of the lead dust?—He may do so—a little bit.

6497. Is not that a source of danger?—I should not think so.

6498. You may take it from me that it is a very great source of danger and that any dust of that sort accumulating on a man's clothes is likely to be breathed by him and he is likely to be poisoned?—I do not think I have taken much harm.

6499. That does not prove anything, because there are some people who are quite immune from lead poisoning like they are from other diseases?—Exactly.

6500. I have seen men who have been working in the potteries for 40 years under the very worst conditions who have escaped, but I have seen other people who have been in it only a few weeks under the very best conditions who have contracted lead poisoning?—Quite so.

6501. How can you ensure that these overalls are kept in a clean state?—I cannot. Every Monday morning a man brings a clean set of overalls.

6502. But supposing he does not bring them clean at all?—Then he should not start work.

6503. Who would prevent him?—I should prevent him.

6504. Could that be generally applied?—He would know if he did not come with clean overalls he would not start work.

6505. Would you make that a condition of his employment?—It is understood.

6506. Would you make it a general condition of his employment?—In my own shop?

6507. No. Would you make it a statutory condition?—Yes. I think no painter who thinks anything about himself would attempt to come in dirty clothes on Monday morning.

6508. Would the Home Office be right in introducing a special rule to the effect that no painter should commence work unless he had clean overalls on Monday morning?—Yes.

6509. How would you enforce such a rule?—It would be a man without much pride that would come without clean clothes on a Monday morning.

6510. Supposing a man put his pride in his pocket, how would you enforce such a rule?—I should let him have a day's holiday.

6511. If the workman has to take the overalls with him in his bag, will they not come into contact with his food?—No.

6512. Why?—Because a man's food would be carried in a different bag from his tools.

6513. Does every painter carry two bags?—They generally carry their food in a piece of paper. More than anything it is in paper. Or it is in a cloth or handkerchief perhaps, or something of the sort.

6514. Where are the overalls kept from day to day when he is working continuously on a job?—In his bag.

6515. Can you always provide a place for a painter to hang up his coat where there will be no risk of dust falling upon it when he is working?—If they were doing this room, their clothes very likely would be in another room.

6516. Can you always be sure of that?—You cannot always be sure. They may be only doing one room.

6517. If they are only doing one room they have to keep their clothes in the room they are working in?—They find ante-rooms or passages or something of the sort to keep them in.

6518. Would it be true to say that there are some cases where the men have to keep their clothes in the room where they are working?—It might occur in odd places.

6519. That would be a source of considerable danger to the men?—In isolated cases it might occur.

6520. In might occur in some cases?—It might possibly.

6521. Would you agree to a rule being introduced prohibiting that?—Yes, I should not be against it.

6522. Do you advocate also a rule requiring mess-rooms, so that no man shall eat his food in the place where paint is being handled?—Yes.

6523. Or where work is being performed?—Yes.

6524. You would make that a special rule?—Yes.

6525. Can you always provide a place quite free from the risk of contamination where a painter may eat his food after his work?—Yes, I think that could be done.

6526. Throughout the country?—Yes.

6527. All these precautions, as well as others, are insisted on for the mitigation of lead poisoning risks in the potteries, but would it not be exceedingly difficult to carry them out faithfully in connection with house painting operations?—I think the white lead in the potteries and in house painting are two different things altogether.

6528. The dangers in house painting are very much more severe than in the other?—I should not have thought so.

6529. At any rate, at the best, such precautions as overalls and washing hands, and so on, would not deal with the most important risk, namely, the risk arising from dust and spray which the workman can inhale during the whole of his working time?—I do not know how to reply with regard to that. I do not see much danger myself in it.

6530. You do not see much danger in the dust that arises from various operations, such as dry rubbing down?—Certainly there is danger in dry rubbing down.

6531. I will put the question again. Supposing we can get rid of some of the dangers by washing the hands and wearing of overalls, there are other dangers which exist from dust and spray which the workmen come in contact with during their work?—Yes.

6532. Now I will ask you a few questions about the latter. First, as regards rubbing down with sand-paper: I understand that this process is indispensable?—There is bound to be a certain amount of rubbing down with sand-paper. I quite admit that.

6533. Is the dry method not invariably applied to newly painted surfaces on which the paint has already dried?—Yes. They are rubbed down slightly between each coat.

6534. I understand that the wet process cannot be substituted for dry rubbing down between the first and second coats when ordinary paint has been used?—No.

6535. Now, where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—The only way is by damping the sand-paper. That is the only point that I can think of.

6536. But damping the sand-paper would not prevent dust coming from the operation, would it?—Yes.

6537. (Mr. Parsonage.) Is that ever done?—Yes, at odd times.

6538. You have seen it done?—Yes, damping with turpentine.

6539. (Chairman.) I must ask you my question again. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—There is no prevention that I know of.

6540. The amount of dust arising from this sand-papering I am told is very considerable?—I have never seen it then.

16 May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

6541. We have been told that it covers the painter's clothing as well as the floor and surrounding objects, but whatever it is, large or small, you say that you consider that there are no possible means of preventing the workpeople from breathing it?—I have never had any occasion to think of anything for getting over that difficulty in my own business.

6542. The next process I want to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work?—Yes.

6543. This gives rise to splashes which frequently fall even on the face of the worker?—Yes.

6544. How can you deal with the spray which arises in this operation?—I do not know that there is any way of dealing with it.

6545. You could not use an exhaust draught to catch the spray?—No.

6546. Then again we are confronted with the problem of how to save the worker from the grave danger involved in breathing the spray?—I do not know of any way.

6547. Then with regard to stippling, there is a certain amount of splashing and spray from that. How would you deal with that?—Well, I do not know that there is a remedy.

6548. Do you have the old paint burnt off with a spirit or charcoal burner?—With spirit.

6549. How can you prevent the worker from inhaling the fumes that arise from this process?—It is impossible.

6550. Where and how do your men mix their colours?—On the job.

6551. Do you adopt any precautions to deal with the dust that arises when colours are handled dry?—We do not use dry colours. All our colour is in paste form.

6552. It appears from your evidence that there are certain indispensable processes in carrying out which a painter must necessarily inhale some dust, some spray or fumes containing lead. How are these dangers to be met?—Well, I do not know. As I said before, from my own experience, I do not all much.

6553. Is it possible to remove the danger entirely in any way than by using a substitute for lead?—Not that I am aware of.

6554. Now, various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience of such substitutes?—No. I have used zinc, if that is what you mean.

6555. What results did you obtain with zinc paints?—I find that zinc is all right for inside, but it will not do for outside work. I use zinc pretty freely for inside work.

6556. The Office of Works and others have succeeded in obtaining efficient non-lead paints, both for inside and outside?—Indeed!

6557. And the Office of Works have told us that after four years' trial they find them very satisfactory. What do you say to that?—I should not consider four years long enough to test them.

6558. What would you consider would be long enough?—If it was like a job I have been on this week, which was done 50 years ago, and still looks beautiful, I would give in at once and say they had found something better than lead.

6559. I want a serious answer. What do you say seriously?—I think that is a serious answer. I am on a job now that my father worked at 50 years ago. That is beautiful, and if a job done with non-poisonous paint were anything like that, I should at once come to the conclusion that something better than lead had been found.

6560. I ask you what do you consider would be a reasonable time?—I should think 10 years.

6561. What are the usual hours worked by your painters per week?—They start at 7.30 in the morning and leave off at 5.30.

6562. What does that come to per week?—Nine hours a day—50 hours a week. They work 7.30 to 12.30 on Saturdays.

6563. Would you welcome a strict limitation of the hours of employment, say, to 48 a week?—No, I should

not. I think they work short enough. They would like to work longer, and they do work longer.

6564. They sometimes work overtime?—They work as long as they like in my shop.

6565. In the pottery industry the working hours are to be restricted to 48 per week for men who work in lead. You would not like that introduced into your industry?—No.

6566. Do you have periodical medical examination of your workers?—No.

6567. You know that in other industries where lead is used, the Home Office insist on monthly or even weekly examination by a certifying surgeon?—Yes, but then painting is a healthy occupation. A man is very often outside and he has plenty of fresh air. It is not like working in a lead mill.

6568. And yet the incidence of lead poisoning among house painters is greater than it is in the Potteries?—That seems strange to me.

6569. It may seem strange, but it is true?—Particularly when I have not had one case of lead poisoning, nor my father who started business in 1868.

6570. It is not strange to me, because there are over 500 potteries, and out of those two-thirds have never had a case of lead poisoning, so it does not astonish me to hear master house-painters come to tell me they have had no cases. But what we have to consider is that the incidence of lead poisoning in the house painting industry is greater than in the china and earthenware industry, so that the question of medical examination becomes a very serious matter for us to consider. Would you welcome a system of periodical medical examination in your industry at the employers' cost?—No, I should not from my own standpoint.

6571. Would you like to give compensation to any workers suspended by the doctor on account of doubtful health, which rule obtains to-day in the earthenware and china trade?—We have to pay compensation when such a case arises.

6572. These are doubtful cases that I am speaking of?—We have to pay according to the doctor's certificate.

6573. But you only pay to-day for cases that are absolutely certified. Under the scheme of regulations for the earthenware and china trade, a certifying surgeon goes in and examines the men once a month and he says, "That man has no actual lead poisoning, but he looks very much as if he might have." The doctor has power to suspend him, and in that case the employers have agreed to pay half-wages for a certain period. I want to bring out this point: If this industry is levelled up to the earthenware and china industry with regard to special rules, you would have medical examination of your workpeople, for which employers would have to pay, and they would also have to pay compensation to any workers suspended by the doctor on account of doubtful health. Would you welcome those two provisions?—If I take my past experience, I should not be against it.

6574. You would have to pay for the examination in any case?—Yes. I have never had to pay.

6575. You realise too that, if the free use of lead is allowed to continue in your industry, the Home Office would have to insist upon the rigid observance of precautionary measures in the same way as in other industries where the workers handle lead?—Well, as I said before, if there is something better to be brought out it is a different matter.

6576. I only want you to say whether you realise the position?—I would rather you put it again, because I have scarcely grasped it.

6577. I want you to realise that, if the free use of lead is allowed to continue in your industry, the Home Office will have to insist on the rigid observance of all the precautionary measures which this Committee may suggest in the same way as in other industries where the workers handle lead. You realise that?—Yes. Well I should have to abide by it of course.

6578. And you realise that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—I see no reason for that.

6579. But you are not asked for your reason. You may see no reason for it, but the Home Office

M 2

17 May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

may. We had the best medical witnesses the country could produce, including Sir Thomas Oliver, before the Potteries Committee, and they convinced them that it was essential to keep the men out of lead as long as possible, and so the committee recommended the restriction of the hours of labour to 48 hours a week. Now the special rules would involve an extremely complicated and elaborate code of regulations. Are you fully prepared to set up the necessary machinery in your business to secure complete observance of all the regulations relating to overalls, lavatory accommodation, mess-rooms, avoidance of dust, limitation of hours of employment, and all other such matters?—I do that now, and if the law passes I shall have to do practically as I do now. There are odd cases certainly.

6580. The dangers you agreed are very serious. We shall have to suggest something to remove them?—Well, I do not agree with it.

6581. Now taking all these points into consideration, and not forgetting that the periodical medical examination which would be insisted upon would have to be paid for by the employer and that payment of compensation to workers withdrawn from work in lead would have to be borne by the employer, would you say that you would prefer that the industry should be regulated by such special rules as I have foreshadowed or as an alternative that the use of lead should be prohibited or very closely restricted?—Speaking from my own experience, there is no need to prohibit the use of lead, and I have no need to go into all those regulations.

6582. But I am putting the two alternatives. I want you to realise this. This Committee has been called together to deal with a very serious evil. We have to do one of two things; we must either prohibit the use of lead or restrict it within very close limits, or we must introduce a code of special rules to deal thoroughly with the evils as they exist. I have foreshadowed to you what that list of regulations would be, and I ask you this question: which would you prefer as an employer—the prohibition of lead or its restriction to a very low amount, or a code of rules such as I have suggested to you. I ask you to consider the two alternatives?—I should think perhaps a code of rules. A well-managed shop is governed by rules.

6583. Supposing that it is found impossible to introduce such a code of rules as would deal with the great evil, then would you be surprised if the Committee suggested the abolition of the use of lead? You have told us to-day that there are certain operations which we consider to be dangerous for which you can find no remedy. You cannot remove the danger?—Just so.

6584. Supposing the Committee came to the conclusion that those dangers are so serious that they can only be overcome by the abolition of lead, would you be surprised at that decision?—No. I should think that the evidence that you have gathered from different experts would lead you to the best conclusions, and that you would frame the law accordingly.

6585. And you would loyally abide by that?—I should loyally abide by whatever was done, or I should try to do so.

6586. (Sir Godfrey Baring.) As an experienced man, would you think it a very serious matter for the trade if lead was prohibited by this Committee?—I should. I think there is nothing on the market that is as good as lead for exterior work—speaking of that more particularly than interior work.

6587. (Dr. Collis.) The question of the amount of dust which is caused has been under consideration. You say that you do not consider it very much. I am, of course, referring to sand-papery?—Well, I am probably in a peculiar position. I carry on a business that was established by my father in 1868. My father is out of the business now really, but still he dodges about and if he came on to a job he would start sand-papery. He would do the dusty work. He revels in the sand-papery, and he is 71 years of age. If this was going to do him any harm it would have done it long ago.

6588. But the point I was raising was not the amount of dust which your father caused, but whether

you considered there was much dust. You think your father causes some dust?—I think he does a bit, but I think it has done him no harm to look at him.

6589. But that is not the point. The chairman has already drawn your attention to the fact that what is one man's food is another's poison?—Exactly.

6590. Some men seem able to absorb into their systems amounts of lead which would kill another?—Yes.

6591. Have you any idea of the amount of lead which is present in the air where sand-papery is being done?—No.

6592. Would you be astonished to hear that experiments, carried on at the breathing level of a man who was sand-papery in the coach-painting trade, showed that the air contained from 180 to 250 milligrammes of lead per cubic metre of air, while in the Potteries, to which you have probably had your attention called by the public agitation which has taken place concerning lead poisoning there, in a process where the exhaust ventilation was not working, and therefore you would have expected the proportion of lead present to be high, 13 milligrammes was the highest amount found, and the investigator who made these experiments on behalf of this Committee found in only one trade he investigated previous to this present inquiry as high as 124 milligrammes of lead, and in no other trade did he ever get above 60. In dealing with sand-papery he found 180 to 250 milligrammes?—That depends in a great measure on the preparation before the sand-papery comes about. If I was going to do these walls, for instance, I should rub them down with pumice-stone and water for a start. They would not require so much sand-papery afterwards. The door would be rubbed down in the same way. It would be sand-papery between each coat. I am speaking to practical men.

6593. (Mr. Parsonage.) Supposing you go into a house where a room is to be fluted and it had been finished in flut two years previously, you would not trouble to rub that down with pumice-stone and water. Before you painted it, you would sand-paper it down?—Not at all necessarily.

6594. You would use pumice-stone and water?—Certainly, from more than one standpoint—for cleanliness, to get rid of the dirt and bring down the grease.

6595. (Dr. Collis.) I want to know whether you appreciate the fact of the danger in what looked to you infinitesimally small amounts of dust. If you went round some places in the pottery trade you might think there had been a lot of fuss there about nothing; because you would not see the danger. It would not be obvious to your eye. I want to know whether you appreciate the fact that the lead contained in the dust at the breathing level (I am not talking about the dust that falls to the floor) of the workmen has been found to be 10 to 20 times the amount that is present in a shop where the pottery lead-worker is working?—No, I cannot go against that.

6596. You said that you used your paint in paste form?—Yes.

6597. Do you prefer matured paint or new paint? You get white lead in paste, do you not?—I like old lead better. I do not know why. I am using some lead at the present time that we have had in stock three years, if that answers the question.

6598. That is what I wanted to know. That is a preference in the trade, is it not?—Yes; we like old lead.

6599. Are you aware that old paint or matured paint (to use a better phrase for it) gives off a volatile lead compound?—No.

6600. Which comes off when it is applied wet and may be inhaled by the workman and have a bad effect on him, and that traces of such absorption have been found in the blood of ordinary inhabitants of a house where painting has been going on?—It is news to me.

6601. This investigation is practically new work. It is probable that you would not have had an opportunity of knowing it. So that I want you to grasp that there is danger, as we have had proved, from the dust that is present in the air; and that, even if you got rid of the dust, the emanation which wet lead paint

16. May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

will give off at the ordinary temperature of the air—what you know as the smell of lead paint in other words—really does contain lead and may be in itself sufficient to poison a worker?—I should have scarcely thought that, but of course I must not go against what you put to me.

(Dr. Collis.) The latter point has been brought out by Dr. Baly, of Liverpool, during the course of the last two months.

6602. (Mr. Parsonage.) You know of no lead poisoning cases at Leeds at all?—I do not know about Leeds, but I can speak for my own shop.

6603. You have none in your own shop?—No. My father established the business in 1868, and, as I said before, there has not been one case of lead poisoning of a man who has worked for us at all in the whole of that time.

6604. I can assure you that I have known several cases?—In Leeds?

6605. Yes, in fact we have a solicitor who takes up all our cases there, and he gets a good deal from us in the course of a year, so that you have been very fortunate in your shop?—Yes. Coming down in the train I made a list of the men and the periods they had worked for my father and myself. Is that any guide, or is it wasting time?

6606. (Dr. Collis.) Have you their ages?—In the first place one man was apprenticed with my father, and he has been 34 years with us and is with us yet. Another man apprenticed has been with us 32 years. Another man who was not an apprentice has been with us 28 years. Another man who was not an apprentice has been with us 25 years. Another man apprenticed has been with us 16 years. Another man who was not an apprentice 15 years. Another man who was not apprenticed 13. Another man that was apprenticed 10 years. Another man that was an apprentice 8 years. Another man who was not an apprentice 6 years. Another man who was not an apprentice 6 years. Another man who was not an apprentice 5 years, and another who was not an apprentice 4 years. That stuff is kept on practically the year round.

6607. (Mr. Sutherland.) That is your permanent staff?—That is our permanent staff.

6608. (Dr. Collis.) Even those figures which you have produced, which sound very long, after all do not establish a case. If you allow the apprenticeship time to be 20 years of age, I gather that the oldest of those men would not be 60?—One of these men is just about 60.

6609. An average age at death of 48 to 49 we look upon as rather young. If the oldest man you are producing to us is 60, what has happened to the people between 60 and 70. It is rather against you than for you. The figures sound big, but when analysed they do not establish the point?—We have not had a chance of keeping the men on until they reach 70. We lost a man a short time ago who had been with us from 1868. He died from cancer a few months ago. He had been with us 40 years.

6610. You follow my point. You give us negative instead of positive evidence?—I hope to go on longer.

6611. (Mr. Parsonage.) We place our men on superannuation benefit at 60 years of age. That would be some guide?—I might say that my father was an indoor apprentice. I am speaking of painters. In the winter time he had to grind his own material, as you know an indoor apprentice had to do. He had to be found something to do, and in those days he had to grind his own material, and he is nearly 72.

6612. You do not find that painters take up any other occupation than painting as a rule, do you, in the slack season?—No, a painter is a painter till he dies.

6613. That agrees with my own view?—I could mention several old men who are painters, master painters, in Leeds alone.

6614. (Mr. Gardner.) You agree with me that the apprentice in the old days, such as your father was, would be more exposed to lead poisoning than men are to-day?—Certainly.

6615. What explanation would you give of the fact that lead poisoning is as prevalent to-day, if not more so, than it was 50 years ago?—They, perhaps, called it by another name 50 years ago, the same as they did appendicitis.

6616. You said that you had not come across cases of lead poisoning, but I suppose you would call a case of a man suffering from lead poisoning a man who was suffering from colic or dropped wrist. A man who was suffering from cancer, or Bright's disease, or phthisis, you would not put down to the credit of white lead?—No.

6617. You realise that working painters are more subject to cancer, and Bright's disease, and phthisis than any other trade?—This man that I was speaking about just now who died from cancer was a grainer and varnisher the whole of his time. He did not come into contact with white lead very much. He was an apprenticed grainer. He was one of the old sort—apprenticed to be a grainer.

6618. Have you worked as a journeyman?—I was apprenticed to the trade. I have been through the mill from spout cleaning to sign painting.

6619. You do not work at the trade now, do you?—I do occasionally now. I worked yesterday morning just before I set off. I was mixing paint.

6620. You have heard of lead poisoning cases you say, and that there are such things as cases of lead poisoning in the trade and in the town, but the employers there collectively took no action to ascertain how many there were?—No.

6621. The insurance companies raised your rates largely, you think, through the inclusion of lead poisoning, and you did not object to their raising your rates?—We had no option.

6622. If a man says to you, "I will charge you so and so because of a certain contingency," and you say, "But that contingency does not arise," as a business man you object?—We did not like paying 5*d.* for an ounce of tobacco, but we had to pay it. They made us pay it because of the combine.

6623. That is a different thing?—There is a combine in insurance.

6624. But there is a little bit of difference that comes in in that. The employers might have said as a body, "Shall we pay this extra insurance. It is monstrous?"—We did so.

6625. But you are surely large enough to form a mutual society, and then having the employers as a body, if they refused to give you a rate that you agreed with you could arrange the insurance yourselves?—No, we are not.

6626. The great Shipbuilders' Association does it. You believe in personal cleanliness as being a preventive against lead poisoning?—Yes.

6627. And that washing materials should be provided?—Certainly.

6628. Does your firm, or other firms to your knowledge, provide washing materials for the men on jobs?—I should think so for their own credit's sake.

6629. Yes, but quite apart from their own credit's sake, do you think that they do it?—Yes, I think so. I know that I do in my own shop.

6630. Do you take steps to see that the men get hot water for washing purposes?—Yes.

6631. If they are working in an empty house?—They would see to it themselves as a natural consequence.

6632. They cannot always see to it themselves. In a suburb, where can a man get hot water if the house is empty?—There is always more or less opportunity for getting it.

6633. If a man goes into a house to do out one room, he is compelled to take his food very often in the room he is working in?—I think if there is a public-house they will go there rather than eat in the open.

6634. But public-houses are not always there, and we do not want men to go to public-houses to take meals?—Quite so.

6635. As a general rule, if a man goes to a house to paint one or two rooms, he has to take his food where he works?—No.

16 May 1911.]

Mr. J. R. CHAPPELL.

[Continued.]

6636. Where is he to go?—A man will go into the fresh air to get away from the paint if he thinks much about himself, and he will get out of the paint.
6637. He would scarcely take his tea or his dinner and go and sit down on the street kerb. He would prefer to take it in shelter than go outside?—Yes, but he would find a place.
6638. (Mr. Parsonage.) I have seen a man turn a can upside down in the paint shop and sit on it?—We do have that sort of thing sometimes.
6639. (Mr. Gardner.) You think that zinc would not do for outside work?—That is so.
6640. Have you ever made any definite experiment with it for outside work?—Yes.
6641. You tried it in different forms?—Yes.
6642. And you were not successful?—No, I have never been successful with it.
6643. (Chairman.) What trial did you give it? For what length of time?—It has had different lengths of time. I have had it under my own personal observation, and it has been a failure.
6644. (Mr. Gardner.) Have you tried it with varnish?—Yes, I have tried it with varnish. I have made a kettle of stuff, and the next morning it has been "livery," and could not be got out of the can.
6645. (Chairman.) Have you actually painted outside places, and given it a good trial?—Yes. The zinc undoubtedly flakes off.
6646. (Mr. Gardner.) Was it sulphide or oxide of zinc?—Oxide.
6647. (Dr. Collis.) Have you used the sulphide?—I do not know; I might have. I cannot say about that.
6648. (Mr. Gardner.) You used what you got from the manufacturer as a zinc paint without knowing what you got?—Yes.
6649. (Mr. Sutherland.) It would be the sulphide?—You do not go into the mixture when you buy the paint. We asked for a zinc sulphide or oxide, as the case may be.
6650. (Mr. Gardner.) Do you think that we could abolish dry rubbing down absolutely without any serious consequences?—I think that it would be a difficult matter to abolish it altogether.
6651. But would it impose any serious inconvenience in regard to the finish of the work or in regard to anything else connected with the work?—That would get rid of a great deal of the complaint that at present is laid against white lead. I should not, from my own personal standpoint, like to abolish rubbing down entirely.
6652. (Mr. Parsonage.) You could not substitute pumice-stone and water between coats?—No, the paint is not hard enough.
- (Mr. Sutherland.) By careful first-coating and careful rubbing down, the other coats could be done without any rubbing down at all.
6653. (Mr. Parsonage.) It is an impossibility to do away with the entire rubbing down, is it not?
- (Witness.) Next door to an impossibility in ordinary painting work.
6654. (Mr. Sutherland.) It is your opinion that the painting trade, as a trade apart from this aspect of it, is a healthy trade?—It is.
6655. And the men work under pleasant conditions?—They do.
6656. The Chairman asked you whether we should not be abreast of other nations. Do you know that Germany have considered the question of the use of lead, and have come to the conclusion that they cannot do without it?—Yes, and I think that we shall come to the same conclusion.
6657. Do you know that the Dutch Government, after very serious consideration, in their report say that for certain positions nothing can replace white lead?—I am of that opinion.
6658. And that the Government of America have not taken any steps for the prohibition?—Yes.
6659. So that, having regard to Germany, Holland, and America, even if we retain white lead we shall be fairly abreast of other civilized communities?—Yes.
6660. I have not the report that Dr. Collis is submitting to us as to the collected dust in a room, but in the normal way of rubbing down it would be something very light?—Yes, I think so.
6661. In the ordinary way of sand-papering it would be very light?—Yes. We must not expect to get the same body of colour off a door. If a door is well rubbed down in the first instance and then painted, the men would not want to rub down to fetch all the paint off again. It would want a slight rubbing down, and in my opinion there would not be much dust connected with that.
6662. That is the normal rubbing down?—Yes.

## Mr. ARCHIBALD WILTSHIER examined.

6663. (Chairman.) Do you attend to-day as a representative of the National Association of Master House Painters and Decorators?—Yes.
6664. What is your business?—Ours is a painters' business.
6665. What is the name of your firm?—A. Wiltshier. I am in business for myself.
6666. Whereabouts is your business situated?—Watling Street, Canterbury.
6667. How long have you been in the painting business?—Twenty-two years.
6668. What is the average number of painters employed by your firm?—I should say about 40 or 41, taking the average number.
6669. Have you known any case of lead poisoning or painter's colic?—Yes, I have known one, not a serious one.
6670. Only one case in how many years?—Twenty-two years.
6671. I am not surprised to hear that there are some firms, especially in the country, exempt from lead poisoning cases, because, as you may be doubtless aware, in the Potteries there are many large works which are entirely immune from the evil. The trouble is that even some of the best works are not immune, and moreover a works that has been free of lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly. Do you insure your liability against payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—Yes.
6672. Do you know that insurance premiums have been raised in the painting trade in recent years?—Yes, I do know that.
6673. Have you known men who have broken down temporarily on account of lead absorption?—I have known one man, to my knowledge.
6674. Have your men had occasional days of sickness due to lead?—No, I think not.
6675. Do you have a periodical medical examination of your men?—No.
6676. Then it is possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—I think not.
6677. You know, I presume, that lead poisoning frequently undermines the health, without immediate violent manifestations?—No, I cannot say I do.
6678. Do you take a prominent part in the work of the Master House Painters' Association?—Not a very prominent part.
6679. Has the question of the serious prevalence of lead poisoning among house painters been discussed at the meetings of the association?—I have not been to many; I am too far away.
6680. You do not know whether your association has ever taken any collective measures to find a remedy for the evil existing?—Yes, I think they have.
6681. What are they?—I know they have tried experiments with non-lead paints.
6682. Do you realise the magnitude of this lead poisoning evil?—Yes, I realise it.
6683. Do you know that the Registrar-General has recorded no less than 284 definite deaths from lead

16 May 1911.]

Mr. ARCHIBALD WILTSHIER.

[Continued.]

poisoning amongst house painters in the last 10 years?—Yes.

6684. And his mortality figures for painters show a death rate considerably higher than the normal from troubles which are the effect of frequent exposure to lead, such as Bright's disease, and nervous diseases?—Yes.

6685. Do you also know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the 10 years?—No, I was not aware of that.

6686. And that these cases, reported voluntarily, are only a fraction of the whole?—No, I was not aware of that.

6687. But you have realised that this lead poisoning evil in the house painting trade is a very serious one?—I have realised that anything which causes the illness or death of a man is a serious question.

6688. And you knew that the rate of mortality was a very high one?—I knew it was 284 deaths in 10 years.

6689. Have you taken any steps yourself to mitigate this evil?—I take every precaution amongst my own men—in fact, I am always on to them about cleanliness and open windows.

6690. I am sure you agree with me that this sickness and death is very deplorable?—Any sickness and death is deplorable.

6691. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes.

6692. Do you not think it regrettable that this country should be behind other nations in this respect?—I do not know that we are behind other nations.

6693. Yes, we are; we have no rules at all regulating the trade. A great many small dangers attend the use of lead. For instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—Yes, very much importance.

6694. Then you consider that lavatory accommodation is essential?—Yes.

6695. Including the supply of hot water for washing?—Hot water is very essential, if you can always get hot water. My men in my shop can always get hot water.

6696. Is it generally practicable for the men to have hot water to wash in?—It depends on the circumstances. When they are out on a job, I think you might say in six out of 10 cases there is a hot water tap where they can get hot water.

6697. You agree that hot water is very much better to wash the paint off the hands than cold water?—I must say it is better, but at the same time at times it is difficult to get.

6698. Do you advocate definite rules regarding the wearing of overalls?—Yes.

6699. How can you insure those being kept in a cleanly state?—Once a week every man must have a clean overall.

6700. Is that the rule in your firm?—Yes, if the man does not have a clean overall on Monday morning, he is told to go home and get one, and if he has not got one he is suspended until he has got one. I will not allow a man on Monday morning to start off with the overall which he has been wearing all the previous week. He might wear it from 6 o'clock until breakfast time, but not longer.

6701. (Mr. Parsonage.) If he has had a clean job the previous week, you allow it, do you not?—No, a man cannot wear an overall for a week, even if he is very clean, without getting it dirty.

6702. (Chairman.) What becomes of the overalls when the men have finished work every day?—They are put down with their basket, and their tools, and so on.

6703. Do the men take their overalls home with them in their bags?—Not every night.

6704. Where can the overalls be kept from day to day when working continuously on one job?—If there is anywhere to hang them up, they hang them up.

6705. Whereabouts are they hung up? Are they hung up in the room where they are working?—Yes.

6706. So any dust that has accumulated in the room can collect on their overalls?—I do not think you would get much dust accumulating.

6707. But any dust that has accumulated can collect on their overalls?—Yes, any dust that will accumulate. The overalls are in the room as a rule. You might have cases where the overalls are down in the stables, or anything like that, when you are doing up a country house.

6708. Can you always provide a place where the painter can hang up his coat, where there will be no risk of dust falling on it?—Yes.

6709. Do you advocate a rule regarding meal rooms, so that no man shall have his food in a room where paint is being handled?—Yes.

6710. Can a place always be provided quite free from risk of contamination?—Yes.

6711. Are you quite sure of that?—Yes.

6712. But supposing the men are working in one room in the winter, where would they have their meals?—They would not have them in the room; they either go down in the kitchen parts, or in most of our cases they go home to their meals. If it is a country house, where they do not get home to their meals, there is always somewhere. It is a very rare thing for a man to have his meals in the room.

6713. Where do the men keep their food during working hours?—Generally, where they hang their coats up, but it is away from all paint.

6714. Where do they hang their coats up?—In an off room, or anywhere like that.

6715. (Mr. Parsonage.) In the room where the paint bench is?—Yes, sometimes in the room where the paint bench is. As a rule that is not in the room where they are working.

6716. But it is where the paint is kept. The foreman will lock that room at night, and the men will leave their overalls there?—Yes.

6717. (Chairman.) And their clothes during the day?—Yes, that might apply, but not in every case. They always endeavour to get a room, so that if they are coming with their breakfast and their dinner they can leave it.

6718. I want you to realise that it is a multiplicity of small dangers that make the big evil?—Yes.

6719. If the men are allowed to hang their coats in any place where there is a likelihood of any lead dust collecting on them, that in itself is a source of danger?—Yes.

6720. And in the pottery district that is not allowed. I suppose the risk arising from dust and spray which the workman can inhale during the whole of his working hours is a very serious danger?—I do not think so.

6721. Not under any circumstances?—Not under the circumstances where one is particular about the eating and cleanliness.

6722. Now I will go through the processes with you. First, as regards dry rubbing down with sand-paper. I understand this process is indispensable?—There is not very much of it done—not the dry rubbing down—in my business.

6723. But where it is done, I suppose it is done because it is indispensable?—Yes.

6724. I understand the wet process cannot be substituted for dry rubbing down between the first and second coats when ordinary paint has been used?—That is right.

6725. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—I take it you cannot prevent him.

6726. Can you use an exhaust draught to remove the dust?—No.

6727. We are told by some witnesses that the dust arising from this sand-papering is very considerable?—Yes, from sand-papering you get a good bit of dust.

6728. As far as you are concerned, you can suggest no remedy by which the workman can be relieved from the dangers of that dust?—I suggest that you should do away with the dry rubbing down.

M 4

16 May 1911.]

Mr. ARCHIBALD WILTSHIER.

[Continued.]

6729. Could you do away with dry rubbing down in every case?—You get the dust when you go to prepare the work in rubbing down, but you do not get very much dust between each coat of paint. You can do away with the dry rubbing down at first, by the wet process. That is practically 95 per cent. of the dust, I should say.

6730. But still there would be a certain amount of dust in the rubbing down between the first and second coats?—There must be a little, but it is a little.

6731. And you can suggest no remedy?—No, I cannot suggest a remedy for doing away with the little dust between each coat.

6732. The next process I want to ask you about is the painting of ceilings having moulded or relief designs. In doing this work, a brush has to be pushed into the background of the ornamental work, I suppose?—That is right.

6733. This gives rise to splashes which must frequently fall on the face of the worker?—Yes.

6734. How can you deal with the spray which arises from this operation?—It is very little; it is very seldom one has to paint a ceiling in that manner. The other alternatives that there are now give you quite as good an effect and at a less cost. Duresco, or any of the water paints, give you just the same effect.

6735. But where the operation is in practice, you have no suggestions to put before us to relieve the workman of any danger that may ensue?—No, not where they are in practice, but I think you will find them very rare.

6736. Then we are confronted with the problem of how to save the worker from the danger involved in breathing the spray?—Of course, if you do not do it, you do not get the spray.

6737. I am speaking of spray which does exist. Have you any suggestions to make?—No.

6738. Then with regard to stippling, there is a certain amount of droppings from that?—Yes, but with a careful man there is very little.

6739. There is a certain amount?—It is a small amount.

6740. Have you anything to suggest as to how we can remove that danger?—Directly the ceiling is done they wash their brushes, and if there are any splatters on their hands they remove them.

6741. What about the splashes on their faces?—The same thing would apply; in fact they would remove them before they had done the ceiling, I should say.

6742. Do I understand that, with your men, they are instructed to wash their hands after they have done any of this?—Yes, always.

6743. Immediately afterwards?—Yes.

6744. How many times does that involve their washing their hands a day?—I do not mind if they wash their hands 20 times a day.

6745. Is that taken out of your time?—Yes, out of my time: it is the custom. I never grumble if I see a man washing his hands.

6746. Do you have old paint burnt off by a spirit or charcoal burner?—Mostly by spirit.

6747. How can you prevent the worker inhaling the fumes which arise from this process?—I cannot prevent him inhaling them. You will always see, when any burning off is done, the whole of the windows are wide open to get rid of the fumes.

6748. You cannot prevent the man breathing a certain part of the fumes?—No.

6749. Where and how do your men mix their colours?—They mix them on the job.

6750. Do you adopt any precautions to deal with the dust which arises when the colours are being handled dry?—Only the same precautions.

6751. What are they?—Cleansing the hands, and so on, when they have mixed it.

6752. Is it possible to remove the dangers entirely by any other way than by using a substitute for lead?—If there are any dangers, I do not know what other way.

6753. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any

personal experience of such substitutes?—Yes, I have tried zinc oxide.

6754. What results did you obtain with zinc oxide?—Not very favourable.

6755. What were the defects which you found with zinc oxide?—The principal one, I take it, is the lasting or the standing, which is considerable; the second one is that the covering power is much less; the third one is that you do not get such a smooth surface, in my experience.

6756. The Office of Works and others have succeeded in obtaining efficient non-lead paints. Why cannot other master painters adopt the same formula?—I think the materials used by the Office of Works sometimes are far from the best materials for lasting. In fact, I have used some myself for the Office of Works. I think, again, the same applies as in my previous answer on the question of cost, and the same applies to the question of leaving the job smooth.

6757. But the Office of Works have given evidence before this Committee, and they have told us that they are perfectly satisfied, after giving it four years' trial, with the formula which they have in use to-day. Is not that fairly conclusive?—I do not think so.

6758. In what respect do you think it is inconclusive?—The lasting.

6759. But they have had four years' experience, and they say it is perfectly satisfactory?—Of course, there is another thing, and that is with regard to cost.

6760. With regard to cost, they say it is cheaper than the old formula, which they used, which contained lead?—I do not agree with that.

6761. I am telling you some facts now. The Office of Works have said that it is durable; they have given it four years' trial, and they tell us it is cheaper. I want to ask you why other master painters cannot adopt the same formula?—If the Office of Works have got a substitute for white lead, I should be only too pleased to use it.

6762. What are the usual hours worked by your painters in the week?—56½ hours.

6763. Would you welcome a strict limitation of the hours of employment to 48 hours?—That means the wages going up.

6764. That is a corollary, I suppose. Would you agree to that?—If it is beneficial to the men in the end, I would agree with it.

6765. You do not have periodical medical examination of your workers, do you?—No.

6766. Do you know that in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by a certifying surgeon?—I was not aware of that. I have heard of it now.

6767. Would you welcome the system of periodical examination for your industry?—If it is beneficial to the men, I would.

6768. At the cost of the employer?—I think the employer has to pay enough now.

6769. I am asking you this question because that is the custom which prevails now in the other industries where lead is used?—I cannot agree to that.

6770. Further, would you agree to pay compensation to any worker who was suspended by the doctor on account of doubtful health?—I think I would agree, if it is solely connected with the painting.

6771. It would only apply to any workshops or any places where lead was used. The men would be medically examined by a certifying surgeon at the cost of the employer, and if there was a case of doubtful health, and the certifying surgeon suspended the man, you would have to pay him half wages till the certificate was cancelled?—If a man is in ill-health the doctors are very sharp to put it down to lead when he is in the painting trade. Of course, part of that rests with the insurance company. We are rather in the hands of them. If they accept it, I accept it.

6772. You realise that if the free use of lead is allowed to continue, the Home Office would have to insist on the rigid observance of all precautionary measures in your industry, in the same way as in other industries where the workers handle lead?—Yes.

16 May 1911.]

Mr. ARCHIBALD WILTSHIER.

[Continued.]

6773. Do you realise that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—Yes, if the client does not object to paying more.

6774. The point is that the painting trade is a very dangerous trade, and it stands to reason that if precautionary measures are introduced they will be introduced to protect the men in precisely the same way as that which obtains in other dangerous industries. I want you to understand this?—Yes.

6775. And all these special rules which I have foreshadowed will involve an extremely complicated and elaborate code of regulations?—Yes.

6776. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation, avoidance of dust—that is, exhaust appliances, wherever they can be introduced—limitation of hours, and all other such matters?—That covers rather a lot. I might agree to a good many of those, but you cannot build a mess-room on every job you might have. I have now possibly 30 jobs, and perhaps two men at a job. In a large job they always provide a mess-room.

6777. But, generally speaking, those are the general rules that you would have to observe?—Yes.

6778. Now, taking all these points into consideration, and not forgetting the periodical medical examination which would be insisted on at the expense of the employer, and the payment of compensation to workers withdrawn from work in lead, would you say that you prefer that the industry should be regulated by special rules, or would you prefer that the use of lead should be prohibited or very closely restricted?—I think, speaking personally, I should say to that question: prohibit lead; but, of course, there are other things to follow. If you prohibit lead, you say you get over a lot of these difficulties, but there are far greater difficulties, I think, which would arise. If you can find, as the Office of Works tell you they have found, something as good as lead, there is an end of it.

6779. What I want to ask you is this. The regulations that would be introduced would be so specific—we shall take care of that as a Committee—that every possible danger which the men undergo will be protected?—I agree to that.

6780. But you do not like the limitation of hours?—I do not object to the limitation of hours, if it benefits the working man.

6781. You objected to some of these suggested regulations?—The limitation of hours means increased wages.

6782. You objected to that; but what I want to ask you is, whether you prefer a strict code of regulations, or whether, on the whole, you think it preferable to prohibit the use of lead?—If you can give me a substitute for lead I should prefer that.

6783. It is not a question of a substitute. I want you to realise that this Committee has been called together for one specific purpose. The Home Office have figures which show a deplorable state of affairs in this industry. We are met here to find a remedy. There are two ways of doing that. The easiest way is to prohibit the use of lead. If that is not done, then we shall have to frame regulations, and enforce them, similar to those which are adopted in all important industries where the use of lead is permitted. Which of the two would you prefer, this code of special rules or the prohibition of lead?—If the prohibition of lead is going to save the death-rate of painters, I agree to it. I agree to anything to help the working man.

6784. (Dr. Collis.) Do I understand that your paint is all mixed on the work?—You would not get 75 per cent. mixed at our paint shop. The materials are taken out and mixed on the job.

6785. Do you buy your lead dry, or do you buy it already mixed as a paste?—Mixed as a paste—the white lead.

6786. Do you prefer matured old paint, or do you prefer to use it new?—Old.

6787. You have had, within your knowledge, no cases whatever, except the one that you have mentioned, of illness among the workpeople?—Yes, which has been

termed as lead poisoning, and that was with a casual man whom, at the busiest time of the year, we had to have. He was a very dirty man indeed. Times out of number I told him to wash his hands.

6788. How long had he been with you before he suffered from the trouble?—I cannot tell you exactly—only a few months.

6789. Are you aware that this question of cleanliness gives no immunity against lead poisoning?—From what you have told me, from your figures, I agree.

6790. And that many of the cases which have occurred have been with men who have been scrupulously clean in their habits, and as careful as they can be in the use of the material?—Yes, I take that.

6791. Do you know that white lead, after it has been mixed with the oil to make paint, for some time gives off a volatile lead compound, which may be breathed by the man who is working with it?—Yes.

6792. Can you see any way in which inhaling that compound can in any possible way be prevented?—Not directly, but by means of plenty of ventilation, and all that, I think it would be greatly diminished.

6793. Turning for the moment to the question of the age of the paint: if you use paint which is not matured, is it so good?—I do not think so. I prefer myself to get old paint.

6794. Do you think that newly mixed paint, not matured, could be placed in the same category with the zinc paints?—I think the lead paint would be far superior.

6795. You think even the non-matured lead paint would be better, in your experience?—Yes, you have lead in it.

6796. But I thought you said it was inferior, if it was not matured?—It is not inferior, I think, but it is not so good as the old lead paint.

6797. I want to get out how far you consider now lead paint is less satisfactory than old?—I should say it is hardly to be compared.

6798. (Mr. Parsonage.) It is a question of how far it will go, a compound of old paint and a compound of the new?—I think not only it goes further, but I think it is better, and I think it is more standing.

6799. (Dr. Collis.) I want to know, from your experience of the lead substitutes, how far other paints compare with these lead substitutes?—I do not think you can compare it. Mine is a business in which we do not do a lot of cheap work; ours is a fairly high-class business, and I might say that in doing a contract job I do not week by week go about and see how it is paying. I finish the job off properly and do the thing properly.

6800. The evidence which has been given before this Committee shows, as far as I have been able to judge, that the value of the substitutes for lead paint, and lead paint, is so close, that although individuals prefer the lead paint, there is not a very great deal of difference, so that when you mention that non-matured lead paints have a distinct difference from matured lead paints, I want to know whether that difference is comparable with the difference which we have had given to us, which is very small, between paints which do not contain lead and matured paints which contain lead?—Of course, if you come to the point of what the Office of Works are using, which you say is as good as white lead, then, of course, the answer is that there are substitutes as good; but I do not know of a substitute as good.

6801. From your experience, you think still that the non-matured lead paint would be superior to the non-lead paint?—Yes. I should like to see the composition used by the Office of Works.

6802. You have not had experience of it?—I have used the Office of Works paint.

6803. Have you used any other non-lead paint?—No.

6804. (Mr. Parsonage.) What hours do your men work at Canterbury?—The average is 56½ hours per week, 10 hours a day, and 6½ hours on Saturday.

6805. Starting at six o'clock in the morning?—Yes.

6806. If they reduced the hours to 48 hours per week, you would have to raise the men's wages?—I presume so.

16 May 1911.]

Mr. ARCHIBALD WILTSHIER.

[Continued.]

6807. What would be the rate of wages in Canterbury?—The rate of wages in Canterbury is very low indeed.

6808. Is it 6½d.?—6d.

6809. 6d. per hour?—Yes.

6810. That is a very low rate of wages?—It is a low rate.

6811. Do the men serve an apprenticeship to the trade?—That is one of my points. I think the Government should enforce apprenticeship, and not have these ready-made painters, old soldiers, and so on.

6812. How can you expect anything else at 6d. an hour?—Some of my men are paid more than 6d. If a man is apprenticed and brought up in the trade and is a good workman, I pay him according to his work. You may be paid 6d., and this man may be paid 7d., and that man may be paid 7½d.

6813. You pay them according to their abilities?—Yes. The apprenticeship system should be enforced if possible. You bring a man up from a boy and you teach him. It is the same as with a child. You teach them at the beginning, and it is in them for life. In the summer time, when you are busy, you get heaps and heaps of men coming round saying: "Is there any chance of a job?" I say: "What are you?" He says: "A painter." In fact, a man last week, who had never handled a brush in his life, assured me that he was a painter.

6814. You would get so many of these casual men that you would not know how many men get lead poisoning in your shop?—This very man who had lead poisoning I found out had had lead poisoning at his other shop.

6815. About how many men do you keep on in the winter time on the staff?—We keep most of them on. There are certain men we take on in the summer time, but we average 40 all the year round. I should say we keep 32 to 35.

6816. In the winter and all?—Yes. When you have really a good man, even if you have nothing to do, you find him a job. The apprentice system would solve a lot of that difficulty, if you could only bring the boys up to it and teach them their business when they are young and teach them to be clean.

6817. I agree it would be better to teach them to be clean, but that would not obviate the dangers of getting lead poisoning?—No, not according to your figures, and I will take your figures.

6818. (Mr. Sutherland.) You are also a plumber, are you not?—Yes, I am a registered plumber.

6819. How do plumbers compare in point of sickness or anything of that kind? Are they off at all?—No, I cannot say that they are. I think a plumber is hardened much more. You cannot have a ready-made plumber. A plumber must be brought up to his trade, and go with a mate, and so on, and he is bred and born in it, but I think with a lot of these ready-made painters, they come in contact with the paint, perhaps, at middle age. I have not found that the plumbers sicken.

6820. (Mr. Parsonage.) These men cannot do the painting properly who come into it like that?—I know they cannot, but what have you to do. You are full driving. You are worried out of your life for men.

6821. Fully qualified men do not come out of their way round to you for 6d. per hour, do they?—I have had a man who was employed by one of the best shops in London, Sturm and Knights.

6822. They employ very few men, do they not?—I gave him a job at Broadstairs last year.

6823. (Mr. Sutherland.) What was your experience of the Office of Works paint? What did you use it for?—The outside of the post office.

6824. Did you supply the paint?—No.

6825. Where did you get it from?—It was Zopessa paint. They stipulate that you have to use it.

6826. That is the granitic paint?—Yes.

6827. When did that take place?—The last time was this last year.

6828. What was the character of the paint?—No covering whatever.

6829. Was it a varnish paint?—An enamel paint.

6830. Was it supplied in bottles ready mixed?—It is all ready mixed in drums.

6831. Mr. Patterson told us it was cheaper?—I cannot tell you exactly.

6832. I worked it out and it did not come out cheaper?—No, I do not think it is.

6833. How did it go on in the working?—It went on fairly well, but I might mention that our post office has been rebuilt, and it was all painted by the contractor, I think it was two years ago, and yet last year it had to be all done over again, after only one year.

6834. Painted all again?—Yes, outside.

6835. Had the old paint worn off?—Absolutely. In fact I remarked on it at the time to the Office of Works man, and I asked him whether he was going to paint every year. He painted last year and he painted the next year.

6836. What have you tried in the way of zinc paints?—I have tried the zinc white.

6837. Did you order it as zinc white, or as zinc oxide?—Zinc oxide.

6838. Was it pure zinc oxide, or was it a prepared paint?—This was rather more of a prepared paint.

6839. That is really a zinc paint. I do not think it is a zinc oxide. I think it is a zinc white. With regard to the hours of work, 52 hours, half his time the painter will not be working?—That is so. The painter is not always working.

6840. (Mr. Parsonage.) Fifty-two hours in Canterbury is very different to 52 hours in the West End of London?—Yes.

6841. (Mr. Sutherland.) But during the man's weekly employment, a great deal of his time will be employed in preparing and distemping and stippling, and so on?—Yes. Sometimes he may not have a paint brush all the week, and sometimes he may have it all the week.

6842. He would divide his time in the whole year between painting and other processes?—Yes, I should say it is about 50 per cent. Of course, I agree you cannot compare 52 hours in London with 52 hours in the country, surrounded by beautiful trees, and birds singing, and so on.

6843. You have had experience of these water distempers?—Yes.

6844. They are very good for flattening or ceiling work, are they not?—Yes; and I think sometimes you get a better effect.

6845. Particularly for relief decoration?—Yes.

6846. My own experience would lead me to say that 80 per cent. of the work is now done with these water paints which are non-poisonous. What do you say to that?—Yes, quite 80 per cent.

6847. You do not mix dry colours? There is very little dry colour except for decorative purposes?—That is so.

6848. But not for painting purposes?—No.

6849. (Mr. Parsonage.) Do you use lead for filling?—Sometimes we use putty; sometimes we use Walpamur filling, or anything like that, or Paripan filler, but I should say 75 per cent. is the Walpamur and all these others, in preference to lead filling.

6850. (Mr. Sutherland.) Do you think that dust is generated in rubbing down an ordinary room?—In rubbing down an ordinary room, in our class of trade, there is no dust at all, because you rub down by pumice-stone and water, and you cannot get dust then.

6851. But even between the coats of paint, after you have first coated it, do you think that the dust you create by that process is a serious item in the health of the men?—No.

6852. But in an ordinary room the proportion of dust to the atmosphere of the room would be infinitesimal?—Yes.

6853. (Mr. Parsonage.) You do not use flat sharp colour so much?—No. There you would get the dust.

6854. You get far more dust in sharp colour?—Yes, you get dust from the sharp colour.

6855. It is sharp colour that is used in all the large towns, different to the country places like Canterbury, is it not?—Of course, then you would get more dust.

16 May 1911.]

MR. ARCHIBALD WILTSHIER.

[Continued.]

6856. In Manchester and London, and so on, it is absolutely necessary to use sharp colour. You would not get ordinary oil colour to dry?—Not outside.

6857. I am speaking of inside work?—Yes.

6858. You get very little oil inside in London?—Yes.

6859. They generally mix in varnish and turpentine, do they not?—Yes, but I take it these washable distempers are used.

6860. They would use them more in a country place than they would in London, where there is a lot of dust and heat; they do not use the washable distempers so much in London?—Of course you are under different circumstances in London entirely.

6861. (Mr. Sutherland.) You understand that we undertook that experiment with the painted panels with a view to this question that might arise, and to ascertain what were the available substitutes or alternatives to white lead?—Yes, you sent me some down.

6862. You have them now exposed, have you not?—Yes. We have given them a good test. We are close to a gasworks, close to a tan yard, and close to a brewery. It gives them a good test. It is no good putting them in the country.

6863. (Chairman.) I want to ask you a few questions about this paint that you used for the Office of Works. What were the buildings that the Office of Works asked you to paint?—The Post Office.

6864. When did they ask you to paint the Post Office?—Last year.

6865. What month last year?—I did not do it the month they asked me.

6866. When did you paint the Post Office?—I could not tell the exact month, but it was very favourable weather.

6867. About when was it?—Getting towards the autumn.

6868. I understand they wrote to you, and said they wanted the Post Office painted, and they specified the particular paint that should be used?—Yes.

6869. You thought the paint was not at all good?—They wrote and told me I could get it from the Granitic Paint Company, and I wrote and got it, and used it. When I say it is not at all good, that is my only experience of the paint. I was compelled to use it.

6870. Then you used the paint on the Post Office, and did you condemn that particular job?—No, I did not condemn the job, I condemned the paint in my own opinion.

6871. You did not condemn the job of the Post Office, but previously to that you had used the paint, and you found that it did not answer?—I had never used this Astrium before; the time they did it before they had Gay's.

6872. Do you know when they did it before?—Yes, the contractor did it after he built the Post Office.

6873. Do you know when that was done?—I should say about 12 or 15 months before.

6874. And that did not answer?—It had to be painted again.

6875. Do you say it was all worn away?—Yes. I assure you that is a fact. We always reckon four years for outside painting, and I will go as far as this: I think before four years are up it will want doing again.

6876. Do you think four years is a good trial to give any paint?—I think white lead paint will last four years.

6877-8. Do you think four years is a good trial to give any paint?—Yes, very often; but, unfortunately, some of our customers make it go five years.

The witness withdrew.

## NINTH DAY.

Wednesday, 17th May 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (Chairman).

LORD HENRY BENTINCK, M.P.  
SIR GODFREY BARING, BART., M.P.  
MR. E. L. COLLIS, M.B.  
MR. F. G. RICE.

MR. W. G. SUTHERLAND.  
MR. A. GARDNER.  
MR. J. PARSONAGE.  
E. A. R. WERNER (Acting Secretary).

Mr. JOHN WILLIAM BARKER examined.

6879. (Chairman.) Do you attend to-day as a representative of the National Association of Master House Painters and Decorators?—I do.

6880. What is the nature of your business and where is it carried on?—It is carried on at 21, Market Street, Leicester; general house painter and decorator.

6881. How long have you been in the painting business?—All my life.

6882. What is the average yearly number of painters employed by your firm?—The average number would be about 27 to 30. There are 40 men employed to-day.

6883. Have you known any cases of lead poisoning or painters' colic?—I have.

6884. Will you give us your opinion about them?—The first case was that of a youth, an apprentice, who was away from work some 15 or 16 days. A local doctor that he went to said he was suffering from lead poisoning, but the official doctor, Dr. Bryan, refused to give him a certificate for that and said that he ought to

have seen him within a day or two of visiting his local doctor. I had a conversation with Dr. Bryan, who said he might have suffered from lead poisoning, but when he saw him he could not certify him to that effect. The second case was that of Richard Wilde, a workman about 31 or 32 years of age. He was away nearly three weeks. The third case was that of an old employé named Thomas Smith. He would be about 50 years of age. He appeared to be suffering very acutely for the first few days, and after that he thought that he ought to stay away and get quite well, and I suggested that he should, especially as work was falling off and he had been paying into his clubs, and such like. I asked him what he was in receipt of, and I found that he would get compensation from us, his employers, and I worked out his remuneration, which came to rather more than if he had been at work, and so he remained away a considerable time. I have questioned each of these men, first the youth, afterwards Wilde, and lastly Smith, and they all declare that to-day they feel no ill effects from their illnesses.

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

6885. What period do these three cases cover?—Nearly two years.

6886. The last two years?—One was in the last year.

6887. The three cases occurred in the last two years?—Yes.

6888. Do you insure against your liability for payment of compensation?—I do.

6889. Has the rate been increased recently?—I think it has.

6890. Is that on account of the incidence of lead poisoning having increased?—It may have been so.

6891. Have you known men who have broken down temporarily on account of lead absorption?—No other cases than those I have named.

6892. Have your men had occasional days of sickness due to lead?—Very seldom.

6893. There may have been some cases?—There may have been some cases.

6894. Do you have a periodical medical examination of your men?—No.

6895. Is it not possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—I could not answer that: they may be.

6896. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—I should think it possible.

6897. You take a prominent part, I believe, in the work of the Master House Painters' Association?—I do.

6898. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—It may have been, between ourselves—in a casual way.

6899. Did you take any steps to discover how much illness there was amongst the men employed by your various members?—I have not done so.

6900. Did the association?—Not that I am aware of.

6901. Have you ever had a paper read to you on lead poisoning at the meetings?—I think there may have been in one case, but I do not know definitely.

6902. You must have heard of the prevalence of lead poisoning among the men who handle lead paint, I suppose?—I have heard more of it by reading the simple accounts in the paper, and in the ordinary sort of way, but more particularly with regard to the Potteries.

6903. Did your association never attempt to collect statistics concerning the number of days absence from ill-health amongst lead painters as compared with men not coming in contact with lead?—I do not think so.

6904. Then collectively your association has done nothing to meet the evil?—We have not felt it so serious an evil.

6905. Were not you cognisant of the number of cases that were occurring year by year?—Only those that came under personal observation.

6906. Did not the association, as a body, take sufficient interest in the matter to go thoroughly into it?—I do not think they have done up to the present.

6907. Did your association ever consider the advisability of having a medical examination of the persons employed?—It has not been recommended to us.

6908. Would not this have been the best way to discover the proportion of painters showing symptoms of lead impregnation?—I should think it would be a suggestion worth considering.

6909. Has your association ever taken any collective measures to discover a substitute for white lead in paints?—The manufacturers are always putting forward substitutes.

6910. But have your association ever taken any collective measures themselves?—They have put some material under tests, during the last year particularly.

6911. Have you employed a chemist to make scientific investigations?—We have a chemist always at our disposal.

6912. But have you employed this chemist to make an investigation of the chemical properties of the different pigments and vehicles?—Only to get the results as to the purity or otherwise of the materials,

6913. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many master house-painters. Is that your experience?—I think, considering that I have had more than 40 years' experience in the trade, and only know of three cases, and those of very recent date, one could hardly be expected to realise it was so serious. No death has occurred that I know of, and I know of no other cases in our locality.

6914. But surely you, as an association, ought to have taken steps to realise the extent of the danger and to bring home its seriousness to all your members?—I think it would be a good thing to take the matter up and do that.

6915. The incidence of lead poisoning is published by the Board of Trade every month; do you not see their publications?—Yes, we get the Board of Trade Report.

6916. You can see there the number of cases that occur year by year and month by month, can you not?—Yes.

6917. Did you ever discuss this amongst yourselves?—No.

6918. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—Among painters?

6919. Yes?—I should scarcely think it, but it might be.

6920. And that the death rates from Bright's disease and nervous diseases, due to work in lead, are very high?—That may be so.

6921. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily, without any legal compulsion whatever, in the same 10 years?—I am very much surprised to hear it.

6922. These figures were all returned month by month in the Board of Trade returns, and were quite open to your members, if they wished to see them, were they not?—Yes.

6923. And do you realise that these cases, reported voluntarily, are only a fraction of the whole, inasmuch as the Home Office have no legal right to pay for such reports and are, therefore, bound to discourage reporting to some extent?—I am very much surprised.

6924. Have you seen a copy of the Labour Gazette, issued by the Board of Trade, published yesterday?—I have not.

6925. On page 187 of that issue it shows a definite increase in the death rate from lead poisoning among painters; 18 deaths in the first four months of this year and only 12 deaths in the first four months of last year. Do not you agree with me that that is a most alarming increase?—I think if those are the facts it is very alarming indeed, and I am very much astonished because, as I have stated, up to very recently, within the last two years, I had no cases of lead poisoning.

6926. I am not surprised to hear that at all, because in some of the potteries, in fact a large number of the potteries in Staffordshire, they have had no cases there at all; and then, quite unexpectedly, without any warning, a firm which has been immune has a crop of cases?—I look at it in this way, that while there may have been cases of lead poisoning slowly going on, they may not have been brought to our knowledge, and men may have been poorly and not known the cause, and now possibly, like other diseases, it may be diagnosed by the medical profession a good deal more definitely than formerly.

6927. From the figures which I have read out to you, the gravity of the danger is seen, if you compare these figures with those for all lead industries under the Factory Act, in which there have been 10 deaths in the first four months of this year, and 15 deaths in the first four months of last year. So that there has been a decrease in this instance, but in the house painters' trade there has been a large increase, and the deaths from lead poisoning in the house painters' trade are more numerous than in all the other industries where lead is used—all of them taken together. I want you to realise that?—Yes.

1 May 1911.]

MR. JOHN WILLIAM BARKER.

[Continued.]

6928. I am sure, from what you have told me, you agree with me that all this sickness and death is very deplorable?—Certainly.

6929. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, I know that.

6930. That the use of white lead has been prohibited to an appreciable extent abroad, and that the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed. Do you know that?—Yes, I know that a good many restrictions are laid down.

6931. Do you not think it regrettable that this country should be behind other nations in this respect?—I think it is regrettable that we should be behind in anything.

6932. Do you consider lavatory accommodation essential?—I think it is very useful.

6933. But is it not essential?—In what sense?

6934. To enable the workers to wash their hands regularly?—Certainly.

6935. Including the supply of hot water for washing?—I think hot water is much better to wash with than cold.

6936. Is it generally practicable for the men to have hot water to wash in?—Our work varies so much. It is practicable where a number of men are together, but when men are singly engaged, or perhaps two of them, just a man and his mate, it might be more difficult. When a number of men are together, a youth or a labourer prepares the water for breakfast and the water for dinner, and it is not difficult.

6937. But you cannot always ensure the men having hot water?—It is not possible.

6938. Do you advocate definite rules regarding the wearing of overalls?—Certainly; we insist upon it.

6939. How can you ensure these being kept in a cleanly state?—If a man came on Monday morning with his overalls dirty we should ask him what he took us for, and say: "Are you fit to go on to your job this morning," and his reply would be to make some excuse. Then we should say: "Then you must get a new set."

6940. Where are the overalls kept when the men have finished their work?—Usually hung up on the job.

6941. In the room in which they have been working?—It all depends on the class of work.

6942. But does it sometimes happen that the overalls are hung up in the rooms in which the men are working?—Yes.

6943. So that they come into contact with any dust that may be in the room?—There would not be very much dust in the room.

6944. I am not speaking about the quantity. I want to know whether the overalls would come into contact with any dust that might be in the room?—Men as a rule take off their overalls and fold them up, and put them sometimes in their basket or their bag. At other times, if there is plenty of accommodation, they will hang them up.

6945. In the room in which they have been working?—That depends entirely on the circumstances.

6946. Does it sometimes happen?—Yes; but it entirely depends upon the building in which they are working.

6947. Does it sometimes happen that the men may leave their overalls in the room in which they have been working?—Certainly; but I ought to qualify that, if you will allow me. If the work is of a limited character, that would certainly apply, but if it covered a large number of rooms the men would very often leave their overalls where they have their food—in another room. They would not mess in the same room as the paints are, if there is another room at their disposal.

6948. But if there is not another room at their disposal, what happens?—They have to mess there, and they would leave their overalls there.

6949. Then it is possible for the men on some occasions to be obliged to leave their overalls in the room in which they have been working?—Certainly.

6950. I want to ask you about the workmen's outdoor clothing. When they take off their coats to

begin work, where do they hang those coats?—They would hang them where the overalls are hung.

6951. In the same room in which they are working?—If the conditions obtained that the accommodation was limited; but it so frequently happens that there is more than one room being treated.

6952. But if there is not more than one room?—They are bound to be there.

6953. And there is the same risk of dust accumulating there?—Yes.

6954. With regard to the men's meals, do they sometimes have their meals in the room in which they are working?—Sometimes.

6955. I suppose it is impossible to always provide a place quite free from risk of contamination?—No, not in good weather. It is nice to sit out-of-doors in nice weather.

6956. But it is not always possible?—No, it is not always possible.

6957. With regard to the risk arising from dust and spray which the workman can inhale during his working hours. First, as regards dry rubbing down with sand-paper, I understand this process is indispensable?—I do not think it is indispensable, but it is very largely used.

6958. Would you agree, as a master house painter, to the prohibition of any sort of sand-papering?—No, not any sort.

6959. Then I am quite right in saying that this process is indispensable in some cases?—It is so, but may I qualify that? I think that anyone connected with the trade will agree, while the sand-paper makers are almost millionaires, we have not had the improvement in sand-paper that we ought to have had. Our sand-paper is made to-day as it was 25 or 30, or even 40 years ago. We ought to have a sand-paper that would wear longer, and, if not moist, would be in a semi-moist condition.

6960. But that does not quite answer my question. I want to know whether sand-papering is not indispensable in some operations to-day?—It is indispensable. We could not do without it to-day. But there is nothing to prevent us having sand-paper in a medium.

6961. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—I should think more falls on to the ground than gets in the atmosphere.

6962. But it must get into the atmosphere on its way to the ground?—The only way to prove that would be to sand-paper a door or a piece of a wall, if you wish; and then you would find that the great quantity of dust is directly below where you have been sand-papering.

6963. We have had an investigation of sand-papering in the coach-painting industry, and it is a more dusty process than occurs in any other lead industry to which the tests have been applied in this country. Could you use an exhaust draught to remove this dust?—I do not know how we could. I have not thought of that.

6964. The next process I wish to ask you about is the painting of ceilings, having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

6965. This gives rise to splashes, which must frequently fall even on the face of the worker?—Yes.

6966. How can you deal with the spray which arises in this operation?—I do not see how we can deal with it. Of course there is not so much of that work done as there used to be because of the introduction of water paints.

6967. Can you use an exhaust draught to catch the spray?—I do not think so. He does not get so much on his face as he gets on his hands, because he does not work exactly over his head.

6968. But he gets it on his clothes and on his hands?—Yes, he does. He gets a lot on his hands, but not on his face so much, because it would make his eyes smart.

6969. Then, again, we are confronted with the problem of how to save the worker from the grave danger involved in breathing this spray. What do you say to that?—I do not know any way, myself, to get over that, unless he wore a respirator.

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

6970. Then with regard to stippling, the same considerations apply there, too, do they not?—Scarcely.

6971. In stippling, the man gets a certain amount of fallings?—I do not think so.

6972. I have seen it myself. I do not say it is a very large amount, but he certainly gets some of the fallings?—The stippler is a large brush (*describing it*), and he thumps it on the ceiling.

6973. As he does that, it would remove the paint to a certain extent, and a little of it would fall on to his clothes?—I have not noticed it.

6974. There is another danger with regard to stippling, that is, that the man is very adjacent to the painter, and splashes made by one man may fall on the other?—That is so.

6975. Do you have old paint burnt off with a spirit or charcoal burner?—Spirit.

6976. How can you prevent the worker from inhaling the fumes which arise from this process?—I do not think it is possible.

6977. Where and how do your men mix their colours?—They are usually mixed by the chieftain on the job.

6978. Are they mixed dry?—No, all in paste form, except a few colours that may be used for painting purposes.

6979. It appears from your evidence, then, that there are certain indispensable processes, in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. How are these dangers to be met?—That is a very difficult question to answer. I am not a scientist and must speak from the practical side of the trade. I should say, with regard to the spray which might come from the stippling or actual work overhead, a respirator is the best thing I know of or could think of, and, with regard to sand-papery, I should not object to a man wearing a respirator if he was sand-papery; but I want to find a better sand-paper than we have found up to the present. With regard to burning off, I do not think there is very much that is injurious from burning off the old paint.

6980. I want you, in answering the questions, to recall to your memory these figures which I have read out to you, showing that this prevalence of lead poisoning is a very real one. It is no use giving your answer assuming that there is no danger anywhere?—No, but although you have figures, I must go on my definite knowledge, and I have quite as much right to what I have seen and what I have come in contact with, as actual figures that have been presented.

6981. I do not think Parliament would take that view of it. Parliament would say: "There are a certain number of men who have been injured year by year in this industry, and, although some firms may be exempt, that does not dispose of the actual facts?"—Just so.

6982. Is it possible to remove the danger entirely in any other way than by using a substitute for lead?—I have not found a substitute for lead at present.

6983. It is not a question of whether you have found one or not. I ask you whether it is possible to remove the danger entirely in any other way than by using a substitute for lead?—That would remove it.

6984. But is there any other way of removing it?—I do not know of one.

6985. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience with such substitutes?—We have tried a few samples that have been sent to us.

6986. What results did you obtain with those samples?—Very poor results.

6987. The Office of Works, and others have succeeded in obtaining efficient non-lead paints?—I am very much surprised to hear that.

6988. And the former have used the non-lead paint for four years, with the most excellent results?—That is not very long.

6989. What period do you consider would be sufficient as a test?—Was that inside or outside?

6990. Both inside and outside?—I should say it was scarcely any test inside: it would be a slight test outside.

6991. What would you consider would be a proper test for inside and outside, for any paint?—Outside painting should be done, of course, in four years, but a good deal of it is not done in that time. Inside, it goes on for 25 and 30 years sometimes, with a cleaning down. It all depends on the class of work. I do not think that four years is a sufficient test.

6992. How many years do you think would be sufficient?—I should want twice four years at least. I should like it to perish. I should like to see the actual wear.

6993. What are the usual hours worked by your painters per week?—56½ hours per week in the summer and about 42 in the winter.

6994. Would you welcome a strict limitation of the hours of employment, say, to 48 hours per week as the maximum?—We could not possibly work at 48 hours a week.

6995. I only mention that limit, because that has been adopted by the Departmental Committee, composed of employers and employed, in the pottery trade?—But ours is a season trade.

6996. All the medical evidence that has been taken shows very conclusively that it is essential to limit the number of hours working with lead. You do not have a periodical medical examination of your workers?—I have never thought of it. I should not object.

6997. Do you know that, in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—I was not aware of that.

6998. I have told you that lead poisoning frequently undermines the health without immediately developing acute symptoms?—Yes.

6999. Then you would welcome a system of periodical medical examinations in your industry?—I should not object to that at all.

7000. At the cost of the employer?—There has been enough cost put on the employer. I would not be unreasonable.

7001. That is the custom which prevails to-day, that the cost of the medical examination has to be borne by the employers?—Yes, I would not object to that.

7002. Together with compensation for any workers suspended by the doctor on account of doubtful health?—We have got a few that would be sick very often—no, I cannot go that far.

7003. I may tell you that that also has been adopted in the earthenware and china trade?—Yes, but that is all under cover, I take it.

7004. It is not a question of the kind of work a man does: it is a question of the amount of risk that he comes in contact with?—But we work under all kinds of conditions. Our work is not localised. He might be at work at the Home Office to-day and at the Foreign Office a week hence, or a private house, or he might be sent to a hotel.

7005. The incidence of lead poisoning in your industry is greater than in any other?—I noted what you said about that.

7006. I ask you, therefore, whether you would agree to pay compensation, as is done in the earthenware and china trade, for any workers who are suspended by the doctor on account of doubtful health?—If it was an Act of Parliament we should be obliged to.

7007. Then you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures, in the same way as in other industries where the workers handle lead?—I should agree to any conditions that would improve the condition of the workmen.

7008. Of course this will involve an extremely complicated and elaborate code of regulations?—They might be simplified.

7009. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to the following: first of all, overalls?—They provide their own.

7010. In other industries it has been decided that they shall be provided by the employers?—They work under different conditions.

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

7011. That is not the question?—But they go to one place every morning to begin their work. We go to one place for two days and one place for a week; or it may be three weeks; or it may be five weeks; and we might go to two or three places in one week, and that would be rather difficult.

7012. I am only telling you what prevails in other industries. I am not telling you what this Committee are going to recommend; because we have not decided that?—I hope you will not attempt to enforce a condition of that kind.

7013. I am only telling you what is the condition in other industries. First of all, providing overalls by the employer and seeing that they are properly washed—taking the responsibility to see that they are properly washed, then taking care that a mess-room is provided, and that in no case whatsoever are any of your workmen allowed to take any of their meals in a room where lead is used?—I think we should agree to that.

7014. That under no circumstances whatsoever would the men be allowed to leave their overalls in the rooms where they might come in contact with lead?—We are speaking now of inside work. There is a very great deal of outside work.

7015. I am telling you exactly the conditions which the Home Office have laid down in other industries. Neither would they be allowed to leave their clothing in any room where the clothes might come into contact with lead; that washing accommodation should be introduced (one basin to every five workers); that soap and nail-brushes should be provided by the employers?—Soap is already provided, but not nail-brushes.

7016. And a sufficient supply of clean towels, so as to prevent what I saw happening the other day, when five men were found washing their hands in one bucket; and they dried their hands, all of them, on their pocket handkerchiefs. Of course, that would not be allowed. Then provisions would have to be made for the avoidance of dust, for which you have told us that you cannot suggest any remedy?—Only a respirator.

7017. That would not be sufficient—something would have to be done to provide means of getting rid of the dust which these men come in contact with. Then there might be a limitation of the hours of labour to bring this industry up to the level of the other lead industries, and other provisions of a similar nature. Is it possible to subject painting operations to systematic and thorough inspection?—I should think it was very difficult.

7018. Taking all these points into consideration, and not forgetting the periodical medical examination which would be insisted on at the expense of the employer, and the payment of compensation to workers withdrawn from work in lead, would you say that you prefer that the industry should be regulated by special rules such as I have foreshadowed, or, as an alternative, that the use of lead should be prohibited or very closely restricted?—That is rather a comprehensive question. There are very great advantages to the employer in the case of lead being restricted, because we would not have to pay such a heavy rate of compensation. If lead is continued, the restrictions that might be placed upon the use of it seem to me almost impossible to carry out.

7019. On the whole, supposing that it was to be prohibited, and you were all alike, would you prefer the prohibition to this very stringent set of regulations?—I think so, if you can give to me the formula.

7020. You must not put that as a proviso?—I say, if another medium could be produced to give the same result as white lead, I would like to use it.

7021. That is not the question put to you. This Committee has been instituted to try and remove this evil. There are two ways of doing it. The one is, to remove the element of danger altogether, which is the lead; and the other is to have rules from one end of the industry to the other, which are to go to check the evil as it arises, which we call a special code of regulations. Now, I have foreshadowed to you what this special code of regulations would be, and I ask you this one simple question: Would you, as an employer, prefer to have this stringent set of regulations, which you would have to keep, or would you prefer, as the alternative, the

prohibition of lead?—Do away with the white lead and let them put up with what was provided; and away with the conditions.

7022. (Lord Henry Bentinck.) Do not you think that, if white lead were prohibited, very soon you would find a satisfactory substitute put on the market?—We should have to use the best there was, and the public would have to take the responsibility, the employer would not. If the Government insists upon any material or medium being used we should have to do the best we could, and; I think, as a whole, we should be prepared to try to do the best we could with it.

7023. It would not damage your interests in any way?—No, and we do not want the workmen damaged. We want our old workmen to live as long as we can possibly keep them. I have men in my employ that have been in my employ for 30 years; and I am as much to them, and I hope they are to me, as it is possible for workmen to be. I speak to them, and I am interested in their families, and all the rest of it.

7024. What did you mean by saying that you paid a heavier rate of compensation?—I think that the rate of compensation was increased some short time ago. I really could not tell you exactly, but when you have to do these things you do them and you let them go.

7025. Do you mean compensation against sickness?—I suppose compensation altogether.

7026. You insure your men, do you?—Yes.

7027. Against what?—Against employer's liability.

7028. And you pay a higher rate than you used to?—Yes.

7029. Then you admit that it is rather a dangerous trade. It is rather contrary to your evidence given at first, is it not?—No.

7030. I understood from your evidence, at first, that you were rather sceptical about its being a very unhealthy trade?—No, I accept the figures, because I am not able to disprove them; but, speaking from my own experience, the only cases I know I have given to you, faithfully and truly. I want to assist you. It is no use our being here unless we assist each other, and I am sure if I could give you any information which would help you I should be very pleased.

7031. (Sir Godfrey Baring.) I understand you have never tried any zinc substitutes extensively, have you?—Not extensively. What we have tried has been prepared by good reliable firms—we do not buy from everybody that calls upon us—and we have found that the zinc paints spread well and are very fine, but they do not possess the body of lead, so that we coat up in lead and finish with a coat of zinc frequently, especially if we want to leave any of our work white.

7032. Where have you tried the zinc paints, inside or outside?—Inside—never outside.

7033. How long ago is it since you first tried zinc paints?—It would be about five years.

7034. And the result has not been, in your opinion, satisfactory?—Far from satisfactory, except in the cases I have named, where we have been able to coat up in white lead, getting our body, and finishing with a white finish.

7035. (Lord Henry Bentinck.) Is that true of all shades of colour?—No. It is principally in the white that we want to do it.

7036. (Mr. Sutherland.) You have not used it for colours, have you?—No, not at all. For instance, take this room. If we were asked to paint the ceiling and cornices here, and it was very dirty indeed, we should prepare it and give it two or three coats of white lead, and finish it with a coat of Griffiths' white, or some other zinc compound.

7037. (Sir Godfrey Baring.) Do you think zinc paints have been improved lately, in the last year or two?—If we read the advertisements they are perfect, but if you ask me the question from the practical side, as I think you do, I say they are still floundering about.

7038. You have not found any satisfactory zinc paint, have you?—I have not found one.

7039. (Dr. Collis.) I should like to ask one or two questions concerning the health of the workpeople. Do you think you had the same opportunity of becoming acquainted with illnesses due to lead in the old days, to

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

the same extent that you have had since the Workmen's Compensation Act came into force in July 1907?—I do not think there has been very much appreciable difference.

7040. But the point that I have in my mind is this, that the workman now, if he has lead poisoning, and gets it so certified, comes to you to get compensation. The apprentice you mentioned, you told us, applied for a certificate, so it came to your knowledge?—Yes.

7041. Did Wilde get compensation for his three weeks?—Yes.

7042. And also Smith?—Yes.

7043. So that those three cases which have occurred during the last two years have all come to your knowledge owing to the fact that the men applied for and obtained compensation?—I have not any actual knowledge of those, but I think that those cases have come to us from the knowledge that is conveyed to the workmen from their respective societies. It is generally known now that if an illness can be traced to lead poisoning there is every chance of compensation.

7044. The point I was upon was this: that these three cases have come to your knowledge owing to the men having applied for compensation?—Not in the three cases—two.

7045. The other did not get it?—The youth did not apply in the same way.

7046. But it came to your knowledge through his making an application for it?—Yes; but he was given his compensation straight away.

7047. But my point is this: had we been in the early nineties, instead of the date we are at now, these three cases might have passed without ever coming to your knowledge, and then you would not even have known of those three cases?—I think we should have known of them.

7048. Do not you think it is a curious thing, after your long experience in the trade, that it is only since compensation for those illnesses has been paid that you have come to know of those three; and that is only since the Workmen's Compensation Act came in?—I do not think it is at all remarkable. If you will allow me to say so, the workmen know as soon as any Act is brought in for their benefit. It is fully advertised and talked about, and they are, like ourselves, of course, ready to take the first opportunity, and quite right too.

7049. Do you follow my point? I say it is curious that it is not until then that you know that any illness among your workpeople had been caused by lead?—I do not know.

7050. If these three cases had been spread over the whole period that you had been acquainted with the painting trade, one would have said certainly you had had knowledge of the cause of illness among your workpeople, but there is this curious point about it, that these three cases of lead poisoning, or people who were said to have been influenced by absorbing lead, as regards their health, have occurred during the last four years of your experience in the trade, during which four years the Workmen's Compensation Act, for this illness, has been in force?—I think the men might have suffered before and not made a claim for compensation.

7051. That is my point, that probably this incidence of illness has been occurring, but you have not had it certified and known what it was?—That is so.

7052. You tell us you have about 25 to 30 workers?—Yes.

7053. These three cases, spread over the four years that the compensation has been in force, give us an incidence of 2.5 per cent. per annum in your own trade. Of course, the figures are very small, but it does give us 2.5, and in the whole of the pottery industry it is only 1.4?—Yes.

7054. Although you have not much knowledge of there being danger in your trade, and you have heard a good deal about the agitation in the Potteries, still your figures, which you yourself give us, present a case which is one and a-half times as bad as the Potteries?—Certainly. I may go on for years without a case.

7055. You said, when you suggested a respirator, that you have no objection to the men wearing a respirator?—Not the slightest.

7056. But do you think the men would have an objection?—I think it would rather cover the nose than the mouth.

7057. But would they object to it?—I do not know.

7058. (Mr. Parsonage.) If you have an improved glass-paper, would that in any way prevent the dust?—Not unless it was used moist. I think it is possible to get a very good effect, if you use oil with sand-paper.

7059. We have been told by one or two that they have used turpentine?—I do not mean bare oil; it would have to be a mixture. You would have to use spirit with it in a small proportion, but the bulk would be oil.

7060. Half and half?—I think rather more than that; but I do not think we have got the right sand-paper by any means.

7061. With regard to lead poisoning cases my experience is that Leicester is rather a bad town for it. At the present time I have two cases on my list of men who are certified as being totally incapacitated from paralysis and lead poisoning in Leicester?—I do not know of any other cases than my own.\*

7062. And I could give you a list of cases that we have settled within this last 12 months, where we have recovered over 200l. of compensation in Leicester. These two cases at the present time are awaiting settlement on our list. We have paid one case this year. All those cases in Leicester practically belong to my society, the National Amalgamated Society. I have here the quarterly report from January to March. I have three cases, all directly certified lead poisoning cases—one at Liverpool, a man of 56 years of age, lead poisoning; one at Taunton, a man of 25 years of age, plumbism; and one at Dublin, a man of 56 years of age, lead poisoning. During the last four weeks there have been three inquests on painters. In each case the verdict has been lead poisoning. That is in Manchester alone. One of these cases is a master painter; the other was a foreman and the other was a workman. This is within these last four weeks—three fatal cases—coroner's inquests—in Manchester alone from lead poisoning. I know that Leicester is rather bad, because we have a good many cases?—Yes.

7063. You have been exceptionally fortunate in not getting them in your shop?—Yes.

7064. But you realise that it is far more prevalent than you had any idea?—I am astonished at the Chairman's figures.

7065. (Mr. Gardner.) Just one question on the point of substitutes for white lead. Is it not the fact that because white lead has been so handy and has been in so general use that you have not bothered to try and find a substitute?—We have tried to find a substitute, because we found that white lead was affected a good deal by the atmosphere, and zinc white kept its colour better.

7066. But you have not experimented at all or tried the combination of zinc with different mediums?—Yes, we have—one of the principal ones.

7067. But you have just taken what the manufacturer gave you?—Certainly.

\* Mr. Parsonage supplied the witness with the names of the two cases to which he referred. The witness, upon personal inquiry, found that one of these cases only was lead poisoning, the other the result of an accident. The following details were supplied by the witness in a letter, dated 30 May 1911:—

In the course of my cross-examination, Mr. Parsonage, in reply to my statement that I knew of no cases of lead poisoning in Leicester other than the three cases in my own experience, stated that there were two of their members, at present in Leicester, suffering from paralysis due to lead poisoning. He gave me the names of A and B.

I have inquired into the case of A and find that he is suffering from a severe accident due to falling from a ladder last July, when he fractured his thigh, for which he got heavy compensation. This being the case, I can only express my surprise that the Committee should have been so misled, and respectfully ask you to allow this letter to be read to the Committee, and if the questions appear in the evidence to have them corrected by this letter. I have communicated with our Secretary, and I believe he has the papers to prove that what I say is correct.

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

7068. The master painter has not experimented on his own account, with regard to finding a substitute for white lead?—Yes, we are trying now.

7069. But you are only trying what manufacturers are putting on the market?—Yes. What we are trying now is this—and I think it is the right thing to try. At the technical school we have an excellent teacher, an old painter, a Mr. Townsend, 70 years of age, a fine old tradesman. He is a man who is interested in the mixing up and combination of things, and he is always trying it.

7070. You tell me that during the last five years you have only used zinc compounds, and that you do not know that there has been any betterment during that time?—That is so.

7071. I have used zinc paint between 25 and 30 years, and before I left the trade I knew a great deal about it. To-day there is a vast difference in what we have to use. Personally, I may say, I have experimented with zinc and varnish and steam-boiled oil?—That works very well, zinc and varnish, does it not?

7072. If you mix it with what we call steam-boiled oil, what Mr. Patterson referred to as refined boiled oil. It is used largely in the shipyards?—We have not come across it.

7073. (Mr. Sutherland.) Who paid the apprentice that you said got compensation? Was it yourself who paid it or was it the insurance company?—Both.

7074. Although there was no legal claim?—No legal claim.

7075. Your experience is the experience of a large number of our members that we have had before us, and I believe it is the experience of the great number of the members of our association, that white lead as regards poisoning has not come before them as a serious matter, except through published reports which many of them do not see?—That is so.

7076. So that it is not in any way a reflection on our association, or on the members, that they have not, as a body, or individually, investigated this question?—In reply to that, I should say that I ought to take responsibility myself. If I had as many cases during the next two or three years as I have had in the past, I shall want to take some precautions.

7077. But if a body of men are in general good health, they are not worrying about the doctor, are they?—That is so.

7078. I do not want anything like a reproach to go out against the association in this matter of neglecting what is obviously now, and especially to this Committee with all the facts before it, a very serious matter?—I think we should take it up now.

7079. You think that as an association we shall be able to respond to the position?—I do, and I think we shall fall short of our duty unless we do that.

7080. There is another point of view that I should like to bring out. In your opinion there is nothing as a point equal to white lead?—I know of none.

7081. When I say a paint, I do not mean a special preparation, or enamel, or anything like that; but taking ordinary paint, is there anything in your opinion equal to white lead?—We have not found it yet.

7082. As a protector—especially for outside work?—We have not found it yet. We are prepared to try one.

7083. Therefore, the question has an interest from a public point of view, and if you are going to set aside a paint which has been used for so many years, and has given good results in protecting property and public buildings and structures, it should be set aside only after very careful and very great deliberation?—I think those who set it aside ought to take on themselves the responsibility of making it good if it fails.

7084. That is a responsibility which they will not accept?—I will not accept it. I shall say to my client: "The Government ask me to use this material for you; I believe it is the best they have any knowledge of on the market; I shall use it, and you must hold them responsible; I will not be responsible."

7085. (Chairman.) The Home Office are not likely to specify any particular formula which you are to use?

—I know that, but you will pardon me if I just divert a little. Almost every month some representative of a decent house comes along with the perfect thing; it may be a lead; it may be a colour; it may be a medium, a mixture of lead and zinc; it may be a compound of one kind or another; but he has got the perfect thing, and he says: "If you will use this, the Home Office are using it, they have booked an order for so-and-so." I say: "Look here, do not talk to me about what the Home Office or the railway companies are doing; if it goes wrong will you undertake to make it good?" He says: "Well, that depends." I say: "Then I will not try it." If a man comes along backed up by the most perfect scientific knowledge and he prohibits lead, he should take that responsibility.

7086. (Mr. Sutherland.) Do you think that before this Committee makes recommendations there should be something like a prolonged test of different substitutes, not for the purpose of recommending any particular firms, but paint made up on different formulæ?—I think it is necessary. I think that this inquiry is only the preliminary to that.

7087. If the Government is going to abolish a paint that has stood the test for 150 years, and given good results, it should take some little trouble to give something satisfactory in the way of a substitute?—They should take all the trouble that is necessary and then recommend a substitute.

7088. Do you think we could abolish dry rubbing down as the alternative to the prohibition of white lead?—For the moment I should say it would be difficult, but I do not see with careful application that it could not be overcome.

7089. A good many of our scientific and professional witnesses have expressed the opinion that work is better when it has a priming on wood of white lead, and that zinc does not make a good priming. Mr. Patterson, of course, said that they had found the formula for that after repeated experiments?—My experience is that white lead is the best priming, and from experience I come to the conclusion that white lead is the best base, as a priming coat, that you can possibly have, but not used alone. If the work is to be finished dark I should prime my work with the white lead stained.

7090. That is only incidental; that would not dispense with the lead?—No.

7091. You say white lead is the best?—Yes.

7092. You said it was impossible to get hot water in some cases. That is a very extreme case, is it not?—Not very exceptional. There are exceptional cases where it is difficult for the men to get hot water.

7093. Do you mean when the house is empty?—Yes; but as a rule when they are working inside there must be a fire to melt size and to boil water for their breakfast and dinner. We provide them with a large kettle for that purpose, and when the fire is made it is not impossible to get hot water.

7094. With regard to the clothes being hung in the room where the workman is painting, that does not often take place, does it?—Not often, but it does take place.

7095. You think he could not dispense with the use of the lamp by solvents?—I think it would be very difficult. It is so messy, and very dirty indeed. I think that we might, with the best solvent, do more work probably than is done with it, if we were assured that the workmen suffered from the use of the lamp.

7096. With regard to the other conditions, do you think it would be better to regulate the industry, however irksome the conditions might be, than to abolish white lead?—I think, from the statistics given by the Chairman, it is absolutely necessary that some restriction should be laid down.

7097. But do you think that the inconvenience to the master painters would be greater by restriction than by abolition?—It depends how numerous the restrictions are.

7098. They would be irksome?—They would be irksome, but if we had to fall into line we should try to do the best we could.

7099. (Chairman.) You have not, if I may say so, adhered to the answer you gave to me. I asked you which you preferred, the imposition of a special code of

17 May 1911.]

Mr. JOHN WILLIAM BARKER.

[Continued.]

regulations, which I foreshadowed, or the abolition of lead, and you said the abolition of lead?—Certainly, if the regulations are going to be numerous.

7100. (Sir Godfrey Baring.) The cost of restriction would be far greater than the cost of abolition?—Yes.

7101. (Mr. Rice.) It would increase the cost of work?—Yes; and besides that, everybody who comes into contact with the British workman to-day, or any workman—I do not want to run my own countrymen down: I have employed Englishmen and Frenchmen—knows that one man will be careful and carry out his

The witness withdrew.

Mr. FREDERICK GRUNDY examined.

7104. (Chairman.) Do you attend to-day as the President of the National Association of Master House Painters and Decorators?—Yes.

7105. What is the nature of your business and where is it carried on?—Painting and decorating only—no plumbing—and it is carried on at 25, Baxter Gate, Loughborough, in Leicestershire.

7106. How long have you been in the painting business?—I myself have been in it 49 years.

7107. What is the average yearly number of painters employed by your firm?—The average is about 10.

7108. Have you known of any cases of lead poisoning or painters' colic amongst your men?—Not amongst my men. I had one apprentice attacked with it.

7109. When was that?—I should think it is 10 years since.

7110. And you have had no cases since?—No, I have not had any cases since.

7111. Of course you employ very few men, and it is quite likely that you have had no cases?—Yes.

7112. Do you insure against your liability for payment of compensation?—I do.

7113. Have you known any of your men who have broken down temporarily on account of lead troubles?—No, I do not think I have.

7114. Have your men had occasional days of sickness due to lead?—No, I do not think they have.

7115. Do you have a periodical medical examination of your men?—No, I have no examination.

7116. Is it possible that some of them may be suffering from the slower and more insidious forms of lead poisoning without your knowing it?—They are very seldom away on account of illness.

7117. But I suppose they are away sometimes?—Some odd times. It is usually a cold, or something of that sort.

7118. But I suppose you know that lead poisoning frequently undermines the health without immediate violent manifestations?—I do not know. I have not known it to be so in my case.

7119. Is it possible for the men to be suffering from a mild attack of lead poisoning without your knowing it?—It is possible, no doubt.

7120. As president, you take a prominent part, of course, in the work of the Master House Painters' Association?—Yes, for the year I do.

7121. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—The last meeting or so, I think, only.

7122. Have you ever taken any steps to discover how much illness there was among the men employed by your members?—No, I have not personally.

7123. You have heard, of course, of the prevalence of lead poisoning among the men who handle lead paints?—Yes, I have.

7124. Does the knowledge of that cover a considerable number of years?—I think my knowledge goes back to the apprenticeship I had.

7125. Have you or any of your colleagues ever attempted to collect statistics concerning the number of days' absence from ill-health among painters they employed?—No, they have not.

7126. Did your association ever consider the advisability of having a medical examination made of persons employed?—No, we have not.

instructions faithfully and zealously, and another man will be just as indifferent to them.

7102. (Chairman.) And unfortunately we know this, as a matter of fact, that even the most careful painter, or the most careful potter, may be more susceptible to lead poisoning than the careless one. I do not say that the careless man does not increase his risk, but he may be less susceptible than a careful one?—That may be so.

7103. (Mr. Sutherland.) If the use of white lead is prohibited, our association will not take exception to it?—That is so.

7127. Would not this be the best way to discover the proportion of painters showing symptoms of lead impregnation?—I think it might be, if it was necessary.

7128. Has your association ever taken any collective measures to discover a substitute, for white lead in paints?—Yes, I believe they have. I believe we tried them, and I believe we have prepared a board now exposed to the weather in different situations.

7129. But have you ever made any collective attempt to discover a substitute, or have you simply taken those which have been offered to you and tried them?—We have not tried to discover a substitute.

7130. You have never employed a chemist to make scientific investigations of the chemical properties of different pigments and vehicles?—The association employs one, but I have not.

7131. Has the association ever employed a chemist to find a substitute for lead paints?—No, I think not.

7132. Do you think that the extent of the danger of lead poisoning to which master house painters are exposed is fully realised by the master house painters collectively?—Yes, I think it is.

7133. But they have taken no steps to realise the extent of the danger and to bring home its seriousness to all your members, have they?—The members themselves should take those steps.

7134. I am asking you whether the association as a body have taken any steps to bring the extent of the danger before the members generally?—No, I do not think they have.

7135. You think that they realise the extent of the lead poisoning evil?—Yes, to an extent.

7136. And they have done nothing to combat it?—No, I think not, as far as I remember.

7137. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—No, I was not aware of it.

7138. And that the death-rates from Bright's disease and nervous diseases due to work in lead are very high?—I was not aware of it.

7139. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—No, I was not aware of it.

7140. And that these cases reported voluntarily are probably only a fraction of the whole?—I am not aware of these statistics at all.

7141. Have you seen a copy of the Labour Gazette, which was published yesterday?—No, I have not.

7142. Do you ever see the Board of Trade Labour Gazette?—Yes, I do occasionally.

7143. The table on page 187 of the last issue shows a definite increase in the deaths from lead poisoning among painters: 18 deaths in the first four months of this year as against 12 deaths in the first four months of last year. That is a very grave increase, is it not?—Yes, it is, if it is amongst actual painters.

7144. The gravity of the danger is seen if you will compare these figures with those for all lead industries under the Factory Act. The deaths were as follows: 10 deaths in the first four months of this year as against 15 deaths in the first four months of last year?—Then there is a reduction there.

7145. Yes, but in the house painters' trade there is a very marked increase. I am sure you will agree with

17 May 1911.]

MR. FREDERICK GRUNDY.

[Continued.]

me that all this sickness and death is very deplorable?  
—Yes.

7146. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I have heard of that in France—yes.

7147. Do you not think it regrettable that this country should be behind other nations in this respect?—I do not wish it to be: I wish it to be before them.

7148. A great many small dangers attend the use of lead, for instance, the risk of contamination of food by unwashed hands?—That is the chief cause.

7149. Do you attach importance to personal cleanliness on the part of the men?—Yes, that is everything.

7150. Then you consider lavatory accommodation for washing essential?—I consider it necessary that they should wash their hands before they touch the food.

7151. Do you include as essential the supply of hot water for washing?—No, not necessarily.

7152. Can you get paint off the hands with cold water as well as with hot water?—You can get the evil influence off easily with cold water.

7153. What do you call the evil influence?—The loose paint.

7154. All of the paint is evil, is it not?—Yes, but you may have your hands stained with it and not suffer from it in eating your food.

7155. But the smallest quantity is likely to come off the hands?—No, if they wash and the paint is removed, that is sufficient for the purpose. If the hands are stained it does not matter so long as the loose paint is away.

7156. You do not think, then, that hot water is essential?—No, not essential.

7157. But it would be better?—I believe it would be—yes.

7158. Is it generally practicable for the men to have hot water to wash in?—Yes, it is generally.

7159. But there are some cases where they cannot get hot water?—Yes, there are some cases—very exceptional though.

7160. Do you advocate definite rules as regards the wearing of overalls?—My men all wear something—an apron and jacket and so forth, or overalls.

7161. But would you make it compulsory for all men to wear overalls?—Yes, I would.

7162. Not only jackets and aprons, but trousers too?—No I would not. I think they should have the choice in that matter—so that they were protected in some way.

7163. How can you protect a man if he does not wear some covering himself?—He uses an apron.

7164. Would the apron cover the whole of his trousers?—Yes, in the front, where the risk is. That is an old-fashioned way for painters.

7165. You would make it compulsory for the workmen to wear overalls?—Not overalls—I would not.

7166. Jacket and apron?—I would give them protection of some kind—a jacket and apron.

7167. To cover some part?—To cover the front part. It does not matter about the trousers behind.

7168. Would you agree that the working garments should be cleaned every week?—Yes.

7169. At the employer's expense?—No, certainly not. I think he has got enough on his hands now.

7170. But in some important industries where lead is used, the employers have to provide the overalls at their cost and see that they are properly washed?—Yes, I think I saw that going through some lead works last autumn.

7171. Do you not think that ought to apply to house painters?—Not in our case; I do not think it applies at all. I think the men should look after themselves.

7172. Why should it apply in the one case and not in the other?—The washing of a painter's overalls should be the same as the washing of his shirt.

7173. These overalls are used by the men to protect them from the evils in the industry in which they work?—Yes, but they are paid.

7174. Do you calculate when you pay them, that they have to pay so much for the washing of their

overalls?—They are paid. Of course they look after all that.

7175. But do you calculate, when the men's wages are arranged, that they have to pay so much for the washing of their overalls?—I presume they get them washed at home.

7176. You have implied, in answer to my question, that the men are paid to wash their own overalls. I want to know whether that is so?—Not a special payment, but the payment they receive covers that. That is what I mean.

7177. You calculate that they have to do that?—Certainly.

7178. That involves taking the overalls home?—Yes.

7179. Is not that a great source of danger?—Not at all.

7180. There must be a good deal of lead paint on the overalls?—There is a certain amount.

7181. Surely, taking home overalls involves a danger which ought to be prevented?—I do not think there is anything contagious at all about paint being moved from one place to another.

7182. But in other important lead industries, the workmen are not allowed to take their overalls home; and I may tell you this, that if the rules regulating this industry are levelled up to other lead industries, the painters will not be allowed to take their overalls home, and then they must be washed somewhere else, because the dirty overall in a home is a source of danger?—In that case they will have to be washed on the job where the men are working. If they are not allowed to take them home from these lead works, then you say that they must not take them from the work where they are, and that makes the painting trade trouble appear as a contagious disease, and I say it is not, because when they take them home the paint which is on them is dry.

7183. But could not they be collected and sent to a common laundry?—They could be, but I think it is quite unnecessary.

7184. That may be your opinion. The Home Office do not think so, because other Departmental Committees have laid it down as an absolute rule that workmen are not allowed to take their overalls home when they are in that dirty condition, because they are impregnated with lead dust, which is a source of very great danger. And you may be certain of this, that if lead is permitted to be used in the house-painting industry, all the restrictions which apply to other lead industries will have to apply to the house-painting industry?—That is a very different thing altogether.

7185. I am only pointing out to you what may be done?—I shall not admit that there is any dust at all.

7186. Where do the workmen hang their overalls when they have finished their job for the night?—They usually throw them across a rail, or something of that sort.

7187. Are they generally kept in the room where the paints are kept?—Yes.

7188. Are they ever kept in the room where they have been working?—Yes, sometimes they would be.

7189. With regard to the men's ordinary clothes, when they take off their coats where do they hang those coats?—They generally hang them in an outside place quite away from the paint as a rule.

7190. But suppose they are only working in one room, where do they hang them?—They are usually put outside. I can hardly answer the question.

7191. Do they ever hang them in the rooms where they are working?—Yes, they do sometimes. When there is only one room to be done, they would perhaps be confined to that.

7192. That would be another matter for prohibition. It would not be allowed in the future, for these men to hang their coats in any place where they can come into contact with the lead dust. Now I want to ask you about the men's meals, because that is another very important matter. In the earthenware and china industry, and in all lead industries, I think, workmen are not allowed under any circumstances to have their meals where lead is used?—Yes.

N 2

17 May 1911.]

Mr. FREDERICK GRUNDY.

[Continued.]

7193. Where do the painters generally have their meals?—When they can, if the residence is not occupied, they will have it out of doors, in the garden or arbour.

7194. Do they ever have their meals in the room where they are working?—It may be, sometimes.

7195. Sometimes as an alternative to having them out of doors?—If it is a wet day, for instance; but it is an exception.

7196. You cannot always provide a place quite free from the risk of contamination, I suppose?—No, not always, but my men usually go home.

7197. I am not speaking about your men only, but the general run of the trade?—Yes.

7198. Now with regard to the dust and spray which the workmen inhale during their working hours. First, as regards the dry rubbing down with sand-paper, I understand this process is indispensable?—Yes, it is a necessity, certainly, to rub down with dry sand-paper.

7199. How can you prevent the worker from breathing the dust in that process?—As I said before, I do not admit there is any dust with sand-papering.

7200. Will you tell us what the operation is. Why do they sand-paper at all?—To smoothen the surface.

7201. In smoothening the surface, they must take off particles on the surface?—Yes, there are particles which, I think, are too heavy to fly about, and they fall on the floor and you can sweep them up.

7202. So that, in the process of falling to the floor, is it not likely that they get on to the men's clothes and into the air?—The particles might get on to his clothes.

7203. And if they can get on to the clothes, they must be breathing them?—No, they shake them off.

7204. But are they continually dusting them off their face?—No, I do not know about their face.

7205. Do you mean you can sand-paper a wall, a hard surface, and generate no dust?—Yes.

7206. But you have told us that dust falls on to the floor?—We will call it dust, but it is not the dust which you are representing as floating about the air, because it is too heavy and it will drop down.

7207. We have had an expert from the Home Office who has taken specimens of the air after sand-papering, and the amounts of sand and dust in the air are so large as to be perfectly appalling, and you come here to tell us there is no dust at all?—Yes; I do not believe there is. I have done it myself time after time as a lad and as a man, and I have never had any ill effects from it.

7208. I am not speaking about the ill effects. I am speaking about the dust?—I have not seen any, and I do not think there is any.

7209. Do you mean to tell this Committee that you can sand-paper a hard wall and smoothen the particles down without creating any dust?—I do not think there is any dust at all really—I do not believe there is.

7210. I may tell you that you are the only employer out of a great many employers who has made that statement?—I am a working employer as well. I do not do much of it now, but I have done.

7211. We have been told that there must be a considerable amount of dust from sand-papering?—Not to fly about the walls.

7212. But you say there is no dust?—No dust floating about—not for a man to breathe—I do not think there is.

7213. I am trying to get you to tell us what amount of dust is generated by this particular process. You say there is none at all?—I am speaking from my own knowledge, and I think there is none at all—what I call dust; that is what is floating about in the air.

7214. Will you give us a definition of dust?—Dust is that which is created which will rise and float about. The dust which we get off by sand-papering will not rise; it will fall.

7215. If you are scouring this wall with sand-paper will not a certain amount of dust fall?—Yes, it will fall down.

7216. And that will get on to the man's cloth and he will breathe it, if there is any?—I do not think it is possible for him to breathe it. The particles are so heavy that they fall on to the floor.

7217. (Mr. Parsonage.) You can see them on the floor and then they are swept up from the floor?—Yes.

7218. (Chairman.) The next process I want to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

7219. This gives rise to splashes, which must frequently fall even on the face of the worker?—It depends upon the workman a great deal whether he is splashed or not.

7220. But this process gives rise to splashes sometimes, does it not?—To a certain amount it would.

7221. And splashes might fall on the face of the worker?—Yes.

7222. How can you deal with the spray which arises in this operation?—I used to deal with it by washing it off.

7223. Off your face?—Yes, in the evening when I had finished.

7224. But you admit it has to be washed off to be removed?—Yes.

7225. Which shows that there must be a certain amount of it which falls on his face?—Yes; most of it could be rubbed off dry. I had some on my face last week, which I rubbed off dry.

7226. Can you use an exhaust draught in this case to catch the spray?—I do not think so.

7227. Then we are confronted with the problem of how to save the worker from the grave danger involved in breathing this spray. How would you prevent the worker breathing the spray?—I do not quite understand what the spray is.

7228. The small splashes of paint?—It is impossible to breathe those.

7229. What about stippling. Can he get any on his face when he is stippling?—No.

7230. Can he get any on his clothes?—No, not at all.

7231. Can he get any splashes from the painters who are adjacent to him?—He could not do—certainly not.

7232. I have seen it myself, and I saw that the painter got it on his hands and the stiplers got it on their faces—not a very great amount, but they certainly got it on their faces?—I do not think so, and I have stippled myself.

7233. Do you have old paint burnt off with a spirit or charcoal burner?—By spirit.

7234. How can you prevent the worker from inhaling the fumes which arise from this process?—I do not know if there are any fumes at all.

7235. I do not think you are serious. You do not admit that there is any dust caused by sand-papering a surface or any fumes from burning off?—No, I do not think there are any fumes.

(The Chairman at this point declined to ask the witness any further questions.)

7236. (Lord Henry Bentinck.) You have not experimented with any paint substitutes?—No.

7237. You have not tried them at all?—Yes, I have tried them.

7238. Have you found them satisfactory?—Some of them are satisfactory for the last coat.

7239. Inside or outside?—Both.

7240. Why should not they be satisfactory for all the coats if they are satisfactory for outside?—There is not body enough for the first coat; we have to cover the surface first with the lead.

7241. Do you mean ironwork in the open air, and that sort of thing?—No, I do not mean so much ironwork as woodwork outside—windows, and so on.

7242. Is that from a covering point of view or a durability point of view?—Both the covering and the durability.

7243. You have had no experience of the durability of the substitutes, have you?—Yes, I have, and I have found it to answer. As I bought it, it has been mixed, I believe, part zinc and part white lead, mixed by the manufacturers.

7244. What percentage of white lead was there?—I do not know the percentage.

7245. You have not given the subject very much attention, have you?—No, I have not.

17 May 1911.]

MR. FREDERICK GRUNDY.

[Continued.]

7246. (*Dr. Collis*.) You mentioned that, in your opinion, if you removed the loose paint off the hands that was sufficient?—Yes, I think so.

7247. On what grounds do you base that opinion?—Because when you have removed the loose you have nothing else to come in contact with.

7248. Have you ever tried to test the skin after you have removed the loose, as you term it, to see if there was any lead remaining?—I have seen the marks.

7249. Have you ever tested the skin?—No, I have not.

7250. Do you not think your statement is rather a bold one to come and make before a Committee like this?—No, I do not think so, because I have done so myself.

7251. After washing this loose stuff off, have you ever, for the purpose of establishing the confident opinion which you have expressed before this Committee, tested your skin, say, with sulphuretted hydrogen?—No, I have not tested it at all.

7252. And you make this definite statement, which you ask us to accept?—But I know there is no more to come off the skin after I have washed my hands.

7253. But you have never tested it?—I have done it for 30 or 40 years and suffered nothing from it.

7254. We know that one man's meat is another man's poison, but you are making the extraordinary statement that lead will not have any effect?—Lead will affect us if we take it into our system, we know. This apprentice would not wash his hands. I had three at the time. The other two washed their hands and never suffered the slightest, and this lad was a stupid lad, and set us all at defiance, and would not wash his hands.

7255. Leaving on one side this point on which you apparently ask us to accept a statement that you have never taken any scientific steps to prove—that by removing the loose paint off your hands you get rid of all the lead—let us go to another point. Why do you say it is impossible to breathe lead paint in spray?—I do not see how it can be breathed in the state it is. It is mixed up in a liquid form.

7256. You said you thought it was impossible to breathe the spray?—I say I do not think it is possible to breathe it.

7257. Would you be astonished to hear that when paint has been applied by the aerograph lead poisoning has been caused—not to the people using the aerograph or to the people using the paint at all, but to other people doing work in the same room?—I am surprised to hear it.

7258. Would that induce you to modify your opinion at all, that it is impossible to breathe spray?—No, I cannot do it, because I do not see that there is anything to breathe.

7259. (*Mr. Gardner*.) When you said that you did not know of men being off through sickness due to lead, I suppose you meant that you know of no men being off through painters' colic or drop-wrist?—No, I have not.

7260. But you might have had men off with other sicknesses which were indirectly due to lead without your knowing it?—It is possible, but I do not think so, because they are most of them in the club and they are under the doctors.

7261. Although they are in the club, you would not know what the sickness was that took them off their work: they might have been suffering from some trouble which was indirectly due to lead?—I cannot say that at all.

7262. You lay great stress on personal cleanliness?—Yes.

7263. Do you provide all the requisites for personal cleanliness to the men in your employment?—Yes, they have that opportunity always.

7264. Soap, towels and hot water?—Soap, cloths and buckets.

7265. Of course they will not need soap if they can rub the paint off dry from their hands?—I said you could rub the loose paint off, but you must wash your hands.

7266. What is the rate of wages in your district?—7½d. now, this year: it has just gone up ¼d.

x 7790

7267. With regard to the dangers from lead poisoning, it is pretty hard on the employers, I think, because you say that you pay the men to protect themselves, and yet you are paying the insurance company to pay the men when they are off work, so that that is a sort of double payment you are making?—Yes, it is.

7268. In calculating a standard wage, how much do you calculate goes to the man's wages for protecting himself?—That I cannot say. I have to leave that to him.

7269. But you said it was calculated in their wages?—I did not intend to put it in that way. They are paid their wages: they must look after themselves with regard to their washing, and so on.

7270. (*Mr. Rice*.) You mean they should look after themselves in the same way as with regard to their feeding, and their homes and everything?—Yes.

7271. (*Mr. Gardner*.) I dare say you agree with me that you cannot clean overalls without boiling them?—We know they take them home to be washed.

7272. Is not that introducing a dangerous element into the home?—I do not think there is any danger, because perhaps they are put in water when they get home. That is the safest plan—to put them in water straight away and let them lie till they are ready to wash them.

7273. I do not know what it may be in your district, but in many of the towns the painter, owing to his average wage not being very high, has to live in a pretty well hand-to-mouth condition?—Yes.

7274. He takes home these overalls?—Yes.

7275. And his wife requires to boil them in a pot?—Yes.

7276. Is not there just a danger of that pot being used for cooking purposes afterwards, although it may be washed out?—She would be a very foolish person if she used it for both purposes.

7277. We have to take life as it is and not as it should be?—I should not think they would do it.

7278. But if they did do it, it would be dangerous?—It would be a folly: I do not know about dangerous.

7279. (*Mr. Sutherland*.) I only want to ask you on the point of the possibility of the employer providing overalls in the painting trade, because in the factory they come to the factory every morning?—Yes.

7280. In the painting trade, if the employer had to provide overalls and wash them, and not take overalls that were dirty to a fresh job, he would have to have a wholesale stock?—Yes, I think he would.

7281. It would not be possible?—And I think we should want a guarantee of safety. We should not see some of them again, I think, if we provided them.

7282. It would not be possible, would it?—No.

7283. (*Mr. Parsonage*.) With regard to glass-papering, you say the particles are so heavy that they fall directly to the floor?—Yes.

7284. You can see them on the floor?—Yes.

7285. And you sweep them up with a duster?—Yes.

7286. There is a quantity, whether it is light or heavy, that does fall on the floor?—Yes.

7287. You can see it on the floor and sweep it up?—Yes.

7288. Your colour generally is about half flat and half sharp colour: it is not all flat, being in a country place?—No, there is very little flattening used now.

7289. Do you think you could do away with glass-papering? Is it possible to do away with dry rubbing down?—I do not think so, but I ought, perhaps, to have said that most of the work is rubbed down with pumice-stone and water.

7290. Before it is painted?—Yes.

7291. Do you ever rub down work with pumice-stone and water after you have given it a coat?—No, never.

7292. That is where sand-papering comes in?—That is where sand-papering comes in.

7293. You could not use pumice-stone on a fresh coat of paint?—No, it would tear the paint up.

7294. So that you would say it is impossible to-day to do away with dry rubbing down?—I think it is necessary.

N 3

17 May 1911.]

Mr. FREDERICK GRUNDY.

[Continued.]

7295. I say it is impossible to do away with it. Do you agree with that?—I have rubbed down with sand-paper on a wet surface.

7296. Taking the ordinary course of work, is it not impossible to do without it?—It is impossible.

The witness withdrew.

Mr. JOHN HENRY McDERMID examined.

7297. (*Chairman.*) Do you attend to-day as a representative of the National Association of Master House Painters and Decorators?—Yes.

7298. What is the nature of your business and where is it carried on?—It is a house-painting business and is carried on in Darlington, with a smaller branch in York.

7299. How long have you been in the painting trade?—I am carrying on the business in Darlington that was established by my late father 59 years ago. I have been in business myself since his death, for some 17 years—previously in his employment.

7300. What is the average yearly number of painters employed by your firm?—The average is probably 20 to 25; in the season, perhaps, a matter of 40.

7301. Have you known of any cases of lead poisoning or painters' colic?—None whatever.

7302. You are doubtless aware that in other industries, such as the potteries, there are a large number of works that are quite immune from the evils of lead poisoning?—I have not a very definite knowledge of these matters. I have latterly heard more respecting them, but I have not any very definite knowledge as to it.

7303. The trouble is that even some of the best works are not immune, and a works that has been free of lead poisoning for many years will sometimes have a succession of cases quite unexpectedly?—Quite so.

7304. Do you insure against your liability for payment of compensation to lead workers for lead poisoning under the Workmen's Compensation Act of 1906?—Yes.

7305. I think the premium has been increased recently?—The rate of insurance was increased about a year ago, and I believe very largely owing to the lead poisoning coming under the scheme.

7306. Have you known men who have broken down temporarily in your works on account of lead absorption?—I have not.

7307. Have your men had occasional days of sickness due to lead?—Not to my knowledge.

7308. Do you have a periodical medical examination of your men?—No.

7309. Is it possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—Quite possible.

7310. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—Yes, I am prepared to admit that.

7311. You take a prominent part in the work of the Master House Painters Association?—Yes, I think I may say so.

7312. Has the question of the serious prevalence of lead poisoning amongst house painters been discussed at your meetings?—It has really only come before us so very recently that there has been, if I remember rightly, no serious discussion on the question.

7313. But you must have heard of the prevalence of lead poisoning among the men who handle lead paints for some time?—I have heard of it, but I have not any knowledge of any single case in my own district: I cannot speak from any personal knowledge of the case.

7314. But did not your association have that knowledge collectively?—I think it is possible that there may have been instances brought forward in connection with claims.

7315. Your association never attempted to collect statistics concerning the numbers of people who are affected by lead in the course of their work?—I cannot give you a definite answer on that.

7316. Did your association ever consider the advisability of having a medical examination made of persons employed?—I do not think so.

7317. Would this not have been the best way to discover the proportion of painters showing symptoms of lead impregnation?—Yes, I think so.

7318. Then has your association ever taken any collective measures to discover a substitute for white lead in paints?—Yes, I think so.

7319. What measures have they taken?—We have a series of panel experiments with substitutes taking place at the present time.

7320. When did those experiments begin?—I am not very definite on that. It is 12 months ago, I think.

7321. Then do I understand that it is only within the last 12 months that your association have taken any active steps to try and combat with the evil existing?—Collectively, I believe so.

7322. Do you know whether they have employed a chemist to make scientific investigations of the chemical properties of different pigments and vehicles, with a view to substituting some other paint for lead?—I do not think so.

7323. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many master house painters. Is that so?—I should think it is quite possible.

7324. But do not you think that your association should have taken steps to realise the extent of the danger and to bring home its seriousness to all your members?—I think it would really have done so if the thing could have been brought forward.

7325. But you know the number of cases of lead poisoning in the house painting trade has been published monthly by the Board of Trade?—Yes, that may be so, and yet there would be very few of us as individuals who would take these matters to heart.

7326. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—I do know at the moment. I did not know until recently.

7327. And that the death rate from Bright's disease and nervous diseases, due to work in lead, are very high?—No, I did not know that.

7328. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatsoever in the same 10 years?—I did not know.

7329. Or that these cases reported voluntarily are only a fraction of the whole?—No.

7330. Have you seen a copy of the Labour Gazette issued by the Board of Trade, which was published yesterday?—No.

7331. The table on page 187 of that issue shows a definite increase in the deaths from lead poisoning among painters. There are 18 deaths for the first four months of this year and 12 deaths for the first four months of last year. Is not that rather a grave state of affairs?—Is that in the house painting trade?

7332. Yes?—It sounds rather serious.

7333. And the gravity of the danger is seen if you will compare these figures with those for all lead industries under the Factory Act. There were 10 deaths for the first four months of this year and 15 deaths for the first four months of last year?—Yes.

7334. So that the deduction to be made from it is that the number of deaths occurring in the house painting trade is higher than that of all the other lead industries put together?—On this one return.

7335. On this one return, this year?—Not on the average; that is that single return.

7336. (*Dr. Collis.*) It has been the same for the last 10 years?—Do you mean there has been an increase every year for the last 10 years?

7337. I mean that the number has been greater than in all the other industries put together?—Yes.

17 May 1911.]

Mr. JOHN HENRY McDERMID.

[Continued.]

7338. (*Chairman.*) I am sure you will agree with me that all this sickness and death is very deplorable?—Most certainly.

7339. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I believe there has been an inquiry taking place in many of them.

7340. Do you not think it regrettable that this country should be behind other nations in this respect?—Quite.

7341. A great many small dangers attend the use of lead, for instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—Yes.

7342. Then you consider lavatory accommodation for washing hands essential?—I consider it very desirable.

7343. Including the supply of hot water for washing?—Yes, desirable.

7344. Is it generally practicable for the men to have proper lavatory accommodation?—I think it is usually obtainable.

7345. Is it generally practicable for the men to have hot water to wash in?—I think it is generally obtainable if they wish it—if they seek it.

7346. But there may be some cases where they cannot get it?—I should say there may be, but those would be very, very few.

7347. Do you advocate definite rules regarding the wearing of overalls?—We have not any definite rule excepting this, that I should be very loath to employ a man who did not provide himself with them.

7348. How often?—Always.

7349. How often would they be washed?—Weekly.

7350. How can you ensure these being kept in a cleanly state every week?—No difficulty whatever.

7351. Will you tell us how you can ensure it?—The very appearance is quite sufficient. They are sufficiently soiled at the end of the week for you to know in a moment if they have not been cleansed.

7352. How can you insist on their being clean every week?—I can scarcely remember the occasion when it has been necessary for me to object, although I have had some instances when I have told a man that I could not allow him to go to work with the clothes he had left in the workshop—a casual worker in the busy season, I am referring to—unless he could provide himself with clean overalls he must not go to work.

7353. Where are the overalls kept when the men have finished their work for the day?—It would be rather difficult to answer very exactly, but usually I think they are taken home.

7354. Every day?—I think so, usually.

7355. With the lead dust on them?—I do not know whether there is any lead dust on them.

7356. In a dirty condition?—In the condition in which they have been wearing them.

7357. If the men do not take them home with them, where do they keep them?—They leave them on the job.

7358. In the room in which they have been working?—Yes. If it is a larger job there is usually a room set apart for it.

7359. But if it is a smaller job?—If it is a smaller job, probably in the room where they have been working.

7360. Where do the men keep their coats when they are taken off before they begin their work?—The same answer practically applies.

7361. You cannot always provide a separate place for the painter to hang his coat?—It is not always possible.

7362. Or to keep his overalls when he is away from his work?—No, it is not always possible, but at the same time, I may say, it is invariably our custom to endeavour to do so.

7363. Do you advocate also a rule regarding meal-rooms so that no man shall eat his food in the place where paint is being handled?—We have no rule. We always encourage them to leave the working apartments for their meals.

7364. But could you tell us that it is invariably the case that they never have their meals in the room in

which they have been working?—Speaking generally, I should think that is right.

7365. But are there any cases you know of where that is not the case? Suppose a man is working in one room on a small job, where would he have his meals?—If he was working in an occupied house he would invariably seek permission to sit in the kitchen or some of the servants' apartments.

7366. But can you tell us that it is invariably the case that the men never have their meals in the room where they are working?—It is invariably the case.

7367. Are there any variations to that?—There may be isolated cases.

7368. You cannot always be certain, then, that the men have their meals in rooms quite free from the risk of contamination?—I cannot give an absolute guarantee, but, speaking generally, I would say yes.

7369. Now as to the risk arising from dust and spray which the workman can inhale during the whole of his working hours. First, as regards the dry rubbing down with sand-paper; I understand this process is indispensable?—On old work it is not at all indispensable, and in my own practice it is very seldom used.

7370. What about new work?—On new work between coats it is used.

7371. And that is indispensable, is it?—It is not absolutely indispensable, but it is perhaps the easiest and one of the most effective methods.

7372. Would you agree to the prohibition of sand-papering between coats?—Yes.

7373. You could get on with your work without sand-papering?—Yes; but I should prefer, rather than the prohibition, to use it in a wet form.

7374. Could you rub down between coats in a wet form?—I had in my mind for the moment using it on old work, which we certainly can do. It would not be so easy to use it in a wet form between coats.

7375. Could you do it at all with the wet process?—I think I could do it, but if I have to give an answer "Yes," or "No," I should say "No."

7376. Then it is indispensable, as other witnesses have told us. You cannot do away with sand-papering between coats?—Well, I should not like to do away with it.

7377. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—I do not know quite how you could prevent him doing it.

7378. Can you use an exhaust draught to remove the dust?—I could not say.

7379. We are told by some witnesses that the dust arising from this sand-papering is very considerable?—I think that might be so on old work.

7380. But you have told us that on old work you could do without sand-papering?—You could, and personally I do without it.

7381. But some firms do not?—I would rather not speak for other firms.

7382. You said just now, in answer to my question, that there would be a considerable amount of dust if you were sand-papering old work?—Yes, it has been the custom. We have done so, but for a long time past I do not remember cases of rubbing down old work dry.

7383. Then would there be a considerable amount of dust in rubbing down new work?—Falling to the ground.

7384. So that it would impregnate the air?—It never occurred to me in that light. It is weighty. It falls and we sweep it up.

7385. But from the fact of its falling, it must disperse and get on the man's hands and clothes, and so on?—I suppose I should admit that that might be so.

7386. The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work, the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

7387. This gives rise to splashes?—Yes.

N 4

17 May 1911.]

Mr. JOHN HENRY McDERMID.

[Continued.]

7388. Which must frequently fall even on the face of the worker. How can you deal with the spray which arises in this operation?—I cannot conceive any method of preventing it, except covering the face, which would be very awkward.

7389. Can you use an exhaust draught in this case to catch the spray?—I do not know; I do not think so.

7390. Then, again we are confronted with the problem of how to save the worker from the grave danger involved in breathing this spray?—What do you mean by the spray?

7391. Fine splashes. These fine splashes are in the air and the workman must necessarily breathe them in the course of his work?—Yes.

7392. Can you suggest any remedy for that?—I am afraid not.

7393. Then, with regard to stippling, there is a certain small amount that falls in the stippling process?—The stippling process is very nearly becoming a dead letter.

7394. But in some places it is used, and it has not been abandoned?—It is not abandoned.

7395. So that there is a certain amount of danger, I suppose, involved in that?—I should say there was—from the same source.

7396. Do you have old paint burnt off with a spirit or charcoal burner?—Spirit lamp.

7397. How can you prevent the worker from inhaling the fumes which arise from this process?—I could not suggest any means of preventing that.

7398. Where and how do your men mix their colours? Do they mix them dry?—No.

7399. I suppose in the course of mixing they get some of the paste on to their hands?—Naturally.

7400. It appears from your evidence that there are certain indispensable processes in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. How are these dangers to be met?—I am afraid that is a matter that I should have to leave to yourselves.

7401. Is it possible to remove the danger entirely in any other way than by using a substitute for lead?—I should say it was not.

7402. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience with such substitutes?—Yes, a little.

7403. What results did you obtain with those substitutes?—I have obtained more or less satisfactory results at increased cost—increased cost in more ways than one—increased initial cost and less stability.

7404. The Office of Works and others have told us that they have succeeded in obtaining efficient non-lead paints?—I am very pleased to hear it.

7405. What are the usual hours worked by your painters per week?—Ordinarily 53.

7406. Would you welcome a strict limitation of the hours of employment, say, to 48 hours per week?—Personally I should not have the slightest objection, although I can see there would be a very great difficulty in carrying out our work. It is purely a season trade, and in the season there would be very great difficulty, I think.

7407. The Departmental Committee upon the Earthenware and China Trade agreed to limit the hours to 48 hours per week because all the medical evidence produced insisted that there ought to be a limitation of the hours in which a man worked with lead?—I can see how they could do it so much more easily than we.

7408. That is not my point. I am only foregrounding the sort of rules that would have to be enforced?—Personally I do not think we could get it down to 48 hours.

7409. You do not have a periodical medical examination of your workers?—No, we have not.

7410. Do you know that in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—I believe that was so in the case of lead manufacturers. I have no knowledge in any other departments.

7411. You know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—Not from personal knowledge.

7412. If I tell you that is the case, would you welcome a system of periodical medical examination in your industry?—I do not know that I would particularly welcome it. It would be a bit of a nuisance, I think. I might agree to it, but I would not welcome it.

7413. Would you agree to a system of periodical medical examination in your industry, the cost to be borne by the employer?—I prefer to say "no" at present.

7414. Together with compensation for any workers suspended by the doctor on account of doubtful health?—Men are away ill occasionally from slight causes which they might then put down to lead poisoning.

7415. Are you quite sure that the illness which these men have is not caused by the lead dust they breathe?—It would be impossible for me to say, I am sure. In my opinion, it is not.

7416. You realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures, in the same way as in other industries where the workers handle lead?—I am quite willing to admit that may be necessary.

7417. And you realise that the hours of labour would probably have to be reduced, as has been done in other dangerous trades?—Yes, but I do not quite see why that should be in our trade.

7418. This will involve an extremely complicated and elaborate code of regulations. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to the following. First of all, lavatories, one basin for every five men?—Do you mean in our workshop?

7419. I mean when they are on the job. One basin or one bucket, or something similar, to every five men?—Yes, any vessel, I suppose, that would answer the purpose.

7420. Hot water, soap, nail-brushes, and a sufficient supply of clean towels?—I would be a party to agreeing to that, if collectively we could agree. Separately I would not unless I could get my fellows of the trade with me. Of course, you could do that if you made it compulsory.

7421. Of course, it would be a general order issued to the trade?—Yes.

7422. Then with regard to mess-rooms, the exclusion of food from any place where lead is used or stored?—I have no objection to that. It might be a hardship sometimes to the worker—turning him out in the cold, perhaps.

7423. You would have to provide somewhere for him?—I could not agree to that. I cannot say that we would provide that. That is easily done in factories, but it is not easily done in private houses. I would not say "Yes" to the provision of mess-rooms. I would only go as far as to say that I would agree to make a special effort, as I always have done.

7424. That would not be sufficient for the Home Office?—Then take the answer as "No."

7425. Then with regard to overalls: that overalls should be supplied at the employer's expense and regularly washed and entirely at the employer's responsibility?—No.

7426. And a place for overalls. They are not to be placed in a workplace where they can be contaminated nor in a mess-room where they can contaminate food?—We should not have any difficulty about that.

7427. Do you understand what it means. It means, first of all, that the overalls must not be left in a room where the men are working in lead, and the overalls must not be taken into the room where the men have their meals, nor in any room where there is any lead about?—I am, of course, more willing than able in matters of this sort.

7428. I am only putting before you what are the rules enforced to-day by the Home Office in industries where lead is permitted to be used, and of course this trade must be levelled up to those industries because the incidence of lead poisoning is worse than anywhere else?—That would not be easy.

17 May 1911.]

Mr. JOHN HENRY McDERMID.

[Continued.]

7429. Now the cloak-room. With regard to outdoor clothing and coats, they must be kept away from any place where paint is used or stored?—We could manage that.

7430. Where lead is allowed to be used in other industries, the Home Office insists on the removal of dust and fumes by an exhaust draught apparatus. Would you agree to that if it was possible?—I have so little knowledge of how it could be done or what it would mean that I could not say that I would agree.

7431. My next point is the medical examination at the employer's expense. That you have not agreed to?—No.

7432. Now I come to my last question. Taking all these points into consideration, and not forgetting the periodical medical examination which would be insisted on at the expense of the employer, and the payment of compensation to workers withdrawn from work in lead, would you say that you prefer that the industry should be regulated by special rules, or that the use of lead should be prohibited or very closely restricted?—I would prefer to try the system under restriction, I think.

7433. Do you mean the prohibition of lead or the restriction by rules?—I would prefer to retain the use of the lead under more stringent conditions rather than to abolish it.

7434. Then I want to ask you, as a practical man, what conditions you suggest which would remove the evil?—You will probably disagree with me there, but I contend that the greatest danger in the house-painting trade is in the paint itself—not in the dust form; in the paste form:

7435. (*Lord Henry Bentinck.*) It comes to the same thing, does not it? It rubs off in the shape of dust?—I do not know. My idea is that it is eaten, as it is practically, and that the painter conveys it by his hands to his mouth, and that there is not sufficient washing and care in cleanliness. In my case they are clean, and possibly that may be why we are so immune from the evil, as I believe we are. I have no knowledge of any case. Mine is only practical, not expert knowledge from a medical standpoint, but I cannot think that the serious evils of dust are such as you wish me to believe.

7436. (*Chairman.*) I want to point out to you that great medical authorities in the country agree that the dust is the great prevailing evil which has to be met?—And that is practically the danger then.

7437. That is the danger?—Then why give so much consideration to the question of the prevention of splashings, and all that.

7438. Because it is a multiplicity of small dangers which in the aggregate make up the big evil. Every little danger has to be contended with. What you employers must tell the Committee is how you propose to assist us in removing the dangers which undoubtedly exist. I have given you a foreshadowing of what the rules are in other industries?—Would not it meet the case to abolish dry rubbing in any and every form?

7439. But then you have told me that that is indispensable?—Under our present lights, to produce the high finish work that we do in many cases, but I have not the slightest doubt that we would devise means. It is reduced now on all good work to a minimum.

7440. (*Mr. Parsonage.*) Glass-papering is reduced to a minimum on all good work?—I did not say glass-papering; I said dry rubbing. I am glad to have you put it in that way to allow me to correct myself. When I was speaking of the dry rubbing, I was referring to old work.

7441. You can rub down old work with pumice-stone and water?—Yes.

7442. But after you have painted it, it is dry rubbing with glass-paper—after the first coat?—You can rub down the other, if it is compulsory, with pumice-stone and water.

7443. New paint?—Yes, not the day after. How often do we do it?

7444. I should like to know how often you do it, after it has had its first coat, with pumice-stone and water?—Not the first coat, but after the finishing coat—as

often as we are paid for it. Whatever you compel the employer to do, the public will have to pay for.

7445. (*Chairman.*) What I want to ask you is this, whether you can suggest, as an employer of labour, any remedies which would do away with the evils which exist in the various operations which the men have to perform?—I would suggest that as one, and qualify it by separating the two classes of dry rubbing.

7446. What would you do in rubbing down new work?—I am suggesting that you abolish it for old work and continue it for new.

7447. As it is now?—Yes.

7448. So that you admit at once that one of the evils has got to remain?—Yes, I suggest that remains.

7449. Then that is not meeting us, is it?—I think it is. I think it is meeting it a long way.

7450. (*Dr. Collis.*) There is just one further point that I should like to bring out in connection with this matter. The dangers which the Chairman has foreshadowed do not quite cover the whole of the possibilities of getting lead poisoning. Are you aware that it has lately been suggested before this Committee that wet lead paint gives off at the ordinary temperatures of the air a volatile organic lead compound?—No, I cannot speak to that.

7451. Are you aware that the workmen have for some time past considered that they get injury from the smell of lead paint?—No, I am not aware of that. One often has heard, in the days of flatting, of feeling temporarily sickly from the fumes of the turpentine.

7452. Are you aware that those symptoms are not present, although the turpentine is present, if lead is not in the paint?—No, I could not say.

7453. Have you ever heard of the inhabitants of a house which is being painted suffering from any form of illness after the house has been painted, or complaining to any extent of the smell of lead paint?—We have plenty of complaints of the smell; but I cannot speak as to any injury—any cases of illness resulting from it.

7454. I speak of this point as one which this suggestion, which has come from Professor Baly, of Liverpool, tends to explain: that, if there is this volatile organic lead compound given off by the wet lead paint, it would explain the symptoms of which we have all heard in the past, and which are indeed, I may say, familiar to us from boyhood; and, therefore, when you are considering the possibilities of preventing a man from getting contaminated by lead paint, will you have this further point in your mind?—Yes.

7455. My point is this, that if you were able to make suggestions to this Committee as to the way the other evils could be met, and if the experiments which are going on to-day, and which promise to carry out the suggestion which I have just been giving you, should prove incontestably that this organic compound is given off, and that it may cause lead poisoning, all the schemes which you may propose might leave this on one side and so be useless?—I should think it almost certainly would. I do not see how you can devise any means to alter a matter of that kind.

7456. (*Mr. Sutherland.*) Except abolition?—Except abolition.

7457. (*Dr. Collis.*) You might, in considering the point, after giving great time and attention (as I am certain you all will) to the subject, have possibly omitted that point. I am myself, as a medical man, inclined to place very great stress upon the suggestions of Professor Baly?—So would I, but I do not at the moment think that any amount of consideration would remedy a state of that kind if it is existent.

7458. (*Mr. Parsonage.*) We are told that you are having a meeting at York, and you may consider this question of dry rubbing down. You have had a long practical experience of paint as a practical man?—I have.

7459. And so have I. Has it ever occurred to you at any time that it could be dispensed with for new work?—No, it never occurred to me.

7460. You could not at the present time suggest anything to take the place of dry rubbing down for new work?—It would be very difficult.

17 May 1911.]

Mr. JOHN HENRY McDERMID.

[Continued.]

7461. You do not think that any suggestion made collectively could alter the individual opinion?—When you are speaking of new work, you mean absolutely fresh.

7462. I mean freshly painted work. Suppose you rubbed that door down with pumice-stone and water, and gave it a coat of sharp colour, and you were going to enamel it, say, and you gave a glass-papery down between the coats: you cannot suggest any substitute for that?—No, I cannot; but I would not say that one could not possibly be devised.

7463. But in the whole course of your experience you cannot call to mind anything which you have had to take its place?—I cannot call to mind anything that we have had to take its place, except that we do use the wet process for the final rubbings, and we could do it between coats if we could get paid for it.

7464. That would not be pumice-stone and water, would it? You would use felt and polish. But that could not be done in the ordinary way. You would do it for some special job, but not in the ordinary way?—We would not do it, but it could be done.

7465. Is it practicable?—Quite as much so as many other suggestions that we have heard, and more practicable than many of them.

7466. You do not think that a man can be ill and get lead poisoning from the smell of the thing?—I would not go as far as to say that he could not, but it never occurred to me during my career that it ever was taken in that way.

7467. That he inhaled it at all?—No, I would not say that he did not inhale it. If he is subject to an atmosphere that is absolutely tainted with dust, then I would agree with you at once.

7468. I am leaving out dust entirely. You know the smell of lead in the kog before it is mixed with the oil or turps?—Yes.

7469. It is a different smell entirely, is it not?—Yes.

7470. Although the smell of that may be poisonous too; when a man is painting a room or painting day after day in the fumes that come off from the turpentine, or whatever it is that carries off the lead, he inhales that, and so gets it into his system?—If it carries poison he may get it in that way, but I was not aware that you did get it in that way.

7471. That is the opinion that has been given to us?—It is not my opinion. I am not contradicting anything. I am accepting and willing to accept expert evidence. It is useful to hear this given and to take it to heart. If your medical expert, Dr. Collis, makes this statement and tells me that that is a proved fact, I accept it at once, and then I should agree with you that the poison could be conveyed in that form.

7472. And if that was proved to be so, none of the other remedies would have any effect, because you could not possibly prevent that?—No, I do not think so. That is practically the doctor's point.

7473. (Mr. Sutherland.) Is it not the case that the painter is very quickly out of the room that he is painting?—Yes. That wants qualifying. I should think the ordinary painter is not half his time—probably not more than a quarter of his time to-day—working with lead paint.

7474. (Chairman.) If they were, I suppose these figures would be very much higher?—They might be.

7475. (Mr. Parsonage.) The conditions are different in London, say, to what they are in a country town. You go into places here where there is no decoration but paint—ceilings, walls, and everything else are painted?—I have had London experience. I have had experience with West End firms in London, working in London and working for them in various parts of the country.

7476. There is a great difference between work in London and work in a country town, is not there?—Yes, to some extent—not very much difference between the work that I did for a London firm and what I have done for myself, except in point of magnitude. And even there sometimes I may undertake and do as big a job as any London job.

7477. (Mr. Sutherland.) What was your experience of the leadless paint: was it outside work or inside work?—Both.

7478. And you say it is less stable and more costly?—Yes, that was my experience.

7479. Did you carefully check that?—Yes.

7480. What were the substitutes you used?—Zinc paint.

7481. Did you buy the paste and mix it yourself?—Yes, in the case of zinc. I have used other things, but long ago I have relegated all those things that are brought to us—proprietary articles—to the waste-paper basket, as it were. I have had such poor experience of them in the past that I do not take any notice of them now.

7482. There is not so much flattening in the ceiling work now?—Practically none.

7483. Water paints, leadless paints, are substituted?—Yes.

7484. You do not mix any dry colours, except for distemper work?—None.

7485. Occasionally there would be one bucket to five men on every job, would not there?—I should say there is a long way more than that, from my experience of the difficulty of finding them at home.

7486. That is the regulation, but there would be more than one bucket for every five men?—Yes.

7487. And you do send soap already?—Yes.

7488. And hot water is in a great number of cases available?—Yes, available—almost in every case; because, where it is not absolutely in the house as a water fixture, we always have our boiling can or bucket on the job, and there is always cold water available.

7489. Do you see any serious difficulty in making provision for the men hanging their clothes in a room where they are not working?—No, I do not see any serious difficulty.

7490. In the great majority of cases?—I think that can generally be done.

7491. In some cases it might be difficult?—Yes, I think in exceptional cases it might be.

7492. (Mr. Rice.) In painting new work between coats, what is the object of rubbing down with sand-paper?—Smoothing purposes.

7493. And if you were to omit the rubbing down, what would be the result?—A rougher surface.

7494. Would you be prepared to agree to the abolition of the use of sand-paper or dry rubbing down?—I should have to give a little more consideration to that before I gave a definite answer. It would be a question whether we were to allow to go forward an inferior finish on our work or, to my mind, use an inferior article.

7495. But that would only be a question of education. The public would soon be educated to a rougher looking paint?—Yes, I am afraid they are getting too rapidly educated to it now.

7496. It is the common practice in the smaller class of work not to use sand-paper, is it not?—Quite.

7497. No sand-paper goes on the job at all?—It does not go on the job at all.

7498. So that it would not be a greater hardship on the public, except less finish, if sand-paper were abolished altogether?—That is so. We should give them a better finished surface from the brush alone than some of the work I could take you to in this building.

7499. You have been very surprised, I suppose, to find this mortality and sickness amongst painters which you have heard of this afternoon?—I am surprised.

7500. And of course it is information which you take rather seriously to heart now, I suppose?—Certainly.

7501. You rather appreciate the action of the Government in bringing it before you, I take it?—I think it is quite the proper course to adopt.

7502. In fact, perhaps, you are rather surprised that they have not done it before?—I am not a man given readily to surprises. I have known in a very matter-of-fact sort of way, but I do heartily agree with action being taken in any case that is going to be for the

17 May 1911.]

Mr. JOHN HENRY McDERMID.

[Continued.]

general good, consistent with other side issues, and other aspects of the case.

7503. Have you ever received a circular, as an employer, from the Home Office calling attention to this appalling mortality and sickness?—I am not aware of it. I could not say "Yes" or "No": I do not remember one.

7504. So that really this thing has come to you quite in a new light to-day?—Quite, absolutely.

7505. And had your attention been called to it, you would have taken steps earlier to go into the matter?—Certainly. If a great number of the members of our association had been as enlightened as I am to-day—and, I may say, as I have been more recently—the matter would already have had their very best and serious consideration.

7506. And I suppose that enlightenment has come to you largely as a consequence of the formation of this Committee?—Yes, I agree.

The witness withdrew.

## TENTH DAY.

Friday, 26th May 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman*).

LORD HENRY BENTINCK, M.P.  
MR. E. L. COLLIS, M.B.  
MR. A. L. C. FELL.  
MR. C. L. MASON.

MR. C. KINGGATE.  
MR. W. ROBINS.

E. A. R. WERNER (*Acting Secretary*).

Mr. X. examined.

7507. (*Chairman*.) Are you a coach painter?—Yes.  
7508. What practical experience have you had in the coach painting trade?—It is 30 years next December since I first went into the trade.

7509. Have you worked at railway coach and tram-car painting, or only at carriages and motor cars?—Carriages and motor cars only.

7510. Have you known many cases of lead poisoning among coach painters?—Not many—a few.

7511. How many do you think you have known of in your time?—Perhaps 12 personally.

7512. (*Lord Henry Bentinck*.) Twelve deaths?—No, they have not all ended in death—about three in death.

7513. (*Chairman*.) Are you prepared to answer questions regarding each of the processes in detail?—Yes.

7514. First, as regards the body makers, are they exposed to any risk?—Very little; it is only in the joints—and it is wet lead. Dust does not arise there at all.

7515. Why is lead used in jointing?—I expect it is used for durability, to keep the water out of the joints.

7516. Would you tell us exactly how jointing is done in the case of wood panels and similar joints?—The lead is put on at the bed joints and round the panel before the panel is put on, before it goes into its proper quarters, according to which panel it is.

7517. In what way is jointing done when metal fittings are being attached to the woodwork?—I cannot answer that.

7518. Does the vehicle in course of construction next pass into the hands of the carriage maker?—Yes.

7519. Will you tell us exactly what his work consists of?—There are very few carriage makers about now. There are no carriage makers on the motors.

7520. Does he make the under-carriage of the vehicle and fit the springs of the wheels?—Yes.

7521. And does he supervise the work of the smith?—Yes, he puts the smith's work on, the springs, and so forth.

7522. Does the carriage maker come into contact with lead?—By the same rule, he would use it at times for his clips and blocks, and so forth, but then again it is wet lead.

7523. (*Lord Henry Bentinck*.) Wet lead dries, does it not?—Yes, but that is not the danger.

7524. (*Chairman*.) If the wet lead dries it must create a certain amount of dust?—I think not—not wet lead.

7525. When the carriage maker has completed the work of fitting up, is the vehicle ready to pass into the painter's hands?—Yes.

7526. The first coats of paint applied are termed priming coats, are they not?—Yes.

7527. How many coats of priming are generally applied?—Are you speaking now of the vehicle or the motor?

7528. The horse vehicle?—Three coats.

7529. Does the priming contain lead?—Yes.

7530. Is it practically all lead?—It is, with the exception of a little black.

7531. Is sand-papering done between the successive priming coats?—Yes, occasionally; not always in that case.

7532. Is it generally done?—No, if the question refers to the vehicles only, and not to the motors. There is a lot of difference between the two. One has got a filling on the top of it. No, it is not sand-papered.

7533. Is the next process what is generally known as filling?—Yes.

7534. How many filling coats are put on?—Five in some cases, six in others.

7535. Does the filling material contain lead?—The filling is composed a little of lead.

7536. Do a considerable number of manufacturers still add a proportion of white lead to their filling?—Yes.

7537. There is no rubbing down, I believe, between the successive coats of filling?—No.

7538. Only the last coat is rubbed down?—Yes.

7539. Is stopping generally done after the last coat of filling has been applied?—No.

7540. At which stage is the stopping done in the ordinary course?—That is a matter for the workman. Some workmen will do it before they fill at all, and others will get two or three coats of filling in before they stop. That is a matter of the workman's option. If I were doing it, I should put it on the fourth coat of filling, if I were giving it six coats, simply because you have got half of your holes done for you then.

7541. What is the stopping material made of?—White lead.

7542. By whom is the stopping material mixed?—By the painter.

7543. By the man who applies it?—Yes, by the man who is going to put it on.

7544. Do you consider that the mixing of white lead is attended by danger?—I should say that in

26 May 1911.]

Mr. X.

[Continued.]

mixing there is no danger, unless a man is very careless.

7545. But if he is not very careful, it might be dangerous?—That is the same as I have already stated, I think, with regard to cleanliness, if he is not careful and does not wash himself before he has his meals.

7546. I suppose some dust must arise from the handling of the dry white lead powder?—Very little.

7547. Is there a staining coat applied after the last coat of filling, and on top of the stopping?—Yes.

7548. What does that consist of?—If you are making it of black, it consists of vegetable black.

7549. For what purpose is this staining coat applied?—So that you know when you have rubbed your body down, how you have done it, whether you have done it fairly and evenly.

7550. How is the rubbing down done after the application of the filling coat and the staining coats?—It is done by pumice-stone and water.

7551. Is it often done dry, by sand-papering it for instance?—No, it is impossible to do it dry if you have filled it up.

7552. What is the extent of the danger in the rubbing down after the application of filling and stopping?—None whatever.

7553. But if it were done by a sand-papering process, it would be dangerous, I suppose?—Yes, that is where the danger is.

7554. Are the wheels and the carriage underwork treated differently?—Yes.

7555. The wheels are always sand-papered, I believe?—Yes.

7556. And a great deal of dust is caused in that operation?—Yes.

7557. Is this dust of a poisonous nature?—Very.

7558. Then that is also an extremely dangerous process?—Yes.

7559. Would you say that it is one of the worst processes in the whole of the coach painting industry?—Do you mean after it is stopped up?

7560. Yes?—Yes, that is the evil.

7561. Is it possible to use wet methods of rubbing down in this work?—Not on wheels.

7562. It is impossible to do it?—Yes.

7563. Is that owing to the prevalence of curved surfaces, and so on?—Yes, and you have not the foundation to rub on. If you rub with hard-pumice-stone you would soon rub through into the wood.

7564. Is it practicable to apply local exhaust ventilation generally. Could you have an apparatus near the wheels to collect the dust as it arises?—I hardly think so. I should like to see that worked.

7565. After the rubbing down of the filling has been completed, what is the next operation?—Lead again.

7566. Do you mean to say that you apply two coats of colour again?—After the rubbing down, yes.

7567. Are they both faced with pumice-stone and water?—Yes.

7568. Is the work then ready to be painted with the desired finishing colour?—Yes, it is ready then for the colour.

7569. How many coats does it receive then?—Four—that is without the spirit colour. That would make five.

7570. Is the carriage then ready for varnishing?—My last answer would include the varnishing.

7571. How many coats would be applied before the varnish?—Three coats.

7572. Then the carriage is ready for varnishing?—Yes.

7573. Do your answers apply equally to carriage building and to the manufacture of motor car bodies?—No.

7574. Only to carriages?—Only to carriages. I was answering on carriages.

7575. Have you anything to say about motor cars?—Yes, I have this to say about motor cars. I think that is where the principal evil is at the present time that you are dealing with—not on the carriages.

7576. Do you consider that the introduction of motor cars has had any effect on the dangers of your employment?—Yes.

7577. A considerable effect?—Yes.

7578. In what way?—With the motor cars you do not fill them up, or very few of them. Of course, if you have a wood body you would fill it up in the ordinary way, but on the other hand you would not give it filling, you would give it the sand-paper stuff. There is too much of the sand-paper stuff used, which causes the dust.

7579. (Lord Henry Bentinck.) What do you mean by sand-paper stuff?—Soft stuff. You have not the material on a motor car like you have on a brougham.

7580. (Chairman.) Can you tell us anything with regard to the fixing of canvas or moleskin on the roofs of closed vehicles?—No.

7581. You have now told us all the operations in which there is any serious risk of lead poisoning in coach building work. Is it, in your opinion, impossible to remove those dangers?—In my opinion, it is not impossible. In my opinion it is possible to remove them, and I think that is the reason I am here to-day.

7582. You think it is possible to remove the dangers?—The great portion of them.

7583. How would you propose to do that?—This is a preparation which I am not here to divulge. (Producing a sample.) That is with two coats on it. If I sand-paper that down with only two on it I shall get a good surface, but if I put four on it I shall get a better surface. I only did it yesterday with two coats. That does not contain one particle of lead.

7584. Do I understand you to say that it is only possible to remove these dangers by having a substitute for lead?—Yes.

7585. No doubt there are many processes in which the workman cannot avoid getting his hands soiled with the material he is using?—Yes.

7586. Is adequate washing accommodation provided by most of the employers?—No.

7587. Are nail-brushes and hot-water available as a rule?—No, in very few cases.

7588. Is time allowed for the men for washing before leaving off work for meals?—I have not known it done.

7589. Is food often kept and eaten in the work-rooms where lead paint is being used?—Very often—mostly.

7590. Are meal-rooms provided equipped with suitable seats and tables and properly warmed in winter?—Very few.

7591. Do the men have the use of a cloak-room?—No.

7592. Do the coach painters wear overalls while at work?—No.

7593. Can you tell us what are the usual hours of work for coach painters?—Nine hours a day.

7594. Do you think that a restriction of the hours of working in lead processes would be a salutary measure to adopt in the interests of health?—No.

7595. (Lord Henry Bentinck.) Do you think that it is a good thing that men should be at work overtime on Saturdays and Sundays?—I am of this opinion, that I think as soon as you start reducing the hours you reduce the wages—and I cannot stand reducing the wages.

7596. (Chairman.) I am speaking from the health point of view?—We cannot stand wages any lower than at the present time.

7597. Have you noticed any alterations in the hours of employment as a result of the development of the motor car industry?—It is a good many hours at the present time. At present there are some in our trade working 68 to 70 hours a week.

7598. If you were told by the highest medical opinion that working long hours in contact with lead was very dangerous, what would you say?—I should believe them, because I know it.

7599. And you would see the wisdom of restricting the hours?—Yes, but when you talked about the nine hours, I thought if we had a reduction on that we should have a reduction in the wages. I may say that I do not believe in overtime at all. I believe in gardening; that is my hobby.

26 May 1911.]

Mr. X.

[Continued.]

7600. (*Lord Henry Bentinck*.) But if the overtime hours were restricted, do you think that would affect your wages?—Yes.

7601. (*Chairman*.) Would it be desirable to have a periodical medical examination by a surgeon of the workpeople?—There is no doubt something of that sort wants doing.

7602. With powers to suspend from employment in lead processes?—Yes.

7603. Is there any other matter you wish to bring before the attention of the Committee?—I have used this now for something like 10 years myself. (*Referring to the sample produced.*)

7604. Would you call that a leadless paint?—This which I have here is leadless, with sand-paper filling—not a particle of lead in it.

7605. Has that been thoroughly satisfactory?—I have tested it myself for my own benefit, because I have to do my own, whereas in shops they generally have labourers to do it. In doing my own I have had to study my own health, and that is the reason I have got this up. One of the manufacturers has asked me to tell him what it is made of.

7606. Has it been satisfactory in its use?—Satisfactory in wear and everything else.

7607. What length of trial have you given it?—I have done two motor cars with it, but I used it on carriages years ago, on small traps. I do not say you could use it on broughams, and so on, because in those cases you put the proper filling on, which is rubbed down with pumice-stone. That is the proper filling. (*Producing a second sample.*) That is the best you could find, with four coats; that is not rubbed down; there is no danger in that.

7608. Have you had any test as to whether those two motors you have painted have lasted as long as others would?—Yes.

7609. When did you paint them?—One last July. That would be 11 months ago, and I see it constantly. The other one I did about eight months ago. This is the one where the danger all is. (*Producing a third sample.*)

7610. (*Lord Henry Bentinck*.) That is the lead filling?—Yes.

7611. Does the paint go over that third one which you have produced as well as on the second one?—Yes, but this second one is the proper filling, the water filling, for rubbing down. I have been dealing with sand-papering, and that is where the danger is, I think. I have heard of an affair brought out, whereby we work in a hood. I think if you trace the lead poisoning cases you will find there are very few of them take it there at all, in either the nostrils or the mouth. I think they take it all through their finger ends, or the greater portion of it.

7612. (*Mr. Fell*.) Do you mean on their food?—No. I am speaking now of sand-paper stopping in their nails.

7613. (*Dr. Collins*.) I want to be quite clear whether the substitute that you are speaking of takes the place of lead for all purposes in the painting of vehicles and motors?—No.

7614. Do you mean that you use lead paints in addition?—I should use lead for the first two coats and leadless after; but you will not come in contact with the lead that you use, because this is on the top of it.

7615. But you have to apply those first two coats, have you not?—Yes.

7616. So that you would only reduce the amount; you would not get rid of the lead altogether?—By putting the two coats on there is no danger there.

7617. That is your opinion?—There is no danger unless you are careless over it. A clean man would never have danger with putting that lead on—not a great amount of danger. I contend that it is all in the dust.

7618. That is not the point I want to get at. Your substitute does not entirely get rid of the use of lead?—Not likely. It would be a clever man who could.

7619. Have you made any experiments in trying to replace the first two coats of which you were just speaking by other paints than lead?—No; and I do not

think I should try. You want something at the bottom for wear.

7620. But you have not tried?—No, I do not know what I should do to try that.

7621. You are not aware, perhaps, that the Daimler Company get up their cars without any lead at all from the first?—Yes, and how do they stand?

7622. They tell us that they stand well, and their finish looks good. I do not know more than that. Your substitute would be of value in getting rid of some of the lead, but it does not get rid of all the lead?—No.

7623. We have had evidence given us that lead paint will give off a volatile lead compound, which the workers inhale as they breathe?—Yes.

7624. So that even those first two coats which you are putting on, if you are using your substitute, would have their danger?—Yes; but which would be the greatest amount of danger?

7625. That is a point which is not yet settled, but we want to get rid of all danger?—Then you will have to get into some other trades besides the lead painting. You will have to get into the printers' trade. They suffer with it.

7626. We want to deal with one trade first?—You want to do away with it entirely?

7627. Yes?—I do not think there is a living man who can do so yet.

7628. (*Mr. Fell*.) You were saying just now that there is much greater danger with motor cars than carriages?—Yes.

7629. And you said that you had come across 12 cases of lead poisoning?—I said from memory I might have come across about 12 during my time.

7630. How many of those 12 are on motor cars and how many are on carriages?—None of them on motor cars at that time.

7631. On what do you base your expression of opinion that the danger is much greater now?—Because of the statistics that have come out of late, since the motor trade has been carried on.

7632. Your opinion is only based on the published statistics?—Yes.

7633. Not on your own knowledge?—No. I do not know of one case since the motors have come out. I know of two very serious illnesses since the motors came out which they thought were due to that, but whether they were or not I could not say.

7634. Do you say that this leadless stuff which you make up could be used for jointing?—No.

7635. Could it be used for bedding canvas?—Yes.

7636. On things like tramecars?—No, not in that case.

7637. It would not stand?—No.

7638. Have you had any experience at all with leadless paints?—I use that as a leadless paint for one. (*Referring to sample produced.*)

7639. I mean paints like zinc white or any of those?—I use zinc white.

7640. Do you find that satisfactory for painting carriages?—I never use it for painting carriages. I always mix it with others as a compound; I have never used it alone.

7641. You have never used any of these patent paints?—Yes, I have, occasionally, when I have had a cheap job, when it would not pay me to go out and get the proper stuff.

7642. Do you find they are not as satisfactory as lead?—Yes, I do. I find there is not sufficient body in them.

7643. (*Mr. Kinggate*.) You say you would not try any other compound. I would like to ask you why you are so certain in this matter?—I am speaking of woodwork. Are you pinning me to woodwork?

7644. Yes?—Because there is nothing like lead for water.

7645. You have not tried a substitute?—I have tried this which I have produced, one of my own making up.

7646. But in the place of lead entirely?—No.

7647. Are you aware that there are substitutes that are quite equal to lead for this purpose?—No.

7648. Then I can hardly understand why you say you would not try them?—You are talking about sub-

26 May 1911.]

•Mr. X.

[Continued.]

stitutes now. You know what substitutes generally are. There is a substitute for turps out at the present time.

7649. That is different altogether?—You are speaking of substitutes.

7650. If it has been proved, what do you say?—I have not seen it yet.

7651. His Majesty's Office of Works have tried a substitute for lead for both interior and exterior work. In every way it has been found quite equal to lead?—What is the length of time they have tried it?

7652. Four years?—On outdoor wear?

7653. Yes, indoor and outdoor?—Carriage work?

7654. No, on the outside of buildings. A member of our society is the head painter of the Daimler Company?—Yes.

7655. He is a thoroughly practical man and he has adopted a method which has been in use there for four years. All the cars that have been painted for four years have stood thoroughly well—equally as well as they have with lead?—Yes.

7656. You know perfectly well that in our trade there are numerous dangers with regard to lead?—Yes.

7657. Illnesses that are not reported. In many cases men are ill from lead in cases that are not reported?—Yes.

7658. But they have in many cases to continually dose themselves to keep themselves in working order?—Rightly they should do.

7659. It is very necessary, of course, that if possible lead should be done away with?—Yes, I say so—if possible. I am willing to have that.

7660. Are you aware that the Midland Railway Company use no lead whatever in the painting of their carriages and have not done for years?—No, I was not aware of it.

7661. Should not you say that the rolling stock of the Midland Railway Company was equal in appearance and wear to any other railway in the kingdom?—No, I do not know that I should.

7662. Can you mention any other railway which is better?—I think when you are speaking of railways you are not speaking of carriages, because there is a difference between railway carriages and vehicles in the street.

7663. In which way?—In the way in which they are used—for washing purposes. With the Midland Railway carriages the heavier the trains the better they are washed as a rule, but a vehicle in the street has to go through the process sometimes twice a day, and that is where the test for your lead comes in—the wheels and spokes, and so on. Is that material which you are speaking of going to stand that?

7664. Undoubtedly, but when the varnish gets off anything you have to get down to the bottom before you get the effect of the lead?—Yes, that is admitted.

7665. All of it has three or four coats of varnish on it?—Yes.

7666. Therefore, it has nothing to do with whether it is washed or not until the water can get at the lead at the base of it. Your argument, of course, would be that this substitute would not be equal to lead, which you have to get at before you get the effect of it?—I should say so, in my mind, but I would not contradict what you are saying if there is proof of it.

7667. There is proof of it?—I have not had proof of it, therefore I cannot say anything about it.

7668. Take another case. Do you know that the Bradford Corporation in their tramcar works do not use any lead and that the tops of their cars are painted white?—No. I know in the Nottingham Corporation they do.

7669. You know that it is a fact that they do not use any lead in the Bradford Corporation Tramway Department, and their tops are painted white?—Yes.

7670. Therefore, it is rather strange that you should say you would not try any substitute. If there are cases where there has been the experience of using a substitute, why should not you try it?—I said so on those grounds—the wear of the vehicle. I did not say I would not on motors. I was asked if I used this (referring to sample produced), and I said: "No, not on a vehicle in the street, but on a motor."

7671. You are only speaking there of a leadless filling?—Yes.

7672. Not of a ground colour?—No, leadless filling: that is all.

7673. We are dealing merely with the case of lead?—Yes.

7674. There are many leadless fillings on the market now. The lead is only put in to give it more body, so that it faces better?—That which this is composed of mainly does not contain one particle of lead (referring to sample produced).

7675. The filling which is sent out by the manufacturer is leadless filling?—Yes.

7676. It is only the painter who puts a certain proportion of lead in so that it gives it more body, and it faces down harder, and is not so porous?—Yes.

7677. Of course, I agree with you with regard to the carriage maker, that there are few carriage makers about now, but there are a number still?—There are a few.

7678. Do not the evils attending the use of lead apply both to the body maker and the carriage-maker?—I think not a great amount—it is mostly by carelessness.

7679. Not necessarily carelessness. You know that a carriage maker or a body maker putting on body plates cannot possibly keep his hands clean?—He cannot, but after he has done that plate he could wipe his hands and get them clean. He could take the precaution then. They do not take the precaution in many cases; they neglect it till they come out at meal times.

7680. But there is danger attending the use of it, and with a carriage maker especially so. Sometimes for days he is using nothing else but lead?—Yes, after he is fitting up.

7681. Again, in the carriage industry especially, the body is nearly always taken to the carriage maker, and the coats of priming are only given while he is working at it. That you know?—Yes.

7682. When you hear from Dr. Collis that it has been proved that the fumes given off from the drying of the paint are also poisonous, you see, perhaps, the bigger extent of the evil than what you imagined it to be?—I have never put it down as a great amount of evil. Of course, there is an evil from any paint—from the fumes of it—but I have not put it down as a great evil. I think the great evil rests with the sand-papery alone—more than all the other evils put together.

7683. Of course, that applies to sand-papery wheels of carriages especially, or a chassis?—Yes, on the soft stuff.

7684. Or on the lead itself, because the lead colour itself is composed of nothing but lead and a little colouring. It is practically all lead?—Yes.

7685. I think you will agree with me that it is desirable at any rate to do everything possible to save the employes in our trade from the poisonous effects of the use of lead?—Admitted.

7686. If a good substitute could be found, it should be used in the place of lead?—Yes.

7687. (Mr. Robins.) With regard to the question of carriage and body makers in the road-vehicle making trade, apart from motors altogether, is it not a fact that on the body maker's and carriage maker's bench, one of the necessary things which you find standing there is a pot of thick white lead?—Yes.

7688. Do you not consider there is a great danger of that pot of thick white lead being under the nose of the carriage maker or body maker all the time he is at work?—I should not say that there is a great amount of danger.

7689. Considering it has been proved that there are fumes coming from white lead, and more so from matured white lead, do you not think there is a great amount of danger?—No, I should not think so, because that pot of lead that you are speaking of does not cause the fumes to rise; it is only oil with it, not turps. If you get turps with it, you get it to rise. I do not consider there is as great an amount of fumes from the carriage maker's pot on the bench as there is in the paint shop.

26 May 1911.]

Mr. X:

[Continued.]

7690. But you would admit there is a great amount of danger from having that on his bench?—Not a great amount. I should say there would be a slight danger.

7691. Would you say that it is not free from danger?—Yes.

7692. I think in the course of your evidence you said that there was less stopping up on the motor than there was on the private carriage?—I did not say so.

7693. Less filling?—I say less filling.

7694. From my experience of seven years in the motor industry there is more white lead used on motors than on private carriages?—You were speaking of filling just now, and now you are speaking of white lead.

7695. With regard to a motor, do you consider that there is more dry white lead used on a motor than on a private carriage?—Yes.

7696. For what reason?—Simply because you have not got the foundation there to rub it down with hard stone, and you have to sand-paper it. I am not speaking now of stopping. Do not pin me to stopping, because a carriage has stopping, with a certain amount of holes, but a motor has not that amount of holes, as you know, with the panels.

7697. But although a motor has not the number of holes in it that a private carriage has, still, from the condition of the panels being hammered, in my experience it requires quite as much stopping or more stopping than an ordinary carriage?—Some do, and some do not. They are got up pretty well without the stopping.

7698. The conditions that I find now are that there are more hammered panels, and consequently they require more stopping?—There are some in excellent condition that do not require a great deal. I can tell you that.

7699. With regard to your leadless filling, that would be the only thing that would be free from lead on a carriage that you would paint?—Yes—up to now.

7700. It would only be the leadless filling after the priming, I take it?—Yes.

7701. You are doing away with the slate filling altogether?—It is a kind of slate now.

7702. I take it then you would sand-paper that—rub it down?—Not rub it down, sand-paper it. I should use proper filling for rubbing.

7703. And after sand-paper you would apply proper filling on top of that?—Then I should apply the lead.

7704. That would be lead for colour then?—No, I should apply lead before the colour.

7705. You would have a lead priming?—Yes.

7706. Then the leadless filling in between?—Yes.

7707. And then you would apply lead again?—Yes.

7708. Then your colour?—Yes.

7709. That would be the formula of the work?—Yes.

7710. Then that is, so far, your experience with regard to leadless paints?—Yes.

7711. (*Lord Henry Bentinck*.) You invented this leadless paint in order to improve your own health?—I did. There may be others that know of the same thing, I do not claim to be the only one, but I say I do it myself.

7712. Therefore, I suppose you will agree that, if it is possible to invent a substitute for the other processes, it would be advisable to do away with lead altogether?—I was thinking about the wearing, but our friend says it will wear, and if I take his word for it I am convinced on that.

7713. You think, if satisfactory substitutes could be found, it would be advisable to do away with lead altogether?—Yes.

7714. (*Chairman*.) Do you speak on behalf of any number of your men?—No; I have no instructions to speak for them.

7715. You come entirely on your own account?—Yes.

7716. Do you know the general feeling of the men. Are they anxious to have something introduced?—That I cannot say. Our friend here knows that it is not a matter of Committee business, but it is a matter of a certain meeting.

7717. Have you ever heard your men discuss the question of the necessity of remedies for relieving the evils that obtain to-day?—No, I do not think that we have many men in Nottingham that have that about them to discuss it.

7718. What do you mean by that?—I think they are too avaricious after money, and not their health. That is the reason I have come here. I think I am about the only one who studies his health.

7719. (*Mr. Mason*.) Did I understand you to say that there was more dry white lead used on a motor than on a private carriage?—Yes.

7720. But less stopping?—Yes, only it comes, as our friend said, in the case of the hammering, and then you would use a little more.

7721. What do you use the dry white lead for?—For sand-papering. They do not use the filling, I am speaking now of the hammering out process—not on the landaulette cars. A landaulette body is practically the same as a brougham, but in the case of these bucket seats, and so on, there is not a deal of stuff on them.

7722. I do not think I quite follow that. What was the dry white lead used for?—In sand-papering the paint—one coat on top of the other.

The witness withdrew.

Mr. ARTHUR FELTON MULLINER examined.

7723. (*Chairman*.) You are one of the witnesses selected to give evidence on behalf of the Society of Motor Manufacturers and Traders?—Yes.

7724. Are you a carriage and motor manufacturer?—I have been at the head of a large manufacturing concern for over 30 years.

7725. Do you manufacture motors?—Not motors, only carriage bodies for motors.

7726. You manufacture motor car bodies?—Yes. That is, of course, the principal part of one's business nowadays.

7727. What length of experience have you had?—Practical experience, over 30 years. Previously to that I was at the London and North Western Railway Company's carriage works at Wolverton.

7728. How many men do you employ?—I should think about 350 to 400.

7729. Have you known of many cases of lead poisoning?—Since I was asked to come here I made a point of seeing all those engaged in my painting department; that is all my painters proper, and all the men who do the work of filling up and rubbing down. They number about 60 in all. I saw them nearly all personally, especially those who have been in my employ for a long while. There is one man has been

45 years in my painting department. In the report I have here I have questioned each to obtain his experience both personally and from his knowledge of others, and in only two cases has any one of those men, in all his experience, experienced temporarily any ill effect. In both cases I find the suggestion of lead poisoning was put into the man's mind by the medical man after inquiring what his occupation was. In addition to that, two others had heard of such cases, but many years ago.

7730. Do I understand that about 60 of your men come in contact with lead?—They are employed in painting. We use a very small quantity of lead, but they are employed in using it.

7731. You tell me you have about 400 or 500 men in your employment?—Yes.

7732. I want to know how many of those men come in contact with lead?—Only 60.

7733. Do you think it is a good way of getting information for the employer to ask the men on a matter of that kind? Do you think it is reliable?—I do, because I am on very, very friendly terms with my men, and they treat me rather kindly, as I think I treat them also.

26 May 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

7734. Do you know that in the coach building industry there have been 767 cases of lead poisoning recorded by the Home Office in the 11 years 1900-1910?—767 reported cases in 11 years, but only 100 of those refer to carriage body makers. The others are railway painting, which, of course, is a different industry altogether, and tram painting, which is a different industry, and perambulator painting, which is also different.

7735. How many of those men do you say are in your trade?—Only 116 in the motor body or carriage body making, and that would include also the painting of chassis wheels or bodies. I refer to makers of motor chassis. Before they send out the chassis to the carriage builders, or other people, they give the chassis a coat of what they call lead colour, so that it would include those manufacturers as well as the body makers.

7736. Do you know how many men have been employed on making these bodies and chassis?—No, I could not tell you how many there are, but it is a very large number.

7737. May I take it, from the figures, that lead poisoning has been on the increase in this particular part of the industry?—From what my own workmen tell me about it, it must have been very much the reverse.

7738. But the Home Office figures show that, if there is no increase, there is certainly no reduction?—I can only speak from the information from about 60 men who gave me information, which they did very willingly indeed. Only one of those men knew of a case that proved fatal, and that was over 15 years ago. The man both inherited it and was also himself consumptive, so that whether his death could possibly be traced to lead poisoning or not I could not say.

7739. (Dr. Collins.) Do you say he inherited it?—He inherited the consumption. So that I do not think that is a fair case, but that is the only case I can trace in any of my men's experience that I have heard of, and that was over 15 years ago. Of course the experience of 60 men during a lifetime is worth something. I am rather anxious you should not class our type of work with that of railway carriages, because we only look to the high finish of carriages.

7740. (Chairman.) Of course the importance of the figures depends entirely on the number of people that are employed?—I do not know how we should get at the number of people employed. We should, of course, include the number of men employed in the painting of chassis, and so on.

7741. Of course the industry has increased enormously the last four years?—Yes—chassis making.

7742. And body making—the whole industry?—Yes.

7743. You quite appreciate the fact that the number may be large or it may be very small, but it is the proportion?—Yes, those are cases which have been traced during the last 10 years, said to have been due to lead poisoning.

7744. Have you, as a society, taken any steps to test the merits of the different substitutes on the market?—No, not as a society.

7745. Or to institute any inquiry as to the precautions necessary to combat the evil which exists in many branches of the industry?—No, we have not had the matter of lead poisoning up before us.

7746. Have you tried substitutes for white lead in your painting work?—I have substitutes, but, curiously, I have heard of another one to-day, which I have had the particulars of. It is a special filler which is said to be absolutely non-poisonous, and is made from the finest quality of specially selected oxide of zinc, tinted with carbon, and ground in a special varnish medium—absolutely non-poisonous. I only heard of it to-day, and I intend to have some of it and have a carriage painted entirely with it.

7747. Have you tried any substitutes in past years for white lead?—No. Until this matter was brought forward we have never realised the slightest necessity for it.

7748. Then you could not say whether it would be possible to prohibit or greatly restrict the use of lead

without inflicting a hardship on the industry?—I do not think that the results that we obtain would be nearly so good if the use of white lead was entirely abolished.

7749. You have not tried, have you?—No.

7750. Then how do you know what the results would be?—I know what the result is with the Motor Company. They say they do not use any white lead. They use a kind of filling, but whether that filling is absolutely free from white lead I do not know. That is composed, I believe, of sulphate of lead—it is called non-poisonous.

7751. What particular form of hardship have you in your mind if lead was prohibited? What sort of hardship would it be to the industry? Are you thinking of foreign competition?—Of course, if foreigners were allowed to use lead, and their goods come in quite free, it would affect us very materially, probably. Many carriage bodies come in from abroad as it is.

7752. Are you thinking of increased cost?—I do not know that it would necessarily increase the cost.

7753. Or do you fear a reduction in quality?—A reduction in quality, certainly.

7754. But you do not know that from your own experience?—No, not from the experience of my own factories.

7755. You would agree, no doubt, that if a substitute could be found which would be in every way as good as white lead, the use of white lead should be prohibited?—I do not see why it should be prohibited.

7756. I have told you that, even supposing the 116 cases which you have put forward to us were very small, still it is something to combat with?—Yes.

7757. You would agree, no doubt, that if a substitute could be found which would be in every way as good as white lead, the use of white lead should be prohibited?—If it is proved there is any danger at all from white lead in the small quantities we use it, and if it is for the benefit of the workmen, we would do anything for the benefit of the workmen.

7758. The Home Office think there is very grave danger, or we should not be sitting here to inquire into it?—Certainly, but it may not be in our particular industry.

7759. You agree with me that if a substitute could be found the use of white lead should be prohibited?—If a substitute could be found, I should not use the white lead at all. If any danger obtained to the workmen at all, I should think it my duty as an employer not to use it—if it was proved.

7760. Supposing that we can prove to you that there is danger in any particular operation, then you would cease to use it?—I should cease to use it, if it was proved there was any danger to my workmen.

7761. Do you know that for the past six years the Midland Railway Company have used no lead in their carriage and wagon works?—I have no knowledge of what they do.

7762. And that they are entirely satisfied with the results obtained with a mixture of zinc and baryta?—I have no knowledge of what they use.

7763. We have also had similar evidence from the representative of the Bradford Corporation Tramways Department. Are you aware that white lead is no longer in use at the Daimler motor car works in Coventry?—I have been told so by the manager.

7764. Do you hold that white lead is the most perfect substance that can be used?—White lead is what we call a very useful substance. We use it for framings as well as for painting.

7765. Do you hold that white lead is the most perfect substance that can be used to-day in painting?—Up to date, it is the best known substance for the filling up of the grain of the wood. That is what we use it for—in order to get the high surface and finish that we want to get.

7766. How does your work compare with the Daimler motor car bodies?—It is rather an unpleasant thing to have to say anything against another person's work, and I object to do so very much.

26 May 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

7767. Are they one of the largest firms in the industry?—They make a large proportion of bodies compared to other people.

7768. And do they turn out work of the highest finish?—Only from their own point of view, I think. We can only look at results.

7769. The buyers of Daimler cars are about the same class as the customers of your own or other leading coach body firms, are they not?—Yes, I suppose they are.

7770. And would they not demand the same finish from the Daimler Company that they demand from you?—The Daimler Company have not been making motor bodies of their own very long—I think only five or six years—and it is only within the last two or three years, at all events, that they have made any quantity of bodies.

7771. The witness representing the Daimler Company told us that they are entirely satisfied with the substitute they are using for all purposes for which white lead is commonly used in coach building works?—Why should he say anything against himself? I have discussed the matter with him myself.

7772. The Daimler Company say that they have used no white lead for two years, and that they have had no complaints from their customers. If there is any defect in their substance, is not that a most remarkable incident?—One sees the results of their work after a few years—yes.

7773. They have had no complaints from any of their customers?—That is rather a broad assertion.

7774. Is not that rather a remarkable statement for them to make?—Perhaps others have had complaints of their work. I know of several instances where very serious complaints have been made of the results of their work.

7775. But their sales have not fallen off; their business is progressing satisfactorily?—It has been up to date. I do not know that it is just at the present moment.

7776. They have had no complaints from their customers and they do not use white lead?—That is rather a broad assertion, I think, altogether.

7777. What the Committee want to ask you is: how do you account for this. A firm like the Daimler Company, of high reputation, with a great business connection, who have used no white lead for two years, are perfectly satisfied with the results, and their customers have made no complaints. I ask you: Why should not the other motor car companies adopt the same formula?—May I ask whether the material they use (which I believe is sulphate of lead) is considered as lead. They use what they call non-poisonous white lead, which is really sulphate of lead. Do you accept the use of sulphate of lead? It has to be proved that it is non-poisonous. You are starting on the assumption that they are using no white lead, but I believe they are using sulphate of lead.\*

7778. Just now you were rather inclined to state that you were not in agreement with them in regard to the perfection of their finish?—Yes.

7779. Now you are rather putting it on the ground that they are using lead?—No. I take it in both ways; that there is probably not so much used in this particular material they use as there is in what we use.

7780. But supposing it is a leadless paint and is perfectly efficacious, why should not this Committee insist on other motor car companies adopting the same formula?—I do not see any reason why you should not insist at all. I think it would be the duty of every employer to use such material, and it would be to his workmen's benefit. I agree with your previous question, that if we can find a really good substitute for white lead we will give up using white lead. I am perfectly prepared to do so myself.

7781. I am now pinning you to a formula which is in use and which the Committee has been told is perfectly satisfactory. I want to ask you why, if it is satisfactory to the Daimler Company, it should not

be satisfactory to a company like your own?—What might satisfy the Daimler Company might not satisfy me.

7782. I am speaking of your customers. If it satisfies their customers why should it not satisfy your customers?—I do not say that the customers are satisfied. I have found a good many customers who were not, because I have had a good many of the carriages to do over again and re-paint. I have rubbed them down and started in the usual way.

7783. Do I understand that your suggestion is that the Daimler Company's work is not as durable as yours, and that you prove that by the fact that the Daimler Company's motor cars have been sent to you to re-paint because the customer is not satisfied?—I do not say that all their carriages are so, but instances have occurred.

7784. Have there been many instances?—To my knowledge about four or five.

7785. Would that be sufficient to allow you to suggest that the formula that the Daimler Company use is not a durable one?—No, it is not—I do not think so—if the result is satisfactory.

7786. Then it comes back to this, that you have not made up your mind absolutely that the Daimler Company's formula is not a good one?—No, I have not. I am perfectly prepared to try the thing myself; in fact I have seen the manager on the subject, and I have told him that, if what he is using has the good result he claims for it, I intend to use it myself. I have given instructions at my works about it.

7787. That is very satisfactory?—It is for the benefit of the workmen.

7788. Then in your opinion the formula that the Daimler Company are using is worth a trial?—It is worth consideration, and also this other one which I have heard of to-day, which I shall also obtain and make use of.

7789. To go back to the number of cases: in the last seven years, there was one case of lead poisoning in 1904 amongst motor body and chassis manufacturers; 4 in 1905; 9 in 1906; 15 in 1907; and it dropped to 8 in 1908; 11 in 1909; and 14 in 1910. So that you may take it that within the last four or five years (when I take it that the increase of this business began to be felt) there has been practically no change?—No. Of course it is a question of the number of cases increasing in proportion to the number of men employed.

7790. But would you not say that in the last five years there has been an average number of people employed?—No. I should say the number is increasing terribly, even now—between last year and the beginning of this year. Of course one has to look at the thing by proportion.

7791. I understand that you are not prepared to answer questions regarding the various processes in detail?—No. I have never been a practical painter. I have been practical in other departments, but not so much in practical painting. It is rather my duty to look at the finished result.

7792. Now I will ask you a few questions about the precautions which must be taken where lead is used. You understand that if lead is allowed to be used there will have to be a special code of regulations introduced?—That is proposed, is it not?

7793. We are obliged to do that under the Factory Act?—That would be in addition to the present requirements of the factory inspector?

7794. Yes. We must have a new code of regulations altogether. I want to bring that home very seriously to the employers, because I want to ask them presently whether they would prefer the abolition of lead or the code of regulations?—The factory inspectors in my place like to have very large airy workshops, and they look after the men. The men have to leave off at a certain time, and I make it a standing rule that they leave off five minutes earlier to go and clean themselves.

7795. Do you attach importance to personal cleanliness on the part of the men?—I do.

7796. Do you provide washing accommodation?—Yes, on every floor.

\* An analysis at the Government Laboratory showed that this paint contains no sulphate or other compound of lead.

26 May 1911.]

Mr. ARTHUR FELTON MULLINEE.

[Continued.]

7797. What proportion of basins to the number of men employed?—There are different numbers being employed each week.

7798. The regulations which the Home Office have laid down are one basin to every five workers?—Then if we employ 60 men it means 12 basins. I do not know. At our place in London we have more than 12, but I doubt whether we have in the country.

7799. What is the proportion of basins to the number of men, approximately—about one in five or one in six?—I am not quite sure, but I believe it is about one in five. I generally carry out all the instructions of the factory inspector.

7800. Is hot water as well as cold laid on?—No.

7801. Do you not think that hot water is necessary?—I do not think so. There is no difficulty about getting hot water.

7802. Do you not think it is imperative, if you want thoroughly to clean your hands of paint, to use hot water?—I should use it myself, but many people do not take the trouble to do it.

7803. Suppose you have to clean your hands of paint, is it not better to use hot water than cold?—Yes.

7804. Because it is easier to get the paint off?—I do not think hot water is absolutely necessary. I should prefer personally to use hot water.

7805. Are clean towels supplied regularly?—Yes.

7806. How often?—I could not tell you; certainly once a week, perhaps twice.

7807. The Home Office lay down regulations with regard to the supply of towels. If cleanliness is indispensable, the men ought to have everything ready to hand for cleaning purposes?—The instructions to my manager are to carry out all the orders of the factory inspector, whatever they may be.

7808. Are soap and nail-brushes always available?—Yes.

7809. Is time allowed to the men for washing before leaving off work and before meals?—Yes, that is the standing rule.

7810. Is a room provided for the men to take their food?—They do not take their food on the premises at all.

7811. So there is no provision necessary for the storing of food?—No, not in my works.

7812. Do you provide overalls for your men?—No.

7813. Is not a cupboard provided for storing them, when not in use?—I do not know that it is necessary.

7814. It is necessary in other industries where lead dust is generated, and it would have to be insisted on in this industry if lead is used?—Yes, if lead is used.

7815. Do you provide a separate cupboard or cloak-room for outdoor clothing put off during working hours?—They have a room apart from the works.

7816. Have you impervious washable floors in your painting shops?—I have in London.

7817. Are they cleaned down wet?—Yes, we use a great deal of water on the floors.

7818. How often do you clean them?—Every morning the paint shops are done.

7819. The Daimler Company have told us that they keep two men to swill and mop their impervious paint shop floors every day?—I am sure we do. I am very particular about keeping the place clean, and I keep a lot of labourers on purpose for the job.

7820. What are the usual working hours for your painters per week?—I think it is 53. I will not be quite sure.

7821. Do they frequently have to work overtime?—Occasionally they do—one or two days a week sometimes.

7822. Do you know that a very great deal of overtime is worked in certain factories in the motor car trade?—Yes, I believe so.

7823. Would you welcome a strict limitation of the hours of employment, say, to 48 hours per week, as has been recommended in the potteries?—I should consider it entirely unnecessary to do so.

7824. All the best medical evidence in this country has strongly urged the Home Office to restrict the hours to 48 hours per week?—I am very sorry for the workmen, and I am very sorry for their wives and

families. It would be a great hardship on the workmen.

7825. That has been adopted in the potteries?—Yes, but that is quite a different industry altogether.

7826. But it is a question of the danger?—Do you not think it depends on what sort of workshops they work in?

7827. It is a matter of the amount of dust they come in contact with?—If you have very large workshops with plenty of air and ventilation, I do not think arbitrary limitation is necessary.

7828. Did I understand you to say that if the hours were reduced to 48 hours per week, the wages would have to be reduced accordingly?—Nearly all my men are on piece-work, and if they only worked a certain number of hours they could do a less quantity of work, and, therefore, they must have less money.

7829. Do you have a periodical medical examination of your workers?—Not necessarily periodical, but a man is called in occasionally to look round.

7830. Do you know that in other industries where lead is used the Home Office insists on a monthly or even weekly examination by the certifying surgeon at the employer's expense?—I was not aware of it.

7831. If you have never had your men examined by a doctor regularly, it is possible that some of them may be suffering from the slower and more insidious forms of lead poisoning, is it not?—I should think we should find some results from it, if we are employing a large number of men.

7832. You find it out for certain if they are examined regularly, and you do not if they are not examined regularly?—You do not find in stables, and so on, where the men are with the horses all day, that the men are medically examined every day. Surely ammonia is pretty bad.

7833. Do you know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—Very possibly it may do in some industries, but certainly not in the carriage building industry.

7834. You do not have your men examined; do you cannot tell?—It is an assertion which I will not contradict. It is a curious thing that the men do not suffer from it.

7835. You do not know whether they suffer from it or not, because I am speaking of the slower and more insidious forms of plumbism?—I do not think the men suffer any more in the department of painting than they do in any other department.

7836. You do not know that absolutely, you hope that is the case?—We do not find cases in the works. We very seldom have any cases.

7837. Would you welcome a system of periodical medical examination in your industry, so as to be quite sure that the men are not suffering from lead poisoning?—If I saw the necessity for such a thing, I should welcome it, but I do not think there is any necessity.

7838. Together with compensation for any workers suspended by the doctor on account of doubtful health?—I think that is quite unnecessary.

7839. I will repeat again the system which prevails in the earthenware and china trade. Medical examination is insisted upon—and so it will be insisted upon in this trade if white lead is allowed—and if a doctor thinks that a man may have the beginnings of lead poisoning, although it is not marked lead poisoning; he has the power to suspend him, and while he is suspended the employer has to pay compensation. I ask you whether you would welcome that innovation in your business?—I should not welcome it; I should do my best against it. I think I should let my customers suffer and not use any white lead.

7840. Do you realise the very great expense which the industry would have to bear in connection with stringent regulations?—Yes, it would be very expensive indeed.

7841. There is a very real danger to be dealt with. You must assume that that is the case, because the Home Office have found that it is. There seem to be only two ways of mitigating the evil; first, to prohibit the use of lead altogether, and, secondly, to introduce a code of regulations which will bring this industry, in

26 May 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

regard to care for the workpeople, up to the standard of all other large industries where the use of lead is permitted. I will give you an indication of what these special regulations are. First, in regard to lavatories, the regulation would require washing accommodation to the extent of at least one basin for every five workpeople. Soap and nail-brushes to be provided and properly looked after. Sufficient clean towels to be provided every day. Secondly, a mess-room is necessary so as to make it impossible for the workers to have meals in a place where they come into contact with lead. Cloak-rooms to be arranged so that it should be quite certain that the men's outer clothes do not come into contact with lead. Overalls to be provided at the employer's expense, and washed at his expense. Washable impervious floors to be introduced, so that they may be swilled down regularly every day?—Does that mean to say that all present carriage manufactories would have to be rebuilt?

7842. The floors would have to be relaid?—That is rather an expensive amusement. It would not affect me so much, because it happens that my floors are already impervious.

7843. Then a periodical medical examination to be made of each lead worker at the cost of the employer, together with payment of compensation whenever a man is withdrawn from work in lead. Efficient exhaust draught apparatus for the removal of dust to be installed wherever it is possible to apply it. Then you must also take into account the cost of setting up a system which will secure continuous observance of all these regulations, for you realise that under the Factory Acts the first duty is laid on the employer of securing the observance of the regulations?—Certainly.

7844. Taking all those points into consideration, and having in view the fact that we must introduce some remedies for the evil which undoubtedly exists, do you still consider that it would be better to regulate the industry by these special rules, or would you, as an employer, rather see the use of lead prohibited?—I would rather see the use of lead prohibited. If you are satisfied with the use of lead by the Daimler Company, which is a sulphate of lead,\* we will use the same as they do. I should like to be satisfied that that would be so, and that we should get the same results.

7845. Do you speak for yourself or for any number of employers?—I am only speaking for myself to-day. Other people do not interest me in the least. Of course, it would be interesting to us to know if you are willing to accept sulphate of lead. You have been speaking seriously about use or non-use of white lead by the Daimler Company, and you have based many questions on it, but the material they use, I am informed—of course I may be informed wrongly—is sulphate of lead.

7846. We should not accept sulphate of lead as a substitute?—Then all the questions you have put about the Daimler Motor Company would not really be fair, would they?

7847. The Daimler Company have sent us the formula they use, and the name of the people they buy it from. We have sent to the people they buy it from, and we have got an assurance from them that there is no lead in it whatsoever?—But you would not accept their assurance; you would have it properly analysed yourself, I take it.

7848. (Dr. Collis.) Lead is pretty easy to trace, is it not?—Yes.

7849. They would hardly make a false statement on that point?—I do not suggest that they would, but it would have been rather interesting to us to know if that material is accepted.

7850. (Chairman.) Let me clear the ground by putting this one further question. If it is proved to us that the Daimler formula contains no lead, are you prepared to give that a considerable trial?—Certainly. I should have done that without knowing anything about this inquiry, if that were so.

7851. Notwithstanding that you have had a few motor cars to re-paint because the customers have not

been satisfied?—There may have been other reasons why they sent it to me besides the painting.

7852. I thought you were rather belittling the formula?—I hate to be finding fault with other people's work, but there is a kind of feeling that the Daimler motor car work is not so good.

7853. I thought you were rather belittling the formula because some Daimler cars were sent to you to re-paint?—I do not wish to convey that.

7854. You certainly spoke in a tone of disparagement of the Daimler formula?—No, I do not wish to do that. I say that the use of white lead, as we employ it at the present time, gives a better result than theirs, and they are not using it. If their customers are satisfied with the result of their work, there is no reason why we should grumble at their work.

7855. You went on to say that some of the customers sent their cars to you to re-paint?—Yes, but I contend that the non-use of white lead does not, and cannot give so good a finish as the use of white lead. Anyone who has seen the white lead in filling up the grain of the wood, must admit that. If the use of white lead is prohibited, the finish of the panels probably will not be so good in the future, and the public will know it, and that will be given as a straightforward reason. May I refer to a special filler. It is absolutely non-poisonous. It is made from the finest quality specially selected oxide of zinc, tinted with carbon and ground in a special varnish medium. As an employer who looks after his men, I shall immediately obtain some, and have a carriage done with it, and if I am satisfied with the result, I shall probably dispense with the use of white lead altogether—even without your having asked me these questions.

7856. (Lord Henry Bentinck.) I suppose you will allow that if your works were old-fashioned and low and badly ventilated, there would be a danger from lead poisoning in the work you carry on in your works?—If it can be proved that there is a certain amount of poisonous fumes.

7857. It is dust, is it not?—Very little dust.

7858. Even in low rooms badly ventilated?—We do very little sand-paperying business.

7859. But there must be dust from the dry paint on clothes and hands and so on?—I do not think so.

7860. Then why are your rooms well ventilated?—They are ventilated for the sake of health or fresh air. I have never taken the matter of poisonous fumes into consideration until this Committee was appointed. I never considered it.

7861. Are your men insured under the Workmen's Compensation Act?—Yes.

7862. And do you pay as low a premium as anybody, or do you pay a higher premium?—I really do not know what premium is paid. I may mention that when the Employers Liability Act was passed, nearly all the carriage-builders combined together, and by that combination they got a special rate.

7863. Then you might get better terms than other coach-builders?—No. Quite a large number combined together, and by taking a large number of workmen the insurance company gave us a preferential rate. That is how it was done.

7864. But the rate which you pay as coach-builders, I believe, is higher than most people's?—That is so.

7865. That is an acknowledgment that your trade is a dangerous one, is it not?—That is only because the insurance company insist on it. If they will not do it for less, we must pay it.

7866. That is because they cannot afford to do it for less?—I should not think cases of sickness occur once a year in my factory.

7867. But you are paying a higher rate of premium than other manufacturers are paying because your trade is not a very healthy one?—That is an assertion that it is not a healthy one.

7868. I think that shows it, does it not, if you are paying a higher rate?—It may be so, but we do not find it in our works.

7869. (Chairman.) Out of 500 potteries there are about 350 which never had a case of lead poisoning at

\* Shown on analysis to be a leadless paint. (See 7777 above.)

26 May 1911.]

Mr. ARTHUR FEYTON MÜLLNER.

[Continued.]

all. The corollary is that the same thing exists in your trade, but it does not say that there is not a very great amount of lead poisoning in the trade?—Then I think you are quite justified in trying to stop it, for the benefit of the workmen.

7870. (*Lord Henry Bentinck*.) There is only one more question I want to ask you, and that is about foreign competition. I suppose your chief competitors are the French coach-builders, are they not?—No, Belgian now. The French used to be, but it is Belgian now.

7871. In France the use of white lead will be prohibited in a year's time or two years' time?—It will be. I think the Belgian trade has increased very materially. A great many carriages come over from Belgium now. I was sent over to Brussels last year to act as a juror in the carriage-building industry, and they are sending me over to Turin this year.

7872. With regard to these Daimler cars that were sent to you to be done, were they sent, do you think, chiefly because the paint had proved unsatisfactory, or was it for other incidental repairs?—I should not like to assert that it was entirely on account of that, but when we do have the carriages we notice it.

7873. The owner probably takes the opportunity of having the carriage painted while it is in your hands for other repairs?—Yes. I do not say it came to us for that.

7874. There may have been a door wrong, or anything like that?—Yes. I should not like to make an assertion like that without being able to prove it.

7875. Very often owners take the opportunity of having their carriage re-painted when it is not absolutely necessary, because it is in your hands for repairs, do they not?—Yes, but having the carriage, we should look into it, and say, "Why is the paint gone here and not there?" and we should take it off and we should say, "There is no white lead here."

7876. The Daimler Company are on the whole a careful firm, they would not adopt any really reckless experiment merely for the sake of trying an experiment, would they?—No.

7877. (*Dr. Collis*.) I think you said you were uncertain as to the amounts that you were paying for insurance of the workpeople?—I have no figures in my mind of what we are paying at all.

7878. Then you cannot tell me whether the insurance paid by the combine of which you are a member has risen since the middle of 1907?—I am not aware that it has.

7879. You do not know whether it has or whether it has not?—No, I am not aware that it has.

7880. Have you had experience at all of the painting of motor car bodies made with Terno plates?—I have never heard of them.

7881. They are largely in use in the trade, are they not?—I do not know the term at all.

7882. It is a plate which is covered with lead and tin?—It is a kind of steel, is it not? They call them galvanized steel panels, I think. We beat them out and we use them instead of aluminium sometimes.

7883. They are coated with lead and tin, about 80 per cent. of lead to 20 per cent. of tin. What material do you use for covering those surfaces?—I believe there is some liquid material put on it to prevent rust coming through, and then we fill it up with ordinary filling, the same as we do wood panels.

7884. With lead paint?—Yes.

7885. I asked the question particularly, because I have been informed that the lead paint will not stick on it and cannot be used on it?—Possibly that is so, unless it is prepared with a certain liquid material, which we put on because the rust comes through, and it scales off.

7886. I was informed at certain works that they did not use lead paint on it, not from the point of view of health, but simply because it all scaled off and it would not stick on Terno plates. They are very big motor people who told me that?—I was not aware of it, because I see the men doing it every day.

7887. I did not know whether your experience was the same?—No, I am sure the men fill up these panels to which you refer exactly the same as the wood panels,

but I do not think they require to use so much, because there is no grain to fill up.

7888. They were using lead paint on their wood-work, but they informed me that if they put lead paint on the metal the whole came off, and consequently they could not use it?—That is not my experience. I will carefully go into that matter and see, but I am quite sure that they use the same filling in our works.

7889. It may be an isolated experience?—It depends what result you want to get.

7890. You mentioned the fact that you always followed the instructions of the factory inspector in all that he asked?—As near as possible, of course, to his satisfaction.

7891. You are aware, of course, that the factory inspector cannot go any further than the Factory Act?—Of course; but if he has to ask more he will get more, of course.

7892. But he cannot ask more until regulations are established by which he may ask more?—Yes, and then we shall do our best to carry out his wishes.

7893. I only wish to point out that in falling in with the requirements of the factory inspector under the Factory Act, it does not mean of necessity that every precaution is taken in the trade to prevent danger, because the Act has not yet made any special regulations for the trade?—We always carry out the instructions of the factory inspector, and if he has further instructions we shall do our best to carry out those.

7894. I only want to call your attention to the fact that there are no special regulations made for the trade under the Act at present?—Quite so; I appreciate that.

7895. On the question of the health of your own men, have you studied much the amount of sickness that occurs among the workpeople?—No, I have not.

7896. So that if only one man is off a year, as may occur with you, you are unaware whether that is 100 per cent. more than other occupations or 50 per cent. less?—I cannot answer that question at all. I shall be happy to obtain the information for you.

7897. The point which you have been rather emphatic upon is that no illness has been occurring among your men. Illness among a group of men is only a comparative term after all, is it not, compared with what they ought to have?—If there was any serious illness of any sort, my attention would be immediately called to it.

7898. If it was a glaring outbreak of plague, it would naturally impress itself on you?—I do not mean that. I mean if, for instance, it was a case of every week or anything of that sort, I should certainly know it, because there would be a claim on the insurance company, would not there?

7899. No, not unless it was a lead poisoning case?—But the insurance of the workmen is against all classes of illness, is it not?

7900. No, it is for accidents and lead poisoning. You made rather a point in your evidence of the healthiness of your workpeople, and therefore I cannot help making, in opposition, the point that you do not know anything whatever about it?—I say that I have no personal information. At all events my attention has not been called to it.

7901. Consequently that part of your evidence—chiefly really has no bearing upon the subject with which we are dealing?—I grant that.

7902. As regards the sand-papery of motor cars, you stated that you thought that after all there was not very much dust?—There is very little sand-papery done.

7903. There is some, is there not?—Very little indeed, to what there used to be.

7904. Do you ever sand-paper steel wings?—Steel wings are filled up with a filling and then rubbed down with pumice-stone wet. There is no necessity to use glass-paper on them.

7905. It is not used, for instance, after one coat of lead colour?—They keep on filling up. There is no necessity to glass-paper them.

26 May 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

7906. They are not done?—I do not think so. I cannot say they are never done. It is the use of glass-paper you are speaking of to create dust, is it not.

7907. Yes?—There is very much less done now than there was five or six years ago.

7908. But it is used, is it not?—It may be in other factories; I cannot say.

7909. Do you not use any dry glass-papering at all?—Not on the wings and the metal works.

7910. On any part of the car?—The men use the glass-paper when they are cleaning up the panels before they are painted, certainly, but no lead has been put on to the carriages then.

7911. Do they ever do any after the lead has been put on?—I believe not.

7912. Tests have been carried out in actual practice where it has been done, so I should have liked you to tell me of a process where it was used?—As far as I know, it is only the filling up, and then the rubbing down with pumice-stone and water.

7913. For instance, this test was made: "Sand-paper stopping process: after one coat of lead colour and stopping, on steel panels of a motor body"?—That is not our practice.

7914. "Sand-paper stopping process: bonnet boards, after one coat of lead colour and sand-paper stopping." Is that not your practice?—No.

7915. "Door of motor body: after one coat of lead colour and quick drying, sand-paper stopping, urgent work"?—I mean to say that after the first coat of paint has been put on a panel, and there is a little rise in a joint, I dare say the men would take care just to rub that joint down, but that is not going all over the panel. I do not say that glass-paper is never used after a first coat of lead paint at all. That would be a ridiculous assertion to make. Just rubbing off a joint or anything of that sort might take place. A man might go round the body and rub little tiny places like that with glass-paper.

7916. Do you think that would give off any dust containing lead?—The thing is quite too trivial. It is quite a little thing, like rubbing your finger like that (*illustrating*). It is not like a man taking a great piece of glass-paper and rubbing a big panel down to create dust.

7917. Would he be doing that for long?—The whole carriage would not take him more than a quarter of an hour, I should think.

7918. Would his neighbours in the same workshop be doing that too?—I do not know that they would.

7919. How often would he be likely to be doing that in a day?—I cannot answer the question. It might be done a dozen times a day, and it might not be done another day at all.

7920. Would there be more than one vehicle in a shop which might be so treated in a day?—Yes, very likely.

7921. So that the combined amount of rubbing down might come to a certain amount in the shop, with all the men at work. This dust when it gets access to the air does not fall to the ground?—If you could see a factory like mine, these questions might be different.

7922. I quite agree with you that factories differ very much, but still we know, from the analyses that have been carried out, that those processes which are only carried on for a short period, during that short period give off dust which contains a very high proportion of lead; and that if it has been carried on for short periods, even, by several men in the same workshop, you would get an amount of lead dust in the air which is not going to be got out very quickly, and it is those small amounts constantly inhaled that do the damage?—Yes. I can only speak for my own factory, of course.

7923. From a medical point of view, one looks upon the trouble from lead when it is not causing absolute lead poisoning, perhaps, as more dangerous, inasmuch as it does not shout out about the damage which it is causing, whereas acute cases you cannot miss. The men who die of Bright's disease and the men who die of consumption in the lead trades are far more

numerous, when you take the number of those that are diseased in the ordinary population, than those who die of lead poisoning?—Then it is all put down to lead poisoning.

7924. I am only stating that in the lead-trade you have a proportion dying of consumption in excess of what you find in other trades, and that with regard to Bright's disease, which lead particularly causes, which is an affection of the kidneys, there again you have a proportion in excess of that for the ordinary population; therefore it follows that we should ascribe it to the influence of lead, wherever it is. These slow and insidious forms of lead poisoning are the matters on which we have to try and concentrate our attention?—May I suggest that the evil is somewhat magnified.

7925. Have you studied it?—I see what goes on in my own works.

7926. But you have already allowed that you know absolutely nothing about your own works in that respect?—That is rather a broad assertion.

7927. You have not compared it with the health of people in other occupations?—But I hear of very little illness in my factory at all. If I had known I should be asked that question, I should have given you the exact statistics for the last five years.

7928. Have you kept the exact statistics for the last five years?—Yes, I do not think there would be any difficulty in obtaining the figures.

7929. And a record of the age of each individual?—Certainly. There would be no difficulty in getting the age of the individual.

7930. It would be useless, without the age of the individual, because the amount of time lost through illness varies according to the age?—But you must not put every case of illness down to lead poisoning.

7931. I do not, but you can only compare the illness in one trade with the illness in another trade to find out where you are?—Of course that is the object of your Committee.

7932. Yes, to try and get such information, and we are finding very great difficulty in obtaining such information, because nobody seems to have paid any attention to the question?—I am sure I shall be only too happy to give you any information which lies in my power. If I had known, I would have had the information prepared, and I shall be happy to have the information prepared now if it will be of any use to you.

7933. The point is this, that you, in your evidence-in-chief, gave the distinct impression that you were giving very definite evidence upon the health of your workpeople. I am not in any way prepared to say for or against the statement, but I am bound to accentuate the point that the data on which that statement is made are incomplete?—Quite so; I may have appeared more emphatic than I should have been.

7934. (*Mr. Fell.*) When you questioned your 60 painters and rubbers-down about this white lead question, did you question any of your body-makers?—No, I did not ask the body-makers.

7935. Do you know that they are as liable to get white lead poisoning as the painters?—I do not see why they should, myself.

7936. They handle white lead in the jointing, and that sort of thing?—Yes, they do, to a certain extent.

7937. So they may suffer from lead poisoning?—Possibly, because they use the white lead in a more pure state than when it is mixed up for the painters, and that would go against them.

7938. Do you provide any washing accommodation for the body-makers?—Yes, in their department.

7939. For all men working in white lead?—Yes, certainly.

7940. (*Mr. Mason.*) Do you think that the evidence of the Daimler Company would be sufficient to justify this Committee prohibiting the use of lead?—I should say it would not be fair. They are only one of many other firms who are doing the business. I do not think it would be at all fair. I think we ought to have the experience of other firms besides that one firm. I think it was rather a broad statement. I do not think it could quite be justified.

26 May 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

7941. (*Mr. Kinggate.*) I am very pleased with regard to the evidence as to the care you exercise with regard to the health of your workmen. With regard to the Daimler cars, of course, you will admit that sometimes cars are painted hurriedly, and, consequently, not so liable to stand. That would occur with any firm?—Yes.

7942. At certain times that would be so?—Yes.

7943. Does the finish of a car depend upon lead? You have stated that you thought you could not get the finish on a car if lead was prohibited?—Unless some satisfactory substitute is found.

7944. Do you think the finish depends upon the use of lead? Its durability might, but does the finish depend upon the use of lead?—The finish must depend upon the durability of the groundwork which is put on the panels before you get the finish. Unless the primary coats that are put on the wood panel are good, the finish never can be good.

7945. But the use of lead as priming, first of all, cannot affect the finish?—It does materially affect the finish, and if I see a car that is finished, I can always tell whether that has been properly started on in the painting, and if it has not had the foundation of filling the result can never be good.

7946. I agree with you with regard to its durability?—I am not speaking of durability at all. I am speaking of finish. By looking at a panel I can tell whether it has been hurried in its earlier coats of priming.

7947. But supposing the grain is filled up from some other source, apart from lead altogether, so that there is no suction, and that the coats of leadless filling that have been placed upon it have been rubbed down, and then the proper coats of colour placed upon it, and then the due number of coats of varnish, the appearance of that car is quite equal to if it had lead upon it—in its actual finish. I am not contending that it might possibly not be so durable, but you made a special point that you would not be able to get the finish without lead?—Without lead, unless some equally satisfactory substitute can be found.

7948. Referring again to the Daimler Company, their method of filling up their wood panels has not been with sulphate of lead or any substance of that character at all. Lead has only been used in very small quantities when it has been used for painting the thing white. They only use zinc now. I do not think they use sulphate of lead at all. The filling up of the panels has been simply done with varnish and japan, so as to entirely stop the suction. You, I understand, to stop the suction in the panel, use priming coats of lead?—Yes.

7949. And they find that it is equally as good as lead for that?—That is their assertion.

7950. The witness who told us is a thoroughly practical man?—That is the assertion of one firm only.

7951. That is the assertion of a practical man with regard to that, that for two years they have stood?—That is the assertion.

7952. With regard to your workmen, Mr. Fell asked you the question with regard to whether the body or carriage makers were asked as to the number of cases of lead poisoning?—No, I did not ask any others than those employed in the painting shops.

7953. You quite understand that in the old carriage-making days the carriage-maker was subject to more lead than any other process. The whole of his work was always put together with lead and his plates fixed with lead?—Are you speaking of a carriage body-maker?

7954. No, of the carriage-maker?—Yes, that is quite right. There is lead put in between the springs, and all the bolts are put in with lead, and the clips and everything else, but there is much less used now.

7955. Apart from that, the body was generally taken into the carriage loft to be hung, and at the same time as he was hanging the body the painter was working on it, doing the priming coat?—Yes.

7956. So that he was subject to more lead than the painter was?—Yes, you are perfectly correct.

7957. The carriage-makers are practically a small body of men, but probably a larger number of them suffered from lead than the painters?—Yes.

7958. And the air was impregnated also with fumes?—Possibly.

7959. With regard to sand-papery, you must, I suppose, sand-paper your wheels between the different coats?—Yes. I dare say the spokes and wooden wheels would have to be, but you must also bear in mind that wire wheels are coming very much into use just now.

7960. I am only speaking, of course, with regard to wood wheels?—Yes, the spokes would be rubbed down with glass-paper between each coat.

7961. With regard to the chassis, there is also a good deal of stopping on the chassis which is rubbed down with sand-paper. There would be a considerable amount of sand-papery in the chassis shop?—We use a kind of stopping just to fill up the surface, and then we put the filling on it and rub down with pumice-stone and water.

7962. Do you rub the chassis down?—Yes.

7963. That is not usual, is it?—It is not usual, but it gives a much better result, and I always have it done that way.

7964. I am very glad to hear it, because I know in most shops there is a great amount of sand-papery done?—Yes, and I follow exactly the same method of filling up the chassis part as I do the body part, but, as you quite rightly remark, the spokes of the wheel are probably glass-papered.

7965. With regard to men being off ill, perhaps you have not been aware, prior to the statements you have heard to-day, of the very subtle influence of lead poisoning. It is quite possible for a man to be off a day or two and perhaps himself not know the cause?—Probably.

7966. Perhaps he has been in the habit of feeling very queer and taking a dose of medicine to put himself right in a day or two?—Everything is put down to lead, of course.

7967. I am speaking from many years' experience in the workshop, and I have known many cases of this character, where men have been off simply for a day or two. They have felt ill, and they have said, "I must have a dose of salts," or something of that sort. Many large firms—railway companies especially to-day supply a drink to the men, and so do some of the coach-making firms?—I have never heard of that.

7968. I know one big shop where there is a specially prepared drink for the men. That is, of course, to ward off the evil effects of the lead. So that some of your men may have been off from lead, and yet you did not know that they were suffering from lead?—I have never heard of that drink, but it is interesting to hear of it.

7969. I do not think your workmen have the fear, but there is a fear, we know, amongst workmen, of attributing their illness to lead for the fear of being discharged on account of the employer's liability under the Workmen's Compensation Act?—I have never heard of that.

7970. You may be aware that in one year a man may be working in your shop and the next year in a tramway works or a railway works?—Yes.

7971. So that we have to take the whole industry?—Yes.

7972. From the workman's point of view, we are all engaged in the same industry?—Yes.

7973. It is quite possible that a man to-day may be working in your shop, and the next day in the corporation shop, and in a week or two for a railway company?—Yes.

7974. So that we have to consider the whole trade?—Yes. It might happen that he might have worked in a tramway or railway carriage works, and have become impregnated with lead and come to us, and we should bear the blame of it.

7975. (*Mr. Robins.*) There have been remarks made before this Committee as to the carelessness of the men. I think you will bear me out, with your wide experience, that the men of to-day are more intelligent and cleaner, and more sober in their habits than they were 15 years ago?—Yes. I am rather inclined to look after the men and say to a man: "Are you going home?" He says: "Yes." I say: "Do not you think

26 May, 1911.]

Mr. ARTHUR FELTON MULLINER.

[Continued.]

"it would be better to wash your hands before you go?" He says: "I did not think of it." If a man does it once he does it another time, but you cannot force a man to wash his hands.

7976. I believe from your evidence you have 60 men employed in your paint shops?—Yes.

7977. What would be the average term of employment of those men; or is it an ever-changing department?—It is changing constantly. Sometimes there are more than others.

7978. So that if men were ill you would have little knowledge of it. Perhaps they are with you two or three months, I suppose?—But the men change themselves and they go off. We do not like to change the men if we can possibly avoid it. We do not dismiss the men, but there are many men who are birds of passage.

7979. With regard to the sand-papery, the point you emphasise in that connection is that there is very little sand-papery done. I take it from your evidence, with all respect, that you know very little about the paint shop, and that you leave that practically to your manager. I think, perhaps, if you were to inquire into the number of quires of sand-paper that were used in the paint shop with regard to painting, you would find it a little surprising. With regard to sand-papery mudguards, from my experience as a painter, there are very rare exceptions up and down the country, where mudguards are filled up and rubbed down, and I am glad to think that it is so with regard to your firm?—I have stated that I fill up the mudguards.

7980. From the very position and shape of the mudguards, in some cases it is impossible to do it, and then there must be a priming coat, and so on. With regard to the use of hot water, you said in your evidence that you did not think the use of hot water necessary for washing. I may have made a mistake, and I am open to correction?—I do not say it is not necessary.

7981. Are you aware that the paint of to-day is more or less of a quick-drying character, and that hot water is more essential than anything to get the paint off the hands. It is far quicker in drying qualities than it was years ago?—That is so.

7982. It is less of an oily character, and, therefore, hot water is very essential to get it off the hands. Should you consider that painting is a healthy occupation?—I do not think that painting is altogether the healthiest of occupations. I should say it is most unhealthy, even in the carriage-building industry. It is less healthy than in any other branch.

The witness withdrew.

Mr. WILLIAM LAWTON GOODMAN examined.

7995. (Chairman.) You are one of the witnesses selected to give evidence on behalf of the Society of Motor Manufacturers and Traders?—I am.

7996. Are you a carriage and motor manufacturer?—No, a motor body builder, and also a horse-drawn carriage manufacturer.

7997. Is your principal business in the motor body building?—Yes, largely so. That is our principal business.

7998. What length of experience have you had personally?—From my apprenticeship. I have been an apprentice, a journeyman, a foreman and an employer the whole of my life.

7999. How many men do you employ on work in which they come into contact with lead?—I could not give you the absolute figures, because in the body-building department the lead may be used probably for five minutes in three months by the body maker, but the number of men we employ all round probably average about 600.

8000. Can you tell us how many painters there are in that 600?—I should say probably the painters, the painters' labourers, and the men handling paint would be about 120.

7983. I take it you would consider the paint shop an unhealthy place to be in?—I do not say that my paint shop is an unhealthy place to be in at all.

7984. But still it is an unhealthy occupation?—There are many unhealthy occupations.

7985. Painting is an unhealthy occupation, but the paint shops are healthy. Is that what you say?—No, I do not say that. If it is an unhealthy occupation, the paint shop cannot be entirely healthy—that stands to reason.

7986. What would you attribute the unhealthiness of the paint shop to?—I should say it is from the odour of the paint used. There is a certain amount of odour from all paints—not necessarily from lead. You know that there is some odour from all paints.

7987. Then you would not consider that it was primarily from white lead?—No.

7988. I suppose you are aware that a large percentage of other colours contain a large percentage of lead?—Yes, I believe so.

7989. Then the primary cause you would consider was white lead, taking it all round, with all colours?—Everybody knows, of course, that many paints have white lead in them, and, therefore, probably the odour from the paints consists of a certain amount of odour from the white lead.

7990. Then you would consider that using white lead was unhealthy?—There is an unhealthiness in it. Everyone knows that. That is why we are here to-day.

7991. White lead is unhealthy?—Certainly.

7992. Then I take it that, if substitutes can be found, white lead should be prohibited?—We hope they will be found.

7993. I can speak from my practical experience. I have painted two carriages, and I say that they can be painted without white lead whatever, irrespective of the Daimler Company. I speak now as a practical painter. I have more than 30 years' experience. We have it from your evidence clearly that you consider that the painter's is an unhealthy occupation, that the paint shop is an unhealthy place, and that the cause of the unhealthiness of the painting is the white lead. After that, I should think you would be prepared to agree to use some substitutes for lead to minimise the danger with regard to painting?—I have said so, some time ago. It naturally stands to reason. Every employer would be willing to do the same thing for the benefit of his workmen.

7994. As a painter I am gratified to hear that, and I have had personal experience of the danger of it myself?—I certainly think it is the duty of everybody to do all he possibly can to protect his workmen.

8001. And a few of the others might be handling paint in the building?—Yes, they all would more or less, but Mr. Kinggate, being a body builder, knows the amount that is used and when it is used.

8002. But the whole of the 600 men might handle it?—No, the trimmers or the upholsterers would not be using it much.

8003. How many of the 600 do you think would come into contact with lead?—I could not give you the actual figures, but I should say quite another 150.

8004. How many cases of lead poisoning have you known?—I have not known of any.

8005. Not in your works?—No.

8006. Do you know that in the coach-building industry, in all branches, there have been 767 cases of lead poisoning recorded by the Home Office in the last 11 years?—I hear that has been stated, but we have never had any absolute proof whether these lead poisoning cases have really arisen in coach-makers' shops, because, as a set-off against that, we have taken a census of the coach-builders of the country, and we have no cases at all. I am rather inclined to think that those figures have been arrived at by including the coach painters who are employed in other trades

O 4

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN,

[Continued.]

than that of coach-building. On a former occasion, when we visited here, we challenged the statement, and it was volunteered to us on that occasion that it was made up of 322 in the railway employ, 42 in the tramways, 116 in the motor trade, and 44 in the miscellaneous, which included bird-cage painting and bedstead painting and a variety of other trades. As we are practically here on trial for manslaughter, having been charged with all these things, it is only right that we should really know how these cases are made up.

8007. (Chairman.) In the carriage building the number of cases of lead poisoning was 116?—During the last 11 years? I could not say with any accuracy at all. My association applied to every member of their institute, and they have received a paper signed by each, and the general census has resulted in no cases being reported to us. I cannot tell you the exact period, but as this circular is a printed one, and the questions are printed, they will demonstrate themselves on production.

8008. Did you get a reply from every one of your members?—I could not really say.

8009. As you want us to make further investigations into the Home Office figures, will you send to the Committee the replies you received from your members, and also a full list of the members that belong to your association?—Yes.

8010. Have you, as a society, taken any steps to test the merits of the different substitutes on the market?—Yes, quite a number of our members have already done so, one firm in particular, the Daimler Company, do not use white lead at all; they use some substitute.

8011. Have you instituted any inquiry as to the precautions necessary to combat the evil which exists in many branches of your industry?—We have fulfilled the obligation placed upon us by the factory inspectors.

8012. The regulations in force under the Factory Act to-day do not cover the whole of the evils which exist in the industry. I asked you whether you have taken any steps to combat the evils which exist in addition to those which are covered by the Factory Act?—My reply to that is that they are non-existing so far as my experience is concerned.

8013. Have you tried substitutes for white lead in your painting works?—No, we have not. Some of our friends have done so.

8014. I suppose you will agree that, if a substitute could be found that would be in every way as good as white lead, the use of white lead should be prohibited?—Undoubtedly.

8015. Do you know that for the past six years the Midland Railway Company have used no lead in their carriage and waggon works?—I attribute no importance to that at all, for the simple reason that the railway companies and tramway companies have only one customer to work for, and if it is not all right they simply do it over again, and they can afford to, whereas we, who are working for thousands of customers, must do it off our own bat and take the responsibility.

8016. You are aware that white lead is no longer in use at the Daimler Motor Car Works in Coventry?—I am.

8017. Do you hold that white lead is the most perfect substance that can be used?—I do.

8018. How does your work compare with the Daimler Company's motor bodies?—As regards paint?

8019. For the whole thing?—Speaking from a practical standpoint, taking the general parcel, I should say the difference would be between a taxicab and a C spring barouche in the park.

8020. But they are one of the largest firms in the industry, are they not?—Numerically yes.

8021. And they turn out work of the highest finish, do they not?—My answer to that is: query.

8022. The buyers of Daimler cars are of about the same class as the customers of your own or other leading coach body firms?—Much about the same.

8023. Would they not demand the same finish from the Daimler Company as from other firms?—I do not know. I should say they would demand it, but I should say they did not get it, most emphatically.

8024. The witness representing the Daimler Company told us that they are perfectly satisfied with the substitute they are using for all purposes for which white lead is commonly used in coach-building works. Are you surprised to hear that?—I am not surprised.

8025. Why?—The reason I am not surprised is that the Daimler Company's business is divided into two classes. First of all, there is the coach building, which is organised to make specific bodies in-series for chassis with as great expedition as possible, so as to enable their engineering works, with no delay ensuing, to place their goods upon the market, to enable them to get the quickest turnover on their money, selling, as they do, a complete car. Then there is the buyer who frequently purchases from an engineering firm a chassis, and thereupon sends it to some first class coach-builder to construct a carriage upon that chassis, giving him a long period of time to produce that body, in many cases four or five months. Hence the difference in the production of the work.

8026. The Daimler Company say they have used no white lead for two years, and they have had no complaints from their customers. It does not seem to me to matter very much whether the body is sent at one time or another. We have before us the fact that the Daimler Company have been using no white lead for two years and have had no complaints from customers?—The answer to that is, because the Daimler Company are manufacturers, and when they sell their car they very rarely see it back again at their works. I am correct, I believe, in saying that in fifteen-sixteenths of their business the repairing and repainting is done in other than the Daimler shops.

8027. But they say they have had no complaints from their customers. Surely if the material was ineffective they would have had some sort of complaint, and their business must have been injured?—On the contrary, it is just the ratio of degree of workmanship. I have had the Daimler painting under observation for the past three or four years, and in my opinion it is less durable than any other motor bodies.

8028. You are a competitor. I am speaking now of the customer. The customer, according to the Daimler Company's evidence, says that he is perfectly satisfied with the car as it is turned out, both with regard to its finish and its durability?—My answer to that is that it does not return to be done up, but it goes to a coach-maker's.

8029. But he would talk to people and find out that the necessity of having the car repainted was less with other firms?—So he does.

8030. But the business of the Daimler Company is just as prosperous, is it not?—Why does the buyer himself buy the motor from the Daimler Company and send the chassis to some coach-maker to build the body? Because he gets a better job.

8031. Do I understand you to say that it is invariably the case that the Daimler Company do not do the bodies?—No, in a general sense the Daimler Company build their bodies.

8032. How would you account for the fact that the Daimler cars, when turned out complete, should satisfy so many of the Daimler customers, if there is any defect either in the finish or durability?—I account for it in this way, that when a new car is finished the external appearance of it to the uninitiated might easily pass muster, and consequently the customer might express his satisfaction, and become the purchaser of it in that particular case.

8033. Do you not think that good work needs no bush, and that if bad work is turned out by any firm it is soon found out by the public?—I am not talking about the execution of the workmanship. I am talking about the durability.

8034. Not the finish?—Not the finish.

8035. Do I understand you to say that the finish is just as good?—Yes.

8036. It is only the durability you are speaking of?—Yes.

8037. What evidence have you to give us, of your knowledge, that the durability is not as good as those cars painted with lead?—The cars running on the streets.

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

8038. How do you know how long they have been painted?—If you take the genesis of the car from 1908 or 1907, and so on, the body would not be built before the car was made in the general sense. You can give them the full length of time, and take 50 or 60 or 100 of them which you can find running about London, and investigate the conditions, and take 50 or 60 or 100 of any other makes with chassis of the same period.

8039. I understand that you base your statement on what you see running in the streets, and set it against the opinion of the customers who have bought and paid for the cars?—Yes, who may be quite delighted with them, notwithstanding they have got a bad job.

8040. Do you contend that the danger of lead painting can be practically eliminated by regulating the various processes, that is to say, something to carry off the dust, and so on?—In my experience it is non-existent.

8041. Are you prepared to answer questions regarding the various processes in detail?—Quite.

8042. First, with regard to the body-maker; he uses jointing paste in putting together the different portions of the woodwork, does he not?—Yes.

8043. What material do you use for jointing paste?—White lead.

8044. Where a lead jointing paste is used, is there no danger attending it?—None whatever, except if a man has cut his finger and gets some in it, then he gets poisoned.

8045. In making up the paste, does the worker use dry lead compounds?—No, wet, mixed with oil.

8046. Then he can hardly avoid the lead paste getting on his hands and clothing?—Yes, he can avoid it.

8047. How?—By keeping his pot clean and his brush clean, but as a rule a lot of body-makers get the white lead pot smothered up with white lead, as much outside as inside, and the brush, up to within close to the top of it, smothered up with white lead.

8048. Is that an element of danger?—An element of carelessness on the part of the worker.

8049. Is that, in fact, an element of danger?—None whatever.

8050. But if the paint gets on the brush and it gets on to his hands, he may put it in his mouth inadvertently, may he not?—I can only give you my own experience of 35 years.

8051. I am not speaking about whether it is careless or not. Assuming that it is careless, and that the man gets paint on his hands and rubs it on his clothing, is not that an element of danger?—No, I should say not.

8052. Do you agree that the use of white lead is an element of danger?—The use of lead, in my experience, is not an element of danger.

8053. I am speaking of the lead which you say, by the carelessness of the man, gets on to his hands and then gets on to his clothes, and I ask you whether that in itself is not an element of danger?—If I must answer that question, I should say certainly not, from my experience.

8054. Do you say that he might not inadvertently put his fingers in his mouth and get some of the lead off?—I should say again it is not in any way dangerous, because he is intelligent enough not to do any such foolish thing.

8055. I am not speaking about that. I am speaking about the carelessness of a man who inadvertently puts his lead stained fingers into his mouth. You say there is no element of danger there?—I am not going to say that if a man eats lead it is not dangerous, because I suppose it is poisonous.

8056. Then you do think that, with a careless man, that might be an element of danger?—Yes, I suppose it would be very dangerous if he ate lead.

8057. Supposing the lead dust gets on to his clothes and then into the air and he breathes it, do you think that is dangerous?—Do you mean the dust of the white lead?

8058. Yes?—The white lead pot used by the body-maker will perhaps have 5 to 7 pounds of white lead at the outside in it, and it is in a liquid state.

8059. I am speaking of the body-maker. If he rubs his lead stained hands on his clothing, and it dries there, and dust is generated, is not that an element of danger?—I should say certainly not.

8060. Why is jointing paste used?—To protect the joints made by the workman and cover up the joints from attacks of wet.

8061. Are there not a number of leadless jointing pastes in use?—I could not tell you.

8062. The carriage-maker or body-fitter attaches the iron work to the wood, does he not?—Yes. I take it this is the under-carriage of a horse-drawn carriage you are speaking of now?

8063. Yes. He uses lead in this operation in the same way as the body-maker, does he not?—To some extent.

8064. Is he likely to get that on to his hands too?—No.

8065. Why?—Because the old-time coach-builder put white lead on to plates and on to compass beds, and then put it on to bolts, and he was splashing about with it, but that was done away with 20 years ago, because it used to exude and show the white edges, with the result that the beds are painted and are allowed to get dry and then put together. It is a better job. If you are talking about 25 years ago, then he was splashing white lead about all over the place.

8066. But is he not just as liable to get it on to his hands as the body-maker?—Yes, I should say about equally the same. I should like to say in answer to that question, that that type of business is eliminated by the motor, and so far as the workman is himself concerned it is very small indeed. That branch of the business has been killed by motor cars.

8067. But where the work is still in existence, the man runs the same risk if it gets on his hands as he does in the other?—Yes.

8068. When the carriage is ready for painting, is it first given priming coats?—Yes.

8069. How many coats?—Four coats.

8070. Does the priming you use contain lead?—It is a lead colour.

8071. Is the work sand-papered between successive priming coats?—No, not after the first coat.

8072. Between which coats is it sand-papered?—The only process of sand-papering on the body is anterior to its getting any paint at all.

8073. But after the paint is on, is there no sand-papering?—Sometimes, if the filling has been put on course.

8074. Can you dispense entirely with sand-papering between priming coats?—Yes, undoubtedly, by using a fine Grafton paint.

8075. Does not that create dust?—No. The filling as supplied by —'s is in various strengths, that is to say, some is like flower pumice, and some is very coarse. If you mix up the coarse filling you get a lot of nibs or lumps on it, and they have to be sand-papered down before they can get the other coats on.

8076. Tell me what proportion of this particular work is sand-papered down?—With regard to the body, none of it at all—not after it has passed from the body-maker.

8077. I am still talking of priming. You tell me that there is no sand-papering between the priming coats?—That is right.

8078. Is there any part of this particular operation where there is any dust created in priming?—No, provided you do no sand-papering, certainly there is no dust.

8079. But is there any other operation similar to sand-papering—any other material used which generates dust to any degree?—If the body has been standing, and you want to make a good job of the painting, you do the filling and you come to the painting in three or four days.

8080. I am coming to the filling in a moment, but I am speaking about sand-papering or anything similar to that at this particular stage of the operation?—This is after it has left the body room and had a coat of colour?

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

8081. Yes?—No, no dust whatever, only what there is in the shop, and that would be dusted off with a duster.

8082. Is it the general practice in coach painting to sand-paper between the various priming coats in other shops?—No—on under-carriages, yes.

8083. But not on bodies?—Not on motors.

8084. Could sand-papering of priming coats be prohibited altogether? Could we lay down a special rule that no sand-paper whatsoever is to be used for priming coats on bodies?—Absolutely, up to the wet rubbing down. You would clean it up before you put the lead colour on.

8085. The body next receives a number of coats of filling, does it not?—Yes.

8086. Do you use a leadless filling?—No, we use a Grafton paint.

8087. That is lead, is it not?—Yes.

8088. Why is lead frequently added to the filling material?—The lead is put into the filling material to give it greater body.

8089. The filling is not rubbed down, between successive coats, is it?—No.

8090. Now with regard to stopping: What stopping do you use on coach bodies?—None at all.

8091. Is it the practice to use hard stopping made from dry white lead and gold size?—No.

8092. Does your answer apply to all coach bodies?—Motor body building you are speaking of now in particular, are you not.

8093. Yes: Does your answer apply to ordinary carriage bodies?—To the bodies, yes.

8094. In regard to carriage bodies, in the process of mixing, there must be danger arising from handling the dry lead powder?—Yes, when you are making the stopping, but the stopping is a process of painting which is not used. Stopping is made of dry white lead and gold size and put on with a putty knife and then sand-papered off. That is the dry process, but it is not employed.

8095. When it is applied to cheap work, or to quick work, as you have told us, there is a distinct danger in it. What safeguards would you suggest should be introduced to protect the worker against this danger?—I do not use it, and I do not think any other coach builder or motor builder uses it at all. It is chiefly used in cab shops, which are generally small places. The only way you can get rid of it is to have a fan or something to drive off the dust that is created, because you have clouds of dust from it if you have a lot of it.

8096. Would you agree to the prohibition of anything like stopping?—I should. I think it is very dangerous.

8097. Now with regard to rubbing down. After the filling has been applied, is the whole surface rubbed down?—Yes, it is.

8098. Is this done with pumice stone and water?—Yes.

8099. In every case?—In all cases, excepting where one has to do one of those quick, cheap jobs, such as with sand-paper stopping, which I will not do—I will not have it.

8100. There are some firms that have to do these quick, cheap jobs?—Yes, they do.

8101. In that case there would be an element of danger?—Yes, there would undoubtedly.

8102. Have you nothing to suggest to mitigate that danger?—Only exhaust fans to take the dust away.

8103. Is that practicable?—It depends entirely on the place. As a rule it is generally done in a little place, the size of this room. Somebody up in a back shed is generally doing that work.

8104. The carriage under-work is generally sand-papered, is it not?—Yes, always.

8105. And the wheels?—Yes.

8106. This sand-papering gives rise to a great deal of dust, does it not?—Yes.

8107. Does this dust not contain a large proportion of lead?—Yes.

8108. A considerable amount of hard stopping is used on wooden and artillery wheels, is it not?—No, there is some used, but not a lot of it.

8109. A certain amount?—Yes, I agree.

8110. And on the wood-work of the under part of the carriage?—Yes.

8111. The sand-papering of such surfaces must create considerable dust?—It does.

8112. And there is lead in the dust?—Yes.

8113. How is this risk to be overcome?—By having proper workshops.

8114. Proper workshops with exhaust fans?—I do not think you want exhaust fans. General ventilation will do.

8115. In the earthenware and china industry in which investigation was recently made, the Committee, comprising both employers and workpeople, agreed that exhaust ventilation should be applied adjacent to every piece of work where dust was likely to be generated, and I presume that the Home Office would require similar precautions to be adopted in your industry. I ask you whether it would be possible to apply such exhaust apparatus to your trade?—No, I think not.

8116. How long does this operation of sand-papering wheels and carriage under-work take? What proportion of a man's time, generally speaking, if he is engaged on motor-car building?—Motors in many instances have wire wheels and not wooden wheels, and the only sand-papering on a motor car is on the wooden wheels. In some shops the chassis wheels are sand-paper stopped, and in others they make a good job of them and fill them up.

8117. You told me that there is a considerable amount of dust generated from this process?—Yes.

8118. What I want to ask you is, how are we to get over that evil?—You cannot get over the evil and prevent the dust. The dust is bound to arise from the process.

8119. And it is very heavily impregnated with lead?—It is really sand-papering the lead.

8120. It must be a serious source of danger?—No, because the time that will be occupied over that job on a set of wheels would be two hours.

8121. Two hours a days?—Yes, on a complete set of wheels.

8122. Do you mean to say by that, that he would only take this dangerous dust in small doses?—That is all.

8123. But you know that this evil has a cumulative effect, and if you take it in small doses it is only a question of time before it begins to act?—My suggestion as an alternative to that is to box off a portion of the factory where that process must be done in, and done in alone, and ventilation could be admitted into it to suit the requirements of your Factory Inspector.

8124. Could you introduce such exhaust ventilation as a matter of certainty to carry off the dust from the worker?—You would have to have a fan up against him, to blow it away—and the man as well, I should think.

8125. You do not think that is practicable?—No.

8126. Could the process of sand-papering be prohibited altogether?—It could be, but it would not make as good a job, because you could not stop up the holes and bumps that the wheel-makers leave. In these oak spokes, coming off the lathe as they do, there are holes and bumps.

8127. Is your conclusion, with regard to this particular operation, that there is an evil, but that there is no remedy for it?—That is the remedy I suggest, that a portion of the works is set apart.

8128. But you only confine the man to a small area of the evil?—That is much better than impregnating the whole body. Supposing you have 500 men in the works, and this one is doing that one process, if you go in for legislation, you do not want to say you must legislate for the 500, but legislate for this one, and make provision.

8129. But you say, so far as you can tell us, you can make no provisions for carrying away the dust directly from this man?—No, I cannot.

8130. Now with regard to the roofs: Do you finish the roofs of your close cars with canvas or moleskin?—Yes, we cover the exterior of them with moleskin.

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

8131. How is that bedded?—It is put on in some instances by dextrin, and in other instances by liquid glue.

8132. Is it not usual to bed the canvas in white lead?—No.

8133. Have you heard of it being done?—Yes, 25 years ago.

8134. Where it is done, could it be prohibited altogether?—In practice it is never employed to-day.

8135. It could be prohibited, then?—Certainly.

8136. Now I will ask you a few questions about the precautions which must be taken where lead is used. Do you attach importance to cleanliness on the part of the men?—Undoubtedly.

8137. Do you provide washing accommodation?—We do.

8138. What proportion of basins to the number of men employed?—The only answer I can give you is that the requirements of the local factory inspector are fulfilled.

8139. There is no regulation?—Yes, there is a regulation.

8140. Only that water for washing shall be provided, but there are no regulations as to it?—We are willing to supply it to a man if he wants it, and if he will use it.

8141. That is not the question. What are you prepared to do?—We are prepared to provide whatever is necessary for the cleanliness of the men.

8142. Hot water as well as cold water?—Yes.

8143. Are clean towels supplied regularly every day?—Yes, with nails on them to nail them down.

8144. And nail-brushes and soap?—Yes; we have them chained up.

8145. Is time allowed to the men for washing before leaving off work, and before meals?—Yes.

8146. How long?—Ten minutes.

8147. Out of the employer's time?—Yes.

8148. Is a room provided for the men to take their food?—Yes, which they will not use.

8149. Is this room kept clean, and equipped with suitable seats and tables, and properly warmed in winter?—Yes.

8150. Where do they have their meals if they do not use the mess-room?—They have their meals on the bench by the side of their job, or on their tool box.

8151. In close contact with the lead dust?—At the side of it. To give an illustration, I have had to issue an order that I must close the works during the meal hours. Although I have a dining-room, and everything provided, and a gas cooker and all that kind of thing, they will not use it. They sit by the side of their job, and in the paint room they are absolutely sitting by the stone that the colours are ground on—sitting on the brackets of the gig, taking their food, although the dining-room is there provided for them, and empty. I have to lock the works up and say, "You are either going to use this dining-room or going outside."

8152. Of course, it is against the law to-day to allow them to eat their meals close to their work. You are breaking the law to-day?—We cannot help it.

8153. Do you provide overalls for your men?—No.

8154. Do you think it necessary?—No.

8155. Is there not a tendency, if they have not overalls, for the dust to get on to their clothes?—They have to buy them. They get paid enough wages to buy their own overalls.

8156. In other industries it has been enacted that men are to wear overalls?—I should make painters wear them too, if I had to deal with it.

8157. In other industries they are provided at the expense of the employer, and washed by the employer. Would you agree to that?—I would not. You might as well ask us to wash the body-makers' aprons.

8158. Have you impervious washable floors in your painting shops?—They are concrete, but I wish they had been wood.

8159. So they can be cleaned down very easily by swilling?—Not so much dust arises from it.

8160. You can swill it down very much easier with impervious floors, can you not?—You cannot make

good painting except on wooden floors. I would like to make a point of that, because I am going to build a new paint room.

8161. Do you clean your floors wet?—Yes.

8162. Suppose you had wooden floors, would you still have them cleaned wet?—I would.

8163. Would it not be rather uncomfortable for the men to have to stand on them afterwards, while they were wet?—I should have them cleaned once a week.

8164. What are the usual hours worked by your painters per week?—53 hours a week.

8165. Do they frequently work overtime?—Yes.

8166. What is the aggregate amount of time they put in now, including the overtime?—The average is, I should think, about 40 hours per week.

8167. What is the maximum number of hours they work?—I should say they are working now in some shops—it all depends on the shops—65 hours a week.

8168. Would you welcome a strict limitation of the hours of employment, say, not to exceed 48 hours per week?—I should not.

8169. I may remind you that this has been recommended by the Potteries Committee—both employers and employees. You would not agree to that?—That is impossible, for this reason, that in coach painting, or motor painting, the body-maker, perhaps, has, at 5 o'clock, got the body ready for a coat of paint, and it takes the painter two or three hours to paint it, and the man has to go on with the job. You save a day on that. It is different in potteries, where you are turning out tea cups.

8170. Do you have a periodical medical examination of your workers?—No.

8171. Do you know that in other industries where lead is used, the Home Office insists on a monthly, or even weekly examination by the certifying surgeon, at the employer's expense?—My suggestion is that, if every workman is examined by the doctor before you engage him, if you are using lead, the result will be that you will throw your workmen into the streets. People will not engage them. That will be the result of it, because they are probably a lot more susceptible to the collection of lead poisoning, not due to the employer probably, but probably due to physical disabilities, possibly through their constitution, and possibly through their own manufacturing during their lifetime. Consequently we must have them examined when we engage them, which will be bad for the worker.

8172. Would you agree to have a periodical medical examination of your workers during the time they are at work?—No, I should certainly not agree to it.

8173. This is in vogue to-day in the majority of other lead industries?—I would like to qualify it in this way, that I am dealing with this question of lead as relating to every coach-maker who is employed in a coach-maker's shop, not the coach-painters only, because lead is used in every nook and corner, with a touch on the bolt head here and that kind of thing, and although there is only half a pint used in a great big room during the day, if a man moves from one portion of the shop to the other portion, the other men, according to what I have heard to-day, come under the scope of that operation. That is why I say I am not agreeable that the men should be examined by the doctor at the employer's expense, and in the employer's time. It is a different thing with the painter.

8174. Do you agree to that, in regard to the painters in your industry, there should be a periodical medical examination of the workers at the employers' expense?—I do.

8175. Then in regard to the other workers who handle lead, but in less quantities than the painters, would you agree to a periodical medical examination of them?—No. They might overcome that by sending a painter to paint the joints, and leave the other men right out of it.

8176. Would you agree that those workers who handle small quantities of lead to-day should be prohibited from using it?—From using it altogether—yes—I should quite agree to that.

8177. So that those particular men would not come under the category of employment in dangerous

26 May 1911.]

MR. WILLIAM LAWTON GOODMAN.

[Continued.]

processes?—I should recommend it very largely, that the body-makers should be excluded—that motor body builders and carriage builders, and all other branches of the motor or carriage building trade should be excluded from using lead in any form, the lead to be only applied by the painters, and their labourers?

8178. Would you agree that the men so excluded should not be in the same shop as those using lead?—That is impossible—absolutely.

8179. I suppose you have realised by this time the very great expense which the industry would have to bear in connection with such stringent regulations?—I have.

8180. There seem to be only two ways of mitigating the evils which we have had before us in your industry. The first is to prohibit the use of lead altogether; the second is to introduce a code of regulations which will bring this industry, in regard to care for the workpeople, up to the standard of all other large industries where the use of lead is permitted?—I entirely concur with that.

8181. I will just give you an indication of what those special regulations would be. First in regard to lavatories. The regulation would require washing accommodation to the extent of at least one basin for every five workpeople; soap and nail-brushes to be provided and properly looked after; sufficient clean towels to be provided every day. Then a mess-room to be provided so as to make it impossible for the workers to have meals in a place where they come into contact with lead?—You could not apply that to small coach-makers' shops, because you cannot afford a mess-room. That applies to a lot of people like myself.

8182. What do you suggest as an alternative?—Insisting on the men going out to their meals. That is all that could be done.

8183. Is it possible to provide a mess-room generally?—Yes, in all the large works, but in the small works it would be impossible.

8184. In that case you suggest that the workshops should be closed, and that the men should have to go out, and have their meals outside?—Yes.

8185. The next thing is: cloak-rooms to be arranged so that it should be quite certain that the men's outdoor clothes do not come into contact with lead?—We cannot do that. We tried that. What happens is, that in a coach-builder's works you have a great variety of different classes and conditions of men; and you have all their coats in one place, and the numbers up for them, and they must leave their coats in those particular places. The result is that the body-maker says: "I am not going to conform to this arrangement; my coat will come into contact with other coats, and it might get dirty; I am going to take it upstairs."

8186. Cloak-rooms to be arranged so that it should be quite certain that the painters' outdoor clothes do not come into contact with lead?—I agree to that.

8187. The next thing is: overalls to be provided at the employer's expense, and washed at his expense?—No, certainly not—not on any account.

8188. Washable-impervious floors to be introduced so that they may be swilled down regularly every day?—It is too much expense, it could not be done—and they must be wooden floors for paint rooms.

8189. That is putting the clock back?—No, it is the experience that we have got. We have passed your time-piece, and we are going back to the wood now, and getting a better job.

8190. It has been proved beyond question that wooden floors suck up the dust. You cannot thoroughly clean a wooden floor by the wet process; it is impossible. If you put a hose on the floor, or if it is done with a brush, you do not get all the stuff away; it dries up, and then it is kicked up again when it is dry?—But you cannot get away from the fact that we know that the best varnishing is done on a wooden floor, better than on the other floor.

8191. Then a periodical medical examination to be made of each lead worker at the cost of the employer?—We agree to that—each worker in the paint room.

8192. Together with payment of compensation whenever a man is withdrawn from work in lead?—We already have to do that now.

8193. You have to do it if he were certified as having contracted lead poisoning, but in the potteries it has been enacted, and the employers have agreed, that if a man is suspended by a certifying surgeon because he thinks he is very near an attack of lead poisoning, then the employer has to keep him going a bit?—That would result in a tremendous lot of malingering, particularly when trade is a bit quiet.

8194. It is the doctor who decides, not the man?—No, I do not agree to that at all; in or out; let us have a case or none.

8195. Then: efficient exhaust draught apparatus for the removal of dust to be installed wherever it is possible to apply it?—I agree with that, to keep the place clean. Where you have got dirt you have got waste.

8196. You must also take into account the cost of setting up a system which will secure continuous observance of all these regulations, for you realise that under the Factory Acts the first duty is laid on the employer of securing the observance of the regulations?—I tell you distinctly that the manufacturer may provide all you require, and you may make your regulations, but in practice, my experience of 35 years, in handling thousands of men, is, that there are, amongst them, men that will not conform to the regulations, and you must make it penal.

8197. There are regulations under the Factory Acts existing to-day which you do not carry out. I only want you to understand that with regard to any new code of regulations, the employer will be responsible for securing the observance of the regulations?—I entirely disagree. Any new regulations that are brought into force for this must be carried out at the instance of the factory inspector, who will be solely responsible. He must see that they are carried out, and not the employer, because the employer fails to do it, or his foreman fails to do it, and nothing will reach it or touch the spot except the Government themselves.

8198. Let me point out to you that it is a question of the proper interpretation of the existing Act of Parliament—that the employer shall see to the observance of the requirements?—It is manifestly unfair.

8199. Then you must get it repealed?—The position is, as far as you are concerned, if you frame regulations for the general safety and welfare of the masses, you should say to us: "You have conformed with all our requirements because you have placed a man in charge and told him to see that the men under him do those various things, and he has assured you that they have done it."

8200. Then you have done all that you are asked to do?—But what is the result. What you want to do is to alter the conditions. The conditions are the same although we are put to all that expense.

8201. If you are allowed to use lead in the future, you will have applied the same sort of regulations as exist in other lead industries. To-day you have only the general Factory Act, which you have broken already?—We always break it every day. It is not the rank and file, it is the submerged that cause all this trouble. As an employer, with four or five different places, I entirely disagree with any arrangements or any obligation that is to be placed upon the employer to see that the workman fulfils his side of the obligations to the State. You say to the employer: "Provide so-and-so, and so-and-so." He does it; he give the men time to do it in, and if the man fails to fulfil that obligation which he owes to the nation, then the nation should say: "Account to me," and not go to the employer and say: "Come this way, Mr. Employer, that man over there has been too lazy to wash, and you must go to gaol, Mr. Employer."

8202. You have conformed with your part of the law if you have provided the accommodation which the Factory Act insists upon. If the man refuses to obey that law, then he is the responsible person, and he can be prosecuted, and not the employer. The law cuts both ways. If you find any workman who has refused to conform to all the regulations of the Factory Act, the factory inspector can prosecute him; and, *vice versa*, if you refuse to conform, the workman can inform the factory inspector and you can be

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

prosecuted?—The question is, what are the results obtained from it, and my contention is that whatever you put down there as regards the provisions, you have got to have your factory inspector behind it to see that it is carried out.

8203. You would want a factory inspector in every factory. You would want about 20,000 factory inspectors, and at present there are 200?—I do not think that matters, does it.

8204. Taking all those points into consideration, and having in view the fact that we must introduce some remedies for the evil which undoubtedly exists, do you still consider that it would be better to regulate the industry by these special rules, or would you, as an employer, rather see the use of lead prohibited?—The answer to that is, that the policy that you have outlined is a destructive policy without any constructive policy in return. We know from experience that lead has been the foundation of our good work, and if you are going to legislate to prevent its use you will place us in an unfair position with our competitors from France, Belgium, and America, who will undoubtedly, from our 35 years' experience, produce more lasting work by using lead than any of the substitutes, or the substitute which we have had under observation as used by the Daimler Company, the result of which will be that the manufacturer and the workman would alike lose business.

8205. But you realise, do you not, that this Committee has been called together to find some solution for the evils which the Home Office have found to exist. What I ask you is this: Would you prefer that the industry should have special rules introduced to protect the workpeople, such as I have foreshadowed, or would you prefer the abolition of lead?—I should prefer the abolition of lead, provided you can prove to us that we have got an alternative non-poisonous paint, which can be used to produce the same work.

8206. That is not an answer to my question. The question I asked you was this. The evils exist, and there are two alternatives. One is to prohibit lead, and the other is to have regulations. I ask you which you would prefer to have?—Regulations, undoubtedly.

8207. (*Dr. Collis*.) You have spoken of white lead as being the most perfect substance you know of to-day for use as a paint. How do you define white lead?—I am not a chemist, and I know nothing about its chemical attributes. My experience of white lead is based on my business knowledge, and the use of it for the period of my lifetime, and upon the durability of the work that has been produced on its foundation.

8208. But it is important for us to be able to know what exact substance has been referred to. Are you referring to process white lead, stack white lead, chamber white lead, or basic sulphate white lead?—What I am referring to is wet white lead.

8209. I have given you four forms of it?—I can answer to none of these, because I am not a chemist. If you want an analytical examination of the lead we use we should be pleased to provide you with it. I can only tell you that pure white lead, as sold by —, has formed the basis of my paint.

8210. You use — white lead?—Yes.

8211. — is stack—the old Dutch process. Then would you be prepared, for instance, to cut out the other three?—I do not know of any—only pure white lead as I use it.

8212. Those are pure white leads that I have mentioned to you?—I am afraid I should be a very poor witness to give you any information with reference to the scientific or the chemical properties of white lead. I can only tell you that the white lead that I use is what is called pure white lead, supplied to me by —.

8213. But there are other white leads besides —, and they are pure white lead, within the definition in the trade. I want to know exactly what it is you want, and what it is you are prepared to admit?—I do not profess to have any chemical knowledge of the matter at all. What I do profess to tell you is, that in my 35 years' experience the article which is sold commercially as pure white lead by — is, in

my opinion, the best form of paint to withstand the attacks of the elements. As regards whether it answers any of those four names, chemically, I do not know.

8214. What is your experience of the other articles, since you have not used those others—what is your position in saying that is better than the others?—I know nothing whatever about that.

8215. Is it not a rather bold statement to say that one article is better than others when you have not used them?—No, I am speaking of pure white lead now.

8216. I am also speaking of pure white lead?—I am afraid we are running at a tangent, because those various leads which you are speaking about may be all understandable to you, but to me they amount to nothing, because my lack of education as regards the product is one that I must deplore; but so far as my commercial knowledge goes, I can only say, as I told you before, that I am using a white lead which is sold to me as pure white lead.

8217. But you have made the statement that this is the most perfect substance on the market. What I want to get from you is, what is your experience of it being more perfect than others, if you have not used those others?—My experience is, by comparing it with non-poisonous leads—it may be some of those names which you speak of—which are used by some of my friends and competitors in the business.

8218. Do you mean non-poisonous paint?—The Daimler people call it non-poisonous lead. I have not tried that.

8219. The point I want to get from you is, the extent to which you yourself have made experiments with any other paint than — paint, which seems to be the one which you prefer?—I have used other people's white lead.

8220. I want to know how far you have used paints not containing lead, and whether your experience of the others not being valuable is merely based upon what you have seen of other people's work?—From observation.

8221. Not from any experience of your own?—None whatever.

8222. Now, on the question of the health of your workpeople: do your men stay with you always, or do they come and go?—Some of them stay with us always, and some come and go. I think, taking it as a shop, our men have stayed with us longer than in any other shops in the kingdom.

8223. What is the longest period that any man you have with you has stayed with you now?—I should think about 25 or 30 years.

8224. Have you many men who have been with you as long as that?—I daresay we have 100 or 120 men who have been with us 14 years on the average—some longer.

8225. I suppose a man's working period of life commences about the age of 20?—Yes.

8226. How long do you expect a working man to live?—I have no idea of mortality tables. I am not in the insurance world at all. I can only tell you that I have apprentices with me who are now foremen, and charge hands, who have been with me all their life. They have been with me from boys to old men, and they are still with me. They are part of my family, and they will probably be with me till they die.

8227. How old are they?—55 and 60, and so on.

8228. Do you expect them to die soon?—I hope not; they have just got their experience now.

8229. This is the point I want to get from you; when do you think they should die? We find the average length of life in various employments varies?—Yes, but a coach-builder is under cover, and it depends entirely on the shop he is working in, and the conditions. If a man is in a constant job, and has a decent shop to work in, as he has in a good number of shops in the country, and his home is set up, that man has a fairly happy, peaceable, long life; but if he is moving round the country on the tramp it is different.

8230. I want to get from you what you consider is a long life?—You are asking me a question which is

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

quite outside the scope of my observations. You are asking me to focus the mortality tables of the working classes.

8231. That is a very important part of this inquiry. Have you any knowledge of it?—No. We can give you an idea of it if Mr. Kinggate will turn up the United Kingdom Society's pension list.

8232. We have got that, but we want it from you. You have made some statements with regard to the health of the workpeople, and your experience may be a very different one to that. You have given 35 years as a long period of employment. I have just had reason to make some inquiries in Nottingham in the lace trade, and I find on an average that is rather short; 50 to 60 years of employment is quite frequent?—That is quite a different business; it is not analogous at all to this question, because the painting side of the business is one of the most transitory sides of the carriage building business, because there is the flotsam and jetsam, and the ser on business.

8233. I asked you that point to start with, whether any of them came and stayed with you?—They do.

8234. Then you ought to have many of them who have been employed 50 or 60 years?—I do not think so, because we made the business ourselves, and we have not got to those ripe years ourselves.

8235. On this question of the health of your workpeople, have you studied the question at all, as to the amount of time they have lost for anything whatever? I am not referring to illnesses certified as lead, but time lost for illnesses?—No, I could not tell you the time lost for illnesses. It is not of very great moment, and it cuts no particular figure compared to the time that is voluntarily lost for pleasure and enjoyment. I am speaking now of Lancashire, where some of the men will lose a week-end or three days to go to a football match.

8236. But you do not, in fact, keep any statistics of the reasons why your men are away from work?—No. If they are away from work too much, we say good-bye to them.

8237. It might be that they were staying away not for football matches, but it might be that they were suffering from recurrent headaches and general feeling of malaise, which kept them from work, and they stopped away from work too much, and you let them go. Would not that be so?—I should say certainly not.

8238. Why not? How would you know the difference between the two?—If a man is suffering from a very violent bilious attack or malaise, or all those headaches and different things, it arises from a very heavy Saturday night in a good number of cases, because most of the time that is lost is on a Monday, when the man has had time to rest.

8239. May I quote the Registrar-General: "Coachmakers are but little addicted to alcohol"?—I agree.

8240. Then we will leave that on one side. I think that is an absurd and perfectly unjustifiable attack on the working man?—You have not had experience of the painter's labourer, and that is the man who comes under this inquiry.

8241. In other words, I take it you have not studied the health of your workpeople closely?—Very.

8242. Will you state in what way?—When a man is ill I get to know about it, and I look into the matter, and I help him if I can. I have no cases of any moment brought under my notice from breakdown of health except in cases of accidents.

8243. But have you kept statistics? The loose statements that we have received from witnesses with regard to the health of their workpeople have been rather astonishing, inasmuch as they have not studied the question, because they have not kept the figures?—Everyone keeps the figures, for the simple reason that you keep a man's record of his time that he works, and there is the wages book there to show the time he works.

8244. But the reason why he is away is not kept on record?—No.

8245. You are no exception to the other trades. Are you, therefore, in any position to make a statement

about the health of your workpeople?—If the absence of the workpeople is to be the standard on which you reckon their illness or health, I say we are in a position, because our wages book shows the time that the men work; and the average time of the man who is in constant employment, or an itinerant labourer, even if he is only there a portion of the time, is a pretty full week; but there are lapses, and you can see that in the books.

8246. Let us take the point now as regards illnesses caused by lead. Are you aware that lead affects the kidneys?—No, I have no idea of what effect lead has on the human anatomy. I am not a doctor. I am afraid, as a manufacturer, with 35 years' use of lead, commercially and practically, it would be impossible for me to epitomise what effect that has on the human frame.

8247. Not having had information, it seems rather bold to inform the Committee, as you have done, that various processes are harmless?—We can only base that calculation upon lifetime experience.

8248. And your lifetime experience has not been a study of the health of the workpeople?—But they are with us still.

8249. It only runs to 35 years?—That we consider quite a long time.

8250. That is curious, because in other trades it is not a long time?—Do you suggest that 35 years is not a long service for any workman with any firm?

8251. I do not consider it very long. In other trades—and my experience is very fair now—I have examined thousands of workpeople, and asked them the length of time of their employment. Taking one that I was at only at the beginning of this week, 45 and 50 and up to 60 years was not unusual?—I quite agree, but in a trade like the carriage building trade, of which I have the most immediate knowledge, I suggest to you that 35 years is a very long service.

8252. I perfectly accept your statement, and therefore I say there must be something in the nature of considerable ill-health among the workers if 35 years is a long service?—No, the men move about more in the motor and carriage trade than they do with a lace machine, because they take their tools in a box, but they cannot take a lace machine about with them from one factory to another. The coachbuilder moves from London to Birmingham, and right about, but the lace people do not. I should say that my experience of coachmakers is that they generally live to about 60 or 70. That is the average life of coachmakers. We have some of our old pensioners who are over that.

8253. You drew a distinction between the work of 20 years ago and the work of to-day, did you not, in the carriage making? Would you allow that the Registrar-General's class: "coach, carriage, and railway coachmakers," in any way represents the class with which we are now dealing? For instance, how many people would you estimate to be employed 10 years, or 20 years ago, before the motor industry came in, in coach and carriage building?—I have not the remotest idea. I am a small manufacturer. I do not know what the railway companies keep.

8254. Do you think it is probable, taking it from its name, "coach, carriage, and railway coachmaker," that the people included under that head would be exposed to any risks that the men would be exposed to in the class that we are now dealing with?—The painting.

8255. Yes?—No. I should say that it is a trade without any dangerous risk in it.

8256. Referring particularly to lead poisoning, you think that they represent what we are dealing with: the coach and carriage painter?—Yes.

8257. It will interest you to know that the mortality from lead poisoning was exactly the same as in the previous 10 years, while there had been a considerable fall in mortality from other diseases. My point is, that the general condition of health, due to rise of wages and better food, shows a distinct improvement in health, but lead poisoning has stayed at exactly the same figure during the two periods?—Yes.

8258. You were telling us that you made a great point of it that 20 years ago there was a great deal

[26 May 1911.]

MR. WILLIAM LAWTON GOODMAN.

[Continued.]

more lead being thrown about and likely to cause more trouble?—Yes.

8259. Then how do you make your statement coincide with the Registrar-General's statement?—Because my statement referred to coachmakers' shops, and I did not include, neither have I any knowledge of, the grouped trades which you have down there.

8260. I asked you if you allowed the group as representative, and you said distinctly, yes?—Coachmakers' shops is what I am dealing with.

8261. You also suggested that if a medical examination was instituted, the result would be to throw many men into the street?—Undoubtedly.

8262. On what do you base that statement?—On the fact that there are a tremendous number of painter's labourers who use lead.

8263. Let me suggest to you that this medical examination is insisted on in the white lead trade, where there is a great deal of casual labour. There is probably more casual labour in the white lead trade, where those regulations are in force, than any other trade. Casual labour occurs, not so much in the pottery trade, where there is medical examination, but it also exists in the tinning, in the manufacture of paints, and several of the other trades. Your statement that men would be thrown out on to the streets has never been found to be justified by our previous experience, when the medical examination was installed. I allow that it is a point that we have been told is going to occur?—And it will occur undoubtedly.

8264. It has not occurred before?—It has occurred in lots of industries.

8265. It has not occurred to my knowledge?—I do not know about the trades you are speaking of, but you have to put yourself in a commercial position in looking at this thing, as well as a humanitarian position. If you are going to have your men examined, you will have to examine the men who have been with you, and the itinerant labourer and the casual labourers who have come to your place and have been there one month, laden with lead—if we are to carry out the theory that lead is poisonous. They start with you one month and they develop this, and the responsibility rests with you. The employer will naturally say: "You must be medically examined before I take you. You must be medically fit." Consequently they will say: "You can do your work all right, Tommy, but we are sorry you cannot pass the doctor"—and Tommy is in the street, and Tommy will be in the street.

8266. I am only giving this as a fact: that it has not occurred before?—My answer is, that, from my own commercial knowledge, that is what I anticipate the result will be in practice—and it has been the practice in other trades.

8267. Can you tell me a single trade in which this has occurred? You may be able to find one or two isolated men, but can you tell me any trade where this has happened in your experience? I cannot tell you of a trade, but I can give you a parallel case, and to-night I can go and show you the case if necessary. When they brought the Employers' Liability Act in, the result was that old servants, in consequence of the risks that ensued, got dismissed from the large public companies in England, and they are in the streets to-day, and they are replaced by younger men.

8268. That had nothing to do with the medical examination of the men's health, had it?—It applied to the chemical trade and others, and so it will be in this trade.

8269. Medical examinations have been welcomed by the employers in other trades, because it has lessened their liability?—I agree.

8270. They found themselves distinctly strengthened by the medical examination being instituted, but as regards the medical side of the question, and the medical men refusing men on account of their ill health; I ask you which trade it has occurred in. I suggest that you are raising for yourself a bogey there which has no existence?—I have answered you that I am entirely in favour of having those men in the painting shop medically examined, and I am quite agreeable that they should be in every way. If we are to be held

responsible for the health of these men, and for the medical examination, it would naturally follow that before we embarked upon any new set of regulations we would have our men examined, and those who had been with us for years would certainly go on with us; but with regard to the men who had just come to us a month ago from some other company, the doctor would say: "This is a very likely case, in consequence of his having had rheumatic fever, or being half-fed or something of that sort, to get lead poisoning." We should say: "We are very sorry, Tommy, but we cannot take you"—because I should consider if I took him I should have to support him.

8271. Do you not think that that would be better for Tommy?—No.

8272. Why not? Tommy would be better off in a trade where he could not get lead poisoning?—No, Tommy would be in the Salvation Army shelter at night.

8273. Your attention has been considerably drawn during your examination in chief to the danger incurred from dust. Have you considered at all the possibility of danger arising from fumes given off by lead—the smell of lead paint?—I have not given the matter any consideration, except from the experience I have had of the number of painters I have had through my hands, and their absolute immunity from illness.

8274. I think we have dealt with that already, and shown that you have no real knowledge on that point?—None whatever.

8275. You can hardly keep on making that statement again and again?—It is a very hard nut to crack, when you have had the men so many years. Whatever science may teach, we can produce the men.

8276. What you want to produce is the exact number of men you have employed, and of whom these are the survivors. It would be rather difficult, because you cannot tell what has happened to those who have left your employment?—We can dig them up. We have the records of them.

8277. (Mr. Fall.) One or two questions about the substitutes. You say that your experience of substitutes is simply limited to seeing certain cars in the streets?—Yes.

8278. You have not tried the substitutes yourself?—No, but I am in close touch with other coachbuilders who have used, and do use these things.

8279. Can you tell the Committee the general effect of using these substitutes on vehicles?—The only case that I have had under my own observation is that of one company, who is the largest user of the substitute. From my experience and my observation of a number of cars in various parts of the country two years old—they can be no older in consequence of the chassis on which they are mounted—and a number of other cars and bodies made by people all over the country, that one, as a parcel, is certainly very much worse in the painting than any other car from any other coach building shops.

8280. There are several motor-car companies using French bodies?—Yes.

8281. Do not some of those companies get their bodies painted abroad?—Yes.

8282. And are they not to a large extent painted with substitutes and not white lead?—I asked about that. Most of the French motor-car bodies are painted with white lead to-day.

8283. Does not the condition of the car which you see in the street depend to a very great extent on the varnishing?—Not in any way as regards durability.

8284. Do you not think it appears to be better, if it is more frequently renovated?—Undoubtedly.

8285. So that, seeing a thing casually in the street, unless you knew when it was varnished last, you would not know what the real state was?—I agree.

8286. So that, unless you get it actually under observation, you cannot tell what the life is?—No, you cannot make a positive statement and say that this one was done with lead, and this one with non-poisonous paint, and they have run so many miles, and so on. I do not know that; I am only speaking collectively.

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

8287. Would you be prepared to paint some cars with substitutes?—No, I am afraid I would not, because I could not afford to experiment on my customers. I would not mind doing one of my own, but I have not one. I have a number of customers, and if a thing was painted white, and it went black, I should have to do it over again.

8288. Do you know that the Midland Railway Company have been using substitutes?—Yes; I understand so. I do not attribute any importance to any railway company or any tramway company using it at all, because they can experiment with the money of large corporations, whereas we are small builders, with all our money on the table, running our business to get a living, with hundreds of customers in different part of the country, and we have to please the lot of them. If the thing is not a success with a large corporation, then they do it again.

8289. But you know the margin in a public corporation is a very small one sometimes, and you have to save everything you can?—We have not found that with the London and North Western Railway Company and the London County Council.

8290. The Committee would like, I am sure, to have some evidence to show that at any rate the manufacturers have tried some substitute. It is not sufficient for you to simply say that lead is the only thing that can be used, and not attempt to try a substitute?—That is quite sufficient for me, because my experience is this: that I have produced very fine work with lead, I have given my customers satisfaction, and I know that the longevity of the work is there. I am not prepared to gamble or experiment with my customers or my profits by trying anything else, for the reason that my workmen's health during that period has been satisfactory.

8291. (*Dr. Collis.*) You have already allowed that you know nothing about that?—No, I beg to differ with you. I think I have told you pretty conclusively that, so far as the workmen are concerned, the fact of their non-absence from their work is proof of their general good health.

8292. (*Mr. Fell.*) If it can be proved to you that a substitute could be used, would you adopt it?—If it can be proved to me that a substitute is as good as white lead, certainly I would adopt it. I will use it if it is worse, if you decide that I must.

8293. (*Mr. Mason.*) You were suggesting just now that you might paint wheels in a certain shop, apart from the general shop?—Yes.

8294. If the wheels, being painted on a horse, were taken to one spot, would it not be possible to apply a process of exhaust ventilation in doing those wheels?—Why I said "make it a portion of one shop," was so that the Act would apply to that one particular man rather than to the 500 who surround him.

8295. Do you think it would be a success?—I am afraid I am not sufficient of an engineer to say what kind of appliances they could find to-day. I think proper ventilation would get rid of a good deal of it.

8296. (*Mr. Kinggate.*) In the early part of your evidence, you have inferred there is no danger at all in the private coach-making trade in the use of lead?—Yes.

8297. With regard to these 116 cases that we know of that are reported, you are aware, of course, that they have to come through the certifying surgeon—definite cases of lead. Do you know that there are hundreds of cases that are never reported at all?—I do not think there are—not lead poisoning.

8298. Take three London shops. In one of the largest London shops I know perfectly well that there were, in the wood loft alone, a dozen men who were suffering periodically from white lead poisoning. It came out mainly in cancer?—Yes.

8299. In another shop in which I worked for a great many years amongst the wood workers, out of about 30 men employed, there were five men that were periodically suffering from lead poisoning, and men that were very careful men too. Perhaps you are not aware of that?—How many years ago is that?

8300. I have only been away from the trade now about eight years. It was in the latter part of my

time?—Do you consider that those cases are only eight years old, and that it is only eight years ago that this happened, or 28 years ago.

8301. Some of them were 20 years ago, and more than that?—The answer to that would be the statistics that you have got.

8302. None of those cases had been reported?—That is quite right.

8303. We have had, in my own organisation, within the last two years, in the coach-building trade, five deaths from lead poisoning besides the other cases. Do you know that it is very possible that a number of your men may have been off ill and not been aware that it was from lead poisoning?—Quite so.

8304. Do you know that many men are away for a short period, and that they periodically dose themselves with medicine for the purpose of keeping themselves at work?—Yes, but I have no knowledge of their taking physic to keep themselves at work.

8305. So that your statement that you have no cases of lead poisoning, if it came to be analysed, might prove to be that you had a large number?—That is supposition.

8306. You have no figures to prove the cause of the illness?—No, but I have the time sheets and the men's records, and the hours that they put in.

8307. Just so, but the men may be off only for a day or two. You have no figures to give to this Committee, and no statement to give, as to the reason why a man might have been off from your works for two or three days?—No. Do you suggest, as secretary of the men's society, that I should say to my men: "Where were you yesterday, what were you away for?" so that I can tabulate it in a book?

8308. You have not done it in the past, and it is not a question of what you are going to do in the future. You have not done it in the past, and therefore any statement you make is not to be relied upon that you have had no cases of lead poisoning. That is the point I wish to get at, because I know from my experience that there are a very large number of these kind of cases that are never reported at all, and that very grave danger exists with regard to the workers in our industry. You say practically there is no danger at all to the body-maker. You know that, in using white lead in putting on the edge plates and the various plates, he is bound to get his hands covered with lead very frequently; he cannot avoid it. There is a possibility then, as the Chairman said, of putting his fingers to his mouth for various reasons, and so it gets into his system, so there must be some danger?—None whatever.

8309. That is your opinion?—Absolutely.

8310. Then how would you account for body-makers suffering from lead poisoning?—I have never had a case of lead poisoning.

8311. Not to your knowledge?—No.

8312. With regard to carriage-making, of course, I agree with you that there is very little carriage-making now, but there may be in the future a reversion to the horse carriage?—I hope so.

8313. I was rather astonished, as a practical man, at your statement with regard to putting together the carriage. To say that the plate was painted and allowed to get dry and then put together, seemed to me an astounding statement, and I was surprised at your making it. What was the object of your putting on white lead?—It is certainly a better job to do it in the way I suggest, because it does not exude afterwards, and you get the lead into the grain of the timber. If you took a transom plate off you would find the white lead bedded down, and you find the water gets in. In consequence of that, we say we will paint these things before we put them together, and it makes a better job, because in the old days they used to slabber themselves all over with white lead. That does not exist any longer in the carriage-making of to-day.

8314. Then, from your statement, lead is practically useless for this purpose, because as soon as the water gets to it it gets rusty?—No.

8315. You just said that that is why they have done away with lead; that you find, where the lead has been used along those edges, it has got rusty?—On the

26 May 1911.]

MR. WILLIAM LAWTON GOODMAN.

[Continued.]

contrary, what I said was, the bed plates were painted with lead colour, and not white lead. The lead colour was allowed to get dry, and two or three coats put upon those beds before the plate was put upon the top of it, and that process gave greater life to those compass beds than the old process of putting them together with a splash of white lead on the plate and one on the bed. I say that that is a better job, and that is the up-to-date process of making under-carriages.

8316. It is an exceedingly strong statement to make. You were speaking of a case to me a little while ago with regard to an old barouche which you had to knock to pieces, and you said that when you had taken the bolts out you had to hammer the plates on account of the casing properties?—Yes.

8317. With a light frame you want something easing for that, or it would spring away?—I am speaking of carriage-making. In carriage-making you have four bolts in that length. There is no springing away if the smith knows what he is doing, and puts the bottom plate on it.

8318. Take from the end of the transom to the spring; in many light carriages you have a distance there in which your bed is not more than three-quarters of an inch thick?—That is right.

8319. And that is where you require lead, if you require it at all?—Yes.

8320. To thoroughly fix it?—Yes. What you require in that case is a good solid smith, with a good lump of iron, with a good bottom bed-plate.

8321. And as regards the stronger bed-plate there is more liability for the bed to get away from it?—Yes.

8322. I am speaking of a practical carriage-maker?—So am I.

8323. You made a statement with regard to there being no hard stopping in motors to-day. That is rather a strong statement to make, is it not?—No.

8324. Do you find that in many cases there is more hard stopping used now than there was in the coach-painting trade?—No.

8325. There are holes to be stopped up?—Where are they?

8326. The inequalities of the panels?—But the panels are filled up and the mouldings are aluminium mouldings, and they are put on with screws, which are countersunk and filed off level and the nicks filled in.

8327. That is not in all cases, is it? There are plenty of wood mouldings and plenty of wood panels still, are there not?—You are asking me what I do.

8328. You may be adopting a different method to what other builders are doing, but you know perfectly well they still use wood panels in many cases?—Yes, and I think I shall possibly go back to wood panels. If I did I should not use stopping, because I should glue my panels, and I should put them on with copper panel pins, and I should fill them up. I should put no stopping in them, because I should not allow body-makers' work to pass with bad joints that you could throw your hat in.

8329. With regard to the use of lead in body-making, you have been speaking of the French coach-makers. Is it a fact that they do not use any lead in the construction of the bodies, but it is all glue?—In France?

8330. Yes?—No, I think they use glue in France and America.

8331. The body-maker does not use lead at all?—No.

8332. In my experience it is all glue in those countries?—Yes.

8333. There is another point with regard to that. If it is possible, as you say it is, and it is done to-day, to put the canvas on the roof with glue, instead of the old plan with white lead or japan, that is for the purpose of keeping the wet away, is it not?—Yes.

8334. We have been told here by most of the witnesses that, with regard to jointing, the object of it is to keep the wet away?—Yes.

8335. If the use of glue upon the roof of a carriage will keep the wet out, surely the use of glue in jointing would be equally as efficacious as the white lead would be, seeing that there is no possibility of the water getting to the joint like there is to the roof?—Glue, as

you know from your own experience, suffers from the humidity of the atmosphere. All American carriages are made of white wood with corner blocks fitted together. When they are put into the atmosphere, here in this climate with the rain, where do they go? Then with regard to the French makers, there is a firm sending 300 bodies into London.

8336. He is not a Frenchman; he is a Belgian?—He is using a lot of glue. What happens? Those things come to London with a beautiful surface on them, but what happens? You can walk through the mitres at the corners of the pillars, and also through the wooden mouldings.

8337. But that cannot be from the fault of the glue. It must be the fault of the timber?—You get a screw head, on the principle of putting in a screw, and then putting a wooden dowel, and levelling it off with the end grain. What happens? Up comes the end grain, and there it stands right out. Glue in coach-making is no good at all; that is my view of it, because it will not stand the humidity of the atmosphere. Then with regard to covering the roof, we use dextrine for covering the roof, and you must not lose sight of the fact that the roofs of the carriages, when they were put on with japan and white lead, were generally jointed in about three pieces. Now they use three-ply American wood, cut to the full length of the roof, and there is no joint in it at all.

8338. That is not my point at all?—Even then, if you look at the top of the brougham, looking down the street, you would find the ridges of the joints.

8339. In those cases they were not put on with white lead?—Japan and size. We used to put a good wet hide on them.

8340. There has been a lot of talk about foreign competition. If the evils are so great with the use of glue, then, of course, we have nothing to fear from foreign competition?—The best illustration of that is to come up with me and see it on my car now. If you will come up to Warwick Wright's, you can see the roofs of bodies made in Belgium.

8341. You are contending that there is very little to be feared from the evil of the use of white lead. You are suggesting that you are going to look your men out from having their meals in the shop on account of the danger attending the use of lead?—Nothing of the kind. I am looking the men out of the shop for their meals on account of the bits of bread and paper, and everything that is rolling about, and I contend that where you have dirt you have waste.

8342. That is hardly the reply that you gave to the Chairman with regard to the factory regulations. You said you should look the men out of the shop, thereby showing that you recognise the danger?—Not in any way. I wish it to be quite understood that in looking my men out of the workshop, and sending them to the dining-room, it is not that I fear any danger from it, but it is with a view to having my shop cleaner, and not having bits of bread, and bits of paper all over the place. It is not a question of danger to health at all.

8343. With regard to the discharge of men suffering from lead poisoning, is not that also, at the present time, the cause of many cases not being reported for lead poisoning. We recognise that your statement is quite correct, that if you were employing a man and he was suffering from white lead poisoning, you would not employ him?—That is right.

8344. There is also this that has to be considered, that there are many cases of white lead poisoning in which the man refuses to report the case, and, in fact, even goes so far as to ask the doctor not to say that it is white lead poisoning—to say that he is suffering from Bright's disease, but not the cause of it—for fear of being discharged?—Not at all; that does not exist at all. If I have got a chap suffering with lead poisoning, the first thing I do is to try and get him right.

8345. I am following up your remarks about the evil effects which you think would come upon the workmen from medical examination. I will put it in this way, that there are a large number of cases, generally, not reported, from the fact of the fear of the man being discharged from his employment, on account of suffering from lead poisoning, and the liability attaching to

P

x 7790

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

the employer for compensation?—Of course, you have had a more general knowledge of that than I have. I should rather think not. I should rather think that the organisation which you are at the head of would see to it, that if you have a case of lead poisoning you would very soon put it on to the counter to the employer. You ought to do so. You would say: "Here is a case of our member, John Jones, suffering from lead poisoning in your employ. What are you going to do for him?" That is your duty.

8346. But you must remember that the man has, in the first place, to go to the doctor, and he may fear his discharge?—Yes.

8347. We may take his case up, and he may get the benefit of the compensation, but that would not make up for the loss of employment?—That could be easily overcome by the Home Office issuing instructions to the doctor that it is a penal offence if the doctor does not report it as lead poisoning the same as in scarlet fever, and so on.

8348. I notice you made a point with regard to some experience by the North-Western Railway Company, which you seem to place some weight upon. It is a most remarkable thing that you do not place any weight at all on the fact that the Midland Company do not use lead at all?—I know very little about the work in railway shops, but it came to my knowledge, through one of the directors of the North-Western Railway Company, that a train had been painted with other than white lead, with the result therefrom that it discoloured and had to be done again. I wanted to illustrate to the chairman that that was a mere bagatelle to a firm like the North-Western Railway Company, but to me it would very likely have meant my being sold up, if a railway train had to be painted over again. I cannot afford to make those experiments. With regard to these gentlemen who have big corporations behind them, let them experiment by all means, and if it is a success I shall be very pleased to benefit by the experience of the money they have already paid for it.

8349. According to the evidence we have had here, there seems to be no substitute, as far as we know, used for lead in the ordinary preparation of a body. Take a wood body now, for instance, with wood panels. The object of the lead, first of all, is to stop the suction of the wood, to fill up the grain, is it not?—Yes.

8350. Again, after the body has been filled up and rubbed down, it is to stop the suction or the porousness of the filling up?—Yes.

8351. The thing that has been used in the Daimler car is not a substitute at all; it is an old thing. Do you know what it is?—No.

8352. It is simply a mixture of varnish and japan—generally the waste that you have from the stone—and that effectively stops the suction. The man who is head painter there is one of the most experienced painters in this country, and he is a very old member of our society. He is the foreman of the painting department?—What is his process. When he has got the thing rubbed down, does he give it a thin coat of japan and varnish?

8353. Yes?—That is entirely his own invention.

8354. Yes, you must know that the more recent productions of the Daimler Company have been of a better character than they used to be?—A long way.

8355. A great improvement?—Yes. I attribute that to using iron panels instead of wood. It is very much better painting.

8356. Then, again, with regard to the standing of the paint, of course many of their things have to be rushed through very quickly. Other firms may do the same. You have not tried any substitute, have you?—No.

8357. If the evidence is forthcoming from this inquiry, and the evidence is conclusive, that a substitute can be found to take the place of lead, you are perfectly prepared to fall in, and use that substitute, are you not?—Undoubtedly. I want you to rightly understand that the health of my workpeople is my first consideration, because my profit must come from

them, and I do not want to use any of these poisonous things as long as I can make a good job.

8358. (Chairman.) But you have told us you do not believe in the dangerous character of the employment, I think?—You are illustrating the dangers as you allege they exist; but I do not believe they do. In the wisdom of counsel such as this, if it is proved in the aggregate that it does exist, and that there should be legislation for it, you must give us something else, and we will give it a trial.

8359. (Mr. Kinggate.) You do not know the insidious nature of the evil, do you?—I know if you cut your finger and dip it in the paint pot, you will get it poisoned.

8360. The evidence has been that a man was dipping in the white lead glaze with a cut finger, and he said it was the finest thing to heal it?—I have seen cases like that.

8361. (Mr. Robins.) I believe you said in your evidence that white lead was not dangerous?—I will qualify it. I admit that white lead, so far as my experience is concerned, has not proved itself dangerous in motor-car painting.

8362. Still, you consider that it is quite necessary that a portion of the shop should be apportioned off to sand-paper the white lead that is on the wheels?—No, I do not consider it necessary at all, but in view of your wishing to legislate for it, rather than that you should legislate for 500 men in a shop, and make your rules applicable to those, you should take off a portion of the shop and legislate for the one, and we should conform to whatever regulation you see fit to impose for the health of that workman.

8363. Do you think that that could be done in very small works?—No, they might use sand-paper stopping all over the body, and everything.

8364. Do you consider that sand-paper stopping is dangerous to health?—It must be. Any dust is.

8365. And you consider that white lead is not dangerous?—I am giving you my experience.

8366. (Chairman.) You say it is dangerous, but not in your works?—Yes.

8367. (Mr. Robins.) In giving the first part of your evidence, with regard to cases of lead poisoning, you mentioned that you were receiving the credit, in the coach-painting trade, of lead poisoning, while many other industries were really the cause of it?—Yes.

8368. One instance you gave was that coach-painters were painting bird cages?—Yes.

8369. Would it surprise you to know that a bird cage painted with white lead would be very dangerous to the bird, and that in bird-cage painting enamel made from zinc white is used?—I must express my ignorance of bird-cage painting, but I know of safe painting and lift painting. A firm of lift makers, when they have, as they do sometimes, a job to take to the International Show, like the Turin Show, they send for a coach painter to paint that lift, which in the ordinary course would just get a coat of paint from one of the works' staff. They finish it up with stopping, and sand-paper it down. In the ordinary course, the man who does that is employed in the coach-painter's shop, whereas he is really a lift painter.

8370. Do you consider that the use of stopping and sand-papering down is likely to give that man lead poisoning?—No. If you have a little room about the size of this table, and they are using it all day long, that is different.

8371. You still hold that to carry on this operation there must be a special ventilator to carry it off, so that it is not dangerous to the man who is doing it?—Yes, I do.

8372. He must have that ventilation, and without that ventilation it is highly dangerous?—I agree with that, such as it is.

8373. Yet in the first part of your evidence you said that white lead is not dangerous at all?—I do say so now.

8374. How do you reconcile those two statements together?—I will give you a very overt explanation of it. I have a shop that is 300 feet long and 90 feet wide, and I am painting in it. You have, or someone

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

else has a shop the size of this room, where they are painting a motor body, and that is the full size of their painting room. I can take you to lots of places in London where they are doing it. In this corner there is a man sand-papering the wheels with sand-paper stopping, and over there is a man with a putty knife laying it on with sand-paper stopping, quite a different process. In that small place the conditions are quite different. That is why, when I tell you that white lead is not dangerous, I say that from my experience in my own particular works—and that is all I am speaking about—from the experience I have had of the number of people in the coach-painting trade, I have never found white lead to be of any danger to my workmen.

8375. (*Chairman.*) Do you not mean by that that they get smaller doses of the poison?—No.

8376. Is not that the inference? You admit that there is a certain amount of dust?—Yes.

8377. So that in your place the men get a certain amount, but in smaller quantities?—Yes.

8378. (*Mr. Robins.*) On that point I must say from my own practical knowledge that since the motor industry has been started, better shops have been made, and better ventilation introduced, but at the same time you must be prepared to bear me out that, in 75 per cent. of the places where the coach building is carried on, it is highly dangerous. They are different to the motor shops as a rule, which are better ventilated, but still that does not say that this question of white lead and the sand-papering is not dangerous. You have to take these precautions of ventilation in order to remove the danger, but the danger exists; or else why would you use these things?—To give you an illustration, on a beautiful summer's day, on a country road, when the dust is blowing up in clouds, when you have got the atmosphere of the fields round about you, you get the same volume of dust, but in a room like this you would be smothered.

8379. But all the way you went along in the country the people would not be raising dust from dry white lead. Would you consider that coach painting was a healthy occupation?—No, I should not.

8380. And would you think a paint shop was a healthy place?—Give me a description of your idea of a paint shop.

8381. An ordinary paint shop. Should you consider it a healthy place?—I should, according to my view of a paint shop. I can take you to some places very unhealthy.

8382. What would you consider was the cause of the unhealthiness of those shops?—What I wish to convey is that paint shops are as varied as private houses. You can either have a hovel down a back street or you can have Buckingham Palace. There is very much variety in the various paint shops in the country. If you say a painter's shop is a dangerous place, how about those poor chaps that are selling paint over the counter in these small shops throughout London?

8383. I do not think that has anything to do with this inquiry at all?—I am giving you an analogy.

8384. (*Chairman.*) Would you not say that you would have to legislate for the average place?—You are going to legislate people out of business.

8385. Would you not have to legislate for the places that are not so well equipped as your own?—In my opinion, if I were dealing with this question, I should classify them, and I should say, under various conditions you may do so and so, but under other conditions we will only permit you to do so and so. I think that is a practical way of putting it.

8386. (*Mr. Robins.*) Seeing that the condition of the painter is unhealthy, and that the conditions under which the men work in your paint shop are far healthier, but that you consider that the workshops generally are not so healthy, what would you consider was the cause of this unhealthiness among the painters? You say that the painter's occupation is an unhealthy one?—Yes, and I qualify that by saying, compared to any other branches of the coach-building trade. I do not say that it is a dangerous occupation, but I say that it is much more unhealthy than that of the body-maker or the carriage-maker or the smith.

8387. What I ask you is, what is it that makes it unhealthy?—I want you to understand that in my definition of the painter's occupation, my comparison is that the coach-painter's occupation is unhealthy compared with his confrères in the other branches of the trade, but if you are speaking of coach painting as a trade in England to-day, compared with other trades, I say that it is not unhealthy. I can find you much more unhealthy trades. It is not an unhealthy trade, but it is unhealthy compared with the body-making or the smithing or any other part of the trade.

8388. What is the cause of the unhealthiness?—It does not exist.

8389. Yet you say it is an unhealthy occupation?—Unhealthy compared with the others.

8390. (*Chairman.*) What makes the difference in the health of the two sets of men. One is not so healthy as the other. What makes it less healthy for the painters than for the rest of the men?—From my observation of the physique of the men myself, I have not noticed any difference between them at all, but I have said that my opinion of the coach-painting trade is that it is the most unhealthy branch of it.

8391. Why is it more unhealthy than the other branches?—It is very largely due to the fact that coach painters are running about from one shop to another, visiting the factories, particularly the small factories, where they are very uncleanly and very small, and very dirty, and the men do not keep themselves clean.

8392. But what is the cause of the unhealthiness? Is it the lead?—No, because my experience during all this period is that I have had no cases of lead-poisoning.

8393. You have admitted that certain sections of the men work under unhealthy conditions?—No, my comparison to our friend here was that, in the coach-building trade, I should consider the most unhealthy branch of the trade is the coach painting.

8394. (*Mr. Robins.*) What is the cause of that?—It is due very largely to the fact that it is a very migratory trade, and the conditions under which they work in a great number of places are absolutely unsuitable for them to pursue their trade in. What I wish to infer is this, that the coach painter's occupation is not so healthy as the other branches of the carriage trade, and it is due very largely to the fact that his occupation is very migratory, and it is the result of him working in small shops particularly, which are quite unfit for the carrying out of coach painting, except to the damage of his health.

8395. (*Dr. Collis.*) I should like to ask whether you would modify your opinion as to the cause of the unhealthiness of this section of the trade in any way, if you know that these people have an average age at death about nine or ten years younger than in the other branches of the trade to which you have referred, and that this average age at death is lowered by the diseases which we know lead specially causes?—No, I was not aware of that.

8396. Would it cause you to modify the opinion you have just expressed as to the cause of the unhealthiness?—No.

8397. It would not cause you to modify your opinion if you had that in figures?—I am afraid it would not.

8398. (*Mr. Robins.*) You have said that it was mainly with regard to the migratory character of the men, and working in little shops?—Yes.

8399. If white lead is not dangerous, it is not dangerous in small confined spaces any more than it is in a large space. If it is dangerous in a small place, certainly it is equally as dangerous in a large place. Even if preventive measures are used, still there is the danger, because preventive measures are used. You would not want to use preventive measures if there was no danger?—You hardly followed my assertion. We were speaking of sand-paper stopping, which is a process with dry white lead. I have agreed that when it is used it should be used in a place enclosed with an apparatus for the withdrawal of the dust that arises therefrom.

26 May 1911.]

Mr. WILLIAM LAWTON GOODMAN.

[Continued.]

8400. (*Chairman.*) Why do you want the dust removed if it is not dangerous?—I have admitted that it is, all along.

8401. (*Mr. Robins.*) You would consider that dry white lead is highly dangerous?—In a small room, yes.

8402. It would be equally as dangerous in a large room?—I disagree.

8403. If you got enough of it?—No, you would get the same particles floating over a much greater area.

8404. But you would only have lessened the danger, you would not have removed it?—Yes, you would have removed it altogether, because the particles would be so small, in a large area, that they would not have any effect.

8405. (*Dr. Collis.*) What scientific evidence have you for this statement?—I have no scientific evidence at all. I have the practical experience of a lifetime.

8406. (*Mr. Robins.*) You still hold that dry white lead is dangerous. Do you hold that opinion?—No.

8407. Then I gather from you that all leads are not dangerous?—I am afraid that your cross-examination is rather begging the question. What we are speaking of is sand-paper stopping, its application, and its uses. I suggest that in large works, if sand-paper stopping is to be used, rather than that the employer should be mulcted in legislation for 500 men, when only two men are using it, we should take off a corrier of the place, conform to the regulations that you may request of us, to carry off the dust, and consequently deal with those two people. That is what I suggest.

8408. You are suggesting remedies, but with regard to my question, it is this, do you consider that the use of dry white lead is dangerous in sand-papering?—Yes, in a small room.

8409. Why do you consider it is dangerous?—Because wherever you have dust you must have a certain amount of sediment rolling about the room, which is unhealthy to anybody.

8410. But we do not have these awful effects from dust on the street that we do from sand-papering of white lead?—I think we have.

8411. I have had experience. I have painted two carriages recently without any lead whatever, one in white colours and one in dark colours, and they have been perfectly satisfactory to the firm?—They have not been out on the road any time, have they? They have not been in use?

8412. No, but at the same time, to all appearances, they are quite as good, and from my experience as a painter, the wearing properties I consider will be superior?—That is what we want. We have no brief for white lead; the durability of our work is what we have a brief for.

8413. I consider as a painter that we want to lessen these dangers. At the same time, I am speaking from a point of view with as much pride in the production of painting as you would speak as an employer with regard to the production of a carriage, and I take it that that is the common opinion of the coach-painter to-day. I say this also, that the average painter to-day is more intelligent, is more sober, and is more cleanly than he was 15 years ago?—Undoubtedly; he is quite another man.

8414. I am glad to have that admission?—Yes, a better man altogether.

8415. You say that a great number of cases that we have of lead poisoning are to be attributed to the dirty, or even drunken habits of the men, or to their lack of intelligence, and yet you find, as you have admitted, that the man to-day is more intelligent, is cleaner, and is a better man altogether than he was 15 years ago. Notwithstanding that, this last three or four years, cases of lead poisoning have not diminished?—Yes, but of course that, again, is a statement that you gentlemen have made. All we can do is to say that we have investigated the matter so far as we are concerned, and we do not find it arising.

8416. I am taking this from the Home Office reports?—What I suggest is, that in fairness to us you should say: "There are the cases, and there are the shops; we have made this statement; disprove it; that is our case"; but what you do say is: "There are coach-painting cases; so far as you are concerned, we tell you they exist in coach-building shops."

The witness withdrew.

## ELEVENTH DAY.

Wednesday, 31st May 1911.

### PRESENT:

SIR ERNEST F. G. HATCH, BART. (*Chairman.*)

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. F. G. RICE.  
Mr. W. G. SUTHERLAND.

Mr. A. GARDNER.  
Mr. J. PARSONAGE.

E. A. R. WEBNER (*Acting Secretary.*)

Mr. JAMES SAMUEL HOLLIDAY examined.

8417. (*Chairman.*) Do you attend to-day as a representative of the Institute of Builders?—Yes.

8418. What is the nature of your business, and where is it carried on?—I am chairman and managing director of Holliday and Greenwood, Limited, contractors. I may say that we built the Victoria and Albert Museum, under Sir Aston Webb.

8419. Whereabouts is your business carried on?—Loughborough Park, Brixton.

8420. How long have you been concerned with house-painting work?—About 36 years.

8421. What is the average yearly number of painters employed by your firm?—Sixty.

8422. Have you known any cases of lead poisoning, or painter's colic?—No.

8423. You will probably not be surprised to hear that such a good record is not unusual; in some of

the pottery works there are a large number who are quite immune from lead poisoning. The trouble is that even some of the best works are not altogether immune, and moreover a works that has been free from lead poisoning for many years will sometimes have a succession of several cases quite unexpectedly?—Yes.

8424. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act of 1906?—I take it that the Employers' Liability covers that. We insure against liability on the general policy.

8425. Has the premium advanced in recent years?—Yes.

8426. How much?—I think we are paying 2s. 6d. in the 100l. this year more than last.

31 May 1911.]

Mr. JAMES SAMUEL HOLLIDAY.

[Continued.]

8427. What did you pay last year?—We are paying 17s. 6d., I think.

8428. That means at least 15 per cent. more?—Yes. We have always insured in the non-tariff offices. I believe the tariff offices are about 25s.

8429. (Dr. Collis.) You are paying 17s. 6d. now, and you were paying—what?—15s.

8430. (Mr. Sutherland.) That is an all-over rate?—Yes.

8431. (Chairman.) Has that increase taken place in consequence of the dangers of the lead in the industry?—Not to my knowledge. It has never been put forward.

8432. Why did they raise the rate?—Because of the extra number of claims for accidents, and various causes, but we have never had it put forward by the insurance companies that any increase has been made on account of lead poisoning or the dangers of lead poisoning. We employ only about 60 to 100 painters—sometimes more and sometimes less, but I put it at the average of 60, and we have at times of pressure employed about 800 men, so that the painting in our business is quite a minor part of the work.

8433. You pay a flat rate for all your men?—Yes.

8434. So that you could not answer as to whether the dangers of lead are taken into consideration by the insurance companies?—The insurance companies have never put forward to us that the increase has been caused by any suggestion of lead poisoning.

8435. (Mr. Sutherland.) What company is it you are insured with?—I rather think it is the Northern Equitable. It is one of the Scotch offices.

8436. (Chairman.) Have you known men who have broken down temporarily on account of lead absorption?—We have never had a case, from my inquiries in the firm.

8437. Have your men had occasional days of sickness due to lead?—We have never had any notice of it.

8438. Do you have a periodical medical examination of your men?—No.

8439. Then it is possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—It may have been, but we have never heard of it.

8440. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—I should say so, but I am not in a position to answer that question.

8441. You take a prominent part in the work of the Institute of Builders?—I am the President.

8442. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—Since this invitation to give evidence has come from the Home Office.

8443. But not before?—Not before.

8444. Did you never take any steps to discover how much illness there was among the men in your trade?—As Holliday and Greenwood, do you mean?

8445. As an institute?—I do not know that we have.

8446. You must have heard of the prevalence of lead poisoning among the men who handle lead paints?—I have heard that there is such a thing as lead poisoning among painters.

8447. Did your association never attempt to collect statistics concerning the number of days' absence from ill-health among painters as compared with workers not in contact with lead?—I believe Mr. Shepherd, who is past president, and I think Mr. Rice, gave evidence some years ago on this, but I cannot answer for what the institute did before I joined. I have only been in the institute four or five years.

8448. During the last four or five years, have the institute collectively taken any steps to combat the known evil?—Not to my knowledge.

8449. Did your association ever consider the advisability of having a medical examination made of the persons employed?—Not to my knowledge.

8450. Would this not have been the best way to discover the proportion of painters showing symptoms of lead impregnation?—Yes.

8451. Has your association ever taken any collective measures to discover a substitute for white lead in paints?—Not to my knowledge.

8452. Have you employed a chemist to make scientific investigations of the chemical properties of different pigments and vehicles?—Not to my knowledge.

8453. There are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead?—Yes, I believe so.

8454. Has your association carried out any practical tests with these?—Not to my knowledge.

8455. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many master house painters?—Perhaps not.

8456. Have you ever had the figures published by the Board of Trade brought before your notice?—I think I have read them lately, but not previous to my being invited to give evidence here.

8457. Then you have not realised the magnitude of this lead poisoning evil?—I have not.

8458. Are you cognizant of the number of deaths and the attack rate?—I have read some figures at which I was astonished.

8459. I am sure you will agree with me that all this sickness and death is very deplorable?—Certainly.

8460. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I believe so.

8461. And that the use of white lead has been prohibited to an appreciable extent abroad?—I believe it has in some countries.

8462. And that in other countries the work of painting has been strictly regulated where the use of white lead is still allowed?—I believe so.

8463. Do you not think it regrettable that this country should be behind other nations in this respect?—I do.

8464. A great many small dangers attend the use of lead. For instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—I do, certainly.

8465. Then you consider lavatory accommodation essential?—Washing accommodation, yes.

8466. Including the supply of hot water for washing?—We do not supply hot water.

8467. Is it not obvious that, if a man can get hot water, it is very much better to use to get the paint off the hands, especially in the winter?—Yes, I should say so.

8468. Is it generally practicable for the men to have hot water to wash in?—No.

8469. Do your painters wear overalls?—Yes.

8470. Do you supply these?—No.

8471. Would you object to a rule that overalls are to be provided and maintained by the employer, as is prescribed in other lead industries?—Yes, but if it is the general custom we should fall in certainly.

8472. How often are the overalls washed?—I think that depends upon the habits of the painter to a certain extent. I should say weekly or fortnightly. Some men are not clean, and they might go for a month, but I should say a week or a fortnight.

8473. Would you be prepared to arrange for the overalls to be washed at your expense, as is done in other industries where lead is used, at least once a week?—No. I think a man ought to keep his own overalls clean.

8474. Would you be prepared, if required, to arrange for the overalls to be washed at your expense, as is done in other industries where lead is used?—I should give the same answer that I gave to the other question—but we should be prepared to do whatever, in the general view, was the best way of obviating this trouble. I have never thought about the question, to tell you the truth.

8475. Where can the overalls be kept from day to day when the man is working continuously on one job?—They are generally kept in a room set apart for the painters.

31 May 1911.]

Mr. JAMES SAMUEL HOLLIDAY.

[Continued.]

8476. Can you always provide a separate room for the painter to leave his overalls?—Painters go into a building when it is very nearly completed, and there would be no difficulty.

8477. I quite understand there would be no difficulty in some cases, but could you lay down as an absolute rule that a room could always be provided for the workman to keep his overalls in?—I should think it would be rather difficult to always provide it.

8478. Can you always provide a place for the painter to hang up his coat where there will be no risk of dust falling upon it?—I should say, no. It is impossible I should say.

8479. Now, about the men having their meals. Do you advocate a rule regarding meal rooms, so that no man shall eat his food in a place where paint is being handled?—Certainly.

8480. That is the law now in factories where lead industries are carried on?—Yes.

8481. Can you always provide a place, quite free from risk of contamination, where the painter may leave his food during his working hours?—Certainly.

8482. Can a place always be found for them to have their meals in?—Yes, except in the case of a private house being decorated, or that sort of thing.

8483. Is it always practicable for a man to be able to eat his food in a place where there is no possibility of it getting into contact with lead dust?—It is rather difficult to give a decided answer in that way, because, supposing a house was being rubbed down, whatever part of the house it was, there might be dust flying about, and, therefore, there would be dust all over the place, but I may say that we make it a rule that no man is to take his food in a place where paint is kept and made up.

8484. That is not the point. Do you make it a rule that a man is not to take his food where work is being performed?—No.

8485. From your answer to my question I take it it is almost impossible for a man to have his meals during his job, unless he goes outside, without coming into contact with some lead dust?—I qualify that by saying, in new buildings, and certainly in large buildings, you can set apart places. Nearly always our mess-room is outside.

8486. But there would be a considerable amount of cases where men would not have that opportunity?—With us?

8487. In the general painting business?—We are contractors, and, as I said at the start, the painting in our business is a very small portion of it, and, of course, the painters go into the mess-room with the other men.

8488. From your knowledge of the trade, do you think it is very probable that it would be very difficult to lay down a hard-and-fast rule that under no circumstances is any workman to have his food in a place where work is being performed?—Where lead is being made up, or anything of that sort, certainly. Where he can get lead poisoning; I should say; yes, it is quite right that a man should not take his meals there.

8489. But I asked you whether it is possible to avoid a man having his meals sometimes in rooms where he can contract lead poisoning?—Generally, certainly.

8490. But there are cases where he could not?—Yes. As I said with regard to house painting, I think if a house was being rubbed down the dust would fly all over the house, and, therefore, he would have to have it outside.

8491. As regards the dry rubbing down with sand-paper, I understand this process is indispensable?—We have always been led to understand so in the trade. To get a good surface for the next coat you must rub down the previous one.

8492. Where dry rubbing down is indispensable, how can you prevent the worker from breathing the lead dust?—I do not see how you can prevent it, unless he has a respirator over his mouth.

8493. Can you use an exhaust draught to remove the dust?—Not in our trade.

8494. The next process I wish to ask you about is the painting of ceilings having moulded or relief

designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

8495. This gives rise to splashes which must frequently fall even on the face of the worker?—Yes.

8496. How can you deal with the spray which arises in this operation?—I hope you will not think that some of my answers are rather qualified when I tell you that we very seldom use white lead on ceilings at all, and I have not much experience. I should say that in 50 out of 100 ceilings it is done with distemper.

8497. When it is done with lead, how are you going to remove the danger of splashes falling on the men in the operation of their work?—Of course there is more likelihood of splashes coming on a painter when he is doing a horizontal ceiling than when he is doing vertical work.

8498. Then I understand there is no remedy?—As far as I know.

8499. Could you prohibit lead for such work?—Of course it is not for us; we do not say what is to be used; but I do not think it would be a very bad thing if Duresco was generally used, or some such thing. We always, or practically always, use it on ceilings.

8500. (Mr. Sutherland.) A washable distemper?—Yes, like Duresco, and so on.

8501. (Chairman.) I suppose your observations which apply in regard to the difficulty of removing the dangers in painting ceilings apply equally to stippling, do they not?—I should say there was not so much likelihood with stippling a vertical place as with a horizontal place.

8502. I am speaking of stippling ceilings. There is a certain amount of splashing in the operation of stippling. Can you suggest any way of averting that?—No.

8503. Do you have old paint burnt off with a spirit or charcoal burner?—I have made inquiries, and I find we generally burn it off with a liquid now. We do not use the burning-off lamp.

8504. Are there any fumes coming from that?—I cannot say; I do not know what it is made of.

8505. But if the process of burning off is still adopted, how are you going to prevent the men breathing the fumes?—If there are fumes they must inhale them, of course.

8506. It appears from your evidence that there are certain indispensable processes in carrying out which the painter must necessarily inhale some dust and some spray or fumes containing lead. How can these dangers be met?—I do not know.

8507. Is there any possible way of removing these dangers unless you prohibit the use of lead?—I should say it is impossible, when a painter is rubbing down dry, to prevent some of the dust getting into his mouth, of course. It is natural that with some of it flying about in the air he would breathe it.

8508. Do you think that we could remove these dangers that we have gone through in these questions unless we prohibit the use of lead?—No, I do not think you can.

8509. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience of such substitutes?—We use zinc white a good deal.

8510. What results did you obtain from zinc white?—It is a very good paint.

8511. Is it as good as white lead?—Not in every way. It is not so dense, and it has not such preservative power. I do not think there is anything that has so preservative a power as white lead, especially for outside work.

8512. The Office of Works, among other people, have succeeded in obtaining efficient non-lead paints. I suppose you would agree that, if an efficient substitute could be found, the use of lead should be prohibited?—Certainly.

8513. The Office of Works have told us that for the last four years they have given up the use of lead altogether?—I did not know that.

8514. Do you not think, if the Office of Works can do without lead, that we should be justified in saying that other people should do without it?—They did not

31 May 1911.]

Mr. JAMES SAMUEL HOLLIDAY.

[Continued.]

do without it on our job. That was a 300l. job at the Victoria and Albert Museum. Most of it was polished work, but all the outside work was painted.

8515. When did you do it?—We handed it over to King Edward two years ago.

8516. When did you begin on that work?—We were there nearly seven years, but of course the paint was not done till the last.

8517. When did you begin the painting?—Perhaps a year before we finished.

8518. That is three or four years ago?—Yes.

8519. The Office of Works were then only experimenting, but they inform us that their formula has been in operation now four years, and their formula contains no lead?—I was not aware of that.

8520. And they find it entirely satisfactory?—I have no knowledge.

8521. Do you not think that with that evidence before us we should be justified in saying that, if the Office of Works can use non-lead paints, other people should be made to do the same?—I do not know that I would go so far as that, I should like to say that if I thought it was conclusively proved—if I may put it in that way—it might be a different thing.

8522. What are the usual hours worked by your painters per week?—It is about 52 hours, I think.

8523. Would you agree to a limitation of the hours of employment, say, to 48 hours per week?—For painters only?

8524. No?—It is rather upsetting the works. I do not think I should like to say yes off-hand to that.

8525. Then you would not agree to a strict limitation of hours of employment, say, to 48 hours per week?—I could not agree to that—not on my own account.

8526. You expressed astonishment just now at the figures showing the number of painters who suffer from lead poisoning. You employ 60 painters?—Yes.

8527. The workers' representatives here are able to speak for some 19,000 painters?—Yes.

8528. You would not be surprised to hear, then, that they have known of a very large number of cases?—It is a surprise to me. I was not aware of it until this question came up.

8529. And much suffering in connection with minor attacks of lead poisoning, such as Bright's disease and phthisis, and so on, which are never reported to the Home Office at all?—Yes. I may tell you that I have been at home unwell with shingles in the head, and I asked my doctor, and he said: "I have had a good many cases of lead poisoning." I said: "You surprise me." It is a surprise to me.

8530. When one is sitting here one is rather surprised that the employers have not taken any collective notice of it?—We have not been aware of it.

8531. You do not have a periodical medical examination of your workers, do you?—No.

8532. Do you know that in other industries where lead is used the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—I did not know it.

8533. I have told you that lead poisoning frequently undermines the health without immediately developing acute symptoms?—Yes.

8534. To bring this industry into line with others where lead is used, each painter would have to carry a health register. I mention a health register, as it would be impossible, as the custom obtains in factories, to have the men examined collectively?—Yes.

8535. So it would mean that individual men would have to be examined at odd times and receive a register which they would carry about with them. They would have to see the appointed surgeon at least once a month, and the employers would have to pay the fee for the medical examination. Would you agree to that?—I cannot answer that individually. I would like to talk to my partners about it.

8536. If a certain painter's health were found to be unsatisfactory, the surgeon would suspend him; that is to say, that man would not be allowed to work with lead; say, for a fortnight or a month, and the employer would have to find him other work or compensate him during that time. Would you agree to that?—No.

8537. Do you realise that if the free use of lead is allowed to continue the Home Office will have to insist on the rigid observance of all special rules introduced, in the same way as in other industries where the workers handle lead?—Yes.

8538. And do you realise that the hours of labour might have to be reduced, as has been done in other dangerous trades?—Yes.

8539. This would involve an extremely complicated and elaborate code of regulations?—Yes.

8540. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation—and washing accommodation would mean a compulsory supply of hot water, nail-brushes, and soap, a proper supply of clean towels—and some sort of arrangement for the avoidance of dust, the limitation of hours, and all other such matters?—I could not agree to that. I would sooner do without lead.

8541. (*Dr. Collis.*) Of course I am aware it is not the custom for employers to study closely the health of the workers. For instance, could you tell me, in the course of your experience, whether many of the people you have had in your employ have died of consumption?—We hear sometimes what the men die of. Unfortunately we had one last week who committed suicide. He was a man who had been with us for 30 years. It was a very sad case. We do hear generally.

8542. If the question had been asked you in your examination-in-chief as to whether many of the men in the course of your experience had died of consumption, what would have been your reply?—I think I should have said I had heard of some cases. Ours is a migratory business.

8543. I understand that quite; but could you quote me straight off an instance of a man who had died of consumption?—Not just at the moment I cannot.

8544. Yet I dare say you are aware that one out of every ten of the general population who die, die of consumption?—I did not know that.

8545. So the fact that you are unaware that any of your workmen may have been suffering from lead poisoning, which even in the trades which suffer most from lead poisoning never reaches such a high mortality as that of the general population which suffers from consumption, can be no matter of surprise? If you are unable to quote off-hand a death from consumption, which produces a death-rate of one in ten of the general population, which is a rate which is a great deal higher than that which lead poisoning produces in any trade, it is not a matter of surprise, if you have not been paying special attention to it, that you have not any knowledge that the men may be affected by lead in your employ?—I will tell you what I did. I saw our general foreman of painters, who has been with us 36 years. I had him in last week and questioned him very carefully. I said to him: "Do you know, or have you heard of any cases of your men being away?" I should have thought the general foreman would know what his men were away for if they were suffering from any complaint. I can only give you what evidence I gathered myself.

8546. I am only trying to bring to your mind that an evil like consumption, which, we know, is the white man's scourge, has passed without your knowledge, and, therefore, lead poisoning, which is a much less evil, would pass?—I am certain if any of our men were away from lead poisoning we should know it.

8547. But the point is that if the one could pass without your knowledge so could the other, even though it was present?—Generally, you mean?

8548. Yes?—I thought you meant the men in my firm.

8549. The men in your firm. If you have no knowledge when they have been away from consumption, you would not have a knowledge of whether they were away from lead poisoning?—I suppose, as a matter of fact, so few men die in our firm. I do not know whether it is that or not.

8550. How many men do you employ altogether?—At the present time we will say we have got about 500 or 600.

P\_4

31 May 1911.]

Mr. JAMES SAMUEL HOLLIDAY.

[Continued.]

8551. And about 60 only of those are painters?—I daresay we have a hundred now; but I am giving you an average.

8552. About one in seven is a painter?—Yes.

8553. For that one in seven the insurance has gone up from 15s. to 17s. 6d.?—Yes. We have had one or two rather heavy accidents, and I think it has gone up on account of that.

8554. You mentioned that you are now using a liquid to burn off the paint?—So our foreman tells me. I called him in the other day and asked him this question of burning off with a lamp.

8555. Is it acid which is used, or something of that sort?—Yes, some kind of acid that they put on, and I take it that it really burns it, and has the same effect.

8556. You have not seen it in use?—I have not noticed it. The fact is that we do mostly large new contracts, and we do not do much burning off.

8557. One question about ceilings; I understand at present the water paints or non-lead paints are used extensively on ceilings?—With us. I can only speak from my own experience.

8558. Will you give me the difference between the ceilings and wall paintings generally that calls for this special form of paint to be used on ceilings rather than on other parts of the work?—We generally use, as I said, Duresco, or some other such liquid on the ceilings.

8559. Why, if it is suitable for ceilings, is it unsuitable for other parts of work?—There is not so much wear on the ceilings as there is on the walls, is there? It is very often used on the walls, too. Architects like flatted walls.

8560. If the architect is not the person to please, and if it is a case of the finish of the work, is there any reason for not using these other paints?—Duresco is not so durable as paint. It is all right on the ceiling, but it would not do on the wall.

8561. Do you mean because of the rubbing against it?—I mean to say it has not got the same body. It is simply a water colour.

8562. (Mr. Parsonage.) It will wash?—Yes, but it will not stand scrubbing. It will wash with what we call a very superficial kind of washing.

8563. (Mr. Sutherland.) It is not like a glossed paint?—No.

8564. (Dr. Collis.) If you are not wanting a glossy paint, but if you are wanting a similar kind of surface on your wall as you have on your ceiling, is there any reason for not using these water paints on the wall?—No, I should not think so.

8565. So that there is a possibility of getting an alteration in the form of paint without anything lost, really?—Yes, the only thing is that the public would have to have it done once in two years instead of once in four years, perhaps, that is all.

8566. What is the difference in the original cost of the paint?—There is a difference in the original cost, but I cannot tell you what it is. It is cheaper, I know.

8567. One always looks upon the rewashing of a ceiling as a small thing in the spring cleaning?—Yes.

8568. But if you have to have anything painted, directly you mention the word "painting," the individual who has to do it presents you with a very long contract?—But the expensive part of white-washing the ceiling is the cleaning off the old white-wash.

8569. I am only considering whether if this Duresco, and these water paint can be used more extensively in the other parts of the building, the public would be suffering much more in the way of expense?—That is a question which wants considering. If you paint a wall well, and flat it and paint it well with several coats, it will last for many, many years, and you can always wash it and sponge it down, but you cannot do that with any of these substitutes in the shape of Duresco. If you get any marks or anything on it you can wash them off if it is painted well. It will stand any amount of washing and rubbing, and almost scrubbing.

8570. It is difficult for you to give an estimate of the expense of the two methods?—Yes, I think I would rather not. I do not go into these little matters in my firm.

8571. (Mr. Parsonage.) With regard to your firm you do not take any ordinary painting jobs only; it is buildings?—We do. We have a branch at Kensington that is managed by my son, close to the Museum.

8572. Is that recently?—Yes, this last four years.

8573. On this very large job which you did on the Victoria and Albert Museum, with regard to the men washing their hands, and so on here, there was no time allowed for the painters to wash their hands, was there?—No.

8574. And no towels provided for them to wipe their hands with?—I think they generally wipe their hands on their aprons, and so on.

8575. There was nothing of that sort provided, was there?—We only provided soap and water.

8576. (Mr. Sutherland.) With reference to the limitation of hours, it would be difficult to curtail the painters and retain the others at the same hours, would it not?—Yes, impossible—impracticable I call it.

8577. It would be difficult to separate the one from the other?—It is impossible, I think. It would necessitate timekeepers for each trade.

8578. In reference to the health examination which the Chairman has spoken about, do you not think that would operate against the men?—I do not think the men would have it.

8579. Do you not think it would operate against the men? If a man had an indifferent record, would the employer take him on?—I should think not, certainly.

8580. Do you think it is impossible or impracticable?—Yes.

8581. Now, in reference to the experiment of the Office of Works. Do you think that an experience of four years is sufficient to change the usage of a trade and a material that has stood the test of competition against all competitors for 100 years?—No, I do not think it is.

8582. When you consider that, after all, the Office of Works has applied this on a limited range of buildings, and in a comparatively limited area, do you think it is sufficient to institute such a great change?—I hardly think it is.

8583. Before such a great change was made as the prohibition of white lead, do you not think this Committee, or some committee appointed by it, representing the architects, the builders, and the master painters, with chemical advisers, should institute a series of tests much more searching and much more to the point than those instituted by the Office of Works, with a view to giving us a satisfactory alternative?—I think that is a suggestion I should have made myself.

8584. My own association is prepared to contribute to that: do you think your institute would be prepared to contribute to that?—Yes, I do, and I think I can answer that the London Master Builders' Association, of which I am senior President, would as well. I cannot say, but I should think they would be prepared to.

8585. What did you use on the Victoria and Albert Museum?—The whole of the joiner's work there was teak, which was either polished and oiled, inside and outside, the sashes; and the whole of the outside of the roofs in teak, but those were painted. Of course it is an enormous area—I mean the wood-work of the roofs.

8586. What were they painted with?—White lead. They had three or four coats of white lead, and then I think they were finished with —'s paint, to the best of my recollection, but they had a foundation of lead.

8587. On the specification of the Office of Works?—No, Sir Aston Webb's specification.

8588. And finished with —'s paint on the lead foundation?—Yes, to the best of my recollection.

8589. Practically, —'s paint is the paint of the Office of Works, is it not?—Yes, I think it is. I think that most of the work is finished with —'s paint.

8590. You are not a practical painter yourself; you have only general supervising knowledge of it?—I cannot say that I have not done any painting in my early days, when I was about 17 or 18, but although

31 May 1911.]

Mr. JAMES SAMUEL HOLLIDAY.

[Continued.]

I profess to have a practical knowledge of painting, I cannot say that I occasionally use the brush now.

8591. (*Mr. Rice.*) You are the President of the Institute of Builders?—Yes.

8592. That institute has been engaged at different times in works of education?—Yes.

8593. I think, as a matter of fact, they have not dealt with lead poisoning?—That is what I told the Chairman—since I have been in it—although I think Mr. Shephard gave evidence that they did some time ago, but I have no recollection of dealing with lead poisoning.

8594. But the institute deals with other matters of education?—Certainly.

8595. Had lead poisoning been brought before them so prominently years ago as it is now, no doubt it would have had consideration from them?—Yes.

8596. I take it from your replies to Mr. Sutherland that the institute would be quite willing to assist in any investigation as to a substitute for white lead?—I am sure of it.

8597. I think you, as an individual, and probably knowing the feelings of some of the other members of the institute, hold no brief for the retention of white lead?—Not at all.

8598. Provided there was an efficient substitute found, you would be quite willing to agree to the prohibition of white lead?—Certainly.

8599. (*Chairman.*) In regard to these experiments that it is suggested should be made by a joint committee representing the various builders' associations, and the architects and engineers, what period do you consider would be a reasonable one for those experiments to extend over?—I think that would have to be guided by experience, as they went along.

8600. You have admitted that there are certain operations in the painting trade which involves a risk of men absorbing lead dust?—Certainly.

8601. What would you suggest should be done in the interval between the deliberations of this suggested committee and now?—I should have thought it was hardly necessary to make any stringent rules for that period.

8602. But you have admitted that there are evils obtaining, and the Home Office have statistics which show that the effects of the lead are very deplorable. You surely would not expect the Committee to let the existing conditions prevail while you are searching about for a substitute for lead?—But it would not take such a wonderful time, I should think.

8603. I asked you what you considered would be a reasonable time to allow the committee to make the experiments?—I have no experience in the time that chemists would want to take in testing and that sort of thing.

8604. Then I come back to the other question. What is to be done for these men while you are searching about for the substitute for lead paint?—I have no suggestion to make.

8605. Knowing the conditions to be deplorable, as is illustrated by the Home Office figures, would you consider it right that the men should be allowed to go on suffering as they are, without anything being done while the committee are experimenting?—I think everything should be done to look after the men's interests, as far as possible, certainly.

The witness withdrew.

Mr. ARNOLD PHILIP (*Admiralty Chemist*) examined.

8617. (*Chairman.*) Have you been instructed by the Admiralty to attend here to-day to give evidence regarding the use of paints in the British Navy?—Yes.

8618. Are you the Admiralty Chemist?—I am.

8619. I understand that you act as chemist for the Admiralty generally, although at present you are stationed at His Majesty's Dockyard, Portsmouth?—That is so.

8620. And in the course of your duties as Admiralty Chemist, I understand that you examine the material supplied to the painting department?—Yes.

8606. Then you have told us that there are some portions of the men's work where it is impossible to obviate the dangers that ensue?—I do not think I have admitted that it is impossible to do without it.

8607. You say it is impossible to obviate the dangers because it is impracticable. For instance, take the scraping down of walls. You told us it would be impracticable to have exhaust apparatus to remove that dust?—Certainly.

8608. You have also told us that the danger must remain?—If you ask me to put it in that way, I can only speak from my own experience, which is that, as far as my own experience has gone, I do not think that the effects of lead poisoning from painting in the building trade is such that the time a committee would take to endeavour to find out something else and to carry on tests is sufficient to make stringent alterations.

8609. Then I ask you again, what period do you think would be a reasonable one to allow for these experiments to be made?—I should think 12 months or 2 years, or something of that sort—12 months, I should have thought.

8610. I want you to give us your idea of what should be the time allowed for the investigations?—Of course, whatever I say is a matter of opinion. I cannot feel that I have any weight behind it, because, as I say, you cannot tell how long a chemist is going to take in making experiments.

8611. Then I come back to this. What is to be done to relieve the men from the dangers they come into contact with?—I cannot say.

8612. Would you leave the men in the deplorable condition they are in to-day?—As far as my experience goes, yes. As I say, I have had an experience of immunity from this trouble.

8613. I ask you to remember, not your own experience, but the figures which the Home Office have put before you, showing that the condition of the men is a very deplorable one. I want to ask you whether, in view of those figures, you would think this Committee were justified in allowing those conditions to remain as they are, while you are to have an unlimited time to experiment and try and find a substitute for lead?—I do not think that unlimited time should be given to the committee.

8614. I want to get from you what you consider would be the proper time?—I am afraid I cannot give you that. I am not in a position to say, not being an expert.

8615. How long do you think the men ought to be allowed to go on undergoing the risks which obtain to-day in the industry?—It is rather a difficult thing to say. I cannot answer that.

8616. Would you think it right that they should be allowed to go on for two years without any improvement in their conditions?—It is a question I do not like to answer, because it is suggesting that I am giving an opinion that these poor men are in that condition; I think every possible effort should be taken as soon as possible, with instructions to the committee that no time is to be lost, so that these men's interests can be looked after, and investigations made, and experiments made, so that the danger can be put a stop to as soon as possible. That is as far as I am prepared to go.

8621. And you also advise the Admiralty on technical points connected with paints?—That is so.

8622. The Admiralty have no doubt had before them for many years the dangers arising from the use of lead paints?—Yes, the Admiralty have, for instance, objected to the use of sprayers for painting, on account of its being prejudicial to health. They have also given general instructions that no mediums or driers detrimental to health shall be used in paint material, and they have been introducing machinery for the mixing of paint at the dockyards, which used to be

31 May 1911.]

Mr. ARNOLD PHILIP.

[Continued.]

done by hand. It is gradually being turned over to machine-mixing.

8623. What has been done in the way of finding substitutes for lead paints?—Red oxide of iron has replaced red lead on double bottoms for a considerable period, and the iron casings of boilers are now coated with red oxide paint instead of red lead. Zinc white paints have also been introduced, partly as a substitute for white lead in the interior spaces, and quite recently zinc white enamels have been used inside the cabins in place of white lead paints.

8624. First, with regard to your red oxide paint, will you tell us what materials it contains?—Red oxide of iron paint consists of red oxide of iron with a proportion of lead driers and boiled linseed oil.

8625. How much lead is introduced in that paint in the form of driers?—The present mixture contains under 1 per cent. in the form of lead oxide, as far as I can make out.

8626. Has the use of zinc white in the Navy increased during recent years?—Yes, quite recently.

8627. What led you originally to make use of zinc paints?—Zinc paints have been used for a considerable time. Overhead surfaces have been painted with zinc white for a long time. Where not exposed to weather, inside decks, a mixture of zinc white and white lead has been used for some time.

8628. (Lord Henry Bentinck.) You do admit some white lead then?—Yes.

8629. (Chairman.) What proportion of white lead do you use in the paint you have just illustrated to us?—I am afraid I cannot tell you the exact proportions. I know the proportions of zinc oxide to lead oxide on the total paint used in the Service, but that would include outside. The exact proportion we use, in enclosed deck spaces, of white lead and zinc white, I am afraid I do not know as a separate figure, but that mixture has been used for a very long time.

8630. What led you originally to make use of zinc paints for the inside of cabins?—Originally, zinc mixed with lead and zinc by itself was used, and has been used for many years, because first of all it was not exposed to the weather, and under those conditions it was considered that zinc white could be used, and for another thing it kept its colour better. I should like, if I may, to state it in this way, the use of zinc has been brought about by two steps. Zinc white mixed with lead as a paint has been used for quite a long time. I do not know how long—before I joined the Service.

8631. How long ago is that?—I have been in the Service ten years, and it was considerably before that, undoubtedly; but recently a further step has been made in painting the insides of cabins with enamels. These enamels are made entirely, as far as I am aware, with zinc white.

8632. Do you find them wear as well as lead paints?—They wear a great deal better, not necessarily because of the paint material, the white, but because the gum resin in the enamel preserves its surface very much better.

8633. Do I understand it preserves its surface with zinc paints better than it does with lead paints?—No, I cannot say that.

8634. Then what do you mean by saying that it is preserved better with enamel?—I mean that an enamelled surface, whatever colouring material the enamel used is made up with, will stand the wear, and look better, and it can be washed and rubbed in better condition, and will last very much better than an oil paint, but I understand that manufacturers find that a zinc white made up into an enamel is a much more satisfactory material than lead. In fact, so far as I understand, many manufacturers do not even like any lead in the flatting underneath. They object to it. Lead flatting has been used underneath the mixtures of zinc white, and some manufacturers have asked that we will do away altogether with white lead for the purpose, and use zinc only.

8635. (Mr. Parsonage.) That is for the finishing coat on the iron, is it not?—It is used on the iron work, first of all, and then over that there are two coats of enamel.

8636. (Chairman.) Does it retain its colour?—As far as I am aware, the zinc white enamels retain their colour excellently, except that if they are covered over, in the dark they change to yellow slightly. That is the only thing I have heard against the use of white enamels.

8637. Are you at liberty to give us the Admiralty figures showing the proportion of zinc used in recent years?—Yes. The figures that have been given are as follows. Up to the recent use of enamel paints, the proportion of the zinc allowances made for battleship painting was 33 per cent. of the total white paint, that is to say, if you add together the zinc white and the lead white issued, 33 per cent. of that total is zinc white. Since the introduction of the enamel paints, which are, as far as I am aware, entirely zinc oxide paints, and contain no lead, the percentage has risen something to the order of 60 per cent. of the total; that is to say, at the present time, a battleship's allowance of zinc white is something of the order of 60 per cent. of the total sum of the zinc white and lead oxide issued.

8638. (Mr. Sutherland.) Does that include the outside painting?—It includes it all.

8639. For the hull, and everything?—Yes.

8640. (Chairman.) Do these figures include pure zinc flattings?—They do not include pure zinc flattings, and, as I stated just now, recently some of the manufacturers of these zinc whites have been asking the Admiralty to employ pure zinc flattings. If these pure zinc flattings are employed in the future, it will increase still further the proportion of zinc white used.

8641. Have the Admiralty sought to use zinc paints instead of white lead from humanitarian reasons?—In my opinion not. That has not been the primary point of view from which the use of paints in the Service were regarded. It was a question of efficiency and of cost. I should like to add to what I have said in answer to a previous question, that the consideration of health has always been in the mind of the Admiralty, but it has not been from that point of view that the decisions have been arrived at.

8642. To what, then, is the increasing use of zinc white to be ascribed?—Officers have in the past not infrequently considered it necessary to supplement the Service allowances, and paint with further material privately purchased, and their experience thus gained has been in favour of an enamel rather than an oil paint for internal cabin work. Even though the prime cost of such enamels was necessarily greater than that of oil paints, in the end the use of these materials was actually found to be economical.

8643. Do I understand you to mean that there are occasions when the officers have had to supplement the work of painting?—That is so.

8644. Out of their own pockets?—Yes.

8645. Why do they do that?—I believe, as a matter of fact, that that is undoubtedly so.

8646. Do you know why it is? Is it a system that prevails generally in the Navy?—I should rather prefer not to express opinions on that.

8647. In what way do you mean that the higher priced paints were more economical?—It has been found that, although they are more expensive, the enamels are much more durable, and they retain a good gloss for a long time without repainting. Therefore it has been found more economical to use these paints instead of using white lead paints and repainting more frequently. Enamels simply want wiping with a damp cloth, and the occasional use of perhaps a little pumice stone powder, but they should not be washed in the ordinary way. I understand they are perfectly satisfactory for outside work.

8648. Have you used zinc paints for outside work?—Not in my own experience. I believe they have been experimentally used by the Admiralty in the tropics, but that was more than 10 years ago—before my time.

8649. Then your experience of zinc paints has been confined to interiors?—That is so.

8650. And that experience has been entirely favourable to zinc enamels?—Yes, quite satisfactory, as far as I am aware.

8651. How do you account for the widespread belief that lead paints are the best?—In my opinion, the use

SI. May 1911.]

Mr. ARNOLO PHILIP.

[Continued.]

of lead paint has a much longer history attached to it than the use of zinc paints. The zinc paints are comparatively modern. The use of paint material is an art, and its manufacture is an art. I think that it is always the case that a workman using a paint will be somewhat prejudiced in favour of a material which he has been accustomed to use, and to which there is an enormous history attached. Zinc white and other lead substitutes have not that history attached to them, and there is not that experience either in manufacture or in use.

8652. The exterior painting in the Navy is almost entirely on metal?—That is so.

8653. What material do you use for this exterior painting?—White lead with a lamp-black staining.

8654. What colour are your ships painted outside?—Grey.

8655. How long has this colour been used?—Eight or nine years.

8656. How often are the ships painted outside?—I believe that the Service allowance is about eight coatings per annum, but the amount which is actually used depends upon several conditions, that is to say, on inspections, on stormy weather, and on service on manœuvres, &c., and so forth.

8657. If you repaint as often as that, is the durability of the paint an important factor?—No, I do not think the durability of outside paint is a very great factor, because the outside paint does not weather off; it is not destroyed by weather conditions, but it is knocked off, and after some of the paint is damaged the whole ship has to be repainted outside.

8658. Have you painted any of the outsides of ships with non-lead paints?—Not to my knowledge, although I believe some experimental paintings have been made in the tropics, as I said previously.

8659. Are you aware that the Dutch White Lead Commission made extensive experiments with the use of zinc on their vessel, the "Argus"?—No, I am not aware of that.

8660. I will read you the report of the experiments made on that vessel: "After the expiration of four years, the Commission are able to state that the zinc white paint has been all the time in a somewhat better condition than the white lead paint. This favourable result was so marked after a couple of years, that the Admiralty started using the zinc white paint employed by the White Lead Commission elsewhere also, and on large surfaces, and the results obtained therewith, according to official communications to the Commission, are again extremely favourable, and in favour of zinc white."—Yes; no doubt that means both financially and otherwise.

8661. Yes?—That is a very interesting experiment on a big scale.

8662. Do you not think that the Admiralty should institute experiments to a similar end?—I should like to make a remark on that, but generally speaking I should not like to answer the question directly, because I feel that it is a question that probably would be better referred to the Board of Admiralty. I should like to say that the use of paint material by the Admiralty is entirely governed by the importance, as far as I am aware, of three conditions. First, rendering the ships as little visible, under ordinary conditions, as is possible. Secondly, preserving the material of the hulls in as satisfactory a manner as possible against weather damage. Thirdly, preserving a satisfactory appearance. To this one may add, fourthly, seeking these three conditions at the lowest ultimate cost in material and labour considered in its widest sense; and it is considered that the use of any paint material which could be shown to improve a paint in any of these uses would be very favourably considered. That is my opinion.

8663. (Lord Henry Bentinck.) You issue, apparently, the two classes of paint, and yet you have no data as to how much zinc white is contained in the paints which do contain zinc white?—It is not in this list.

8664. It is rather an important point, is it not, because if your zinc white paints contain a certain amount of lead it is important to know that?—When I say that I believe zinc white enamels do not contain

any lead, that is my own belief, but they are bought as proprietary articles, and we do not buy the materials and mix them and make them ourselves, therefore we do not know, except by analysis, what they contain.

8665. Then you have very little to tell us as to the possibility of employing leadless paint on the outside of ships, have you?—No, nothing at all. It has not been done.

8666. You have formed no opinion yourself?—Yes, I have an opinion. I think, seeing that paints used for the sides of ships do not wear out, but are knocked out, even comparatively cheap paints, containing, for instance, baryta white, might be found to be equally serviceable.

8667. How do you mean knocked out—knocked out by the force of the waves?—With tenders coming alongside, and with weighing the anchor, and so on.

8668. (Chairman.) Do I understand you to mean, not wear and tear, but accidental damage?—It is really wear and tear, it is not accidental damage. Tenders constantly come up alongside, and so on, and if a ship is out on manœuvres she will probably have a good many more tenders than if she happened to be in reserve, for instance, when she would have comparatively few tenders coming alongside.

8669. (Lord Henry Bentinck.) Then if zinc white were used, you do not contemplate that it would be necessary to allow more coats of paint a year, do you?—Of course that is a matter of experience. We have had a long experience of lead paints for outside work, but I believe that some ships in the mercantile marine use cheaper paints for outside.

8670. What do you mean by cheaper paints?—A cheaper paint, for instance, would be a grey paint made with baryta white, instead of lead and zinc oxide, and lamp-black. For instance, instead of using the ordinary lead paint, supposing you used a quarter of the zinc oxide now used and made it up with baryta, that would make up a cheaper paint. My own opinion is that it is a paint which would probably not last so long if it were exposed to the weather, but the fact of the matter is that external paint is not destroyed by the weather on battleships, but it is destroyed by mechanical action.

8671. It seems to me to be an extravagant estimate to allow for eight coats of paint a year?—It certainly sounds rather a big allowance, but it is based upon actual use and experience, and it is necessary to do so; but that allowance sometimes is not used, and sometimes more is required, and then the amount is made up by external purchases.

8672. Do your men suffer from lead poisoning at all?—Not that I am aware of, but the facts as to lead poisoning, in my opinion, would really come more before the cognizance of the Home Office than myself. I think all cases of lead poisoning are reported to the Home Office under the Home Office Regulations.

8673. (Dr. Collis.) Does the question of the weight of the paint come to be of importance in the Navy?—I think it is of importance. It is a question that is always under consideration by the Admiralty undoubtedly.

8674. So that the substitute, being a lighter paint than lead paint, might lead to a war vessel carrying some tons less paint?—I should not like to commit myself to how many tons, or what the weight was.

8675. But it might be a consideration?—The paint weight is a consideration undoubtedly. If we were to use such paints, for instance, as these enamel paints, which are now being used for cabin work; as it is contemplated that the renewal of that paint would be much less frequent than the renewal of lead paints, it will be carrying a smaller amount of paint material undoubtedly, and that means not only a saving in weight, but, perhaps, what is more important, in stowage accommodation.

8676. (Mr. Sutherland.) Why do the Admiralty restrict the use of zinc paints to interior surfaces?—There again I believe that the use of zinc paint being restricted to internal surfaces is that there is no real experience as to its weathering properties. My own opinion, without actually having carried out experiments, would have been to say off-hand that I do not fancy zinc paint will weather so well as a similar

31 May 1911.]

Mr. ARNOLD PHILIP.

[Continued.]

paint made up with oxide of lead—but I do not think sufficient experience exists with regard to it.

8677. (*Chairman.*) Would the experience of the Dutch Commission influence your opinion at all? I have not had the opportunity of considering it. If I had to pronounce an opinion I should like to ask a very great number of questions about it, as to the covering power of the paint used, and the labour used in putting it on, and I should like to have the opportunity of going into the question in very great detail. But undoubtedly, if such an examination showed that there was a saving in cost, such an experiment would, I should imagine, be a considerable inducement to the Admiralty to carry out similar practical tests.

8678. (*Mr. Sutherland.*) Would you regard efficiency as the first qualification for a paint for outside work—effective preservation?—I think that the first consideration would be its tactical value in rendering the ship invisible.

8679. That is only a question of colour, not a question of pigment at all?—That is only a question of colour. Then the next important point would undoubtedly be the preservation of the hull.

8680. That comes in your three steps, does it not?—That is so.

8681. (*Mr. Sutherland.*) You have never really applied it as a test outside to examine it, have you?—To my knowledge, zinc paints for outside work have not been used in the Navy.

8682. (*Chairman.*) With the exception of the experiments in the tropics?—There was an experiment, before my time in the Service, in the tropics.

8683. You told us that the ships in the tropics were painted outside with zinc white paints?—I believe experimental paintings have been made, but those were made before the period during which I have been in the Service of the Admiralty.

8684. (*Mr. Sutherland.*) Before the use of white lead was prohibited, you would consider it very important in the interests of the Navy that sufficient tests should be made if any other material or paint was substituted?—Yes, with regard to paint materials generally, whether they are compositions for ships' bottoms, or whatever they are, I have always said that really practical tests on a small scale should be made tentatively before making further experimental tests.

8685. As against chemical tests?—I do not believe in chemical tests, merely.

8686. In reference to the enamels, you could not call the enamels that you use "paints" in the ordinary sense of the word?—That is so, in fact I always prefer to call them simply enamels, and not enamel paints, because those latter are varnishes mixed with paints.

8687. They are very expensive, are they not?—They are very expensive, but I should like to qualify that by saying that that is only in the first cost of the material.

8688. The wearing is good?—The wearing is so good that the saving of labour and material becomes very important.

8689. We could not take into regard the use of enamels for our ordinary material—I am speaking now of house painting as well as ship painting?—That, of course, I could not say.

8690. The proportion of work that is painted without enamel to that which is painted with enamel is 90 to 10, I should say?—Yes?

8691. If not a less proportion of enamel work?—Yes?

8692. The Admiralty have not been moved in this matter by any considerations of the health of the employees other than prohibiting spraying machines?—Yes, there are one or two other points. I think I may say that they have undoubtedly always kept the health question in their mind, but the important thing is to keep the Navy efficient. They have taken several steps to secure health as against lead poisoning. For instance, although cheap, the Admiralty objected to spray painting, and, with regard to the inside of double bottoms, stopped the use of red oxide of lead.

8693. The supplementing by the officers of the painting is a matter of getting a more decorative surrounding, is it not?—I am rather disinclined to speak for the officers, if I may say so. It is a private

matter for the officer himself, and I should prefer not to say anything about it.

8694. Then it really does not bear either way on the question before this Committee?—I think not.

8695. Neither for nor against it?—I think not, so far as I am aware. The importance of it is this, that the actual use by the officers of enamel paints has called attention to the fact that they really are cheaper for internal work.

8696. In a prolonged service?—Yes, for a prolonged commission of two or three years.

8697. But that is only in the officers' quarters, and not the men's, is it not?—The proposals are that it is only intended for the cabins, but it is to be used also, I think, for grey enamel.

8698. For outside?—Not for the sides, but for work which is exposed to sight on deck.

8699. But protected at the top?—Yes.

8700. (*Lord Henry Bentinck.*) Not altogether protected?—The works outside are painted grey for invisibility, and, therefore, any paint work outside which may be visible must be grey, and not white. Therefore, these enamels have been proposed for use for deck work, on gun turrets, and so on, which are exposed to the weather.

8701. (*Mr. Sutherland.*) Would there not be a danger of a glint of white revealing itself with enamel paint?—There again I should not like to answer. That is a tactical question really.

8702. You have no actual figures as to the relative cost of the two paints in use by the Admiralty, have you?—No, I have not. I think I may say generally that the view is that the use of enamel paints for deck work—not the sides, but for deck work in grey paint and for cabin work in white paint—will be not at all more expensive.

8703. Excluding the enamel?—No, replacing oil paint by enamel paint will cost very little, if any, more, and perhaps there will be no increase in cost.

8704. By reason of the greater prolongation of the service?—Durability; and, of course, the question of labour is of very high importance in the value of paint. If you can do away with two or three paintings, one coat of enamel paint will actually come cheaper than several paintings of oil paints.

8705. (*Mr. Gardner.*) If you are thinking of using this grey enamel for the outside of gun turrets, and so on, why could it not be used for the top sides, which are just as much exposed to weather and the sea. I am referring to the grey top sides above the composition on the ship's bottom?—I should imagine, as I said before, that the tendency rather is to get something which is less expensive. Paint on the sides does not wear out. It is smashed out; it is damaged, and consequently the use of enamel for top sides would be a step in exactly the opposite direction to the one which I was just now mentioning had been considered by the Admiralty, of putting in a cheaper paint material—because it does not wear out, it is knocked out.

8706. But the life of oil paint on an ordinary merchant ship's top sides is anything from one to two years. Of course on His Majesty's ships they are coated three or four times a year, as apart from a merchant ship?—Yes.

8707. So that a zinc paint might do quite as well, and it is a question of experience, because enamel paint is purely a zinc paint made up with varnish?—Yes.

8708. Just as we also used to make up enamel paints with white lead?—I have not really any experience in the making up of enamel paints, but I understand the manufacturers now object to lead.

8709. That is for the grounding purposes?—Yes, but I think, as far as I am aware, the actual enamels themselves do not contain lead.

8710. Of course your experience has been dockyard experience?—Yes. I am stationed at Portsmouth, but as a matter of fact I am the only Admiralty Chemist. I am sole representative of my tribe, and I do all the advising work, and all the chemical work for the

31 May 1911.]

Mr. ARNOLD PHILIP.

[Continued.]

whole of the Admiralty in all the yards and buildings all over the country everywhere.

8711. With regard to the use of sprayers, was that prohibited only in the dockyard, or with contractors?—That I cannot say.

8712. Why did you object to the use of sprayers?—From the point of view of the health of the men. It was considered unhealthy.

8713. And from the point of view of the finish of the job, it not being a properly painted job when it was sprayed?—I saw the experiments carried out myself and the whole thing was stopped. As far as I recollect, I think it was stopped entirely from the point of view that a man who was using a sprayer got simply immersed in a vapour of lead particles, and it was considered absolutely unhealthy, and the Admiralty would not have anything to do with it.

8714. (Chairman.) If the Committee decided to prohibit the use of lead for the painting of the interior of ships, would the Admiralty raise any objection, do you think?—Would that refer to the ships in the Royal Navy or to merchant ships?

8715. To both?—I am afraid I am not in a position to answer that.

8716. But do I understand the interiors of all ships to-day are painted with non-lead paints?—No, that is not so, only parts. White lead paints, and white lead and zinc paints, are both used in the deck spaces—the mess-decks.

8717. Is there any particular object in doing that?—First of all, they must have white for the light, and for seeing that the place is clean, and, secondly, mere plain white lead I believe is found not to keep its colour so well as mixed white lead and zinc. As to why they have not gone over entirely to zinc white, I am not quite certain whether that is due to the fact that no experience exists as to the duration of zinc white by itself.

8718. How often is it painted in the deck-spaces?—I do not know; fairly frequently.

8719. Several times a year?—I think so.

8720. Who would be the best people for us to apply to to ask specifically whether the Admiralty would have any objection to the prohibition of the use of lead for the interior work of battleships and other ships?—It appears to me that it certainly could not come from myself. It would occur to me that your Committee itself should be able to apply directly to the Admiralty.

The witness withdrew.

Mr. GEORGE BEVAN MÖCKFORD examined.

8721. (Chairman.) Have you been instructed by the Admiralty to attend here to-day to give evidence regarding the use of paints in the British Navy?—Yes.

8722. Are you the foreman of painters at His Majesty's Dockyard at Portsmouth?—Yes.

8723. How long have you held that post?—Six months as foreman at Portsmouth, with a previous experience of 7½ years at Sheerness in a similar capacity.

8724. How many men are employed under you at Portsmouth?—320.

8725. Are they all connected with painting?—Every one.

8726. Have you, in the course of that experience, known cases of illness resulting from the use of lead paints?—Several cases.

8727. Then you have realised from your own experience that the use of lead constitutes a very decided danger?—Decidedly.

8728. Do you consider that the use of red lead, as well as white lead, involves serious danger?—Yes.

8729. In confined spaces more than in the open?—In confined spaces you will find the Admiralty have decided not to use it at all.

8730. Not to use lead paints?—Not to use lead paints.

8731. What steps have the Admiralty taken in view of the danger arising from the use of red lead?—In the case of confined spaces we have distinct instructions not to use it on any account. Those confined spaces include all double bottom apartments, fore-peaks and wing spaces, and, in the bunkers of all war vessels, oxide of iron paint is used exclusively.

8732. How long ago was this order given to abolish it?—About 15 years ago.

8733. What did they substitute for red lead?—Oxide of iron paint.

8734. With what medium is that used?—Boiled linseed oil.

8735. Does that give satisfactory results?—Generally we find very good results from it.

8736. What other changes have been made in the paint used in the Navy of recent years?—Oxide of zinc has been used very greatly in preference to white lead for the finishing coats.

8737. What is used for the other coats?—Our work being principally iron and steel, the priming coat is a mixture of red and white lead, the proportions being 55 lbs. of red lead to 24 lbs. of white lead, with the necessary thinnings.

8738. What do you consider the principal danger to which painters are exposed?—The inhalation of

lead dust arising from the rubbing down of surfaces, and possibly the inhalation of the smell of lead itself.

8739. Is there much dust in the process of rubbing down?—A considerable amount, and oftentimes almost imperceptible.

8740. In such small atoms that you can scarcely see it?—Exactly.

8741. How can that danger, in your opinion, be obviated?—By a greater and more extended use of zinc paint.

8742. Have you noted injurious effects arising otherwise than from the lead dust?—From what I have just explained—the smell of the paint in some cases. The men have complained very much, and have been dealt with accordingly.

8743. What is being used in the Navy in place of white lead?—Oxide of zinc.

8744. Is that confined to the interiors of the cabins and the like purposes?—Not entirely. We use it to a great extent in the living spaces where the men are, as well as in the officers' cabins.

8745. Does that apply to wood-work as well as metal surfaces in the interior parts of the ship?—Yes, except the priming coats.

8746. Is there much wood-work to deal with except in the Royal Yachts?—Not a great deal. Usually in the building of warships of all descriptions wood-work is put out of court, because of the danger of fire from shellfire, and so on, which would possibly cause combustion.

8747. Have any of the Royal Yachts been in the dockyard for repainting recently?—At present the "Victoria and Albert" is undergoing the process of redecoration for the Coronation Review.

8748. What paints are you using at present on the "Victoria and Albert"?—Practically zinc—all zinc.

8749. You say "Practically." Will you explain that?—I might possibly have used a little lead in some preparations where new wood-work has been put in. Apart from that, zinc is used exclusively.

8750. For both inside and outside?—The outside of the yacht is painted black, and in that case we use —'s preparations. We have no knowledge of the component parts of that. The final coat is —'s black enamel.

8751. Are the Committee to understand that the paint being used on the "Victoria and Albert" yacht for internal work is practically all zinc?—Yes. I must qualify that by stating that is so in the King's and Queen's apartments particularly, but the remainder of the work on the upper deck, and in the apartments used by the officers, enamel is used for a final coat, and the enamel, of course, is made with zinc.

31 May 1911.]

Mr. GEORGE BEVAN MOCKFORD.

[Continued.]

8752. What other parts of the Royal Yacht are painted with zinc paint exclusively?—Apart from the Royal apartments, there are the suites of rooms further aft. The Royal apartments occupy the amidships portion of the vessel, the other suites being aft, and the officers' quarters being forward of the Royal apartments.

8753. Is any lead used at all in the seamen's quarters, for instance?—Yes, but we in the dockyard have very little to do with that, except when granulated cork is applied in the first instance.

8754. Can you tell me what part of the Royal Yacht is painted with any part of lead?—The first painting in the seamen's quarters; but that has been done some time ago now. It is only refreshed now with a coat of zinc paint.

8755. But supposing you were to paint similar apartments to the seamen's quarters, would you use a lead priming coat?—Probably in the parts covered with granulated cork, a first coat of half lead and half zinc would be applied, to be finished finally with zinc.

8756. What objection would there be to the use of entirely zinc for such work?—The zinc oxide has not the covering power or body or capacity of the lead. Lead has always had a greater covering power.

8757. Do you say that from your own knowledge?—That is my experience.

8758. Have you tried any of the non-lead paints which are on the market now?—Only as supplied by the Admiralty. We have tried them for experiments only, but they have not been brought into actual use. We have never found the leadless paints to give such good results as the white lead.

8759. When did you make these experiments last?—From time to time, as ordered by the Admiralty. I can give you no specific date.

8760. But have you made them in the last few years?—As recently as 18 months ago.

8761. Do you know what the formula was that you used then?—That I could not state off-hand.

8762. Is there much work on the Royal Yachts which has to be sand-papered?—A considerable amount. The whole of the cabins have to be sand-papered down.

8763. And are there considerable surfaces to be stippled?—Yes, the stippling process of course is very fine work, and while that is in process there is always a very fine vapour of paint. The paint is first applied and then stippled.

8764. Do I understand that you can eliminate the risk from all this work by using only zinc paints?—I believe we can.

8765. But you cannot eliminate the risk without using zinc paints?—I think zinc is the cure for it.

8766. I understand that, in the Royal Dockyards, the painters are required to observe carefully certain precautions?—There are several regulations laid down by the Admiralty.

8767. What provision do you make for personal cleanliness?—Soap, towelling, nail-brushes; and the provision of hot and cold water is also made for them.

8768. Do you consider that the provision of hot and cold water is essential?—Very, especially in cold weather, because then the men have very great difficulty in removing the paint. Hot water is most essential, I should think.

8769. If you heard anyone state that the use of hot water was not essential, what would you think of that?—I should say that, on a very cold day, I should experience very great difficulty in removing the paint. A man's hands are sometimes so numbed with the cold that he has not the power to remove it except by hot water.

8770. Is time allowed for washing in the dockyards?—Yes, five minutes before noon bell ringing and five minutes before the afternoon bell ringing.

8771. Do you take any steps to ensure that they make use of the washing conveniences supplied?—The men have to proceed to the wash-house provided, and the men's tickets are held there by the chargeman, and they are not given to them until they have washed their hands, which means that the washing of their hands is under the supervision of the chargeman.

8772. Do you provide overalls for painters?—Yes, all men are supplied with overalls.

8773. By the Admiralty?—At the expense of the Admiralty.

8774. How often are they cleaned?—Approximately, once a fortnight.

8775. At whose expense?—The Admiralty's expense.

8776. Where are they washed?—A large washing laundry or house is supplied, and steam machinery is used.

8777. Then is no painter allowed to take his overall off the premises?—No, they are Government property, with the broad arrow on them.

8778. Do you have a periodical medical examination of your painters?—At Sheerness the men were examined regularly every Saturday morning, and at the Portsmouth Dockyard, where the numbers are great, the men are seen at convenient seasons by the surgeon of the dockyard. We send them in batches of 20.

8779. Have you noticed any difference in the amount of time lost for illness, even transitory, now as compared with, say, eight or ten years ago?—There is a great improvement.

8780. You have told us earlier in your evidence that you consider the abolition of lead the only way to remove the evils. Would it, in your opinion, be practicable to prohibit the use of lead?—I think it would, except in our priming coats on iron and steel surfaces.

8781. Both inside and outside?—For all purposes, except confined spaces, where we have no option in the matter. We are forced to use oxide of iron paints.

8782. Have you made any experiments yet on iron and steel surfaces with non-lead paints?—No, not on any large scale.

8783. Have you made anything which is worthy of being called a serious test?—No.

8784. Then why do you say that you cannot use non-lead paints for priming coats on iron and steel surfaces?—Only that we have observed the use of red and white lead mixed, and it has stood the test very satisfactorily on our warships.

8785. And you think that no other mixture would stand the test?—I would not go so far as that.

8786. How often is the painting done in these ships on the iron and steel surfaces?—On a new ship which is building, as soon as the shipwright and other people have finished, we commence scraping down the whole of the hull, freeing it from rust, and then we commence the application of red and white lead mixture followed by the other coats.

8787. But after the ship is once painted, how often is it repainted inside?—That depends very greatly on the result of the survey.

8788. What is the average period of repainting of a ship?—Three years.

8789. It is painted every three years?—Every three years inside.

8790. How often is it painted outside?—The outside hull is really done now by the ship's staff. It is done by the crew. They repeatedly repaint it. As the vessel gets shabby, so they repaint it.

8791. Have you any experience of the durability of zinc paints when exposed to the weather?—Yes, considerable. The zinc stands well as compared with white lead.

8792. Does it stand better than white lead?—Quite as well. Our surfaces are constantly washed by salt water.

8793. When you say that the ships are repainted inside every three years, do I understand that they are never painted more frequently than that?—Yes, it is generally painted on the survey in three years, but the officers' quarters are painted oftener, and so are the crews' spaces.

8794. How often would you say the insides of a ship are painted?—That is rather indefinite, because we have to take the ships in hand as sent to us by the Admiralty.

8795. Can you give me an average time? Are they painted every year, or more frequently than every year?—I will give you a case in point. If a ship is

31 May 1911.]

Mr. GEORGE BEVAN MOOKFORD.

[Continued.]

paid off, and is brought in to us, if the paint work in the officers' quarters is discoloured, or scraped off, or anything, we have to go right through them, and that may be every 18 months, but the officer may have had his cabin done quite recently. The same officer would not get his cabin done if he remained in the ship.

8796. I want you to give me the average time?—Once every two years would be a fair average.

8797. (*Lord Henry Bentinck.*) You have no cognizance, I suppose, of how many times the interior of the ships would be painted by the officers themselves?—No.

8798. It may be every two or three days, I suppose, as far as you know?—It would not be as often as that, of course, but they have an establishment allowance of stores, and that amount must last them, unless the officers of the ship choose to pay for it out of their own pocket.

8799. The last witness said that zinc white was not used on the mess-decks?—Yes, it is.

8800. Is it entirely used on the mess-decks?—No, I would not go so far as to say it is entirely used. The ship's establishment allowance may be a proportion of white lead and a proportion of zinc. If the ship's officers found they had not sufficient zinc to do an apartment out, they would naturally turn to the next paint which was at hand and use the lead.

8801. Are the men's mess-decks painted by their own staff as well as the officers' quarters?—Yes, more often than by the dockyard.

8802. And you do not know what they paint it with?—No, I do not.

8803. They may paint it with what they like?—Yes.

8804. You could not tell me whether they prefer zinc white to lead white, could you?—I know they prefer zinc white, for this reason—I do not know that they would study it from the health point of view, but because of the superior qualities of zinc in keeping its colour. It does not discolour like lead.

8805. I do not quite understand why you say that lead should be used in priming coats for iron and steel surfaces?—There is a greater adherence than in the coats of zinc. My personal impression is that for priming coats zinc is likely to chip.

8806. Your experience has shown you that?—Yes, although we have not carried out any big tests.

8807. That is for inside work?—Yes; but still we have never done it for testing purposes.

8808. You do not mean to say that you could not arrive at a satisfactory zinc white paint, do you?—I think that would be possible.

8809. But your present idea of it is that it chips?—Yes; I think that is the idea.

8810. (*Chairman.*) If this Committee decided to prohibit the use of lead for all interior painting of ships, would that be considered a hardship by you?—Not at all.

8811. (*Dr. Collis.*) As regards the care of the workpeople in the dockyard, the Government exerts considerable care in looking after the health of its workpeople, does it not?—That is so.

8812. There are medical examinations of the men once a week at Sheerness, and periodically elsewhere. Overalls are supplied and kept rigorously clean, and lavatories with hot water. Can you suggest any other possible precaution for the health of the workpeople besides those which are already adopted?—I think in some cases the Admiralty might grant us a longer time for the men. I can explain that by stating that some of the men are working on ships at a considerable distance from the lavatory, hence the hurry and scurry to pick up their tickets and get away to their dinners.

8813. Has there been any alteration in these precautions during the past ten years?—Only the supplying of hot water.

8814. Has that been more insisted upon recently than formerly?—Yes.

8815. When was there any special injunction on that point?—At Sheerness no hot water was supplied until I insisted on its supply.

8816. You insisted on it, personally?—Yes, and I was backed up by the surgeon of the dockyard.

8817. But there has been no special instruction by the Admiralty on the point to the yard as a whole?—No. I know, when I left Portsmouth to go to Sheerness, eight years ago, no hot water was supplied, but it has been since.

8818. Notwithstanding all the care which is exerted, cases of lead poisoning occur?—Undoubtedly. We have had several cases, and the men have been sent away from the Department—not punished or discharged, or anything of that sort, but sent away, and not allowed to use lead again. You asked me about precautions, and there is one other point. We issue twice a day, to every man employed with red and white lead, a wine-glassful of sulphuric acid orangeade, made up by the surgeon of the dockyard, and carried to the men at their work.

8819. (*Chairman.*) Do they drink it?—They do.

8820. (*Mr. Sutherland.*) Do you go round and see that they drink it?—No, I cannot do that.

8821. (*Chairman.*) How do you know they drink it?—Only by the bottles being brought back empty.

8822. Do they like it?—Some do, others do not.

8823. You say you think it is done for their good, and they help the authorities by drinking it?—I am convinced that they fully understand that this is a measure for the benefit of their health.

8824. (*Lord Henry Bentinck.*) But is the swallowing of sulphuric acid conducive to anybody's health?—I do not think I can answer that.

8825. (*Dr. Collis.*) The point I wanted to make was this, that notwithstanding every possible care that is taken in the Government dockyards in these ways to protect the workpeople, yet cases of lead poisoning occur?—Frequently.

8826. And, without interfering with the process carried on, it would not be possible to protect the men further?—I do not know of any other thing that could be done to eliminate it.

8827. It seems to me there has been a large substitution of other paint for lead paint in recent years?—Yes, as I have stated, zinc paint has been used.

8828. And that has been associated not only with what you have already stated of your personal knowledge of the improvement in the health, but it has also been associated with fewer cases being notified from the dockyard. Are you aware of that fact?—Yes.

8829. So that the sum of your experience in the use of paints is, that notwithstanding the strongest possible precautions to prevent lead poisoning it will occur, but that when you commence substituting other paints for lead, the number of cases of lead poisoning falls and the health improves?—It certainly does.

8830. (*Mr. Gardner.*) Do you find oxide of iron satisfactory in the double bottoms and the shell rooms, and the tanks and all those other places?—Not the shell rooms.

8831. In the tunnel, and all the rest of it?—Yes.

8832. Why do not you use it as a primer instead of the red lead?—There would be the covering property to commence with. Oxide of iron is quite a dark red paint, and then you have to study your covering power afterwards. You would require more coats, and it would be an expensive thing. Then again oxide of iron paint never dries so hard on a surface, as a preparation of red or white lead, with the result that in the coats following, the rubbing down process tears up or brings up the primer, and so you get a pink instead of a white coating, which of course you gradually get rid of at a great expense.

8833. In the mess-rooms do you use red lead only, or a mixture of white lead and red lead?—In the first case, on the iron and steel work, a mixture of 55 lbs. of red lead to 24 lbs. of white lead.

8834. Then your only objection to using iron oxide as a primer all through, on the steel work of the vessel, is the darkness of the colour as a grounding coat, and the fact that it does not dry quite so hard as the white lead does?—That is a very strong objection.

8835. Do you not think that could be obviated by taking more care in the mixing with oil—using special oil and special mixing?—The nature of oxide of iron

31 May 1911.]

Mr. GEORGE BEVAN MOCKFORD.

[Continued.]

paint is always more or less to keep soft, and to skin up.

8836. Can you give me an idea why the Admiralty prohibit you from using lead in the double bottom, and in the ballast tanks, and allow outside contractors to use it?—I am not aware that that is the fact. I have no knowledge of contractors being allowed to use lead paints in confined spaces on Admiralty-built vessels.

8837. Do not you know that?—No, I do not know that. I have examined plenty of vessels that have come from the contractors' works, and found invariably that oxide of iron paint has been used. If a priming coat of lead was used, it was always coated finally by the oxide of iron.

8838. What deck work have you done with zinc?—The "Victoria and Albert" upper deck is done with zinc, and finished with zinc now.

8839. Have you done any battleships with zinc?—They are always finished in grey.

8840. But you can tint zinc?—Yes, but in that case we have an Admiralty shade board to work to. We usually have 73 lbs. of white lead and 8½ lbs. of black to form the grey, and that is used in board and out except on special parts which the Admiralty decide have to be finished in grey enamel. Then the preparation coat must have a proportion of zinc because of the bluish grey which follows with the zinc enamel, because as you know enamel, even when the black is used, produces a different greyish tint to what a lead does.

8841. But, if you find it satisfactory for deck-work as a white paint, do you not think you could get over

The witness withdrew.

Mr. FREDERICK HIGGS examined.

8852. (Chairman.) Do you attend to-day as a representative of the National Federation of Building Trades Employers of Great Britain and Ireland?—The federation asked me to come.

8853. What is the nature of your business, and where is it carried on?—I am a builder and contractor of the ordinary type carrying on business in London.

8854. How long have you been concerned with house painting work?—Ever since I began carrying on the building trade in 1880.

8855. What is the average yearly number of painters employed by your firm?—I have two businesses, one in London, contracting, and the other in the country, jobbing, at Cobham, in Surrey. Thirty-five is the average number we employ in London and 12 in the country.

8856. Are they all painters?—Painters.

8857. Have you known any cases of lead poisoning or painters' colic?—None that have ever come to my notice. I do not know of any in my business at all.

8858. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—All my liability is transferred to the insurance company.

8859. Has the premium in recent years been raised?—It has been raised. I expect you have the same evidence from everyone. The premium is going up.

8860. Is that in consequence of the dangerous nature of the trade?—I take it that it is because we have accidents, and that they have to pay more.

8861. Is the reason to be assigned to the danger of lead poisoning, do you think?—I cannot conceive that in my case, because I have never had a case.

8862. But the insurance people know that the use of lead is a dangerous element?—They may know that, but as far as I am concerned I have had no cases, and I think the insurance companies will tell you that they keep records of the particular cases. If I am covered to-day with one company, and next year I have to go to another company, that other company knows my record.

8863. Do you pay a flat rate for all your men?—Yes.

8864. Whether they are employed in lead or not?—Just the same.

the question of colour, and use it on top-sides?—Yes, we should do it at once if the Admiralty gave us instructions to do so.

8842. It is all a question of getting permission to do it?—Yes.

8843. And do you think it would stand quite as well?—I think so.

8844. (Chairman.) For the upper decks?—Yes.

8845. And for the outside painting of the battleships?—Yes, I think so.

8846. (Mr. Sutherland.) You have no experience of it?—No.

8847. (Lord Henry Bentinck.) For the hull as well as the upper deck?—Of course the outside of the hull gets a greater quantity of washing with salt water than the upper deck. The bluejackets spill the salt water over everything of course with their pails, but there is not so much gets on the upper deck as on the hull. There is very little fresh water that gets on the upper portion of a battleship.

8848. (Chairman.) I suppose the reason you have not painted the outside of battleships with leadless paints is because the Admiralty have not instructed you to do so?—Exactly.

8849. And you have made no tests because you have not been asked to?—We are not permitted to. We are very much bound by our instructions.

8850. In your experience you think there would be no objection to using the non-lead paint for the outside of battleships?—I see no objection to it.

8851. And for the hull—the whole of it?—Yes, the whole of it, in board and out

8865. I am pleased to hear that you have had no lead cases in your firm, but I am not surprised, because you may be aware that in the Potteries there are a large number of works which are quite immune from lead poisoning, whereas others have a good crop of cases every year?—It is most peculiar that both myself, and many other builders that I have talked to have had absolutely no experience of lead poisoning with painters.

8866. Have you known men who have broken down temporarily on account of lead troubles?—None which come under my notice. Of course you can understand perfectly well that, in employing a large number of men of various classes, one does not know personally in each case what is the matter.

8867. You have not an opportunity really of knowing, I suppose?—No, not unless you miss a man and say: "Why is not he here?"

8868. Have your men had occasional days of sickness?—I could not tell you; I should think most likely; most people have.

8869. And that may be due to lead, I suppose, as far as you know?—I could not tell you. I would not like to say so.

8870. Do you have a periodical medical examination of your men?—No, I have nothing of that sort.

8871. Then it is possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—I could not say yes or no to that.

8872. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—Yes, I have understood that.

8873. Do you take a prominent part in the work of the National Federation of Building Trades Employers of Great Britain and Ireland?—I am one of the junior officers, and that is the reason I have come here.

8874. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—Since this Committee has been sitting.

8875. Not before?—Not before.

8876. Did your association ever consider the advisability of having a medical examination made of persons employed?—I never heard of it.

31 May 1911.]

Mr. FREDERICK HIGGS.

[Continued.]

8877. This would be the best way to discover the proportion of painters showing symptoms of lead poisoning, would it not?—I daresay it would. If there was anything the matter with a man, he would go to the doctor to find out what it was.

8878. A medical examination would be the best way to discover whether any of the painters you employ showed symptoms of it?—I know of no better way.

8879. Has your association ever taken any collective measures to discover a substitute for white lead in paints?—Not since I have been connected with it.

8880. They have not employed a chemist to make scientific investigations?—No, not as yet.

8881. There are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead. Have you ever heard of them?—I believe most of the patent paints that we know are supposed to be leadless, but I am no chemist, and I cannot tell you whether they are or not.

8882. Has your association carried out any practical tests with these?—No, not as far as I know.

8883. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many master house painters?—It would not be if it does not come under their notice.

8884. The amount of injury caused to workpeople is published every month in the Board of Trade returns. Have you seen those returns?—I confess that I get a Board of Trade journal once a month, I think it is, but I have not had time to peruse that regularly.

8885. The secretary of your association has not called the members' attention to the serious injury caused by lead amongst house painters?—No, I suppose he has not known of it.

8886. Do you know the number of definite deaths from lead poisoning in the last ten years?—I have no personal knowledge, but I have heard that it is rather large.

8887. It is 284?—I do not know what the total number of painters would be. Everything is a matter of relative proportion. If you say 284, I cannot controvert you.

8888. And that the death-rates from Bright's disease and nervous diseases and phthisis, due to work in lead, are very high?—It may or may not be, I cannot tell you, but I know this, that there are plenty of people besides painters who have phthisis, Bright's disease, and nervous debility.

8889. But do you know that the proportion of house painters affected by those diseases is very much higher than that of other workpeople?—No, I did not know that. Is it suggested that these diseases are part of the symptoms of lead poisoning, or that lead poisoning is an assistance to the production of such diseases?

8890. These diseases are sometimes caused by the absorption of lead. In other cases they are very much aggravated by the absorption of lead. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—I did not know that.

8891. And that these cases reported voluntarily are only a fraction of the whole?—That I cannot tell you. You are asking me about these points which have never come under my notice.

8892. I am bringing that forward because I want you to realise how very serious the evil is?—I think we are all beginning to realise that, because we understand that the Registrar-General's returns give certain facts which have never come under our notice before, or else we should have seen their gravity.

8893. I am sure you will agree with me that all this sickness and death is very deplorable?—Certainly.

8894. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—I have heard so recently.

8895. That the use of white lead has been prohibited to an appreciable extent abroad?—I have heard that.

8896. And that the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed?—That I have heard, but what the regulations are I do not know.

8897. Do you not think it regrettable that this country should be behind other nations in this respect?—It is a question of proportion, of course.

8898. But do you not think it regrettable that this country should be behind other nations in respect of protecting workpeople in regard to the dangers from this evil?—I think that Great Britain should act as a pioneer in most matters.

8899. We have found, in investigating other industries, that a great number of small dangers attend the use of lead. For instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—I should think that is clearly one preventative.

8900. Then you consider that washing accommodation is essential?—Yes, the men must wash their hands, of course, if they use lead.

8901. Including the supply of hot water for washing?—I do not know if hot water is better than cold. I have not adopted it.

8902. Take your own practical experience. Suppose on a winter's morning you had a good deal of paint on your hands, you would get it off easier with hot water, would you not?—I think I should try and use turpentine, or something of that sort.

8903. But supposing you had no turpentine about you?—Hot water would cleanse my hands better than cold water, certainly.

8904. Then, do you not think it is better for the men to use hot water?—Yes.

8905. But is it generally practicable for the men to have hot water to wash in?—It depends on the circumstances.

8906. Is it generally practicable? Can they generally get it?—On a building, yes. The buildings that I have to do are mostly new buildings, and in all buildings of a moderate size we provide a man to do the cooking. There is always hot water for boiling the tea at breakfast time, and generally at dinner time. It would be practicable in those cases.

8907. Do you think from your experience as a master house painter, that it is always practicable for the men to get hot water to wash in?—It would not always be practicable.

8908. Do your painters wear overalls?—They are generally in white—I suppose they do.

8909. Do you supply these?—No.

8910. Would you object to a rule that overalls are to be provided and maintained by the employer as is prescribed in other lead industries?—I should think it would be better for the men to provide their own overalls the same as a carpenter provides his own apron.

8911. But carpentering is not a dangerous trade?—Not in this sense.

8912. How often are the overalls washed?—Not being my overalls, I do not know.

8913. Do you insist on the men having clean overalls from time to time?—I do not make any such rule.

8914. Would you be prepared to arrange for the overalls to be washed at the expense of the employer, as is done in other industries where lead is used?—I should object to that. I think the men ought to wash their own overalls.

8915. It is insisted that lead workers in other trades shall not take overalls home to be washed owing to the danger that that involves?—I cannot tell you about the danger. That, I suppose, is where they get very dusty.

8916. They get dirty. The men wipe their hands on their overalls, and the paint dries, and then the lightest touch creates a regular puff, so that they inhale it, and that is one of the small dangers. Where can the overalls be kept from day to day when working continuously on one job?—They would be hanging up in the painters' shop as we call it.

8917. Now with regard to where the men have their meals. Do you advocate a rule insisting that

31 May 1911.]

Mr. FREDERICK HIGGS.

[Continued.]

no man shall eat his food in the place where lead paint is being handled?—I think it would be a wise rule under the circumstances that you speak of.

8918. Can you always provide that?—Generally on the job there would be the painters' shop, which would contain all those things, and the pegs, and there would be the mess-room, and the mess-room is where the men ought to mess, but they do not always do it there. They do not always mess together.

8919. Could you say from your own knowledge that a room could be always provided for the men to take their meals in where there is no work being performed?—There always is on jobs of any magnitude.

8920. But take a small job?—Painting out a house.

8921. Supposing you paint out a couple of rooms?—Then, probably, they would have their meals downstairs, in the kitchen or the scullery.

8922. But supposing they were not allowed there, where would they have them then?—They would have to go outside, I suppose.

8923. Is it not the practice, on some occasions, for the men to have the meals in the room in which they are working?—Probably it might be the case that they would have to.

8924. All these precautions, as well as others, are insisted on for the mitigation of lead poisoning risks in the Potteries. Would it not be exceedingly difficult to carry them out faithfully in connection with house painting operations?—I am afraid it would. It would not be difficult in the case of a large contract, but with the multitude of small things it would be exceedingly difficult.

8925. Now, with regard to the processes. First, as regards the dry rubbing down with sand-paper. I understand this process is indispensable?—I think so, to make proper work. With regard to that, since this thing has come up, I have been going round my works, and seeing them rubbing down, and I tell them they must either breathe through their nose or get a kind of respirator.

8926. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—Only by the method I have spoken of. A doctor would tell you whether it was any good to breathe through the nostrils under those circumstances, but that is what the nostrils are for, to take up the impurities, and probably the nostrils would do it better than a respirator.

8927. I suppose you could not use an exhaust draught to remove the dust?—Absolutely impossible.

8928. The amount of dust arising from this sand-papering is very considerable. We have been told that it covers his clothing as well as the floors and surrounding objects. How is it possible to save the workman from the very serious danger involved in breathing this dust?—Either to adopt some sort of respirator or to make him breathe through his nostrils.

8929. Have you ever known a respirator that is comfortable to wear?—Fortunately I have never had to wear one, and I cannot tell you.

8930. The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Quite.

8931. This gives rise to splashes which must frequently fall even on the face of the worker?—I say the danger connected with that is far less than with the rubbing down, but still there might be some.

8932. But there is some danger in it?—A careless painter would splash. A careful man would splash much less.

8933. How can you deal with such splashes as arise in this operation?—I do not see very well how that can be dealt with. A man ought not to splash much.

8934. No, but you know what men are; they are not automatic machines?—I quite agree with that, but the painting of enriched cornices is really a small quantity as compared with the whole painting.

8935. I quite understand that, but I want to bring out all the small points that have to be considered?—The point which was in my mind was this; you should

not propose regulations to govern and perhaps harass the whole painting trade of the country for the sake of just a few exceptional cases.

8936. Not unless the few exceptional cases in the aggregate amount to an evil which we consider sufficiently serious to interfere with. Then with regard to stippling, the same point arises there?—I do not think there is much splashing in stippling. A dry brush is used.

8937. There is a little splashing from the painter to the stippler. Take a ceiling, a man paints a ceiling adjacent to the man who is stippling?—Yes.

8938. Sometimes a splash from the painter's brush gets on to the stippler?—Yes, it might, but I should think that that is a very remote case.

8939. But I saw an instance the other day where a man got a splash in his eye. He may get it on his lips, and a careless man may suck it in. I am only bringing out these small dangers?—Yes.

8940. He got it on his hands too, slightly. Do you have old paint burnt off with spirit or charcoal burners?—Spirit generally.

8941. How can you prevent a worker from inhaling fumes that arise in this process?—I should think it is rather impossible. It is not a very nice smell—fumes from burning paint. Naturally he would stand on the side away from that to which the fumes are being blown.

8942. He must inhale some of the fumes?—It is almost impossible to prevent it.

8943. It appears from your evidence, then, that there are certain indispensable processes, in carrying out which a painter must necessarily inhale some dust, spray, or fumes containing lead. How are these dangers to be met?—I have no remedy for those, not for the fumes at any rate.

8944. (Lord Henry Bentinck.) Not even breathing through the nose?—I am afraid that that would make it worse.

8945. (Chairman.) Various witnesses have told us about non-poisonous substitutes for lead. Have you any personal experience of such substitutes?—We have used a good many of these patent paints which they say are leadless.

8946. What results have you obtained from such paints?—In my view they are not good pigments. They do not cover well.

8947. What results did you obtain from zinc paint?—It makes a satisfactory finish, if you put enough coats on, from what I have seen of zinc white. I have not seen much of it. You want about twice as many coats as with lead, if zinc is the basis, they tell me.

8948. Is that your own personal experience?—I have seen it used.

8949. Have you employed these paints yourself for work that you have undertaken?—Yes. I have done a good deal of work for the Office of Works. The last I did for them was with a paint called —. I do not think that zinc makes such a solid paint.

8950. You contend that white lead is better than any other paint you have tried?—Yes, for pigmentary purposes.

8951. For what reason?—It covers better. It is a better pigment.

8952. What have you to say with regard to preservation and protective qualities?—I should think that it is better on that ground, but I could not tell you from my own knowledge.

8953. Your only point is that it is better with regard to its covering properties?—Yes, and lasting. You get a house painted with white lead and it lasts a long while. If painted with zinc paint you do not know how long it will last. You cannot compare.

8954. You mentioned the Office of Works just now. Would you be surprised to hear that they, and other people, have succeeded in obtaining an efficient non-lead paint?—I know that they require these paints. I have had to put them on, and they are satisfied that they are efficient. How long they are going to last I do not know.

8955. They have given their non-lead paints, now, four years' trial, and they have been here and have told us that they are eminently satisfactory?—Yes!

31 May 1911.]

Mr. FREDERICK HIGGS.

[Continued.]

8956. Would that cause you to alter your opinion about them?—Well, you see, the Office of Works and others make it their business to look into the lasting qualities of paint on houses, and that sort of thing. We have to do what we are told—put on white lead or put on —, or anything of the sort, and until we go back to it again we do not know how it has lasted. With regard to any property of our own we know.

8957. But it is a very striking fact that the Office of Works, after nine or ten years' experimenting, have at last found a leadless paint which from their point of view is highly satisfactory?—We should welcome anything of the sort.

8958. With regard to the hours of labour, what are the usual hours worked by your painters per week?—Fifty in the summer and 44 in the winter.

8959. Do they ever work overtime?—They do, if necessary arises.

8960. Would you agree to a strict limitation of the hours of employment to 48 per week?—That is a question of policy, I suppose. I am not restricted myself.

8961. The evidence we have received from the medical profession shows very clearly that the fewer hours the workman is employed in coming in contact with lead the better?—It may be. I have nothing to say against that.

8962. You have no periodical medical examination of your workers?—No.

8963. Do you know that in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—I never heard of it.

8964. Do you know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—I have heard so.

8965. To bring this industry into line with others where lead is used, each painter would have to carry a health register?—Yes.

8966. He would have to see the appointed surgeon at least once a month?—Yes.

8967. And the employer would have to pay the fee for the medical examination?—I have not heard of it.

8968. Would you have any objection to that?—I would sooner see white lead abolished than all these vexatious restrictions.

8969. (*Lord Henry Bentinck*.) You said that your men lost time through occasional days of sickness?—I said that sometimes they were off. I could not say whether it was through sickness or not.

8970. You do not inquire, when they go off, whether it is sickness, and if it is what the sickness is, do you?—No. You see the men do not come under my own personal supervision, so far as that goes. If I was the foreman on the job, and some of my men were away, I should want to know why they were away.

8971. You do not ask, "Is that man suffering from lead poisoning?" or "Is he suffering from Bright's disease?" or "Is he suffering from phthisis?" You do not make any inquiries?—No. I do not make inquiries.

8972. Your evidence as to the existence of lead poisoning is not very valuable, is it?—No. No cases have come before me, particularly since the Workmen's Compensation Act.

8973. Your men, for all you know, may be suffering from lead poisoning?—I could not say if that were so or not. You must not take it either way.

8974. (*Dr. Collis*.) You spoke of the possibility of the men wearing respirators. Is that a theoretical suggestion, or have you any practical knowledge whatever of the wearing of respirators by the British working man?—It is purely theoretical. It is only the last month or so that the idea has occurred to me in consequence of what I have heard of this Inquiry.

8975. Are you aware that seven or eight years ago there was a Committee of Inquiry into ventilation in factories, and the question of respirators came up very strongly there, and that the Committee stated that they only looked upon respirators as a very last resort when everything else failed?—I did not know that. I have not heard of it.

8976. For all the various forms of dust, quite apart from lead dust, and they came to that conclusion owing to the fact that no suitable respirator was yet invented, and that if you had got one you could not make people wear it?—I should think that that is very likely.

8977. So that, after all your suggestion probably would not be practical if it was attempted to be carried out?—The best respirator is the human nose. I know that perfectly well.

8978. (*Lord Henry Bentinck*.) But you cannot pass an Act of Parliament that everybody shall use his nose?—No.

8979. (*Mr. Sutherland*.) Your good opinion of white lead is founded on your experience?—Yes, such experience as I have been able to gain during thirty years of business as a master builder, painting being one of the sections of the trade I practise.

8980. And you know that white lead saponifies with the linseed oil and strengthens the linseed oil, and the linseed oil strengthens the product which comes from the white lead, and a protective film results?—Yes.

8981. In the case of zinc the oil simply holds the zinc, and does not amalgamate with it?—I see.

8982. So that when the oil perishes the zinc is exposed to the weather and also perishes?—I did not know that.

8983. That is really the difference between the two. What other substitutes have you had experience of—only proprietary paints?—Only proprietary paints.

8984. No Committee could really recommend that purely proprietary paints should be used in substitution for a basic article like white lead?—No, except so far as proprietary paints are leadless.

8985. From that point of view possibly, but a committee could not take it on itself to recommend particular articles?—No.

8986. It can only deal with broad substances?—I perfectly understand that.

8987. Do you know that for 40 years, at all events, certainly the last 40 years, paint manufacturers have been trying all they can to produce a paint that shall be a satisfactory substitute for white lead?—I should think very likely that is so.

8988. And that up to now nothing has been produced that is as good and as easily applied and as easily mixed as white lead paint?—Very likely not.

8989. And that, apart from its evil effects as a paint on the health of the workers, there is nothing to compare with it in value as a paint?—Nothing.

8990. (*Mr. Rice*.) You told us that you were covered by insurance in respect of your workmen. In arranging terms with the insurance company, did they ask any extra rate on account of the risk to painters?—None at all. The question of painters' risk has not come into my business as far as I know.

8991. You have had to make no claim on your insurance company in respect of any painters?—Not in respect of any painters at all.

8992. You say that you have an average employment of 35 men. I take it that most of those men are working on buildings?—Yes.

8993. And there they would have a mess-room provided in the usual way?—Yes; two thirds probably are employed on buildings.

8994. Two-thirds would be working under conditions whereby they would not have to have any meal whatever in the paint shop or room where they were working?—No.

8995. I take it that the number of ceilings that you deal with would be mostly distempered?—Mostly distempered. Painting ceilings is very rare. Sometimes I have ceilings painted once—when I line them—when they are very bad in order to keep them up.

8996. The conditions outlined by our Chairman are very seldom found?—Very seldom, indeed, as far as my experience goes. A West End business might have a different experience, might it not?

8997. With regard to the limiting of hours to 48; I think that in London the working hours are 50 per week?—Yes, in the summer.

8998. It would be very inconvenient to alter that to 48 for painters, would it not?—Yes.

Q 2

31 May 1911.]

Mr. FREDERICK HIGGS.

[Continued.]

8999. It would mean starting at a different time or leaving off earlier?—Yes.

9000. (*Mr. Parsonage.*) With regard to the working hours in London, is it not a fact that in decorators' shops, apart from builders' shops, the painters work 10 hours per day?—I cannot answer any question about decorators. I do not know.

9001. That is so. The builders' shops work nine hours and decorating firms work 10 hours?—Nine is our time.

9002. With regard to washing hands, do you allow men time to wash their hands?—I think that they generally take it.

9003. They take it, but they must not let you catch them taking it, I suppose?—We should not object.

9004. Do you provide towels?—We do not provide towels.

9005. They have to find what they can for wiping their hands. They wipe them on their aprons generally?—Perhaps so; I cannot tell you, but I know that towels are not a part of my stock yet.

9006. You agree that the principal danger is the dry rubbing down?—I am not a chemist or a painter, but I should think that that is the case.

9007. That is my experience. You would agree with that?—Yes.

9008. Would you agree that, if dry rubbing down before the first coat of paint is applied was prohibited, that would considerably minimise the danger?—I do not know whether you would get the same results. You mean to say, if you get an absolutely smooth surface to start with, and you put half a dozen coats on would you get the result you wanted?

9009. What I mean is this. Years ago there was far more rubbing down with pumice stone and water on old paint than there is at the present time?—Yes.

9010. You agree with that?—Yes.

9011. In the West End of London now, unfortunately, the use of pumice stone has pretty nearly died out, and they use sand-paper before the first coat is applied?—That is in renewing paint?

9012. Yes. So that nearly all the rubbing down now is dry?—With sand-paper?

9013. Yes?—I daresay that is so.

9014. I wish to bring out the point that the use of pumice stone and water has very nearly died out altogether. Pumice stone and water could be used, you will admit, equally well or better than the dry rubbing on old paint before the first coat is applied?—I should think, quite as well.

9015. It would be better really, would it not?—Yes; you would get a better surface to start with.

9016. One of the principal causes of the evil is the introduction of what is entirely unnecessary, that is, the dry rubbing down before the first coat of paint is applied?—I could not speak to that, because I do not know the causes of the diseases. If they are more frequent among painters working on old houses being repainted than among those working on new work, then I should say your theory is correct, but I do not know if that is so.

9017. With regard to the principal causes of lead poisoning, dust arises far more from dry rubbing than from the wet process?—Undoubtedly. There would be hardly any dust or none with the wet process.

9018. And the wet process is the best for getting a good surface before the first coat of paint is applied?—Yes, but not with new work.

9019. On old work?—Yes.

9020. But why has pumice stone and water been discarded and the more dangerous process been adopted; can you give me an idea?—No. It is an interesting point. I must find that out.

9021. Is it not a question of cheapness and competition?—I could not tell you. They may have had something to do with it.

9022. (*Mr. Sutherland.*) Would you prefer prohibition for inside work rather than regulation?—Judging from the type of regulations that have been foreshadowed to me, I should say, most distinctly, yes.

9023. Prohibition?—Yes.

9024. (*Chairman.*) I understood you to say that you prefer prohibition altogether to regulation?—If I have to register myself as a worker in white lead, which I suppose I shall have to do, whether I use it inside or out, I shall be subjected to a thousand and one forms, letters, visits, and inspections of all sorts, which Heaven preserve us from! We have sufficient already.

The witness withdrew.

Mr. F. L. WALKER examined.

9025. (*Chairman.*) Do you attend here as a representative of the London Master Builders' Association?—Yes.

9026. What is the nature of your business and where is it carried on?—I am in charge of the decorating department of Messrs. Janies Shoobred and Co., Tottenham Court Road.

9027. For how long have you been concerned in house-painting work?—For about 25 years.

9028. What is the average number of painters employed by your firm?—The average number per week is about 40, taking the year through.

9029. Have you known any cases of lead poisoning or painter's colic?—I have only known of one serious case. That was a case of alleged lead poisoning.

9030. Are you aware that in the Potteries, for instance, there are many large works which have had no cases of lead poisoning at all?—I was not aware of that.

9031. Whereas in others they have had a considerable number of cases?—Yes.

9032. Do you insure against your liability for payment of compensation under the Workmen's Compensation Act of 1906?—The firm do.

9033. Have the rates been increased recently?—Not to my knowledge.

9034. Have you known men who have temporarily broken down from illness?—One man—the man to whom I referred just now.

9035. Have your men had occasional days of illness due to lead?—No, I cannot say that they have, beyond this particular man to whom I refer.

9036. Do you have a periodical medical examination of your men?—No.

9037. Then is it not possible that some of them may be suffering from the slower and more insidious forms of lead poisoning?—Yes, it is quite possible.

9038. You know, I presume, that lead poisoning frequently undermines the health without immediate violent manifestations?—So I understand.

9039. Do you take a prominent part in the work of the London Master Builders' Association?—No, I take no part in the work of the London Master Builders' Association.

9040. You never attend their meetings?—Never.

9041. You have heard, I suppose, of the prevalence of lead poisoning amongst men who handle lead paints?—Yes, I have.

9042. Messrs. Shoobred are members of the London Master Builders' Association, are they not?—Yes.

9043. But you do not attend the meetings?—No, I do not.

9044. Do any of your people?—Not to my knowledge.

9045. Now there are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead?—Well, I have not met with them.

9046. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many master house painters?—I can quite believe that.

31 May 1911.]

Mr. F. L. WALKER.

[Continued.]

9047. Have you yourself realised the magnitude of this lead poisoning evil?—No. As I say, in the course of my experience I have only met with this one serious case.

9048. Do you know that there have been 284 deaths from lead poisoning amongst painters in the last 10 years?—I do not know the actual number.

9049. And that the death-rate from Bright's disease and nervous diseases and phthisis, due to work in lead, is very high?—You are referring to painters only now?

9050. Yes?—Yes, I knew that the rate was fairly high.

9051. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion during the last 10 years?—I did not know that.

9052. And that all these cases which have been reported voluntarily are only a fraction of the whole?—I was not aware of that.

9053. Have you seen a copy of the "Labour Gazette" which was published recently by the Board of Trade?—No.

9054. The table on page 187 of the last issue shows a definite increase in the deaths from lead poisoning amongst painters—18 deaths in the first four months of this year, and 12 deaths in the first four months of last year?—I have not seen that particular extract.

9055. The gravity of the danger is seen if you will compare these figures with those for all lead industries under the Factory Act, in which there have been 10 deaths in the first four months of this year, and 15 deaths in the first four months of last year, showing that the death-rate amongst painters has increased, whereas the death-rate in other lead industries has decreased. Now I am sure you will agree with me that all this sickness and death is very deplorable?—Undoubtedly, unquestionably.

9056. Do you know that this evil has attracted the most careful attention in many foreign countries?—Yes.

9057. Do not you think it is regrettable that this country should be behind other nations in this respect?—Very regrettable.

9058. Now a great many small dangers (I want you to realise this) attend the use of lead; for instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—Certainly.

9059. Do you consider washing accommodation essential?—Certainly.

9060. Including the supply of hot water for washing?—Hot water I cannot speak about.

9061. But just realise; in the winter months, when it is extremely cold, would it not be much more difficult to get paint off the hands with cold water than with hot water?—It would be more difficult certainly. I would not say much more difficult.

9062. Is it generally practicable for the men to have hot water to wash in?—It all depends upon where the job is.

9063. But is it generally practicable. I am not asking whether it is universally practicable, but is it generally practicable to have hot water?—Generally practicable—no.

9064. Do your painters wear overalls?—Yes.

9065. Do you supply those?—No, we do not.

9066. Would you object to a rule that overalls are to be provided and maintained by the employer as is prescribed in other lead industries?—I do not at the moment see any reason why the employer should provide them.

9067. I have told you it is prescribed in other lead industries?—Are you asking me as an employer whether I should object to it?

9068. Yes?—I am not an employer actually.

9069. I ask you, as a witness, whether you would object?—The only answer I can give to that is that I see no reason why the employer should provide them.

9070. How often are the overalls washed, could you tell me?—I should say once a week; but that is a question I cannot answer definitely at all.

9071. Would you be prepared to arrange for the overalls to be washed at your expense at least once a week, as is done in other industries where lead is used?—On the question of expense, I cannot answer. We should be quite prepared to arrange for the washing of them, certainly. There would be no difficulty in that.

9072. It is insisted in other trades that lead workers shall not take overalls home to be washed, owing to the danger that that involves. A man takes an overall home with him; it is covered with paint which dries and goes to a sort of dust, and that is a danger that one has to guard against?—Yes.

9073. Where can overalls be kept from day to day when the worker is continuously at one job?—They are usually kept in the same place as what the foreman on the job calls his shop—the particular room that he has set apart for the mixing of his materials and so on. Usually they are kept there. It may be an empty house, for instance.

9074. Now with regard to meal-rooms. Do you advocate a rule that no man shall eat his food in the place where paint is being handled, or is that impossible?—I should say it is advisable that he should not do so. In certain cases undoubtedly it is impossible.

9075. Now all these precautions, as well as others, are insisted on in mitigation of lead-poisoning risks in the Potteries?—Yes.

9076. Would it not be exceedingly difficult to carry them out faithfully in connection with house painting operations?—Yes, I should say that it would be distinctly difficult.

9077. Now about the various processes. First, as regards dry rubbing down with sand-paper, I understand that this process is indispensable?—Yes, indispensable I should say, on new work certainly.

9078. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—I do not think you could prevent it entirely by any means. You might reduce the danger to a minimum by the use of a respirator.

9079. Have you ever heard of a respirator that is comfortable to wear?—I have never worn one.

9080. Have you ever heard of one that is comfortable to wear?—I have not interested myself in that particular question.

9081. The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work, the brush has to be pushed into the background of the ornamental work?—Yes.

9082. This gives rise to splashes, which must frequently fall even on the face of the worker. How can you deal with the splashes which arise in this operation?—I do not think that you can possibly deal with them. I do not see how they are to be avoided.

9083. Then with regard to stippling, a certain amount of splashes fall on the stippler?—Yes.

9084. Can you suggest any way of avoiding that?—No, I cannot suggest any way of avoiding that.

9085. Then when the old paint is burnt off, either by a spirit or a charcoal burner, how can you prevent the worker breathing the fumes?—I should be inclined to think that the burning-off lamp is used to a very limited extent to-day; the adoption of liquid paint removers has reduced the use of it to a minimum.

9086. Would you advocate the prohibition of burning off altogether?—I do not know that I would advocate its prohibition, but it would be a very very hard paint or material that could not be removed by the use of a strong liquid paint remover.

9087. But in cases where burning off is still in practice, how would you prevent the worker from breathing fumes?—I do not think that you could prevent it, and I doubt if there is really very much in that. I can quite understand that the fumes from a burning-off lamp would perhaps upset a delicate stomach, just the same as the smell of paint might do, but that there is any serious or real danger from the smell of the fumes I do not believe.

9088. But supposing that medical evidence was produced to show conclusively that there is great danger in it?—Well, if it was, I should bow with all

31 May 1911.]

Mr. F. L. WALKER.

[Continued.]

deference to it, but still hold my opinion. That is all I can say about that. Even doctors differ.

9089. Now it appears from your evidence that there are certain indispensable processes in the carrying out of which the painter must necessarily inhale some dust from spray and some fumes containing lead. How are these dangers to be met?—I do not see how you are going to meet them. Ample ventilation of a room may minimise the danger where dry rubbing down is going on.

9090. Is it possible to remove the danger entirely in any way than by using a substitute for lead?—I see no reason myself why the use of white lead should not be entirely abandoned as far as internal work is concerned. That is my present opinion. I know of nothing that I have ever tried or that is on the market, to my knowledge, that has the covering properties of white lead, and I think that the use of white lead is indispensable for outside work in view of the protection of the woodwork. But for inside work I see no reason why white lead should not be done away with altogether.

9091. The Office of Works, and many other people, have succeeded in obtaining efficient non-lead paints for outside work?—Have they?

9092. Yes. Would that weigh with you at all?—Certainly it would. If they have succeeded in securing an efficient non-lead paint, why should not that be used.

9093. The Office of Works have been experimenting for the last nine or ten years, and they maintain that during the last four years they have found a substitute which is highly satisfactory. That weighs with you considerably, I suppose?—Certainly.

9094. What are the usual hours worked by your painters per week?—56 or 56½, but I think it is 56. They work 12 hours a day in the country, I am speaking of London men.

9095. Would you agree as an employer to a strict limitation of the hours of employment to, say, 48 per week, as agreed in the Potteries?—I am not an employer.

9096. (Mr. Sutherland.) But you represent an employer?—I represent an employer.

9097. You can answer for them?—I cannot altogether answer for them on that particular question.

9098. (Chairman.) I put the question to you for this reason: that the medical evidence obtained in a recent inquiry into the earthenware and china trade clearly showed the importance of the workmen being employed as few hours as possible when they came into contact with lead, and both the employers and the employed agreed to restrict the hours to 48?—Yes.

9099. I ask you whether you think that that would be agreed to by the firm you represent with regard to house painters?—Yes, I should imagine that the firm I represent would agree to it if it was agreeable to the employees.

9100. You do not have a periodical medical examination of your workers, do you?—No.

9101. Do you know that, in other industries where lead is used, the Home Office insists on a monthly or even weekly examination by the certifying surgeon?—Yes, I have heard of that.

9102. Do you know that lead poisoning frequently undermines the health without immediately developing acute symptoms?—I have understood that it does so.

9103. Now, to bring this industry into line with others where lead is used, each painter would have to carry a health register?—Yes.

9104. He would have to see the appointed surgeon at least once a month?—Yes.

9105. And the employer would have to pay for the medical examination. Would you object to that?—Again I am answering for my firm. I should say yes, they would object to that.

9106. If a certain painter's health was found to be unsatisfactory, the surgeon could suspend him?—Yes.

9107. That is to say, the man would not be allowed to work with lead for, say, a fortnight or a month, and the employer would have to find him other work or compensate him during that time. Would your

employers agree to that?—I should say they would strongly object to that.

9108. Now, you realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures in the same way as in other industries where the workers handle lead?—Yes, I clearly realise it.

9109. And you realise that the hours of labour might be reduced, as has been done in other dangerous trades?—I realise that also.

9110. This would involve an extremely complicated and elaborate code of regulations. Are you fully prepared to adopt the necessary machinery to secure complete observance of all the regulations relating to overalls that I have spoken of, mess-rooms, washing accommodation, avoidance of dust, and all other such matters?—No, it would be an impossibility in my opinion.

9111. Taking all these points into consideration, would you say that you prefer that the industry should be regulated by such a code of rules as I have foreshadowed, or that the use of lead should be prohibited?—I should be disposed to say that I should prefer the use of lead being prohibited.

9112. (Dr. Collis.) You mentioned that you knew of one case of severe illness due to lead?—Yes, an alleged case. I have heard it said of this man that he would make a very fine cask of white lead if he was ground up. His, as far as I know, is the only bad case of lead poisoning that I have any personal knowledge of, and I understand that I am only required to give evidence of things which are the result of my own personal observation and experience.

9113. When did this illness occur?—That I could not tell you. I have known this particular man personally for about twelve or thirteen years.

9114. When did you become acquainted with the fact that he suffered from illness due to lead?—Then.

9115. Twelve years ago?—Yes.

9116. And not at all since. Has he remained in your employ?—Yes, he has remained in our employ ever since. He has been away a few times, but not much.

9117. He is still in your employ now?—He is not at work for us at the moment, and he has not been for a week or so, but he regards himself as one of our regular men, and unless he was very hard driven I do not suppose that he would seek work elsewhere.

9118. He has had no serious illness recently to keep him away from work?—No.

9119. You mentioned that you thought that respirators might be of value. What is your experience of respirators?—None whatever.

9120. So that your suggestion is rather hypothetical?—Exactly, purely.

9121. Could you tell me at all what is the constitution of these liquid paint removers about which you spoke?—No, I could not. There are one or two on the market now which are very very powerful, and which I have tried just recently myself. I have observed their action.

9122. I understood you to say in your examination-in-chief that nothing will convince you that the fumes from burning off old paint would be dangerous?—No I did not say that nothing would convince me that they are dangerous. What I did say was that if medical evidence to the contrary was brought before me I should bow to it, but I should still hold my opinion. But I am open to conviction.

9123. I do not detect the difference?—As far as my own experience and observation go, I see nothing to make me grasp or realise that any serious amount of lead could get into the system through smelling the fumes from the burning off. That is my point.

9124. Experiments were carried out for this Committee in the burning off of old paint, and the analyses showed 3·4 milligrammes of lead in 10 cubic meters of air on one occasion, and on another occasion 1·3, on another occasion 0·3, and on another 1·2. Would such results as those in any way cause you to modify your opinion that there can be no danger from the burning off of old paint?—I did not say that I thought there was no danger from it, you see. What I say

31 May 1911.]

Mr. F. L. WALKER.

[Continued.]

is that I have not realised and cannot realise—I will put it that I have not realised that there can be danger.

9125. But my question was this: Would these analyses cause you in any way to modify the opinion which you have already formed. I did not ask the opinion you have already formed?—Yes, I should say that they would to some extent. On that point, as I say, I am open to conviction.

9126. (Mr. Parsonage.) Are Shoobreds members of the Master Builders' Association? I understood you to say they were?—Yes, I believe so.

9127. But do you know that they are members, because I have reason to think that they are not members of the Master Builders' Association? You do not know positively?—I know positively that they have been members of the Master Builders' Association up to this year.

9128. I will accept that?—The paying of the fee does not come under my personal observation. I assume that the firm are still members. They were up to a few months ago at any rate.

9129. You have not been foreman for Shoobred's for so very long, have you?—I have been in charge of the decorating department of Messrs. Shoobred for five years. For seven years previous to that I was in charge of the whole of their outside work.

9130. Men may have worked for Shoobred's and have suffered from lead poisoning without it coming to your knowledge at all?—I am quite prepared to grant you that. That I have no knowledge of.

9131. Does your firm provide towels and allow time for washing the hands?—Yes, we provide ample accommodation in that way, and soap.

9132. I am very pleased that they do. I know that they do, and I wish that all the other firms in London did the same?—Why did you ask me the question if you knew?

9133. I wished to bring it out. I have asked everyone that question. In your case it is quite correct that your firm does allow time and also provides washing accommodation?—Accommodation exists in 90 per cent. of the London jobs, which are probably done in empty houses, and the ordinary conveniences of the house are at liberty for use, of course. But, assuming that that is not so, we provide everything in the shape of soap, towels, and everything else, and pails, that the men need for personal cleanliness.

9134. On country jobs your men work 12 hours per day?—Yes.

9135. And on all country jobs you provide a mess-room apart from where the painting work is done?—Yes.

9136. And also someone to cook the food for the men?—Yes.

9137. (Mr. Gardner.) When you say that you have not known of men being off work through illness due to white lead or due to lead poisoning, I suppose you mean that they were not off due to direct lead poisoning, that is, they were not off through colic or dropped wrist, or anything of the sort. If they had been off for that, you would have said that they were off for lead poisoning?—If I had known of it, certainly.

9138. But are you aware that Bright's disease and phthisis and some other things are aggravated by lead?—I am not aware of it. I can quite readily understand that they would be.

9139. A man may be off through these troubles and you would not know anything about it?—The particular reason why a man is away is not reported to me as a rule.

9140. Owing to the intermittent nature of the employment of a painter, men might very often be ill and you would know nothing whatever about it?—No. I should know very little about their personal affairs and movements when they were not employed by us.

The witness withdrew.

## TWELFTH DAY.

Thursday, 1st June 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (Chairman).

Lord HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B. (Oxon).  
Mr. F. G. RICE.  
Mr. W. G. SUTHERLAND.

Mr. A. GARDNER.  
Mr. J. PARSONAGE.  
E. A. R. WERNER (Acting Secretary).

Mr. A. G. WHITE examined.

9141. (Chairman.) Do you attend here to-day as the secretary of the National Federation of Building Trades Employers of Great Britain and Ireland?—Yes.

9142-3. Before becoming secretary of the federation were you an employer in the building trade?—I was.

9144. For how long?—For about twenty years.

9145. What is the average number of painters employed by your firm?—It varied a good deal, but somewhere from 100 to 200. Sometimes we had much more than that.

9146. An average of 100 to 200?—Yes, I think so.

9147. What cases of lead poisoning can you recall among your workers?—I can only recall three cases.

9148. Covering what period?—In the period I refer to—twenty years.

9149. What was the name of the firm you were with?—Alexander White and Sons, of Liverpool.

9150. Your experience as an employer was prior to the Workmen's Compensation Act of 1906, I suppose?—Yes.

9151. Did your men have occasional attacks of illness due to lead apart from the serious cases you mention?—There was occasionally colic. One used to hear occasionally that a man was off. We inquired what it was for. He had a little touch of colic.

9152. Did you have periodical medical examination of your men?—No.

9153. Is it not possible that some of them might have suffered from the slower and more insidious forms of lead poisoning without you knowing it?—It is possible, but there was no evidence of that to the ordinary observer.

9154. Not one way or the other?—No. We could not say that the men were inefficient or unable to follow their occupation.

Q 4.

- 1 June 1911.]

Mr. A. G. WHITE,

[Continued.]

9155. If you had had the men medically examined, you would have ascertained at once whether slight attacks of lead poisoning had occurred amongst them?—Yes.

9156. I will now ask you a few questions which you will kindly answer in your capacity as general secretary to the National Federation. The question of the prevalence of lead poisoning among house painters has been discussed at your meetings, has it not?—Not in any general way. It has occasionally been mentioned, but not as a specific discussion.

9157. Have you collected any statistics from the branches of your federation?—Only such as I have given you.

9158. What are they?—In what I sent in I mentioned the information I had, consisting of communications received from our branches and certain statistics which I had gathered together from time to time.

9159. What is the purport of these communications from your branches?—The purport of the communications from the branches is to show that the disease is not at all common, in most cases very rare, and that the tendency of the statistics is to show that it is rather on the decline.

9160. (Mr. Sutherland.) Have you those statistics?—Yes; I sent a copy to the Committee, and I have them here. With a view of eliciting information from the membership of the federation, I issued a circular letter of inquiry on 1st March last, which has so far yielded the following results: The Southampton and District Association says no cases of poisoning have come to the notice of any of the members. The secretary of the Lancaster and District Association says: "I have brought your circular before my committee and also before a meeting of painters and plumbers. So far as we can get any information on the subject there have not been any cases of lead poisoning during the last thirteen years, and the average number of painters employed is about 60." The Portsmouth and District Association says: "As regards the question of lead-poisoning cases these appear to be 'practically nil'; and the secretary encloses several letters from members of his branch emphasising the necessity for cleanliness and so on. The secretary of the Otham and District Association reports: "I have brought your circular on the above matter before my association, and am instructed to inform you that 'not one of the members present at the meeting could recall to mind a case of lead poisoning in this district for many years past.'" The secretary of the Nottingham and District Association reports: "In reference to your circular of 1st inst., I find that one of my members, who is a master painter, has already handed in his name some months back to give evidence on the above matter. He informs me that in his own experience of 45 years as workman and master he has never had before him a case of lead poisoning." The Liverpool and District Association has appointed two members, Messrs. Griffiths and Morton, both experienced master plumbers and painters, to give evidence before this Committee. They do not state whether they have had any cases of lead poisoning or not. The Newcastle and District Association referred my circular to the local Master Painters' Association, who are probably submitting evidence through the National Association of House Painters and Decorators. Dublin have done the same. Mr. McIntyre, of Dublin, says: "Dear Mr. White,—Your letter to Mr. John Good re Home Office Departmental Committee on dangers attendant on the use of lead in house-painting was sent on to me through Mr. Sibthorpe, to whom Mr. Good sent it. I have given some time to gathering statistics of the nature asked for, and to a certain extent succeeded. My information as far as definitely stated herein is absolutely reliable. Since the present Act came into force on the 1st July 1907 this association has had its risks under the Workmen's Compensation Act in three separate offices. The statistics I now give are official, and the communication now lies before me. From 1st July 1907 to 30th June 1909 three cases occurred, none of them fatal. From 1st July 1909 to 30th June 1910 three cases, one alleged permanent disablement; two

fatal, a plumber and a painter. From 1st July 1910 to date hereof, two cases, one trifling, which was settled for a small payment, and the second is alleged permanent disablement. These cases cover all Ireland as far as this association is concerned. The number of workmen is not so easily got at, but the Dublin district holds 400 Amalgamated Society men officially furnished to me by their delegate. The Metropolitan (old) did not reply to my letter, but I should say it is less; from 250 to 300 would be about right. In addition to this, you might put the non-society men at about 300 more. This association covers Belfast, Derry, Limerick and Cork."

9161. (Mr. Sutherland.) Mr. McIntyre is the president of the Association of Master Painters in Ireland?—Yes.

9162. (Chairman.) Have you analysed these figures with a view to bringing before us any deduction from them?—I have not analysed those figures. I only received them yesterday.

9163. Have you analysed any of the figures?—The only figures that I have taken into consideration are the official reports which I have referred to here—Board of Trade publications. Those are the only ones I have analysed in any way. Later on I wish to call attention to the Board of Trade publication of Workmen's Compensation statistics, Od. 5386, and quote cases which show that there is a considerable prevalence, equal to 15 per cent. (497), of lead-poisoning cases out of 3,313 cases of disablement without touching the house-painting or building trades at all.

9164. (Dr. Collis.) Is it claimed that some of the cases which we at present ascribe to the house-painting trade are cases occurring in factories?—I do not know what you ascribe to the house-painting trade.

9165. I only ask whether that is the purport of your evidence?—The purport of my evidence is to show that lead poisoning in the house-painting trade is not a serious evil, and that it is a diminishing evil, and can be remedied by reasonable regulations. That is the purport of my evidence.

9166. (Chairman.) That is only an assertion?—Yes.

9167. You must not come here to make assertions. We want facts?—I am giving the facts which I think bear that out.

9168. You shall have an opportunity of proving anything you wish to prove. Did your association ever attempt to collect statistics concerning the number of days' absence from ill-health among painters as compared with workers not in contact with lead?—No.

9169. Did your association ever consider the advisability of having a medical examination made of persons employed?—No; we have no right to make such a medical examination.

9170. But you had perfect liberty to do it?—I think that we should have got into trouble with the workmen; if we had tried they would have objected.

9171. In other lead industries it is compulsory?—It may be, but it is not in our trade.

9172. Would not this have been the best way to discover the proportion of painters showing symptoms of lead impregnation?—Yes, if it had been within our power to do it, certainly; but a voluntary association cannot expect its members to comply with regulations of that sort. They will not do it. We have no power.

9173. You think that, before you do anything of the sort, it ought to be on the initiative of the Home Office?—It would have to be under compulsion by law, or else they would not do it.

9174. Has your association ever taken any collective measures to discover a substitute for white lead in paints?—No.

9175. There are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead?—I have heard of such things. I have not found anything satisfactory.

9176. Has your association carried out any practical tests with these?—Individuals have tested them, of course, but not as an association.

9177. We have been told that the extent of the danger of lead poisoning to which house painters are

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

exposed is not fully realised by many employers?—Well, I do not agree with that statement.

9178. Do you infer that the employers do know the extent of lead poisoning?—I think that they realise the danger, and take all reasonable precautions against it as far as their powers go. That is my experience. They may not realise the extent in the sense that they have any statistics before them. They can only go on their own personal experience. They have no other information.

9179. But do not you think that your association should have taken the Board of Trade returns, published every month, and had these discussed before the general body of your association with a view of bringing out the alarming condition which these figures suggest?—I do not know, I am sure.

9180. You do not think they ought to have done that?—Well, I do not think it is for me to express an opinion.

9181. But have you, as secretary, ever suggested it?—No, I have never suggested it.

9182. Did you yourself realise the magnitude of this lead poisoning evil?—My whole position is that the magnitude is very much exaggerated, as far as the painting trade is concerned.

9183. Do you know that there have been 284 definite deaths from lead poisoning in the last 10 years?—I do not know that I know it of my own knowledge, but I am quite willing to accept such a figure if you state it.

9184. And that the death rate from Bright's disease and nervous diseases and phthisis due to work in lead is very high?—No. I could understand that if a man's system was reduced by lead or any other poison he would be more liable to take diseases. May I refer to the 284 cases in 10 years. Are there any figures as to the number of workmen that refers to?

9185. No; we have not the return. Do you know that about 2,000 cases of lead poisoning in your trade were reported to the Home Office voluntarily without any legal compulsion whatever in the same 10 years?—No, but I am quite willing to accept your statement that it is so.

9186. Do you realise that these cases reported voluntarily are only a fraction of the whole, inasmuch as the Home Office have no legal right to pry for such reports and are therefore bound to discourage reporting to some extent?—Yes; they are probably only a fraction of the whole, but they may be a very large fraction; I could not say.

9187. Have you seen a copy of the Board of Trade Labour Gazette which was published in the middle of May?—I think I have. I do not know whether that is the one I refer to here. I saw some figures.

9188. The table at page 187 of that issue shows a definite increase in the deaths from lead poisoning amongst painters?—Yes. I suppose it has been more fully reported now, has it not?

9189. No. The deaths are reported, in any case?—Yes.

9190. Eighteen deaths in the first four months of the year, and only 12 deaths in the first four months of last year, which shows that, at any rate, the death rate is not decreasing?—It is heavier.

9191. It is heavier. The gravity of the danger is seen if you compare these figures with those for all lead industries under the Factory Act, in which there have been 10 deaths in the first four months of this year and 15 deaths in the first four months of last year?—Your point being that there are more deaths in the house painting and plumbing than there are in lead industries proper?

9192. Yes?—I should think that that is probably so. It bears out what in my opinion is the trouble which wants proper regulation. There are precautions taken in lead industries which are not taken in ours.

9193. How do you reconcile those figures with the reports you have submitted to us from various branches where, with the exception of Ireland, not a single member of the associations which have reported has ever heard of a case?—I think that I can account for it. The people that you get the reports from through us represent the best employers in the trade. Employers

of a lower class do not as a rule belong to our organisation. The members of our association take care of their workpeople, and they take precautions. If you walk about the country, going to any railway station, you will see the class of men painting there with no overalls on—beastly dirty clothes and no precautions whatever taken. That class of men, I have no doubt, suffer extremely from lead poisoning. But with regard to that class of men you are not getting any evidence from our members.

9194. Could you tell us the number of men that these firms employ who have reported that they have had no cases?—No, except so far as they give them themselves. I do not know. I tried to get information. I wanted the number of men referred to. That was part of my inquiry.

9195. Without going into it closely, as far as I have seen in the aggregate they come to a very small number. If you say they are picked men employed by the best class of employers, that evidence is not of very much service to us?—Except this: I want to impress on this Committee that this trouble can be kept down by proper precautions, and that those employers who take such precautions do not have the trouble.

9196. In your proof you refer to a statement made by Mr. Gibbs, the secretary of the National Society of Operative House and Ship Painters, before the Departmental Committee in 1907, on the dangers attendant on building operations?—Yes.

9197. Would you kindly read the paragraph that you wish to quote in relation to lead poisoning?—Do you want me to read it?

9198. Or I will read it for you, if you like?—Yes, if you please.

9199. The following question was put to Mr. Gibbs: "I notice in connection with lead poisoning that, during the last twelve months, you have had no less than nine members of your society rendered totally unable to follow their occupation owing to the effects of lead poisoning. About how many members are there in your society?" Mr. Gibbs replied: "Roughly speaking, about 17,000." That refers to the period 1905-6. Now the quotation speaks of nine cases of total disablement in that year. Does that not appear to you to confirm the serious figure already quoted?—Well, I quoted it to show that when you refer to the large number of men it is among, the number of cases is small per thousand.

9200. I have just sent for the statistics of compensation for the year 1909, referred to by you,\* and I find that those statistics do not include anything relating to the painting of buildings, for the following reason. In the introduction to that document it states that the statistics in these tables are obtained from the returns made by or on behalf of employers in pursuance of the order of the Secretary of State under section 12 of the Act. Section 12 gives power to the Secretary of State to require every employer in any industry to which the Secretary of State may direct that this section shall apply to send to the Secretary of State a correct return specifying the number of cases in respect of which compensation has been paid by him under the Act. The order made by the Secretary of State on the 15th June 1908 directed that the industries to which section 12 of the Act should apply should be as follows:—Mining, quarrying, working of railways, any industry under the Factory and Workshop Act, 1901, the business of a harbour, dock, wharf, or quay, and constructional work which shall include the construction of railways, tramways &c., but it specifically says at the end that it does not include the construction of buildings. You also refer to the number of lead poisoning cases for which workmen's compensation was paid in 1909, namely, 497 out of the total of 3,313 cases under the Workmen's Compensation Act?—Yes.

9201. How many of these 497 cases do you consider arose from the building trade?—It will be noted that the bulk of the cases are reported from factories; of these only some of the woodworking section can be

\* See Question 9163.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

held to apply to the building trade, and in that section only two lead poisoning cases occur out of 497. The only other section where the building trade is concerned is that given as "Constructional Work," which only covers the construction of buildings when they form part of an engineering work; here again there are only four cases out of 497. Two refer to the woodworking trade and four to constructional work, and the building trade portion of the constructional work is very small. It is only where on the railroad a station is built or on a dock a small house is built.

9202. (*Mr. Parsonage.*) Do you mean only two cases of compensation to painters?—That was in the wood-working industry. Whether it was painters or not I do not know.

9203. (*Dr. Collis.*) From what are you quoting?—From the Board of Trade statistics.

9204. Are you aware that the cases published in the Board of Trade report are only those which are disputed in the Courts and only represent perhaps one-tenth of the total cases which occur in the Kingdom?—I have no idea what percentage it is.

9205. Neither have we, except that we know that they contain a very small fraction of those notified with regard to factories quite apart from those outside. If there is no dispute on the case and the claim is paid immediately, it does not come to the notice of the Board of Trade, so that the returns are most incomplete?—I do not want to press this too far. My point is that the building trade cases are extremely few out of the total.

9206. (*Mr. Parsonage.*) What year was this?—1909.

9207. How do you explain the smallness of this number?—I do not know; I have not attempted to explain it.

9208. It does not coincide in any respect with the figures that the Home Office have got of certificates of death?—I cannot reconcile it.\*

9209. Nor does it take into account the fact that there were 2,000 cases reported voluntarily to the Home Office from the doctors in the country. Do you not think that it is rather due to the fact that a very large number of painters suffering from lead poisoning have not claimed compensation?—They have only just been able to obtain that within the last four years.

9210. (*Chairman.*) You said just now that you did not wish to make too much of this. You do not assume, I suppose, that those are the only cases that have happened in your industry?—No, not in the least. My evidence is rather cumulative in its effect. The next point bears out again what I have said. This deals with the death rate.

9211. What have you to say about the death rate amongst house painters?—I had occasion to get this information for another purpose altogether, and I obtained it by application to the Registrar-General's Office. It refers to the period of 1890-92, according to his report. I have this: "Bricklayers, 14 per 1,000; carpenters and joiners, 11 per 1,000; plasterers, 14 per 1,000; painters, 13 per 1,000; masons, 14 per 1,000; slaters and tilers, 17 per 1,000; plumbers, 13 per 1,000." My object is to show that there is no extraordinary death rate among painters and plumbers as compared with other trades.

9212. (*Dr. Collis.*) Are the painters a pure class?—These are according to the Registrar-General's returns, and that is all I know about them.

9213. (*Chairman.*) Probably all these death rates which you have quoted are higher than that for all males, but that the trades of bricklayers, plasterers, and masons and slaters and tilers are very dangerous, and the death rates for those might be expected to be considerably higher than that for painters because of accidents?—But you are going to legislate particularly for painters on the ground that they are so affected and that there is such a high death rate amongst them.

9214. (*Dr. Collis.*) With regard to the high death rates, you have not stated the age constitution of these people. No death rate can be read without that?—These

were not obtained for this purpose, but for another purpose I had the information, and it appeared to back up my view, and that is why I brought it.

9215. But it does not back up anything unless you can give the age constitution. Take an age constitution in which there are 1,000 people with no one over 50, the death rate may be only 10. Take an age constitution in a case like that of agricultural labourers, 60 to 65 and over, the death rate may be 14 or 15, and yet the latter people with that death rate may be far more healthy than the others: so the figures of mortality you have at present stated have no meaning without the age constitution?—I submit that, when viewed comparatively, they have a meaning.

(*Dr. Collis.*) I submit that you do not understand the figures, sir.

9216. (*Chairman.*) Are you aware that the average age of all painters as compared with all males is between eight and nine years less?—No, but I would not alter my faith in these figures unless I heard the death rates for the others. Take slaters and tilers, for example.

9217. I understand that the median age at death of a painter is considerably below that of all males—between eight and nine years lower; and that the median age at death for carpenters and joiners is 56 to 57, which is eight to nine years higher than for painters?—What is the median age for painters?

9218. From 48 to 49?—What is it for bricklayers?

9219. From 52 to 53, which is four to five years higher than that for painters?—What is it for slaters and tilers?

9220. In the case of slaters and tilers the figures that we have are very small, and any deduction must be received with a good deal of caution, but even those show the median age at death to be four or five years higher. Now I put this question: with these things before you, do not you agree that the occupation of painters is an extremely dangerous one?—I agree that it is a dangerous one.

9221. Extremely dangerous?—I do not know that I would say that it is extremely dangerous.

9222. How do you account for the median age at death being so much lower than that of any other industry?—There is a good deal to account for it. A painter's life is a very irregular one. He is heavily employed during the spring and summer months. He works long hours in the summer time, and during the winter he is starved, or nearly so; a great many of them are. It is usual to turn off all the men except a few of the best hands, and I have been very sorry many times at what I have had to see painters suffering in winter time. That must tell on the death rate.

9223. I am sure you will agree with me that all this sickness and death is very deplorable?—Yes.

9224. Do you know that this deplorable evil has attracted the most careful attention in many foreign countries?—Yes, it has attracted attention abroad; that is true.

9225. The use of white lead has been prohibited to an appreciable extent abroad, and the work of painting has been most strictly regulated in many countries where the use of white lead is still allowed?—I believe that it is regulated in Germany, and that the regulations have been successful in diminishing very largely the amount of the trouble. I understand that it is prohibited in France at the end of five years, which expire, I think, in 1914. I do not think that the prohibition has come into effect yet. There is, however, a very large loop-hole there for exemptions, which makes it very doubtful, to my mind, whether the Act will be effective.

9226. It has been prohibited in Austria for interiors for the last two years?—I am not aware of that. I understood that there was practically no regulation in Austria of any consequence. They do not allow you to use it, I think, in powder form.

9227. Do you not think it regrettable that this country should be behind other nations in this respect?—I agree that the industry ought to be regulated.

9228. Now a great many small dangers attend the use of lead. I am going to ask you some questions

\* The return referred to by this witness does not include ordinary house painters. See Question 9200.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

with regard to the various operations, and I should like you to remember that the evidence produced to a former Committee showed that it was the multiplicity of small dangers in the industry which made up the great evil; for instance, the risk of contamination of food by unwashed hands. Do you attach importance to personal cleanliness on the part of the men?—I do.

9229. Then you consider washing accommodation essential?—Yes.

9230. Including the supply of hot water for washing?—Hot water would take it off easier than cold water.

9231. Is it generally practicable for the men to have hot water to wash in?—Yes, it is generally practicable if they like, because there are always size cans, and water has always to be on the painter's job, and heating arrangements always have to be there.

9232. Would you say that there would be no cases in which it would be impracticable?—Very few in which it would be really impracticable.

9233. We have had evidence to the contrary?—There might be cases. I once sent a man to the Isle of Man to paint a lamppost standing at the pier head. It would have been impracticable there.

9234. For example, when the exterior of a house only is painted and the men are not expected to go inside for any purpose?—The men have to get their meals somewhere, and they generally require water, even if the outside of the house only is being painted. It is a necessity of painters' work, and they must have some means of cooking their food, and where they do that they can get hot water.

9235. Is it not rather a pious hope on your part that they can get it? Would you say that they can invariably get hot water in such cases?—I say there is no good reason why they should not have hot water, and that if it was made necessary that they should have it they could get it. At present it is not made necessary.

9236. If the Home Office made it a compulsory rule that employers were to see that hot water was provided for the men to wash with before meal times, do you think that the employers could put that into practice?—I think so.

9237. Do your painters wear overalls?—My painters did; I would not have them on the job without.

9238. Did you supply these?—No.

9239. Would you object to a rule that overalls are to be provided and maintained by the employer as is prescribed in other lead industries?—Yes, I should object for the reason that the employers in a lead industry, like a factory where the same men are employed continually, are in a very different position from the employer who takes on a number of men for a month or two, and then disposes of them, and has all these clothes left on his hands. Next year another lot of men come. He does not know what will fit and what will not. He would have to have a slop shop. We do not always employ the same men, you see.

9240. Are you aware that in the china and earthenware trades, where this rule has just been introduced, there are a very large number of casual labourers taken on from time to time for whom overalls have to be provided?—Then they have to have something like a slop shop. It might be practicable in a case like a factory, but it would not be practicable in the case of ordinary painters with so many small employers.

9241. How often are the overalls washed?—We require them to be clean on Monday morning.

9242. Would you be prepared to arrange for the overalls to be washed at your expense, as is done in other industries where lead is used?—I do not think that it is reasonable, but I would not mind. I think that the men ought to have them done at home. It would be very much easier.

9243. It is insisted that lead workers in other trades shall not take overalls home to be washed, owing to the danger that that involves?—That might be a good ground for it; but I can see considerable difficulties in carrying it out, because men have to go to country jobs.

9244. Where do the painters keep their overalls when they go home?—Usually there was a place found for them in the cellar or in the stables as the case might be, and they used to undress there, change their things, and leave them there.

9245. A good many employers have said that very often the overalls are kept in the paint shop?—I dare say it does obtain, but usually it did not obtain with us; because we used to expect the foreman who had charge of all the paint, and so forth, to keep them quite separate for other reasons than this.

9246. You understand the danger which would ensue if the overalls were allowed to be kept in the place where the men had been working, and so to allow an accumulation of dust on the overalls. That is one of the small dangers that I referred to?—I think that it is a very small one, but there may be something in it.

9247. I assure you that in the pottery industry it is one of the real dangers, because the very fact of the overalls becoming impregnated with continuous layers of dust means that only a touch creates a dust?—But in the paint shop to which you refer there is less lead dust than anywhere. The lead dust is on the job where the men are rubbing down or doing the actual work. It is only lead paste that we use, not the dry white lead.

9248. Is it not the fact that in some cases the overalls are left in the rooms where the men are actually working?—It might be so in some cases.

9249. But can you always provide a place for the painter to hang up his coat where there would be no risk of dust falling on it?—We could if we had to.

9250. But at the present moment you do not?—We do not take the trouble. We try to make the men comfortable. When I went to a customer to make arrangements, I used to ask, "Where can my men have their workshop?" and so forth.

9251. Do you advocate a rule with regard to meal-rooms, so that no man shall eat his food in a place where paint is being handled?—I should decidedly agree with such a rule.

9252. Is it a fact that in a great many cases, now, the men eat their meals in the rooms where they are working?—They sometimes do, but there is no real need for them to do it.

9253. Would it be very difficult to carry out the rules that I have foreshadowed for these various operations in connection with house painting?—There is always difficulty in carrying them out, but if they are necessary, it will have to be done.

9254. But is it always possible to insist on the observance of such rules as those which I have put to you? How would you know whether a rule was carried out?—I suppose that the responsibility would be placed on the employer to carry out certain regulations.

9255. Yes?—He now has to carry out certain regulations under the Factory Acts, and it is only a few more of the same kind of thing. If he had to do it, he would do it. I do not say that he would like it; I am sure he would not.

9256. Now with regard to the processes. First, as regards the dry rubbing down with sand-paper. I understand this process is indispensable?—Well, I do not know that it is always indispensable. I have heard of it being done without. It is in general use.

9257. I do not want you to cite instances. I ask if dry rubbing down in some instances is indispensable?—In some instances it would be indispensable.

9258. In the majority of cases?—I will tell you what makes me hesitate. A few days ago I should have said yes, but I was told that it was customary in London (and perhaps Mr. Rice can help us in the matter) to use a wet process with sand-paper. That is to say, they use the sand-paper wet.

9259. You say that that came to your knowledge in the last few days?—Yes, quite lately; in talking over this very question.

9260. Was that brought before your association?—No; it was merely information given to me by another man in the trade; that was all.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9261. You would not go so far as to agree to the prohibition of dry rubbing down with sand-paper?—I should not like to off-hand.

9262. Where dry rubbing down with sand-paper is indispensable, how can you prevent the worker from breathing the lead dust?—He could use a mask of some kind.

9263. Is your only suggestion that the men should be compelled to use a mask?—Yes, that is my suggestion for it.

9264. Is that a practical suggestion?—I think so. It is my own suggestion entirely.

9265. Have you seen a mask that would be suitable for the purpose?—No.

9266. Supposing that we cannot find a mask that would be suitable for the purpose?—I think that I could undertake to make one.

9267. Will you undertake that the men would wear it?—I could make one that would be no more objectionable to wear than a pair of motor goggles.

9268. The next process I wish to ask you about is the painting of ceilings having moulded or relief designs. In doing this work the brush has to be pushed into the background of the ornamental work, has it not?—Yes.

9269. This gives rise to splashes which must frequently fall on the face of the workers?—Yes, they do get splashes.

9270. How can you deal with the splashes that arise from this operation?—You can only wash them off afterwards. They will not do any harm unless the workman gets them in his mouth.

9271. Then, with regard to stippling, does the same thing apply to stipplers? Do they get a certain amount on their faces and hands and clothes?—They get a little on their clothes. I do not think that they get much on their faces in stippling.

9272. Not much, but they get a little?—There is a certain amount of spray. I used to consider that stippling a flatted wall was one of the things that gave men colic sooner than anything else.

9273. Do you have old paint burnt off with a spirit or charcoal burner?—A charcoal or spirit burner.

9274. How can you prevent the worker from inhaling the fumes which arise from this process?—He would have to have a mask.

9275. It appears from your evidence, then, that there are certain indispensable processes, in carrying out which a painter must necessarily inhale some dust, spray, or fumes, containing lead. How are these dangers to be met?—My suggestion wherever there is any dust made, or where there are any fumes, is that a mask should be used, a small respirator, to cover the mouth and nose—to be used whenever working among lead dust or fumes, or when engaged in the flattening process. There is something analogous to it in the printers' operation, where they make matrices for printing. There they use lead and antimony, and it is very dangerous. They have to wear masks.

9276. If the men refuse to wear these masks on the ground that they are inconvenient or laborious in their work, what other suggestion would you tender to us for removing the dangers which I have enumerated?—I have no other suggestion than that.

9277. Is it possible to remove the dangers entirely in any other way than by using a substitute for lead?—I should not like to answer that without qualification. I consider that regulations properly carried out—

9278. You are going beyond my point. I have brought you up to this point—that you have admitted that there are certain dangers which the men must come into contact with, and you have suggested that those dangers might be removed by the wearing of a mask. I have asked you how, if the men refuse to wear a mask for any reason whatever, the dangers could be met. You say that you cannot suggest any other means?—I cannot suggest any other means. I would not like to say that there are no other.

9279. Then is it possible to remove the danger entirely in any other way than by using a substitute for lead?—The question does not seem to quite follow. Your question seems to go farther than your former question took me.

9280. Is it possible to remove the danger that remains when they will not wear a mask?—If they will not wear a mask to remove the danger that remains, I see no other way out of it but the prohibition of lead.

9281. Various witnesses have told us about non-poisonous substitutes for lead. Have you had any personal experience with such substitutes?—I have tried various oxide of zinc substitutes, but I have not found them satisfactory.

9282. You contend that white lead is better than any other paint that you have tried?—Better than any I have tried. I have never found an efficient substitute.

9283. Can you give us the reasons?—The chief reason is that its body, its covering power, is so much greater. It is also more durable.

9284. The Office of Works and many other witnesses have told us that they have succeeded in obtaining efficient non-lead paint. I assume that you would place some reliance on such evidence as that of the Office of Works?—I have no doubt they think they have got what they say, and perhaps they have up to a point. Whether that expression "efficient substitute for lead" goes as far as they think is another question. I doubt it myself.

9285. When you have the consideration of the health of a large body of working men in your mind, you do not want to be too hypercritical as to the words used?—No, I do not want to be too hypercritical, but we have to consider that house painting in particular is done not only for the preservation of the building, but that it is also done as a matter of amenity, as a matter of hygiene, as a matter of cleanliness, and a good deal of that work can be done or left undone. If you make it unduly expensive, it will be left undone, and the trouble as far as the workmen are concerned will be worse. They will lose with one hand what they gain with the other, if prohibition is to have that effect.

9286. The Office of Works tells us that the substitute they are using is not only as efficient as lead, but that it is just as durable. They have given it four years' trial, and they assert that it is as economical?—I should say that four years is an insufficient trial. Taking your question with regard to the prohibition of lead, I cannot think that the tests have gone far enough. Take, for instance, ship work. The opportunities for lead poisoning are very great in connection with the painting of the hull of a ship and the painting of the state rooms of a ship. They are very confined little places. Ceilings and walls and everything are painted, and there is every opportunity offered for lead poisoning to take place. If it would take place in a room like this, it would be far more likely to take place in a room like that. I am of opinion that no tests of a substitute can be considered generally satisfactory unless tried on a ship, because the circumstances are so different. The test that it has to stand as regards durability and satisfaction are much greater in the case of a ship than in the case of a house. I could give you other illustrations, but I merely give that one.

9287. What are the usual hours worked by your painters per week?—They are working now only about 50. Those are the normal hours. In the summer time they work longer. Within my experience they have been working as high as 55.

9288. Would you agree to the limitation of the hours of labour, say, to 48 hours a week?—If there was any particular advantage to be obtained by it, I should not object in the least.

9289. It has been agreed in the Potteries that that shall be the limit. The medical expert evidence showed us very clearly that the fewer the hours men worked in lead, the better it was for them?—I should see no objection myself to it, but I would like to say that some of the employers may kick about it; personally I would not.

9290. You do not have a periodical medical examination of your workers?—No.

9291. Do you know that, in other industries where lead is used, the Home Office insist on a monthly or even weekly examination by the certifying surgeon?—I should not object.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9292. To bring this industry into line with others where lead is used, each painter would have to carry a health register?—Yes.

9293. He would have to see the appointed surgeon at least once a month, and the employer would have to pay the fee for the medical examination. Have you any objection to that?—I think that the medical examination might be a good thing.

9294. If a certain painter's health were found to be unsatisfactory, the surgeon would suspend him?—Yes.

9295. That is to say, that a man would not be allowed to work with lead for perhaps a fortnight or a month, and the employer would have to find him other work, or compensate him during the time. Would you agree to that?—I do not like to answer that.

9296. You realise that, if the free use of lead is allowed to continue, the Home Office will have to insist on the rigid observance of all precautionary measures, in the same way as in other industries where the workers handle lead. This will involve an extremely complicated and elaborate code of regulations. Are you fully prepared to set up the necessary machinery to secure complete observance of all the regulations relating to overalls, mess-rooms, washing accommodation, avoidance of dust, limitation of hours, and all other such matters?—Personally, I should not object.

9297. Taking all these points into consideration, would you say that you prefer that the industry should be regulated, or that the use of lead should be prohibited or very closely restricted?—This is what I think; I think you ought to have the regulations wherever lead is used. Where a painter does not use lead, and registers himself as one who does not use lead, and will not use lead, he should be free. I think then the thing would cure itself. If it was possible to find substitutes, the employers would find them to get rid of the regulations; but where it is not possible to get satisfactory substitutes then regulations would be required.

9298. You have told us that there are certain dangerous operations which can only be overcome by the men wearing a mask?—Supposing that this substitute that you have spoken about is used—the one that the Office of Works has found, the rubbing down of that substitute afterwards, if it has no lead in it, is innocuous, is it not?

9299. But that is not my point. I am speaking now of where there is no restriction on the use of lead. The evils exist in certain operations, and the only suggestion you can make is that the men should wear a mask?—I would make other suggestions that have a bearing on it.

9300. You have had every opportunity of dealing with them. You have told the Committee that there are certain operations, the dangers of which cannot be overcome unless the men wear a mask, and then I ask you if you have any other suggestion to make, and you suggest nothing. I ask you how the operations are to be regulated, and the men kept from danger?—I take it that the employer would be responsible for carrying out the regulations, and he would have to employ men who carried them out.

9301. Up to now you have only suggested that the men should wear a mask. I want to know what regulations you would suggest?—I did not think it was up to me to make a series of regulations. I was asked to make my suggestions as to the prevention of lead poisoning, and I have made certain suggestions in my proof.

9302. But you do not answer the question. I must go back to the rubbing down with sand-paper. You have told me that you prefer a code of regulations to the prohibition of lead. I want to know how you are going to get over the difficulty of sand-papering and the dangers which occur in other similar operations, if the men refuse to accept your suggestion of wearing a mask?—I cannot get over it if they refuse. I do not say that it is not possible to do it, but I have no suggestion to make.

9303. From your knowledge, the Home Office could not introduce a special rule to deal with that part of the danger?—But the men might not refuse.

9304. I am assuming that they do refuse?—How do they do in other industries where they have to wear a mask?

9305. But that is not the point. There is no industry where the Home Office insist on a mask being frequently worn, except with regard to the manufacture of white lead, and that is only for a short time, about two hours of the day?—I do not think that it would be necessary to wear a mask the whole time or anything like it. My suggestion is not that they should continue wearing a mask.

9306. You have not got over the point. You leave us where we were. If the men do not wear a mask, the danger is still there. That is what I want to point out?—I follow.

9307. (Dr. Collis.) You said, in your examination-in-chief, that you thought that the greater part of the evil of lead poisoning of which we have heard occurs among the smaller occupiers, who are unable to take special care about their workpeople?—They are not necessarily small firms. It is more a question of the class of work. Take, for instance, the work done about a ship's bottom.

9308. Shipbuilding would not be included in the statistics given?—The same class of men would be used for station work. It is a rough class of work. It is generally done by sailors or men who can climb, and it is dirty work.

9309. People like the National Society of House and Ship Painters or the Scottish Society would not be the class of people you include?—I do not know anything about their membership. They may have the kind of men.

9310. I understand that their men are men who have been trained under the apprenticeship system—the cream of the house painting industry. They are not casuals?—I do not know enough about them to form an opinion.

9311. If that is so, that they are from the better class of workers, you would not expect as much trouble from them as from the others, as I understand your evidence?—Probably not.

9312. We have statistics from these two societies that, out of 1,240 deaths, 39 were due to lead poisoning. When you take the excess compared with all males due to Bright's disease and consumption, you get it that about 13 or 14 out of every 100 of these deaths are due to causes connected with lead poisoning. You would consider that to be a smaller amount of lead poisoning than is occurring among the others, according to your evidence?—I do not follow your question.

9313. You said that lead poisoning was occurring more among the dirty and casual labourer. We have statistics here which represent the sickness of the cleanest and most respectable members of the house-painting trade, and these statistics show that between 13 and 14 of every 100 deaths that occur are due to the influence of lead, and, therefore, according to your evidence there must be a good deal more among the others?—I do not know.

9314. Excuse me; that is the logical inference from your own evidence?—The Chairman asked me how it was that our people had not had the same experience of lead poisoning cases as the returns you had appeared to show existed.

9315. May I put it in another way? Do the employers from whom you have obtained information employ the better class of house painters?—Yes, I am of that opinion.

9316. Now, taking the Irish cases, there were two deaths. Would you tell me among whom those occurred?—They occurred in 2½ years since the Compensation Act came into operation.

9317. I am referring to the two fatal cases which you mention occurred in Ireland?—From the 1st July 1909 to 30th June 1910 there were three cases; one was alleged permanent disablement; two fatal, a plumber and a painter.

9318. What were the numbers among whom they occurred?—My informant says: "The number of workmen is not so easily got at, but the Dublin district holds 400 Amalgamated Society men officially" furnished to me by their delegate. The Metro-

1 June 1911.]

Mr. A. G. WHITE,

[Continued.]

"politan (old) did not reply to my letter, but I should say it is less, from 250 to 300 would be about right. "In addition to this you might put the non-society men at about 300 more." That is only Dublin, and the Association that it refers to, whose insurance statistics he is dealing with, covers Belfast, Derry, Limerick and Cork.

9319. Would it double those figures?—I have no idea. The painters in Belfast I should think would be a very large number. There is a lot of ship work there.

9320. You consider that in ship work painters are exposed to risk more than in house painting?—I should think so.

9321. And that the internal painting of ships is somewhat comparable with the internal painting of houses except that the danger would be greater perhaps?—Yes.

9322. You have suggested that precautions should be carried out to prevent it. Are you aware that in the Government Dockyards every precaution that can be suggested is carried out without waiting for any legal compulsion?—I was not aware of that.

9323. Medical examination, the supply of hot water for washing, towels, nail-brushes, wearing of overalls, and medical inspection of the men who are removed if there is the slightest sign of any trouble. And yet, notwithstanding that, in the Admiralty Dockyards it was impossible to bring down the number of lead poisoning cases. They began to fall during the last five years. When we enquired why, we found that it was because they had been substituting non-lead paints for lead paints?—Am I to understand that the Admiralty experience is that all the precautions are absolutely useless?

9324. The conclusion is that they have not prevented the occurrence of lead poisoning to any appreciable extent?—You very much surprise me, because our experience is that, if precautions are taken, the men are not troubled.

9325. I have not gathered what precautions you would suggest would stop it?—Those that I have suggested. These go further, and that astonishes me.

9326. But your precautions do not seem to have been used?—Our experience is that with no special precautions, but just the precautions which our experience has gradually forced upon us and upon the men, we find a very small number of cases out of a very large number of men, and I am therefore very much astonished when you say that all these elaborate precautions taken by the Admiralty have had no effect.

9327. You have no evidence whatever that your precautions are based upon experience?—I do not know where we got them from if we did not get them from experience.

9328. I do not know either. We have the Admiralty evidence that, notwithstanding these precautions, the cases continued to occur. You can give me no statistics of an employer who has been employing 100 people and had them examined, and supplied overalls, and given washing accommodation, mess-rooms, and the like, and produced less sickness among the men, than among 100 men where such precautions have not been adopted?—Our experience in our own business, which is a long one, shows us that the cases of lead poisoning are extremely few.

9329. May I suggest that you are ignorant of the cases that are occurring in the trade?—No, we are not ignorant of them. These cases come under our notice. I have evidence here from various people who have written to the same effect.

9330. How many people replied to you from Southampton?—I do not know how many the secretary represents. He might represent about a score of the employers.

9331. How many employers are there likely to be in Southampton altogether?—I do not know, I am sure.

9332. You have a reply from Lancaster representing 60 employers. How many would there be in that town altogether?—I do not know. It is not a large place. It is a very small place.

9333. You had some replies from Portsmouth. How many do the Portsmouth employees represent?—About 50 or 60.

9334. How many employers are there likely to be in Portsmouth?—I do not know.

9335. How many are there in the Oltham district?—Not a large number.

9336. You have some replies from Nottingham?—Yes.

9337. How many do they represent?—The Association is about 70 strong.

9338. How many in Nottingham altogether?—I think the Association is fairly representative of the trade.

9339. You have some information from Liverpool?—No. You have two witnesses coming from Liverpool. The Liverpool Association is well organised. It represents the trade fairly well.

9340. Those towns do not represent anything like the total employers in the district for which they speak?—I do not say that; but our experience, as far as it goes, is so contrary to yours that we find it difficult to understand it.

9341. (Chairman.) Precisely the same conditions prevailed in the potteries. There were 500 potteries, and 350 of them had no cases at all. The whole of the cases occurred in the other 150; so what you cite to-day does not prove anything with regard to the poisoning?—I would not have mentioned it, but I am surprised at the doctor's statement that all these regulations are absolutely ineffective.

9342. (Dr. Collis.) I suppose that the intermittent occupation of a house painter varies with the rest of the building trade?—Yes, it does a good deal.

9343. The fact that he may be thrown out of employment and consequently not be getting wages, and the effect of that on his health, would apply to the builders' trade as a whole?—No, not necessarily; it would affect joiners, for instance. When I said that it followed the building trade, I was looking at the general rise and fall in the building trade. You mean that the building trade as a whole is a season trade?

9344. Yes?—I think that the painter's trade is more distinctly a season trade than the rest of the building trade.

9345. More like paperhangers?—Yes; painters and paperhangers go together; if one is not busy the other is not.

9346. Yet I find that the paperhangers' medium age at death is three years older than that of a painter. He is apparently healthier?—He is a man who has served his time to the painting as well, generally.

9347. He does not seem to die with lead poisoning, anyway. Now where have you seen printers compelled to wear these masks?—I have not seen them at all, but a man who lives next door but one to me, who makes these things, tells me that he has to take this precaution to protect himself from the fumes. It is a very small trade, I understand, with a very few men: it is a highly specialised trade.

9348. You said that printers have to wear the masks?—I said that they are used in the particular trade I mentioned.

9349. I would not say for a moment that individuals in individual trades may not do certain things, but you said that they have to wear them?—I understood him to say so. I will ask him when I go back.

9350. There are no regulations, and they do not have to wear them unless they like. Now, you said that you were prepared to make a mask from your own ingenuity, something in the nature of motor goggles, which would be effective for catching dust and fumes. Will you be so good as to give me some idea of the line your ingenuity would take?—I cannot; I have not gone into it.

9351. We have gone into it a very great deal. A committee investigated the question of respirators, and reported in 1902-3 on the "Ventilation of Factories for the Protection of Workpeople," and decided that there was no form of respirator that it was reasonable to ask the workpeople to wear?—I was not aware of that. If that is correct, my suggestion is useless.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9352. Then with regard to fumes, can you tell me what form of filter will stop gas?—You could not very well stop gas.

9353. And yet you stated that you were prepared to find a respirator to stop the gaseous fumes which arise from burning off paint?—It is not so difficult as you might think. A man, say, is burning off that door. He uses the light at a certain height, and the fumes rise above that height. If the intake of the respirator was below the height at which he ordinarily worked he would not get any fumes.

9354. He might just as well be breathing below that level without a respirator. I do not see that the respirator would be of much use in keeping off the fumes?—He can do without a respirator if he takes care to avoid the fumes.

9355. Where is the value of the respirator?—For the careless person.

9356. But the respirator will not keep off the fumes if a man is careless. A gas will go through any respirator?—Yes, but you could have the intake of your respirator in such a position that unless he stood on his head or something, he could not possibly get the fumes.

9357. Excuse my pressing the point; he has to breathe freely, and how are you going to allow it?—You have machines in coal mines, for instance, where there is trouble with gas.

9358. You want the painter to use such a mask?—No, I do not, but I say that it is not absolutely necessary that he should have the free intake immediately opposite his mouth. It might be in a position which would be below any line of fume.

9359. Whereabouts? You have given us, as a serious suggestion, the wearing of a mask. This subject has received attention from men like Dr. Haldane, one of the greatest scientists we have to-day, and from men of the greatest mechanical skill, and they have failed to discover a suitable mask. I want to know how you suggest you are going to succeed. You have not made a single experiment?—I should have thought that it was a simple thing. I have not gone into the matter. I have not experimented with it. That is all I say.

9360. If the preparation of a mask is the simple thing which you appear to consider it, has it not occurred to you that the Home Office would have considered it before they interfered with the processes of a trade? Do you think that we should be sitting here on a Committee like this without immediately having given such a point attention? As a serious practical man, do you not think we must have considered that first?—Well, I suppose so.

9361. (Mr. Sutherland.) Have you formed any estimate of the number of masters who employ painters in the United Kingdom?—No, I have not.

9362. For other purposes than this Inquiry, I have had on many occasions to address the employers, and for this Inquiry (unfortunately I have not the papers with me) I got three circular addressing companies to send me their estimates of master painters. I checked them from my own experience, and I formed the opinion that, subject to the actual returns from the Census, there are 22,000 or 23,000 master painters and London builders who overlap. I have made every allowance. I got out a circular to all our members for the purpose of this Inquiry. I had to whip them up twice. We have only 741 returns of employers, and the number of men they employ ranges from an average of 1 to 100. I asked them to fill up the average number of men and boys employed per week in 1910 as painters or as plumbers. A large number of our men do not touch plumbers' work. We got from 741 members a return of 9,224 painters, and 682½ plumbers. That gives us an average roughly of 12½. I estimate 22,000 as the number of master painters, so that by multiplying we get 275,000 painters throughout the United Kingdom?—I follow.

9363. I should think that there were not more than 20,000 plumbers. If you take off 20,000 for those, and say 250,000, that is sufficiently near, is it not?—If I had hazarded a guess I should have said a quarter of a million of painters.

9364. That gives us some data for getting at the relative percentage of lead poisoning?—That is what I would like to see.

9365. According to Dr. Collis, that works out at 1 per cent. of all deaths amongst painters?—The deaths, according to my return, were 13 per 1,000. Taking 1 per cent. of that would give you the figure.

9366. (Dr. Collis.) There is a difference between the percentage of deaths and the number that die per 1,000?—The deaths are 13 per 1,000 according to the figures I have given, and that on 220,000 will give you the number of deaths.

9367. It works out at 30 deaths per annum?—I make it at 28·60.

9368. What is the percentage of the whole number of men employed?—If it is one death from lead poisoning out of every 100, it is 1 per cent. of that. If 28 is divided into 220,000, it gives 13 per 1,000 employed as the percentage of deaths. The deaths from lead poisoning alone are 13 per 1,000 painters at work.

(Mr. Sutherland.) How does that square with your figures, Dr. Collis? Does it make any comparison between your figures and those that have been put in? Is there any basis of comparison?

9369. (Dr. Collis.) The two societies show a much higher death rate?—I suppose that their evidence is true and our evidence is true. There may be room for my figures being true on merits. The societies have opportunities of getting more information than we have.

9370. The societies show a larger proportion of injury due to lead than the figures which you have now given?—I see your point. This is directly in support of my contention that the damage is small compared with the total number of men employed.

9371. Yes, but it is a case of preventable damage?—I do not say that it ought not to be prevented; but I point that out.

9372. (Mr. Sutherland.) The experience of your members confirms the experience of a number of our members who have come before this Committee; men like Mr. Laidler, and Mr. Puttrel, and Mr. Barker?—I know those gentlemen.

9373. Mr. Laidler stated that he did not know of any case of lead poisoning in his own employ or in that of his father, extending over 60 years. Mr. Barker had three cases?—It is that sort of thing that I had in mind when I rather took exception to the view that is taken of the precautions of the Admiralty being inefficient.

9374. The point I sought to make before was that a man in good health does not realise the dangers of sickness, and men like our members, who conduct very good shops, and who are very largely exempt from experiences of lead poisoning, have not been called upon to summon the Association, or consider the question, or make provision for lead poisoning cases. There are general returns issued by the Board of Trade, I know, which everybody does not read unless his attention is specially drawn to them?—There has been nothing striking enough to induce our people to pay any special attention to this question.

9375. It is much the same with our Association. Now I want to ask your opinion of substitutes. In reference to a pigment like white lead, which has held its own successfully against the efforts of all the manufacturers of Europe interested in zinc and other substitutes, and which has maintained its character as a strong preservative, with good covering power and easily fixed; do you think that that could be set aside on the judgment of the Office of Works, with an experience of four years?—Certainly not. I think that there would be an awful row if it was, when the trade realised it.

9376. Do you know anything of the Office of Works paints?—No.

9377. I think that we may say that they have special formula, and in some cases they are proprietary paints, and in all cases they are more expensive than the ordinary paint mixed with white lead, pure linseed oil and pure turps, which give us a perfect paint, apart from its ill effects on the men. Now, with reference

1 June 1911.]

Mr. A. G. WHITE

[Continued.]

to the fumes of burning off; what do you think would be the average number of hours a man, taking painters all round, would work at burning off per week?—Taking one man with another it would be extremely small. You could hardly express it by a whole number.

9378. An average of one hour per week would you say, taking it all the year round?—I think it would be much less than that, taking it all the year round.

9379. So that really the danger from fumes of that kind is not serious?—It is very small, and it is generally done in the open air as well.

9380. You do not think that the question of an efficient substitute could be determined by the experience of one body like the Office of Works, with a restricted area of buildings such as they deal with?—Certainly not.

9381. Do you think that, for the purposes of this Inquiry, before such a drastic step is taken as the prohibition of so useful a pigment as white lead, some kind of test under an absolutely independent body of experts should be instituted?—Most certainly I do.

9382. How long would you give as the term of such a test?—I should think that somewhere round about ten years, probably, would be the time.

9383. I would be prepared to take a very much shorter time than that?—For some purposes I would, but not for all.

9384. Do you think that the test should include all kinds of purposes?—It should be tested for all kinds of purposes. It should be tested for iron structures such as railroad bridges, for buildings inside and out, and not only in one place but in many places, because paint behaves quite differently at the seaside from what it does inland. It should be tested for ships, particularly for the hulls outside, because paint behaves differently in different waters: If you send a ship with a certain preparation to the East, it may be quite satisfactory; but if you send it to the West, it may not. In fact, in all the arts where lead is used, it wants to be tested, because there are peculiar circumstances influencing it in all cases.

9385. (Dr. Collis.) Do you consider that this Committee is to make no recommendation short of ten years?—No, I do not. I say that the recommendation of this Committee might very properly be that there was evidence that it was extremely desirable to find a substitute for white lead, but that white lead is such a stable paint in use by all those who have occasion to paint structures of any kind that it is absolutely necessary before making any recommendation that a satisfactory substitute should be found and certified by an independent authority, but as to the time it would take would be for that authority to satisfy itself upon. In some cases there might be a *prima facie* case good enough to act upon even in a shorter time than I have said, but I am looking at this: Take the outside of houses in Liverpool, where my experience is. In some positions paint will last four years, in some positions it will last six years, and I have known it to last for ten years. That is for outside painting of cement. Take inside work. St. George's Hall is a well known building in Liverpool. When it was painted through the last time, it had not been painted for 18 years. The paint on all the walls and on the woodwork and grain-work was perfectly sound. A great deal of it was only repaired and varnished. Those are facts that you cannot very well get over.

9386. You are suggesting a very long period during which the experiments are to go on. What do you suggest is to go on during that time? The Home Office has appointed the Committee to examine into the question and make a report, and on the figures before us of illness occurring I am sure that the Home Office will not consider the question of postponing all action for ten years?—I do not suppose that they would. It will have to be regulated in the meantime.

9387. In what possible way can it be regulated?—You can regulate it, as far as possible. You may not achieve perfect regulation, but I do not say that there should not be any because it would not be perfect. The evidence of Mr. Laidler and other evidence and my

experience indicates that there is a great difference in certain circumstances in the degree of lead poisoning, and those circumstances are due to the precautions which some people take.

9388. But please keep yourself a little more closely to the point. You say that you would not personally be satisfied without something like a ten years test. What is to be done during those ten years?—I do not say that I should not be satisfied under a ten years test, but I think that the Committee themselves would not be satisfied altogether.

9389. I am not asking you to speak for the Committee, but I want your opinion?—My opinion is that it might take as long as ten years.

9390. Your suggestion is that some regulations, indefinite, should in the meantime be enforced?—Yes.

9391. (Mr. Sutherland.) You do not bind yourself to any term of years. You think that the decision as to that should rest with the Committee?—If such a Committee is appointed, certainly. I can only judge from my own experience.

9392. You think it very essential in the interest of all the trades concerned and in the interests of the public?—Certainly. I am looking at it all round. For one ton of anything else used by a painter, he uses 10 to 20 tons of lead.

9393. With reference to the attitude of the trade to this question, it does not matter to the painter if an architect specifies to him that he is to paint a house with milk and water, so long as the architect takes the responsibility for it?—Yes, but he does not.

9394. No, but if an architect specified for a man to paint a house with milk and water?—If he did it and it was bad, the responsibility is on the contractor.

9395. That is another question. The responsibility would be on the architect who specified?—On the contractor, excuse me.

9396. He might try to put it on him, but if the contractor carried out the instructions of his architect, he would be absolved from any liability. My point is this, that as a body, we, as painters, are not concerned selfishly in this question of lead?—No. We do not care a button if we can get anything else to do as well.

9397. If Parliament and the Home Office see fit to prohibit lead, painters will go on working with substitutes, but in my experience and in my judgment there is nothing to equal white lead now as a protective paint?—That is so.

9398. Do you think it desirable to mitigate some of these troubles by abolishing white lead for inside work?—You possibly might do that for inside work.

9399. We have a number of substitutes, basic articles, that can be used for inside work without damage to the public interest?—For domestic inside work?

9400. For domestic inside work?—Yes.

9401. You are strongly of opinion that the public interest would suffer if the prohibition was extended to outside work?—If it was a general prohibition, I am sure it would.

9402. You know that during the last 10 or 12 years in America and on this side tremendous efforts have been put forward to find a substitute that will give anything like the service of white lead?—Almost every manufacturer has been working at it in one form or another.

9403. In America it has been especially so?—I did not know that.

9404. Up to now nothing has been found comparable with white lead for general service?—I have never heard of anything.

9405. That in itself is strong evidence that the experience of the Office of Works should not be accepted as final on this question?—Quite so.

9406. Do you think that there would be any difficulty in separating outside painting, where lead can be permitted, from inside painting, where it would be prohibited. Do you think that there would be a likelihood of evasion if the penalties were made sufficiently definite?—I think it might be. There would be this about it: that the workmen would be perhaps considerably interested in reporting it, and they would have full opportunity of doing so, and if

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

the workmen's interest was clear on the point, I do not think that any employer would venture to disobey. It would depend on the workmen.

9407. If a man attempted to evade a law that was passed in the interest of the health of the workman, he would fall very much in public estimation if he were convicted, would he not?—Yes, he would.

9408. If it were prohibited for inside work, you think that that fact would be a protection?—I think that the reporting by the workmen would be a sufficient check.

9409. A sufficient check on the master painter?—Yes, I think so.

9410. Would you prefer the abolition of it for inside work to the irksome regulations which the Chairman foreshadowed?—Yes, if we were left free to use it outside, but it seems to me like playing with the question.

9411. Inside and outside work are in two different categories?—Yes, but the inside work is such a small fraction of the whole use of lead (even if you take the inside and outside together it is a small fraction) in the arts, and I think that we are playing with it to take only that.

9412. This inquiry relates only to the building trade?—Yes. It is a very small fraction of the use of lead, and why should we put that trade to such great inconvenience where the larger portion of the evil is going to remain?

9413. Where will it remain?—In ship painting, and the painting of such bridges as the Forth bridge, and all the rest of it.

9414. That can be dealt with by another committee. Now in the case of railway stations where there is always the presence of sulphuric acid and sulphurous gas ascending, the paint is insensibly softened where zinc is used?—I have never seen zinc used in that position.

9415. No, but if lead is prohibited it will have to be used. The protective power is decreased, and therefore the resistance of the structure is weakened. That is one reason why it should not be prohibited for outside?—In so far as lead paint is a better protection than any other known paint at present, anything else must be inferior, and therefore more dangerous to the structure.

9416. Now if it is not prohibited but regulated, do you think that we could dispense with the dry rubbing down of inside work, because that seems to be the source of a great deal of the danger?—It is the source of a great deal of the danger. I do not say that it could not be dispensed with. I would not like to give a definite opinion about it without very careful consideration. If one was going to do the very best class of work inside one would rub down with pumice stone and water, even between coats. The use of the sand-paper is only a cheap substitute really, and for a minor degree of rubbing down I do not say that it is impossible to do away with it.

9417. The amount of time that a painter spends in rubbing down is relatively small to the amount of time he is engaged in painting?—Yes, very small indeed. A man goes over a door in a few minutes with sand-paper. If he is rubbing down with pumice stone and water he has to be much more careful.

9418. (Mr. Rice.) How long have you been secretary of the National Federation of Building Trades Employers?—For nearly six years.

9419. Have you received during that time any intimation from the Home Office, calling attention to the dangerous state of the painting trade?—No. The only thing was that there was an Inquiry with regard to scaffolding, and in connection with that there was something said about this trade, and we, I think, submitted some evidence in connection with that at the time. That is all that I have ever heard about it.

9420. But was it danger from lead or danger from scaffolding?—There was some suggestion that in connection with the scaffolding regulations there should be some provision for workmen having cleansing arrangements and so on; but nothing came of it.

9421. Apart from that you have received no intimation from the Home Office?—No, nothing official, or it would have been brought before the association.

9422. You have said that the employers among whom you have enquired have known very few cases of lead poisoning?—Yes.

9423. Is not that a reason why they would not fully appreciate the alleged dangers of the trade?—No doubt that influences their opinion. The general opinion of my trade is that this is really not a serious matter.

9424. And their reason for that opinion is that very few cases have come under their observation?—That very few cases have come under their observation.

9425. You have heard our Chairman ask you about the conditions that obtain in foreign countries, and on the prohibition or the limitation of the use of white lead?—Yes.

9426. Are you familiar with any of those conditions?—Only slightly; I know a little about them; not much.

9427. The Chairman asked you about Austria?—Yes.

9428. Do you remember your reply?—My reply to that was that in Austria the only prohibition is with regard to the use of lead as a powder.

9429. Not lead as a paste?—Not lead as a paste. That is not objected to, I think.

9430. How is lead used in England mostly?—In a paste.

9431. (Dr. Collis.) Are you certain that the statement with regard to Austria is correct?—I am under the impression that it is.\*

9432. (Mr. Rice.) Have you any experience of the Belgian regulations?—I have not any actual experience. I understand that there is some small regulation there, but I do not know its exact nature.

9433. You could, I suppose, conveniently from your position obtain all that information?—Yes, I can write for it if you like.

9434. Not from the official sources, but from the Federation of Belgian Builders, perhaps?—Yes, I could get information with regard to that, I daresay.

9435. And, if the Committee desire, you could probably find out from the Belgian builders whether the regulations are carried out, or whether they are a dead letter?—Certainly.

9436. Whether they are in actual use, or whether they are honoured in the breach?—Yes.

9437. (Mr. Sutherland.) You might ask whether they find the regulations difficult to observe or easy to fulfil. If we found that other nations submitted to them easily that would help us?—I will write at once.

9438. (Mr. Rice.) You could probably obtain the same information from France?—Certainly.

9439. Now with regard to the limitation of hours to 48 per week, do you think that could be simply and properly worked, seeing that it would mean opening the shops or the works at different times. I understood you to say that painters in some parts of England worked 56 hours per week, and I take it that their hours are the same as in the other trades?—They are not always the same. They are very often longer. There is hardly a place in England but what you can find some of the branches of the building trade working different hours. I do not think that that is a serious objection in an important matter like this. I think that the greatest objection would come from the men themselves. Painters desire to work as much as they can in summer and to average their wages for the year. The trade cannot be carried on in winter in the same way as in summer, and in all cases they seek overtime in the summer, and they would be probably the heaviest sufferers individually although there would be more men employed, and to that extent looked at in a broad sense it might be all right. The men themselves who have been accustomed to work overtime in the summer would no doubt feel considerable loss in their yearly earnings.

9440. I have in my mind London, where the hours worked in the building trade are 50?—I should have thought 50 preferable to 48. Fifty is a very fair time.

\* For Austrian Regulations, see Appendix IX.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9441. That would be in accord with a considerable number of towns?—The tendency of the time all over the country is to come to 50.

9442. Now the Chairman said that the dangerous part of the trade is made up of many little things. Do you attach much importance to the necessity of dry rubbing down for instance, except with regard to the appearance of the work?—It has a certain effect in ensuring bite between one coat and the other apart from the appearance. That is the chief reason for it.

9443. To ensure a key or bite?—Yes.

9444. Is that essential?—It is very desirable. I have seen cases where coats have separated.

9445. But generally is it necessary?—I think it could be often dispensed with.

9446. The Chairman instanced the case of stippling and painting of ceilings?—Stippling is not very much done now.

9447. That is what I wanted to bring out. It is not so much done now as formerly?—No. Old-fashioned flatted walls are rather out of fashion.

9448. With regard to enriched ceilings, is it your experience that they are mostly done with water paints or distemper?—Mostly with water paints now.

9449. From which no danger would arise?—I should think no danger would arise, but I do not know what the constituents are.

9450. (Mr. Sutherland.) They are leadless?—They could all be done with water paint. You could prohibit the use of lead for ceilings. There are quite suitable substitutes.

9451. (Mr. Rice.) You do not wish the Committee to understand that the building trade employers hold a brief for the continued use of white lead?—Not the least. I have said so in my evidence.

9452. Your interest is to have an efficient substitute if lead is prohibited?—Yes.

9453. What is your reason for asking for that?—On general grounds. You must consider the public to some extent. You might say that war is a thing that ought to be put a stop to on the ground that it destroys life, but you cannot do it. You must have war. You must draw a line. And when the cost of regulation becomes very prohibitive and is going to interfere with the use of very important preservatives, and all that kind of thing, there comes a point where a line must be drawn. To my mind the line should be drawn where the cost of the work is seriously increased by prohibition as compared with regulation. That is my point—where the cost is seriously increased.

9454. (Dr. Collis.) Do you refer to the cost of the work to the public?—Yes. You cannot enhance the cost to a great extent without interfering with the use of painter's work as a whole, and that is going to reflect very seriously on the men themselves, and on everybody. If you make it too expensive people will not have as much of it. We know perfectly well that there are times when painting work is put off, and it can be put off almost indefinitely.

9455. (Mr. Rice.) One of the usual excuses for putting off painting is on account of the high income tax?—People say: "I cannot afford it just now. My wife wants the place done up, but I cannot afford it just now." It is put on the Budget, or on the want of money, or something else.

9456. (Dr. Collis.) The amount of ill-health occurring in the match-making trade, due to the use of yellow phosphorus, was infinitesimal compared with what is occurring in the house-painting trade, but the use of yellow phosphorus has been abolished. The total deaths in the last ten years before that Act was passed did not come to four. All the phosphorus cases only came to about 20 in ten years?—But I suppose that there was a suitable substitute available?

9457. The substitute is a more expensive thing?—I do not think that a moderate amount of increase would affect the matter. The point is that it shall be effective and not outrageously costly.

9458. When the point was before the House, it was considered that the public would suffer considerably and that matches would be much worse, but I do not know that they are much worse to-day?—I see your point.

9459. I have looked up the figures in regard to phosphorus, and find that in the last seven years there were nine cases with three deaths?—It is not a very large trade. It is very concentrated—in a few factories, I think.

(Mr. Sutherland.) The security of structures does not depend on what you use in matches, but in our case the structure is at stake.

9460. (Mr. Rice.) If an efficient substitute can be found and if it does not make the cost of painting so high as to prohibit or rather to diminish its use, you would agree?—Yes, I would agree with that.

9461. (Mr. Parsonage.) In the returns that you got from these employers, you got no returns of lead poisoning. They have very little knowledge of it?—Yes; they have very little knowledge of it.

9462. Would not that be on account of the employer generally not finding it necessary to make inquiries into the causes of illness of the workmen?—I can only judge from my own experience. My own experience is that, if a regular hand was absent, you would want to know something about him, but if he was a casual hand you would probably not bother much.

9463. The same thing as you were referring to this morning would account for the cases not coming before them?—Yes; it has not come to their knowledge.

9464. This morning you said that probably painters suffered more on account of their seasonal employment and being more liable to disease through being half-starved, as you said, in the winter-time?—Yes.

9465-6. My experience, taken from our returns, is that the death rate and the amount of sickness is higher when trade is good, and that has been confirmed by a debate in the House of Commons. Mr. Lloyd George, when he was speaking on the National Insurance Bill, mentioned that statistics proved that when trade was good and more men were employed, the rate of sickness was higher and the death rate was higher. I do not think it can be taken that the fact of the painter being out of work in the winter time has any effect on his health, except that being away from the paint for a month or two may make him more liable to have lead poisoning when he returns to work?—Supposing that you have a very busy summer, a man may be doing very well and he would probably spend a little more. Many men are rather lacking in foresight and providence, and they spend their money pretty freely when they are getting it.

9467. And so make themselves ill that way?—No; but when the winter comes, they are without work and without money. What you put to me does not seem to me to touch my point, because the men are more employed during the summer season and not during the winter season.

9468. I am taking the first three months of this year, January to March. January and February are the two worst months?—Not always; they used not to be with me.

9469. But on the average they are?—January is the worst month for painters. We used to get the ship work in January.

9470. That is localised. I am taking the whole country. Now you mentioned railway workers and that kind of men who did not wear overalls; but I am speaking of the best class of men, who have served an apprenticeship to the trade. We do not take railway men into our society because they get a lower rate of wages and they are not qualified men; they are good enough for ordinary railway work, but they could not do house painting. Therefore they are not qualified according to the rules of our society, so I do not think that what you said would apply?—My point was that that class of men largely created the heavy mortality.

9471. Now you mentioned Dublin, and you gave the number of men employed. I have four cases here of total disablement, paralysis, and blindness from lead poisoning. This last month we have disposed of two cases, one at Kingston, just outside of Dublin, and one in Dublin, of paralysis and lead poisoning?—The cases I gave you from Dublin were entirely cases where workmen's compensation had been paid by insurance companies, and they did not go beyond that.

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9472. Now, with regard to dry rubbing down, you said that you had been led to believe that dry rubbing was being dispensed with in London, or that sand-paper was being used wet?—Yes, I was told so.

9473. Were you led to believe it?—The statement was made seriously by a master painter.

9474. You mentioned that Mr. Rice was aware that the statement was made to you, did you not?—No; I thought that possibly Mr. Rice's experience in London might confirm that or otherwise. I do not give it as evidence; it is hearsay. I only gave it as a reason why I hesitated to answer the Chairman's question straight away.

9475. Unfortunately the statement has gone on the Notes, and I would like to say that it is absolutely incorrect. It was a very extravagant statement; it could very easily be disproved.

9476. (Mr. Rice.) Do you mean damping the glass-paper with turps?—The party who gave it said either turps or water.

(Mr. Rice.) If you appeal to me, I have seen sand-paper damped with turps, and Mr. Parsonage would agree with me. Probably he has seen it, I should think.

9477. (Mr. Parsonage.) I cannot say that I have. It may have happened once in the course of my career as a painter, and I cannot honestly say I have ever seen it done. I have asked a score or more whether they have seen it, but I have never found one in London who has seen it done. (To the witness.) In your experience, did you ever see it done?—No; it is quite new to me. I do not see anything impossible about it. I think that it might be tested. It is a very simple precaution if it would work.

9478. (Mr. Gardner.) Are you a practical painter yourself?—I am not a practical painter. I have never served.

9479. You think that white lead poisoning is not at all common? That is, I suppose, because you personally have not come in contact with many cases?—That, and the impression I have got from conversation with other members of the trade.

9480. Do not you think that one of the reasons for that is the intermittent nature of the employment? You really do not know always when the men have been suffering from some trouble associated with white lead?—That may be so. As I explained earlier, you have a certain number of men usually who are your regular men. You know a great deal about them. Then there are a certain number of men who come on for the season, and go off again, and you may never see them again. That class of man you will not know very much about unless something happens while he is in your employ.

9481. I take it from your evidence-in-chief that your firm did fairly large jobs?—Yes.

9482. How many on the staff would you have in the season as compared with your winter staff, your permanent hands?—The winter staff would be down to from 20 to 40, and the summer staff might be as high as 300.

9483. So there is a vast difference between the number of men employed. Many of the 250 men employed in the summer only might have trouble from lead, and you would know nothing whatever about it?—A large proportion came back year after year. We usually saw them again. If a man was a decent man and liked the shop, he would come back again. It was a regular thing for men to turn up and remind the foreman that they were there last year and so on.

9484. But until there was a claim under the Workmen's Compensation Act you would not know when men were off for illness?—We used to know when men were off jobs.

9485. That was during the time they were in employment?—Yes. We did not follow them, but the foreman would want to know where they were.

9486. What precautions have employers taken to try to obviate white lead poisoning?—Only the precautions I have mentioned of making men be as cleanly as possible, using overalls, and not messing their hands any more than they could help. If you saw a fellow sticking his hands into the paint, you would naturally tell him that he was a fool, and that that was not the

way to do. And you would not let him clean his brush with his hand in *this* sort of fashion (*describing*). You meet with all kinds of things like that in painting, especially with some of the "stuff" that comes for employment. You naturally put an end to all that kind of thing on the general grounds that it is dirty and injurious to the men. You know that it is bad. The two things go together. The cleaner your men are on a job the better your clients like it. Any decent house-painter tries to get a reputation. The customer says, "I want some nice clean men about the job." That is the very thing you want. Therefore your own interest, as well as that of the painter with regard to lead poisoning, jump together, and you naturally make the men as clean as you possibly can.

9487. That brings us back to the position that the employers are taking no precautions whatever except advising the men in their own interest to be as cleanly as possible?—Quite so; using the expression "their own interest" in a broad sense.

9488. Yes, in a broad sense. Your firm was a builder's firm?—Both painting and building.

9489. You would have no special insurance rate for painters?—Yes, we had.

9490. Had you to pay a special rate for the painters apart from the other men employed?—We paid a cheaper rate for painters than for builders.

9491. (Mr. Sutherland.) That was under the old Employers' Liability Act?—Yes, and under the first Workmen's Compensation Act. That was before the new arrangement.

9492. (Mr. Gardner.) The premiums have been increased under the new arrangement. You were out of business when that came into force?—Yes.

9493. You are aware that rates have gone up?—I am aware that rates have gone up.

9494. You are aware of the present seasonal nature of the trade?—Yes.

9495. And that is rather against the men's health, is it not?—Yes, it is.

9496. Do employers ever try to alter that? Have they done anything to try to get the season extended?—Yes; they have assisted the men sometimes by making representations to the local authorities to have public work done in the off season as much as they can. It is very difficult to do.

9497. With a view of spreading the work over an average number of hours per week?—Yes.

9498. You agree that an excessive number of hours is bad?—Yes, decidedly. I think it is most objectionable. It is no benefit to the employer.

9499. If painting on walls has largely gone out of fashion, as it has, and stippling and painting of ceilings, and if a good deal of non-poisonous paint has been introduced, to what can you attribute the increase of lead poisoning which has taken place of recent years?—I am not at all convinced that there is an absolute increase. There may be an increase in reporting it. You may know more about it because you have been paying attention to it, but I have seen nothing to convince me of an actual increase.

9500. Even in the face of the returns in the "Gazette"?—Even in the face of the returns in the "Gazette" I would not say that there is a real increase. It may be a difference with regard to reporting.

9501. (Chairman.) There is no difference in reporting?—Are these cases only Factory Act cases?

9502. No, they are deaths?—Have all deaths been previously reported?

9503. (Dr. Collis.) Inquests were held on them in the past?—Then I do not understand it.

9504. (Mr. Gardner.) In speaking of a mask you said that a man could use a mask when flatting. I suppose you agree that there must be a poisonous vapour arising from flatting paint?—I am very doubtful about there being, strictly speaking, a poisonous vapour. I think generally that most of the trouble from flatting is due to the spirit which the men inhale. There is a good deal of spirit in the room when that is going on, and my impression is that it upsets the men. We usually had cases of colic reported in connection with flatting jobs, and very seldom in any other way.

R 2

1 June 1911.]

Mr. A. G. WHITE.

[Continued.]

9505. Would not that show that the turpentine and volatile matter in the paint was carrying off a certain amount of lead into the atmosphere?—Lead is so heavy and turpentine is so light that it seems to me a practical impossibility for turpentine to carry the lead.

9506. Even in the form of solution?—Even in the form of solution. I should say that it is impossible, but I do not like to dogmatise on it for a moment.

9507. I suppose that you are not acquainted with present-day substitutes for turpentine?—I have heard of so-called substitutes. I never used them; I did not believe in them. I have no experience of them.

9508. They are ranker and more volatile than turpentine?—They are more volatile and ranker. They have a kerosene smell.

9509. You would not care to rub your hands with such things?—Petrol is a splendid thing for cleaning your hands, and I do not think that they are any worse than petrol in that respect. I have often used petrol. You can clean your hands like winking with it.

9510. With regard to railway workers, I take it you mean the unskilled painter who is employed in doing rough work on railways?—I do not know anything about his skill, but I have seen the sort of man I describe working about railway stations and docks and so on and doing bridge work.

9511. He does not wear overalls, and from the way in which he goes about his work, and so on, you would take it that he has not been trained to painting?—Some men seem to handle the brush all right, but they seem careless about their appearance and do not wear overalls. If you went into a shop where all the men wore overalls you would feel yourself strange if you did not. They would point at you. You would jolly soon get them. You know what men are. If you go into a shop where they are not wearing overalls and you are wearing them you do not continue to wear them.

9512. Do you suggest that there are painters' shops in England where men do not wear overalls?—Well, I do not know where these men come from if not from painting shops.

9513. Would it do away with lead poisoning entirely if these men were prevented from coming into the trade at all?—I think that careful training would have a lot to do with remedying lead poisoning. I am strongly of that opinion, and one of the suggestions that I make is that they should be specially taught about it.

9514. (Chairman.) How are you going to teach the men to avoid dust, which it is admitted is inevitable?—We have had a suggestion here to-day that is well worth testing. There is a difference of opinion about it, but it is quite clear that, if there is anything in the suggestion about using turps to reduce the dust in sand-papery, it is a very important suggestion.

9515. But how are you going to prevent a man inhaling dust if this particular suggestion is not carried out; it is in the air, I take it?—If a man in

sand-papery will take notice of the direction of the draught, and not stand any closer than he need, and not put his nose up against the work.

9516. The lead dust gets into the air?—It does not fly about to that extent. It is pretty heavy, and it is between the sand-paper and the door, and it falls down. You see it at the bottom. It does not fly about like flour in a flour mill.

9517. We have had tests made, and we find that there is more lead in the air in sand-papery operations in coach-painting than there is in some of the worst pottery operations?—There is far more sand-papery in coach-building.

9518. But, still, it was dust, and the air was taken at the breathing level of the man?—Of course, a test like that is worth a great deal of theory. If the dust is in the air, I admit that the man must breathe it, of course.

9519. (Mr. Gardner.) With regard to the moistening of the sand-paper, which I understand you were told was prevalent in London?—I was not told that it was prevalent in London.

9520. It was used in London, you were told?—I was told that it was used in London.

9521. You would be surprised to hear that London is one of the worst places with regard to lead poisoning?—I have been told since I came into this room that Lancashire and London are the worst places, but my answer to that is that they are the two most densely populated portions of the country.

9522. On the question of the prohibition of white lead, are you aware that there is a great deal of zinc used in the interiors of ships?—Yes; I have used plenty in the form of a finishing enamel, but in my experience it was always with a white lead base.

9523. Then with regard to the hull. I understand that you worked on the Allan Line ships?—Yes.

9524. What did you paint the outside with?—The upper part would be painted with a lead paint with a good deal of black in it, and some flesh colour for the boot top, and below was usually —'s patent. Probably it had lead in it, because it covered very well, but I do not know.

(Mr. Sutherland.) It is a composition.

9525. (Mr. Gardner.) Usually a hull is painted black?—It is brought up with lead colour, and the deckhouses are white.

9526. On the question of paint protecting the hull, it is really very little protection. Do you agree with me if I tell you that many of these vessels are painted with a piece of waste dipped in the paint, without brushes at all?—I cannot say that I have ever seen them done in that way.

9527. The ship's crew do it with a piece of cotton waste?—Probably.

9528. You have never experimented with zinc on deck work?—No.

9529. You have been too long away from the trade. During the last five years there have been great improvements in zinc paints?—Have there? I am very glad to hear it.

The witness withdrew.

Mr. THOMAS HALL examined.

9530. (Chairman.) Do you attend to-day as the representative of the London Master Builders' Association?—Yes.

9531. What is the nature of your business?—Builder and decorator.

9532. Where is it carried on?—The Pitfield Wharf, Waterloo Bridge.

9533. How long have you been connected with house-painting work?—For 45 years there, and 30 years as master.

9534. What is the average yearly number of painters employed by your firm?—Fifty a week on an average for the year round.

9535. Have you known any cases of lead poisoning or painter's colic?—In 30 years I have only been told in my establishment of one serious case.

9536. Do you insure against your liability for payment of compensation for lead poisoning under the Workmen's Compensation Act, 1906?—Yes.

9537. Has that been increased lately for painters?—I could not say.

9538. Have you known men who have broken down temporarily in your works?—No.

9539. Have your men had occasional days of illness?—I have not the slightest idea of anything except one case in 30 years.

9540. Do you have a periodical medical examination of your men?—No.

9541. Is it not possible that some of them may be suffering from the slower and more insidious forms of lead poisoning without your knowledge?—Yes, that is very possible.

1 June 1911.]

Mr. THOMAS HALL.

[Continued.]

9542. You take a prominent part in the work of the London Master Builders' Association?—Yes.

9543. Has the question of the serious prevalence of lead poisoning among house painters been discussed at your meetings?—Just lately.

9544. They must have heard of the prevalence of lead poisoning amongst the men who handle lead paint for some time?—It has always been talked about on occasions.

9545. And yet your association has never attempted to do anything to mitigate it?—I have not been a member of this association long enough to say about that.

9546. There are a number of substitutes offered on the market, the makers of which claim that they will successfully replace white lead. Have you heard of them?—Yes.

9547. Has your association carried out any practical tests with these?—Not that I am aware of. I have carried out one myself.

9548. We have been told that the extent of the danger of lead poisoning to which house painters are exposed is not fully realised by many employers?—I think that everybody realises it.

9549. Do not you think that your association under those circumstances ought to have taken some steps to realise the extent of the danger, and to bring home its seriousness to all your members?—Possibly that may come about yet; I do not know.

9550. Do you yourself realise the magnitude of this lead poisoning evil?—We know it exists; certainly we do.

9551. I am sure you agree with me that this sickness and death are very deplorable?—Yes, certainly.

9552. Do you know that the evil has attracted the most careful attention in many foreign countries?—I know that it has in France, because it has been done away with in France.

9553. Do you not think it regrettable that this country should be behind other nations in such a matter?—I agree with doing away with it entirely for house painting.

9554. You would agree with that in this country?—I would, most certainly.

9555. If that is the case I need not ask you anything else?—The Office of Works is using this new stuff extensively.

9556. I was going to ask if you know that the Office of Works and many other people have succeeded in obtaining an efficient non-lead paint?—Yes.

9557. Have you heard that it has been quite satisfactory in all respects?—I only know that it is being extensively used; that is all I know.

9558. You have not heard anything against it?—I have heard nothing against it; I have heard everything for it.

9559. To sum up your evidence, rather than an extremely complicated and elaborate code of regulations, you would prefer the abolition of lead for house painting both inside and out?—I certainly would. I am most decided about that.

9560. I understand that you are one of the largest firms in the Master Painters' Association?—We are rather extensive. I should like to add that I have already done away with white lead in one of the most dangerous proceedings; that is, in the rubbing down, as I have stated in my letter. You have seen white patches before re-painting. To rub that down to an even surface gives off a very small dust, and that is worse than painting. It gets into the inside. You sometimes use a respirator. I have done away with white lead and got a substitute quite as good with no lead.

9561. Could you tell the Committee what it is?—Yes, Duresco.

9562. (Mr. Parsonage.) That is for filling up?—Yes.

9563. There is now much lead used for filling up now?—I did not know whether anybody else used it.

9564. (Dr. Collis.) You say that you have conducted one experiment with leadless paint?—Yes.

9565. Was that an extensive one?—No, not long enough to speak from, but as far as I can see I am satisfied.

9566. With regard to the one case of lead poisoning, of which you had knowledge, when did that occur?—Thirty years ago.

9567. You have had none since?—No, not a single case. I believe that one was a sort of paralysis. I have never seen it, but I am told.

9568. (Chairman.) Lead poisoning takes all sorts of forms. You may get wrist drop or paralysis. It may affect the eyes and it may affect the kidneys?—The breathing of lead dust is a great deal worse than the handling.

The witness withdrew.

## THIRTEENTH DAY.

Wednesday, 19th July 1911.

PRESENT:

SIR ERNEST F. G. HATCH, BART. (Chairman).

LORD HENRY BENTINCK, M.P.  
Mr. E. L. COLLIS, M.B.  
Mr. W. G. SUTHERLAND.  
Mr. A. GARDNER.  
Mr. J. PARSONAGE.

Mr. A. L. O. FELL.  
Mr. C. L. MASON.  
Mr. C. KINGGATE.  
Mr. W. ROBINS.

E. A. R. WERNER (Acting Secretary).

Commander W. H. COYSH, R.N.R. (Marine Superintendent of the Great Eastern Railway), examined.

9569. (Chairman.) Are you the marine superintendent of the Great Eastern Railway Company?—Yes.

9570. You are attending to-day to give evidence in regard to the paints which you use on the ships at Parkeston Quay, Harwich?—Yes.

9571. Do you exercise full control of the painting work on the ships of your line?—Yes.

x 7790

9572. How many painters are employed at the Great Eastern Railway steamship workshops?—We have only two painters in the shops. The whole of the ship painting is done by the crew.

9573. To what extent do you use lead paints in painting the ships of the Great Eastern Railway line?—Up to the present we have used lead paints for a basis for all our paints except black outside.

R 3

19 July 1911.]

Commander W. H. COYSH, R.N.R.

[Continued.]

9574. Do you intend to continue to use lead?—No. We propose to deal with white-zinc paints in the future.

9575. What reasons have you for having determined to discontinue the use of lead?—Because with white paints we find that lead turns the enamel a yellow colour. It does not give such a pure white as the zinc paints do. May I point out that when I say "the base" I am referring merely to stone-colour paints used on the ship for the bulwarks and that sort of thing. In all white paints under deck and in the cabins, I propose in future to use zinc foundations, because they are, as I say, a purer white, and not so liable to turn yellow as the lead paints.

9576. With regard to the interiors of the ships; have you been using leadless paints for some time for internal and external painting of the Great Eastern Railway steamships?—No, we have not. As I say, the groundwork is always a lead paint. The outside after that is enamel paint. What the enamel paints' constituents are I am not prepared to say.

9577. Have you had any experience with leadless paints at all?—Only the zinc paints.

9578. Those are leadless paints. Have you found them entirely satisfactory?—Yes.

9579. Now, first with regard to the interiors of ships; what material do you use for the painting of the interior of cabins?—Enamel paints only.

9580. Zinc enamel paints?—I do not know what the constituents of the enamel paints are, but we buy the enamel paints of various makers and apply them to the cabins.

9581. You do not know whether they are leadless or not?—I am not prepared to say that.

9582. Is that for the finishing?—Yes, that is for the finishing.

9583. You have never specified, in giving your orders for these enamel paints, that they should be leadless?—Never.

9584. Yet you say that you have determined in future to use nothing but leadless paints?—In the future, as the old stock of lead is used up on our ships, I propose to use white zinc paint, because it is better paint, and, although it is rather more costly, in the first instance, I believe it goes a great deal further.

9585. Will that apply equally to the exteriors as well as to the interior of ships?—That will apply to the whole of our ships—interior and exterior. You mean by the exterior painting the bulwarks and so on?

9586. Yes, and the funnels?—Yes. We use a tremendous quantity of enamel paint on our ships. All our white paint is enamel.

9587. May the Committee take it that, as soon as you have exhausted your present supply of lead paint, you will use exclusively zinc paints which are leadless?—Yes, that is right.

9588. Have you taken into consideration the question of the durability of the zinc paints in your ships?—We have not had a long enough experience to tell you that as to lasting.

9589. You are making this experiment without any misgiving?—Without any misgiving. I have had experience of white zinc paint before, but as to how long it lasts in comparison with other white paints I am not prepared to say.

9590. Do you think that your directors would have any misgiving if we were to prohibit the use of lead entirely?—I do not think so. These things are left entirely to the chief officers.

9591. If the Committee saw fit to prohibit the use of lead in the future, it would not affect you?—It would not affect us in the least as far as the marine dock department was concerned.

9592. (Dr. Collis.) Is the reason why you propose giving up the use of lead paints the purely commercial reason that you think you will get better value for your money?—Not altogether that, doctor. As I say, you get a better effect for your money. The value has to be proved yet. We have no experience of that, but the effect is better.

9593. It is not for any hygienic reason?—Not for any hygienic reason at all.

9594. So that you are leaving the danger that we consider to be associated with lead paints on one side?—It has never occurred to us.

9595. You make your change entirely on business lines?—Yes, precisely.

9596. (Chairman.) Do you ever use red lead?—We have used a considerable amount of red lead in our ships.

9597. For what purpose?—Outside painting. It is put on by the builders and has always been specified.

9598. Could that be dispensed with?—If you could get another paint equally as good and protective I should say there is no objection.

9599. You say "if you could." What do you mean?—I mean red lead, to the best of my knowledge, is the best protective paint for the first coat on iron at the present day.

9600. Do you know any other adequate protective paint?—There is a good protective paint oxide which is coming very much into use, but in our service up to date we have used and specified always that all the painting should have a priming coat—two coats—of best red-lead paint. That has been very efficient. We have found it very effective.

9601. Would you have any objection to the prohibition of the use of red lead?—I have an open mind on the subject, if you can find a paint equally as good.

9602. That is not the point quite. Of course you would change at once then; but would you be content to substitute oxide of iron for red lead right off?—I should have to have a trial of it first. I would not say right away that I could discard one paint that I know is excellent for one that I have not much experience of.

9603. You understand why this Committee has been sitting?—Yes.

9604. It is to prevent the continuance of the very high rate of lead poisoning?—Yes.

9605. We have to remedy that in some way or another?—As far as the white lead paints on board ship are concerned, we could dispense with it so far as our service is concerned to-morrow.

9606. Have you tried oxide of iron?—Yes, I have tried oxide of iron.

9607. Has it been satisfactory?—Yes, so far.

9608. For what length of time have you used it?—I have used it before in other ships, but you are here, there, and everywhere. You do not continue in one ship, and therefore you cannot altogether judge of the results. I daresay that some of the other gentlemen round the table could give far more information on that point than I can.

9609. Is the application of red lead difficult?—It is difficult. It is an objectionable paint to deal with, to mix, and apply. It has a very heavy specific gravity, and is not easily put on, and there is a tremendous amount of wastage attached to it.

9610. Is it used principally for protective purposes?—Yes, wholly and solely as a protective paint and for no other reason.

9611. Might it be a serious detriment to substitute paint less protective?—I daresay that there are plenty of equally good protective paints on the market, and after having once coated the ships with red lead we discontinue the use of it afterwards, and use only anti-corrosive protective paints.

9612. We are very anxious not to do anything that would interfere with the stability of the ship?—That would not interfere with the efficiency or stability of the ship.

9613. But would protective paint as a substitute for red lead, if it was not quite as efficient, interfere with the stability of the ship?—In no way whatever. The stability of the ship does not enter into the question at all.

9614. Then why is protective paint used?—As the name implies, purely to protect.

9615. Protect what?—To protect the iron of the ship from atmospheric conditions.

9616. If you had a paint less protective than red lead, would that interfere?—Yes; deterioration would set up, of course.

19 July 1911.]

Commander W. H. COYSH, R.N.R.

[Continued.]

9617. Supposing the Committee saw fit to prohibit the use of lead, white and red, and gave two years interval, do you think that would be a sufficient time in which to find an efficient substitute?—Quite a sufficient time. You would be able to tell by a comparison between one paint and another. There is any amount of excellent anti-corrosive protective paint on the market now which we use, but I cannot tell you what the constituents are. I do not know what their basis is. We find that they are very effective and very efficient.

9618. Have you used —'s paint?—We have used —'s, and we are using other protective paints.

9619. Do you use —'s as protective paint for the holds?—Yes.

9620. Do you find —'s protective paint as efficient as red lead?—We never use red lead after the first coating. After the ship is built and the plates are coated, we discontinue the use of red lead altogether. It is the builders who deal with that, not we. We use anti-corrosive paint after that.

9621. Could you use —'s protective paint for the base?—I could not say; I have never tried it.

9622. (*Mr. Sutherland.*) Is it a proprietary paint?—Yes. It is an ordinary protective paint. There are dozens of them on the market. Ships that are 17 years of age show no signs of deterioration when coated with red lead, and I cannot say that with regard to other protective paints.

9623. With regard to the use of white lead or zinc paints in buildings, your evidence does not help us in that respect, because you have not made any comparative examination of the two?—Not of the zinc paints.

9624. The red lead and the zinc?—No.

9625. You only use the zinc as a matter of colour?—Yes, as a matter of colour. Hitherto we have always used white lead as our base mixed with oils.

9626. That zinc as an under-coat for enamel would preserve the colour better we are all agreed, but that does not help the Committee with regard to the durability of the paint on building structures?—No.

9627. (*Chairman.*) I understand that, as regards your shipping, which is a great organisation, you have decided to abandon the use of lead, not as a question of colour only, but taking other things into consideration as well?—I propose, as far as my department is concerned (that is the shipping pure and simple), to discontinue the use of white lead and to adopt white zinc, from the point of colour principally, and also because I think it goes further than white lead, and is a finer quality of paint—a better paint.

9628. You have come to that conclusion, knowing perfectly well that it would be a very serious step to take if you were not quite sure that it would be satisfactory?—Precisely.

9629. (*Lord Henry Bentinck.*) For outside work as well?—You must bear in mind that nearly all is for outside work.

9630. (*Mr. Sutherland.*) Do you enamel the hull-warks, for instance?—No, the ordinary stone-colour paint that you have on the inside of the well deck of a ship or around a deck house, we do not enamel.

9631. Do you varnish it?—No, we do not varnish it.

9632. Do you mix it?—We mix it with oil and turpentine.

9633. You have no experience of zinc there?—No.

9634. Really the evidence does not carry us further?—We are experimenting at the present moment, and propose to discontinue the use of white lead and adopt zinc as far as my ships are concerned.

9635. (*Chairman.*) You do that without any misgiving?—Without the smallest misgiving at all.

9636. (*Mr. Mason.*) How long is this paint expected at last?—Are you speaking of interior paints?

9637. No I am not, but of the stone colour. We know about enamels?—As soon as it gets dirty it is washed, and we are continually touching up and painting our ships.

9638. Really the question of durability does not enter into the question?—What do you mean by durability? We are subject to rough usage, and if paint is knocked and chipped about we take steps to make it good. A ship may be painted for one trip, and she comes back and, in your opinion, wants painting again. She may go for several weeks and not have a coat of paint put on.

9639. It is mechanical damage rather than chemical damage?—Yes—rather than deterioration from atmospheric conditions, you mean?

9640. Yes. So that even whitening would almost answer the purpose?—I should hardly say that.

9641. With oil—mixed as a paint?—It would not have a very good appearance on our ships.

9642. But as far as lasting qualities are concerned?—No, certainly not. I think that after you have broken away the oil and disintegrated it to a certain extent, the whitening would depreciate and go away much quicker than white lead or zinc. It would powder into dust at once.

9643. Would it not last for weeks?—I do not think so. Put a strong solution of soap and soda on it, and you have the whole of the substance off at once.

9644. That would be so with any paint would it not?—No. You continually use soap and soda on paint.

9645. Soda is used to remove paint in the trade is it not?—You cannot get it off with a solution of soda. You have to rub and wash. Ask any people who are trying to remove paint, and they will rather smile at the idea. You either burn it off or take one of these patent paint removers for it.

9646. What are they made of?—From a strong solution of caustic I should think, but I do not know.

9647. I understand you to say that, if lead of any kind were abolished, it would not affect you in the least?—I have an open mind on the subject. I do not care a red cent. White lead, so far as we are concerned, has treated us very well and served us very well as a protective paint, and has given very good results, but I believe that zinc will give equally good results, and that is as far as I am prepared to go in the matter.

9648. In the case of repairs or anything of the sort, do you think you could find a substitute in the time?—Yes, I think so.

9649. Do you mix your zinc paint at all with varnish?—No. If you do that it spoils the paint. It discolours it.

9650. (*Mr. Robins.*) What kind of oil do you use in the zinc white?—I should use raw oil with zinc white.

9651. Not boiled oil?—No, not boiled oil.

9652. Do you find that it dries all right with raw oil?—It would dry quicker with boiled oil as a matter of course than it would dry with the raw oil, but it would not give such a good effect. With raw oil it takes longer to dry, but the results are better.
